## Summary

A comparative study of the hydrodistilled oils of *Pinus pinea* L. and *Pinus pinaster* Aiton by GC and GC-MS was conducted. The combined essential oil of *P. pinea* was rich in limonene (56.5%), followed by  $\alpha$ -pinene (6.5%) and  $\beta$ -phellandrene (6.2%). The major compounds from the combined essential oil of *P. pinaster* were:  $\alpha$ -pinene (36.4%),  $\beta$ -pinene (12.3%) and (E)- $\beta$ -caryophyllene (7.1%). The results showed that the oils have a great potential as antibiotics against some microorganisms: *Klebsiella pneumoniae*, *Enterococcus faecalis* and *Candida albicans*. The maximum zone of inhibition of *P. pinea* was obtained against *Candida albicans* (23 mm). Antioxidant capacity was assessed by *in vitro* testing using 2,2-diphenyl-1-picrylhydrazyl (DPPH) assay and significant activity was found for the various oils. These results suggested that essential oils of *P. pinea* and *P. pinaster* possess antimicrobial and antioxidant properties, and could, therefore, present potential source of active ingredients for food and pharmaceutical industry.

## Key words

*Pinus pinea*, *Pinus pinaster*, essential oils, GC, GC-MS, biological activities

## Introduction

Essential oils are complex mixtures made up of volatile compounds with strong odors, that are synthesized in several plant organs, including buds, flowers, leaves, stems, twigs, seeds, fruits, roots, wood or bark, and stored in secretory cells, cavities, canals, epidermic cells or glandular trichomes (Bakkali et al., 2008; Franz and Novak, 2010). These volatile compounds have diverse ecological functions, acting as defensive substances against microorganisms and herbivores, but can also be important to attract insects for the dispersion of pollens and seeds (Bakkali et al., 2008). Essential oils have found therapeutic applications in human medicine due to their anticancer, antinociceptive, antiphlogistic, antiviral, antimicrobial and antioxidant properties (Edris, 2007; Buchbauer, 2010; Teixeira et al., 2013).

In folk medicine, various parts of *Pinus species* (bark, needle, cone and resin) have been used for treatment of diseases such as rheumatism, bronchitis and low blood pressure. Furthermore, *Pinus* is known for its anti-inflammatory, antioxidant, antiseptic and antimicrobial activities (Dob et al., 2005). Essential oils from *Pinus* species have been reported to have various therapeutic properties (Fuentes et al., 2006; Kozan et al., 2006). The chemical compositions of essential oil from many *Pinus* species have been reported by many research groups (Dagne et al., 1999; Stevanoic et al., 2004; Dob et al., 2005; Fekih et al., 2014; Nam et al., 2014), and have shown variations in compositions according to their regional sources and locations. The presence and the concentration of certain chemical constituents also fluctuate according to the season, climate conditions and site of plant growth (Bakkali et al., 2008).

In this study, we aimed at evaluating the antimicrobial and antioxidant activities of *Pinus pinea* L. and *Pinus pinaster* Aiton essential oils. Additionally, the intra-species variations of essential oils and the volatile fractions obtained from twenty locations of two *Pinus* species are discussed using statistical analysis.

## Material and methods

### Plant Materials

The aerial parts of *P. pinea* and *P. pinaster* (needles, twigs and buds) were collected from twenty regions near Tlemcen (northwestern part of Algeria; Table 1). The voucher specimens of the plants were deposited in the Herbarium of the Laboratory of Botany, Department of Biology, University of Tlemcen (Algeria).

### Essential oil isolation

Each fresh aerial part (400-500 g) was submitted to hydrodistillation for 5 h using a Clevenger-type apparatus according to the *European Pharmacopeia* (Council of Europe, 1997). The essential oils were stored in sealed vials in the dark at +4°C before analysis and bioassays tests. The obtained essential oils were yellow, with an aromatic odor.

### Gas Chromatography (GC) Analysis

GC analysis was performed using a Perkin-Elmer Clarus 600 GC apparatus (Walton, MA, USA) equipped with a single injector and two flame ionization detectors (FID). The analysis

was carried out using two fused silica capillary columns (60 m; 0.22 mm i.d.; film thickness 0.25 µm) with different stationary phases: Rtx-1 (polydimethylsiloxane) and Rtx-Wax (polyethylene glycol). The operating conditions were as follow: injector and detector temperatures were maintained at 280°C. Helium was used as carrier gas (1 mL.min<sup>-1</sup>), the injection volume was 0.1 µL, split ratio was adjusted at 1:80, the oven temperature was programmed from 60°C to 230°C with an increase rate of 2°C.min<sup>-1</sup> and then held isothermally at 230°C for 30 min.

### Gas Chromatography - Mass Spectrometry (GC-MS) Analysis

The oils were analyzed using a Perkin Elmer Turbo Mass quadrupole analyzer, directly coupled to a Perkin Elmer Autosystem XL equipped with two fused-silica capillary columns (60 m x 0.22 mm; film thickness 0.25 µm), Rtx-1 (polydimethylsiloxane) and Rtx-Wax (polyethylene glycol). Other GC conditions were the same as described above. Ion source temperature: 150°C; energy ionization: 70 eV; electron ionization mass spectra were acquired with a mass range of 35 – 350 Da; scan mass: 1s; oil injected volume: 0.1 µL.

### Component Identification and Quantification

Identification of the components was based (i) on the comparison of their GC retention indexes (RI<sub>ap</sub> and RI<sub>p</sub>) on non-polar and polar columns, respectively determined by the retention time of a series of *n*-alkanes with linear interpolation, with those of authentic compounds or literature data (Mc Lafferty and Stauffer, 1994; König et al., 2001); (ii) on computer matching with commercial mass spectral libraries (NIST, 1999; Brereton, 2003), and comparison of spectra with those of our laboratory made library.

### Statistical analysis

Data analyses were performed using principal component analysis (PCA) and cluster analysis (Massart, 1998). Both methods aim at reducing the multivariate space in which objects (essential oil samples) are distributed but are complementary in their ability to present results (Yilmaz et al., 2013). Indeed, PCA provides the data for diagrams in which both objects (essential oil samples) and variables (essential oil components) are plotted while cluster analysis informs a classification tree in which objects (sample locations) are gathered. PCA was carried out using functional 'PCA' from the statistical R software. The variables (volatile components) were selected using a function from the statistical software. The cluster analysis produced a dendrogram (tree) using Ward's method of hierarchical clustering, based on the Euclidean distance between pairs of essential oil samples.

### Antimicrobial activity

The antimicrobial activity of two essential oils was tested against twelve strains of bacteria: four gram-positive bacteria: *Staphylococcus aureus* (ATCC 25923), *Bacillus cereus* (ATCC 10876), *Enterococcus faecalis* (ATCC 49452), *Listeria monocytogenes* (ATCC 15313); eight gram-negative bacteria: *Pseudomonas aeruginosa* (ATCC 27853), *Escherichia coli* (ATCC 25922), *Salmonella typhimurium* (ATCC 13311), *Acinetobacter baumannii*

**Table 1.** Origins, latitudes and longitudes of Algerian *Pinus pinea* and *Pinus pinaster*

Areas	Samples Regions		Latitudes	Longitudes	Altitudes

\*S - *P. pinea* collecting sites; L - *P. pinaster* collecting sites

(ATCC 19606), *Citrobacter freundii* (ATCC 8090), *Proteus mirabilis* (ATCC 35659), *Klebsiella pneumonia* (ATCC 700603) and *Enterobacter cloacae* (ATCC 13047), and one yeast: *Candida albicans* (ATCC 444), *Candida albicans* (ATCC 10231), *Candida albicans* (ATCC 26790). The microorganisms were obtained from "Institut Pasteur de Paris (IPP)".

The antimicrobial activity was tested by the agar-well diffusion method (Mighri et al., 2010). All bacterial cultures were first grown on MHI agar (Mueller-Hinton infusion) plates at 37°C for 18–24 h prior to inoculation onto the nutrient agar. One or several colonies of similar morphology of the respective bacteria were transferred into API suspension medium and adjusted to 0.5 McFarland turbidity standard with a Densimat.

The inoculums of the respective bacteria were streaked onto MHI agar plates using a sterile swab. A sterile filter disc (diameter 6 mm, Whatman paper No. 3) was placed. The disc was impregnated by the tested essential oils (10µL/disc). The treated Petri dishes were placed at 4°C for 1–2 h and then incubated at 37°C for 24 h. Antimicrobial activity was evaluated by measuring the zone of growth inhibition around the discs after 24 h of incubation at 37°C.

The diameter of the inhibition zones of each of the discs was taken as measure of the antimicrobial activity. Each experiment was carried out in triplicate and the mean diameter of the inhibition zone was recorded. The scale of measurement was as follows (disc diameter included) (Sheng-Hsien et al., 2007): ≥ 8 mm: good activity; 7.5-7.9 mm: average activity; 7-7.4 mm: moderate activity; 6.5-6.9: low activity; ≤ 6.4 mm: no activity.

### Antioxidant Activity

The hydrogen atoms or electron-donating ability of the corresponding essential oil was determined from the bleaching of purple colored methanol solution of DPPH (Badarinath et al., 2010). This spectrophotometric assay uses the stable radical DPPH (2,2-Diphenyl-1-picrylhydrazyl) as a reagent (Alam et al., 2013). A solution of 0.135 mM DPPH in methanol was prepared and 1.0 mL of this solution was mixed with 1.0 mL of extract in methanol at different concentrations (0.2 to 3 mg mL<sup>-1</sup>). The reaction mixture was vortexed thoroughly and left in the dark at room temperature for 3 h. The absorbance of the mixture was measured spectrophotometrically at 517 nm. Ascorbic acid (AA)

and gallic acid (GA) were used as positive controls. The ability to scavenge DPPH radical was calculated by the following equation:

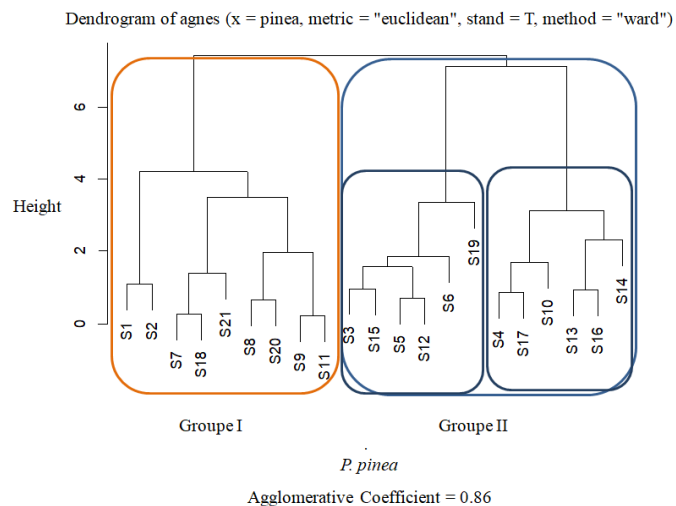

$$\% \text{ DPPH radical scavenging} = [(A_0 - A_t)/A_0] \times 100$$

A<sub>0</sub>: Absorbance of blank;

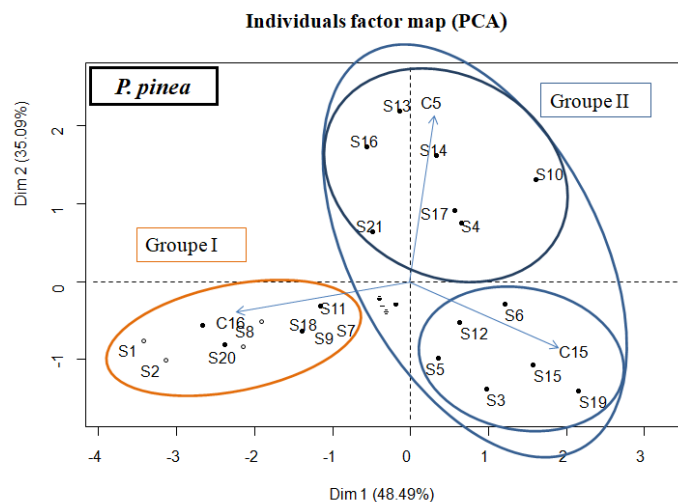

A<sub>t</sub>: Absorbance of tested sample solution.

### Results and discussion

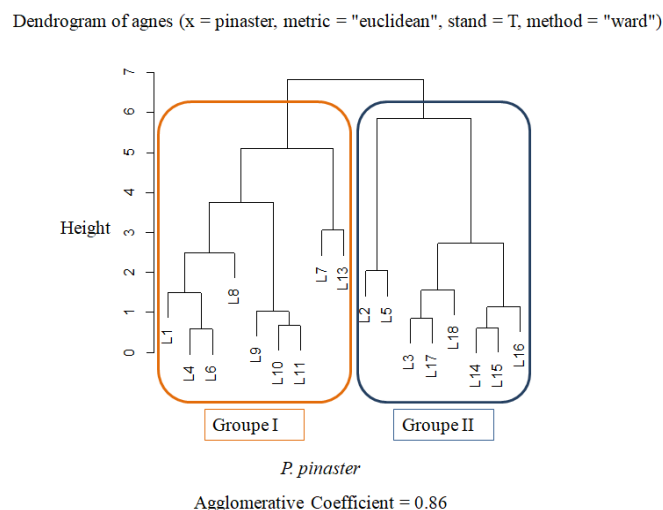

In Table 2 are presented the components identified in the essential oils of *P. pinea* and *P. pinaster* aerial parts. To identify the relationship between the chemical compositions of oils, taxonomic classification and environmental parameters, principal component analysis (PCA) and cluster analysis (CA) were applied to a matrix linking essential oil composition to subspecies identity. The data mentioned in Table 2 and presented in Figures 1 - 4 were obtained from the correlation matrix and the standardized matrix. Preliminary analysis of twenty oil samples of each *P. pinea* and *P. pinaster* showed that their GC chromatograms were qualitatively similar but differed by the abundances of their main components. GC and GC-MS analysis of both combined essential oils of *P. pinea* and *P. pinaster* allowed for the identification of 52 and 64 compounds, respectively, accounting for 96.0% and 92.3% of the samples of essential oils (Table 2). The majority of the identified metabolites in *P. pinea* combined oil were found to be monoterpene hydrocarbons and sesquiterpene hydrocarbons. Monoterpene hydrocarbons account for about 75.8%. The principal component is limonene (56.5%), followed by α-pinene (6.5%), β-phellandrene (6.2%) and myrcene (2.3%). All essential oils contained other monoterpene hydrocarbons in trace amounts, which did not reach 2% in the oils. Sesquiterpene hydrocarbons (8.9%) found in the studied oils are mainly constituted of (E)-β-caryophyllene (4.6%). For the combined oil of *P. pinaster* among these compounds, monoterpene hydrocarbons (64.5%), sesquiterpene hydrocarbons (14.4%), oxygenated monoterpenes (4.9%) and oxygenated sesquiterpenes (1.4%) were identified. The main components of this oil were: α-pinene (36.4%), β-pinene (12.3%), (E)-β-caryophyllene (7.1%), 3-carene (5.2%) and myrcene (4.9%). Previous studies found similar chemical compositions for *P. pinea* and *P. pinaster* essential oils, but in different proportions (Roussis et al., 1995; Hmamouchi, et al., 2001; Tumen et al., 2010; Nasri et al., 2011; Amri et al., 2012).

**Figure 1.** Cluster Analysis of chemical composition of essential oil of *P. pinea* from Algeria

**Figure 2.** PCA of chemical composition of essential oils of *P. pinea* from Algeria

**Figure 3.** Cluster Analysis of chemical composition of essential oils of *P. pinaster* from Algeria

**Figure 4.** PCA of chemical composition of essential oils of *P. pinaster* from Algeria

The essential oil of *P. pinea* from Greece was studied and the major compounds were found to be limonene (39.05%),  $\alpha$ -pinene (5.13%),  $\beta$ -phellandrene (13.8%) (Roussis et al., 1995). Analysis of essential oil of this plant collected from Turkey was also reported and the characteristic components were limonene (54.1%),  $\alpha$ -pinene (7.7%), and  $\beta$ -pinene (3.4%) (Tumen et al., 2010; Amri et al., 2012). Nasri et al. (2011) analyzed the needle's essential oil of *P. pinea* from Tunisia. The most abundant components were limonene (35.9%) and  $\alpha$ -pinene (6.4%). Other studies revealed different main compounds, e.g. the most abundant compound in the needles of *P. pinea* oil was  $\beta$ -pinene (37.0%), and  $\beta$ -caryophyllene (22.2%), in *P. pinaster* (Hmamouchi et al., 2001). This variability in chemical composition can be attributed to the species, part of the plant, geographical region, climate conditions, period of collection of the plant, and the method of essential oil extraction (Viljoen et al., 2005; Jordan et al., 2006; Mejri et al., 2010).

To identify the relationship between the chemical composition of essential oils from *P. pinea* and *P. pinaster*, volatile fractions and

environmental PCA (Figs. 2 and 4) and cluster analysis (Figs. 1 and 3, Tables 3 and 4) were applied to a matrix linking volatile compositions to sample location from discriminate family compounds. The principal factorial plane constructed using axes 1 and 2 accounts for 58.59% and 51.60% of the variance of *P. pinea* and *P. pinaster*, respectively.

The antimicrobial activities of *P. pinea* and *P. pinaster* essential oils originating from the northwestern part of Algeria were evaluated by paper disc diffusion method against fifteen microorganisms. Table 5 showed that these oils have variable antimicrobial activities against all tested strains. From our results, the variation in quantities of different components might be responsible for the different antimicrobial activities. The inhibition zones of essential oils of *P. pinea* and *P. pinaster* were in the range of 6 to 23 mm and 6 to 12 mm, respectively. Most of the bacterial strains showed low susceptibility to the essential oil of *P. pinaster*. The essential oil of *P. pinea* however showed good bacteria inhibitory effects on some tested microorganisms. The maximum zone of inhibition was recorded against *C. albicans*

(ATCC 444): 23 mm followed by *C. albicans* (ATCC 26790: 12 mm. In contrast, the oils did not show bacterial inhibitory effects on *E. cloacae* (ATCC 13047) and *P. aeruginosa* (ATCC 27853).

The antimicrobial activity of *P. pinea* essential oil is seemingly related to the oxygenated monoterpenes. However, it is difficult to attribute the activity of a complex mixture to a single or particular constituent. Major or trace compounds might give rise to the antimicrobial activity. In oils, a possible synergy of two or more compounds is very likely to play an important role in bacterial inhibition (Cox et al., 2000).

<sup>a</sup>: normalized % abundances

Antioxidant properties of essential oils were evaluated with the aim of discovering a new natural source of antioxidant. The potential antioxidant activities of the *P. pinea* and *P. pinaster* essential oils were determined on the basis of the scavenging activity of the free stable radical DPPH (2,2-diphenyl-1-picrylhydrazyl), and the activity was compared with two antioxidants, ascorbic acid (AA) and gallic acid (GA), which were used as reference standards. DPPH radical scavenging is considered as a good *in vitro* model widely used to assess antioxidant efficacy within a very short time. In its radical form, DPPH is reduced by an antioxidant compound or a radical species, to become a stable diamagnetic molecule, a process accompanied with a change from purple to yellow; such color change is an indication of the hydrogen-donating ability of the tested sample (Lee et al., 2007; Marxen et al., 2007; Allali et al., 2013). DPPH assay is a stable free radical method. It is an easy, rapid and sensitive way to survey the antioxidant activity of a specific compound or plant extract (Koleva et al., 2002). The free radical scavenging activity of the tested samples was evaluated based on the ability to scavenge the synthetic DPPH (Rackova et al., 2007; Alizadeh et al., 2013; Sathya et al., 2013). The results obtained at different concentrations are shown in Figure 5. The best percentages of antioxidant activities were observed for the synthetic antioxidants AA and GA, generally used in food industry, more evident for low concentrations. At 12 mg mL<sup>-1</sup>, the percentages of DPPH reduction reached 94.5% for AA and 92.6% for GA after 15 min of incubation time.

<sup>a</sup>: normalized % abundances

For essential oils, the antioxidant capacity was dependent on the used concentrations. As shown in Figure 5, the antioxidant activity of *P. pinea* increased with the increase of its concentration from 0.46 to 12 mg mL<sup>-1</sup>. Indeed, for the high concentration of 12 mg mL<sup>-1</sup> of *P. pinea* essential oil, after 3 h of incubation time at room temperature the percentage of DPPH reduction reached 88.3%, while the percentage was only 13.8% for low concentration (0.46 mg mL<sup>-1</sup>). The oil of *P. pinaster* showed the highest antioxidant capacity at 12 mg mL<sup>-1</sup> (47.9% after 3 h incubation time). From these results, we can conclude that the antioxidant activity depends on the chemical composition of *P. pinea* and *P. pinaster*. The results showed that the inhibitory activity of the essential oil of *P. pinea* at concentration 12 mg mL<sup>-1</sup> was higher than 50%, after 9 min of incubation time at room temperature.

<sup>a</sup>na: not active

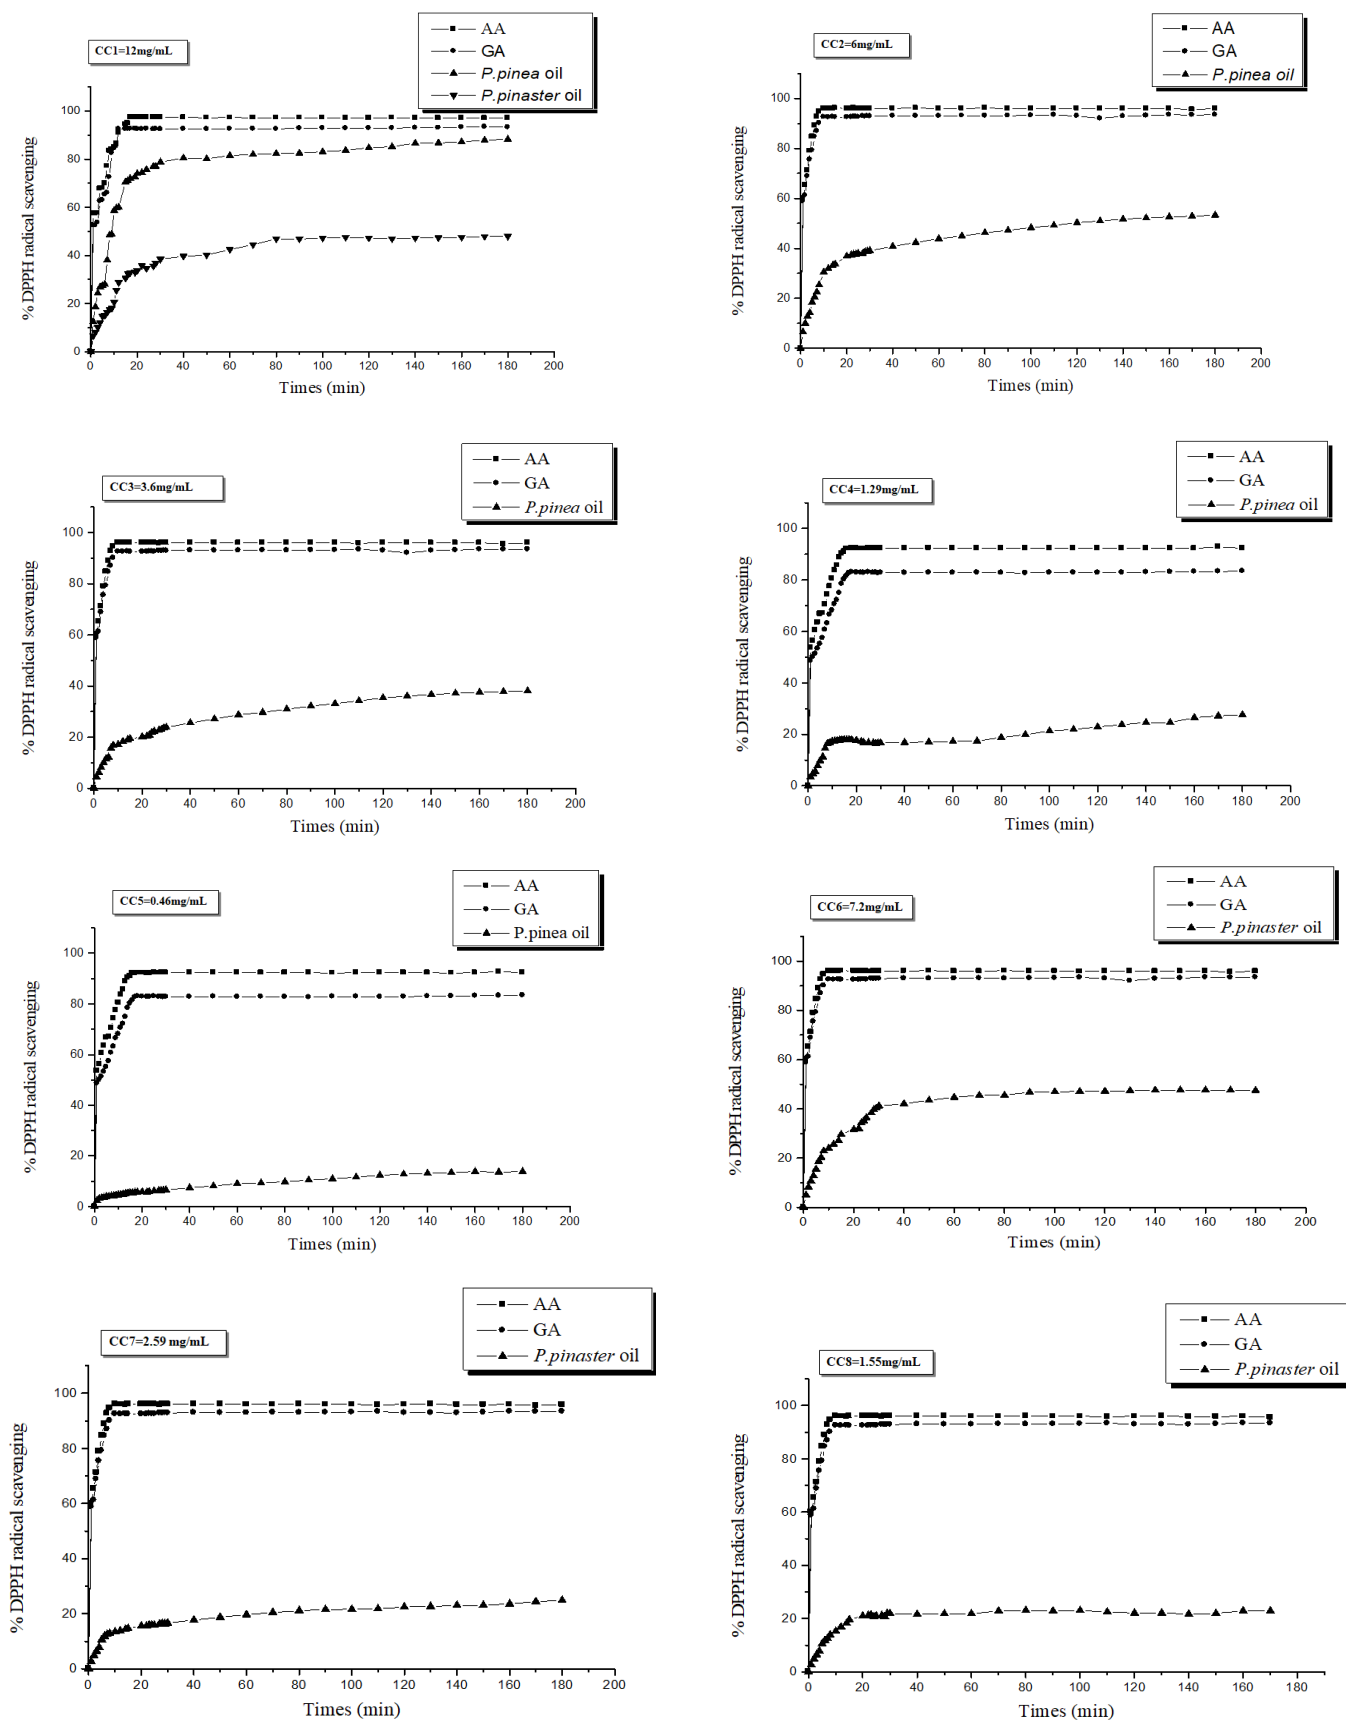

Figure 5. Percentage of DPPH radical scavenging as a function of reaction time for essential oils extracted from the aerial parts of *P. pinea* and *P. pinaster* and tested at different concentrations. AA, ascorbic acid; GA, gallic acid.

It is possible to conclude that the essential oil isolated from *P. pinea* was able to give a proton to the stable radical DPPH. Additionally, the inhibitory activity of the *P. pinea* essential oil (88.3% at 12 mg mL<sup>-1</sup>) was considerably high for its inhibition ability when compared to the positive controls GA (93.3%) and AA (97.1%).

Antioxidant activities of essential oils from aromatic plants are mainly attributed to the compounds present therein. This may be due to the high percentage of the main compounds, but also to the presence of others constituents in small quantities or to a synergistic effect (Younes et al., 2012).

While the anti-oxidant activity of natural compounds is widely described, little information is reported on their kinetic behavior, which is an important factor in the reduction process. In terms of reaction kinetics, Yen and Duh (1994) postulated that the faster the absorbance decreases, the more potent is the antioxidant activity of the sample. Halliwell (1990) linked the antioxidant power to two parameters: first, the ability to prevent the autoxidation of the free radical at low concentrations and second, the stability of resulting radical after scavenging. Es-Safi et al. (2007) also showed the evolution of the remaining DPPH with time of each compound's family (flavonoids, iridoids, etc.). They showed that compounds have a low kinetic behavior. Figure 5 shows the evolution of the percentage of DPPH reduction with time for each sample at different concentrations. It showed that AA and GA have a rapid kinetic behavior. At 17 and 19 min, they reached the maximum percentage of reduction, respectively. For the AA, this confirms the result obtained by Cal et al. (2003). In contrast, the essential oils at different concentrations have slow kinetic behavior (equilibrium time is greater than 30 min). According to Yen and Duh (1994), the samples AA and GA are more potent than *P. pinea*.

The IC<sub>50</sub> is conversely related to a compound antioxidant capacity because it expresses the necessary quantity of antioxidant and decreases the concentration of the free radical for 50%. The lower value of IC<sub>50</sub> has the most important antioxidant activity (Chanda and Dave, 2009). The essential oils of *P. pinea* and *P. pinaster* could bring back the stable free radical 2,2-diphenyl-1-picrylhydrazyl (DPPH<sup>•</sup>) to the yellow colored diphenylpicrylhydrazine (DPPH) with IC<sub>50</sub> of 4 mg mL<sup>-1</sup> and 12 mg mL<sup>-1</sup> respectively, showing an antioxidant activity lower than that of AA. It seems from these results, that AA is the most effective antioxidant with an IC<sub>50</sub> of 4 µg mL<sup>-1</sup> compared to the studied essential oils. The presence of oxygenated compounds and acids in *P. pinea* essential oil may be the reason of their considerable radical-scavenging activity.

## Conclusion

The results of current study suggest that the presence of oxygenated compounds and acids in *P. pinea* essential oil may be the main reason of their good bacteria inhibitory effects against *Candida albicans* and their considerable radical-scavenging activity compared to the synthetic antioxidant ascorbic acid and gallic acid that were used as antioxidant references.
