# An empirical study of oil and gas supply chain agility in the UAE

## Abstract

### Purpose

The aim of this research paper is to investigate the agility of oil and gas value chains in the United Arab Emirates and to understand the impact of implementing supply disruption strategies, outsourcing strategies and management strategies on oil and gas value chain agility. The results can support oil and gas industry across the UAE to build resilience in the value chain.

### Design/methodology/approach

The research design consists of a comprehensive literature review, followed by questionnaire based survey responses of 106 participants and comprehensive statistical analysis, thus validate the developed theoretical framework and contributes to both practical and methodological approach.

### Findings

The findings indicate that oil and gas value chain in the UAE have a good combination of supply disruption and outsourcing strategies in place that are synchronized with the overall management strategies. The implementation of these strategies have a positive and significant effect on the agility of the value chain and therefore the company's competitive position.

### Research limitations/implications

The research provides guidance for oil and gas supply chain managers to better understand the critical factors that impact and determine value chain agility. The paper also describes relevant strategies that should be taken into consideration by these managers in order to build agile value chains. The research contributes to social dimensions of supply chain sustainability of how resilient are the oil and gas value chain during uncertain conditions so that it can respond to uncertain changes in order to contribute to corporate social responsibility. Some of the limitations of this research include the geographic coverage of the study region and other methodological limitation.

### Originality/value

This research is the first of its kind in the UAE region to assess the link between dimensions of agile value chain, outsourcing strategies, supply disruption strategies and management strategies primarily from the Emirates of Abu Dhabi and Dubai.

### Keywords

Supply Chain Agility, Oil and Gas supply chain, Empirical research.

9 **1 Introduction**

10  
11  
12 In the last few years, Global Value Chains (GVCs) have increasingly become the center around which  
13 production and world trade are structured. A value chain classifies the complete series of activities and  
14 processes that firms perform to convey a service or a product from its foundation stage to its finishing stage  
15 to be used by end consumers (Gereffi & Fernandez-Stark, 2011). This range of activities include product  
16 conception, design, sourcing for intermediate inputs and raw materials, prototyping, production, marketing,  
17 distribution and support. In other words, global value chains today are complex networks of sourcing, pre-  
18 manufacturing, manufacturing, marketing, and consumption. Nowadays, this chain of activities is no longer  
19 confined in one place. As the cost of communication and transportation falls and the technological growth  
20 advances, the opportunities of international trade with intermediate and final services and goods have  
21 enhanced (Andersen, Nellemann & Thomsen, 2015). Moreover, factors like cost, access to raw materials and  
22 other resources, access to new markets, and commerce policy improvements have enabled the geographical  
23 destruction of the value chain activities throughout the globe. This global fragmentation of manufacturing  
24 processes is a significant source of competitive advantage and improved efficiency. Today, it is reported that  
25 intermediate services constitute 70% of the world's service imports and more that 50% of world  
26 manufactured imports are in the form of semi-finished products, parts and components (Backer & Miroudot,  
27 2013).

28  
29  
30  
31 There are two kinds of global value chains. The first kind initiates with a natural resource like mining,  
32 farming or any other kind of resource extraction. The start point of this kind of value chains is specific and  
33 pre-determined. The second kind is unattached to nature, this type of global value chains is free to search for  
34 the best location, influenced greatly by cost reductions. In addition, by looking into the literature, we can see  
35 that there are many indicators that give a better understanding of the global value chain sensation. First is the  
36 global value chain participation index, which indicates in absolute and relative terms the level to which a  
37 specific country is participating in a steeply fragmented value chain. It differentiates between the forward  
38 participation which is the use of local resources in the production of exports, and backward participation  
39 which using non-local resources and intermediates in exports. The second indicator is the index of the  
40 number of manufacturing stages, which shows the international and global parts of the VC and gives an  
41 indication of how long the global value chain is. Third, the distance to end market. This indicator shows the  
42 "upstreamness" of the country and define its location in the global value chain (Backer & Miroudot, 2013).

43  
44  
45  
46 One of the significant signs of the global value chain phenomena is that we should take a better look pass the  
47 industries to realize production and trade patterns. The global value chain literature asserts on business  
48 functions, such as design, R&D, purchasing, operations, distribution, advertising, customer services and all  
49 other activities along the value chain. While, on the other hand, countries incline to specialize in a particular  
50 business function that involves specific tasks instead of specializing in specific industries. Moreover, some  
51 countries tend to specialize in upstream activities like R&D, production of inputs and components, design  
52 and innovation while other countries prefer to specialize in downstream activities such as logistics,  
53 marketing, final assembly of products and branding.

54  
55  
56 In the field of global value chain applications in specific industries, it is clear that the chemical  
57 manufacturing industry is one of the top industries to be characterized by the existence of a large number of  
58 different global value chains. Probably, because it involves a large number of manufacturing and production  
59

1 processes along with many final and intermediate products. Looking into the value chain and the complete  
2 structure of the chemical manufacturing industry, we can see that it starts with oil and gas as inputs that are  
3 then converted in the subsequent production stages to different products such as active ingredients,  
4 petrochemicals, specialties, basis chemicals and polymers (Kannegieser, 2008). The chemical manufacturing  
5 industry produces inputs and raw materials that can be used in different other industries. The chemical global  
6 value chain has mainly two types of products. First are commodity products that are sold at low prices in  
7 mass quantities and are produced in large volumes at the early stages. The second type of products are  
8 normally produced at later stages and are called specialty products, because they integrate a higher degree of  
9 complexity and require larger investments when it comes to marketing and research and development such as  
10 the raw materials used in the pharmaceutical industry. Global market growths vary through the different  
11 phases in the chemical value chain. Evidence in the petrochemical industry, particularly “propylene  
12 polymers” which are affected by the expensive and unstable prices of crude oil around the world. On the  
13 other hand, the latest studies on shale rock as an important source of natural gas offers an increasing supply  
14 of raw materials used in the production of ethylene based products. The geography of the chemical industry  
15 is changing as a result of these different progressions. In the specialty products, new competitors are trying to  
16 increase their market share in this high money-making market. As a result, an obvious trend in the direction  
17 of commoditization is detected.

18  
19  
20  
21  
22 The chemical manufacturing industry sources its inputs internally from chemical sub-industries in addition to  
23 the inputs sourced from other industries. Moreover, there is a significant part of these inputs that is being  
24 obtained locally, mirrored in the fairly high average local size of the chemical global value chain among  
25 countries. There is no surprise that smaller countries illustrate relatively more global stages; on the other  
26 hand, the chemical manufacturing industries in large countries like China purchase more than 90% of its  
27 inputs locally (Backer & Miroudot, 2013). Which means that the chemical manufacturing industry in China  
28 is highly grouped with other supplying industries geographically. Nowadays, the opportunities and the  
29 challenges in the global market force chemical manufacturing organization to concentrate their efforts and  
30 source of added value on the manufacturing of high quality products and implementation of effective,  
31 flexible and strong global value chains (Caiazza, Volpe & Stanton, 2016). Furthermore, Yusuf et al. (2014)  
32 indicated that the agility of different service providers along the oil and gas value chain and the influence of  
33 their performance on the value chain are of significant importance in realizing associated value chain  
34 competitiveness. In fact, the early supporters of agility describe it as an overall system that has extraordinary  
35 capabilities to deal with the fast changing requirements of the market with flexibility and speed. Which make  
36 agility an important trade that every oil and gas value chain needs to have in all areas of the world including  
37 the UAE. All value chain agility definitions have a few themes in common, these themes are known as the  
38 four dimensions of agility which include improving the customer experience, empowering the influence of  
39 information and people, facing change and uniting to compete (Yusuf et al., 2014).

40  
41  
42  
43  
44 The survey used in this research paper sought to investigate the agility of oil and gas value chains in the  
45 UAE. In addition, it strived to understand and evaluate the critical factors that impact and determine UAE’s  
46 oil and gas value chain agility including supply disruption strategies, outsourcing strategies and management  
47 strategies. The results can support oil and gas companies across the UAE build resilience in the value chain.  
48 The remainder of this paper is divided into five parts: after this introduction the first part explains the  
49 problem and its background. The second part is the literature review that defines global value chains, oil and  
50 gas value chains, value chain agility and UAE oil and gas value chain. It also includes the research tree and  
51 identification of research gap. The third part is research methodology including research approach,  
52 measurements, questionnaire design, sample profile, sample size and data collection process. The fourth part  
53 is the analysis of data using IBM SPSS statistical package, the fifth and final part is discussions and  
54 conclusions.

## 2 Literature review

### 2.1 Global Value Chains

Looking into the role played by global value chains in specific industries will give a better understanding to the idea that the competition is no longer between companies but entire value chains. In their paper Giovannetti & Marvasi (2016) offer a company level perspective of the participation of global value chains in the food industry specifically in Italy. The paper analyzed the link between the global value chain participation and the probability to export, showing that the later will increase significantly as a result of participating in a global value chain. Moreover, the possibility of selling finished goods through large sales points will contribute significantly to internationalization. Moreover, there is no doubt that value chain management assisted organizations to optimize manufacturing and distribution costs, meet their customers demand and manage their production volumes. Specifically, in the chemical manufacturing industry where companies that have very high complexity in distribution networks and production processes used value chain management to effectively run their operations. Moreover, challenged by globalization and the fluctuation of raw material prices, it is not enough to optimize the costs in order to guarantee the overall profitability (Kannegiesser, 2008).

### 2.2 Oil and Gas Value Chains

The value chain of the oil and gas industry is very complex compared to the value chains of other industries. This value chain has two very different, yet very much related, major sections. First is the upstream value chain which involves getting hold of crude oil. This segment of the value chain contains many processes starting with crude oil exploration and drilling, forecasting production needs, production process and finally managing the logistics of moving the explored crude oil from remote locations to refineries. The upstream value chain processes is the responsibility of oil companies, while the processes of the second segment which is the downstream value chain are the responsibility of petrochemical companies and refineries. In the downstream processes the crude oil is converted to consumable derivatives at the refineries. Other downstream activities include forecasting of manufacturing quantities, manufacturing process, and logistics management of transferring the manufacturing outputs from the refineries to the end customers around the world. (Hussain, Assavapokee & Khumawala 2006). Figure (1) represents the total value chain for the oil and gas industry.

[Figure 1: Value Chain of the Oil and Gas Industry]

Hussain, Assavapokee & Khumawala (2006) state that the value chain management in the oil and gas industry has many challenges, more than any other industries, especially in the logistics management area. One of the major challenges is supply disruption. It is important to understand what external security threats may cause a disruption to the flow of oil and gas and how oil and gas companies are facing these threats through value chain strategies. Urciuoli et al. (2014) used multiple case studies to identify security threats to the oil and gas flow to Europe and the strategies companies used to face them. The results showed that a decent combination of strategies is being applied in the European oil and gas value chains such as safety stocks, portfolio diversification, transport capacity and flexible contracts. The study also identified the biggest security threats to the value chain including terrorism, vessel hijacking and war. There is no doubt that economies that depend on energy need to use their energy security strategies to manage the supply disruptions to the oil and gas flow. According to Gülpinar et al. (2014) the disruption to the oil and gas flow has a substantial financial effect on economies that are oil-dependent and many companies in these economies have faced cash- flow and revenue catastrophes because of such disruptions. Moreover, in their paper Modarress, Al Ansari & Thies (2016) examined the concept of outsourcing and looked into the challenges, the positive outcomes and the risks behind this strategy. It was clear that oil and gas exporters have a positive position toward outsourcing because it can provide significant savings along the oil and gas

1 value chain, on the other hand, it creates a disturbing resistance as a result of the fear from the unknown and  
2 compromising value chain privacy.  
3  
4

### 5 **2.3 Oil and Gas Value Chain Agility**

6 The oil and gas value chain includes a variety of service providers in the form of small and medium sized  
7 companies that have a supporting role in the operations of oil and gas companies. It is of substantial  
8 importance to the efficiency and effectiveness of the oil and gas value chain to make sure that these  
9 providers are well managed as a significant part of this chain. Moreover, Yusuf et al. (2014) reported that  
10 the agility of these enterprises along the oil and gas value chain and the influence of their performance on the  
11 value chain are of significant importance in realizing associated value chain competitiveness. In fact the  
12 early supporters of agility describe it as an overall system that has extraordinary capabilities to deal with the  
13 fast changing requirements of the market with flexibility and speed. These capabilities include highly  
14 motivated experienced management members, state of the art information technology, and capable human  
15 resources (Youssef, 1994). Agility of a value chains can also be defined as the ability of the organization to  
16 master market instability (van Hoek, 2000, 2001; van Hoek et al., 2001). Moreover, Gligor and Holcomb  
17 (2012) argued that an agile value chain has the ability of quickly engage in strategic alliances to serve it is  
18 own benefit, can speedily satisfy customer orders and can always announce new products in an consistence  
19 and timely manner. All value chain agility definitions have a few themes in common, these themes are  
20 known as the four dimensions of value chain agility which include improving the customer experience,  
21 empowering the influence of information and people, facing change and uniting to compete (Yusuf et al.,  
22 2014). In another paper Yusuf et al. (2014) look at how agility is distributed in the oil and gas industry and  
23 examine the influences of physically belonging to an industrial cluster on the agility of an organization. The  
24 findings of the paper described the important role of belonging to a cluster as an effective strategy for  
25 profitable exploitation and utilization of oil and gas natural resources. There is no doubt that oil and gas  
26 companies have a high level of uncertainties circulating its value chain and therefore these companies need  
27 dynamic value chain capabilities. Saad, Udin & Hasnan (2013) state that dynamic value chains requires  
28 constant reevaluation of organizational structures, technologies and partners. The more agile the value chain  
29 is, the more likely for the organization to invest, explore and create dynamic competences and therefore a  
30 better performance level with time.  
31  
32  
33  
34  
35

### 36 **2.4 UAE Oil and Gas Value Chain**

37 In the continuously changing world of oil and gas, United Arab Emirates is considered an important partner  
38 and an accountable producer in the global energy market having the world's 7th largest crude oil reserves.  
39 Nowadays, Oil and gas exports makeup for 25% of the country's total domestic product (uae-embassy.org).  
40 At this time the United Arab Emirates does not perform refining processes because this kind of activities  
41 needs advances and progressive expertise. Only basic refining is being performed by Abu Dhabi Oil  
42 Refining Company (TAKREER) while developing other facilities to support the overall value chain  
43 responsiveness. Other aspects of the oil and gas value chain include inventory management, supplier  
44 selection, new fields researches and transportation. In terms of supplier selection, the strategy now is based  
45 on safety, speed, quality and flexibility. The oil and gas value chain strategy asserts on always having a  
46 buffer inventory while conducting advanced researches to locate new crude oil wells. Transportation across  
47 the value chain is extremely responsive, and is steered through ADNATCO (Binlootah & Sundarakani,  
48 2012). Nevertheless, the UAE oil and gas value chain have to keep working on improving its agility to face  
49 the increasingly unstable energy market.  
50  
51  
52

### 53 **2.5 Research Tree**

54 A comprehensive research tree representing the core articles reviewed across the themes of the various oil  
55 and gas value chain elements are presented in Figure 2. The identified key research gaps are discussed in the  
56 proceeding section.  
57  
58

59 [Figure 2: Research Tree]

## 2.6 Identification of Research Gap

Based on the previous in depth review of the existing literature, it is obvious that the need for agile value chains with increased responsiveness in the field of oil and gas industry has been recognized. Nevertheless, unlike in the other process industries where there is a plenty of data on the role of agility in organizational success (Azevedo et al., 2012; Gunasekaran and Ngai, 2012; Sarkis et al., 2011; Khan and Pillania, 2008; Abdulmalek, and Rajgopal, 2007; Lin et al., 2006; Yusuf et al., 2004) this issue remains untapped in the area of oil and gas industry especially in the United Arab Emirates oil and gas value chains. The following table summarizes three core journals and shows how the findings were used to identify research objectives and research gap.

[Table 1: Identification of Research Gap]

## 3 Research Framework and Hypotheses

The purpose of this research is to assess the link between dimensions of agile value chain, outsourcing strategies, supply disruption and management strategies in the context of the UAE oil and gas industry. The continuously growing and vibrant nature of the oil and gas value chain presents many challenges for effective structure coordination. Members of the value chain stakeholders cannot compete independently any more due to the nature of the today's competition unless they innovate and sustainably differentiate their service or product offerings. The final product delivered to the end customer moves across a chain of entities that add to the value of the product. Moreover, recent aspects like outsourcing, globalization and cost savings along the value chain increased uncertainty and risk exposure.

[Figure 3: Research Framework]

Nowadays, both researchers and practitioners are highly interested in managing supply disruptions however not much emphasize are paid to design agile value chain. It has been frequently noticed over the years that oil and gas value chains in general do not operate smoothly as planned because supply disruptions usually arise in different areas. For example, natural disasters, extreme weather conditions, workers strike, products theft, machinery break down, oil spill-off and explosions at sea ports and so on. As a result, many researches has asserts on the necessity of implementing adequate strategies to handle supply disruptions (Deane et al., 2009; Krishnan and Ulrich, 2001). A good combination of supply disruption strategies include building safety stocks and transport capacity planning (Urciuoli et al., 2014), are expected to enhance the overall agility of the value chain and therefore increase the responsiveness to unplanned events. Henceforth the research designs the first hypothesis as follows;

H1. There is a positive relationship between implementing supply disruption strategies and oil and gas value chain agility

Alternatively, to mitigate supply disruptions, Urciuoli et al. (2014) confirmed the importance of diverse management strategies. Top management should work on implementing the concept of information sharing to build a ground base of data to face supply disruptions and manage outsourcing activities. Moreover, value chain risk management tools must to be implemented to enable supply chain managers to continuously monitor external threats and re-evaluate their strategies and respond to their clients accordingly. This kind of management strategies are expected to have a positive effect on value chain agility. Based on these natures the second hypothesis has been designed as;

1  
2 H2. There is a positive relationship between implementing management strategies and oil and gas  
3 value chain agility  
4

5 Another issue facing the oil and gas value chain management is to sustain a good economic growth line in  
6 geopolitical zones as required by investors, especially with the unprecedented low oil and gas prices in the  
7 past few years. Therefore, outsourcing has become a significant part of the oil and gas value chain strategy  
8 for cost-saving across all segments of the value chain. Nevertheless, the likelihood that outsourcing strategy  
9 can contribute to the profitability of the oil and gas value chain has unexplored areas. For example, hidden or  
10 unexpected costs, quality of product or service and knowledge partnership and its effect on companies  
11 security (Modarress, Ansari & Thies, 2016). It is expected that the outsourcing have a negative effect on  
12 value chain agility. Therefore the research designs the third hypothesis as follows;  
13  
14

15 H3. Outsourcing has a negative effect on oil and gas value chain agility  
16  
17

## 18 **4 Research methodology** 19

20 This research is a study with an inductive nature that proposes a model with a causal relationship between  
21 value chain agility and implementing supply disruption strategies, outsourcing strategies and management  
22 strategies. This proposed relationship requires validation using empirical data. A quantitative approach is  
23 adapted in this research using information gathered through a survey based questionnaire to obtain  
24 categorical data needed for the statistical testing. The statistical analysis of the data gathered through the  
25 questionnaires was performed using IBM SPSS Statistics (v.23)  
26  
27

### 28 **4.1 Research Approach** 29

30 Questionnaires are considered one of the best methods for data collection because non like other methods,  
31 for example observations and interviews, the sample population is spread over a large area which allows a  
32 countrywide or even global coverage. In addition, questionnaires used to contact people that would not be  
33 reachable by other methods like interviews. Moreover, questionnaires considered very economical for both  
34 the researcher and the respondent in terms of cost, time and effort. There is no need to travel or to hire a team  
35 to conduct interviews, which can also be time consuming. In the case of researches that need repetitive  
36 information, questionnaires are considered more useful and less expensive in comparison with other methods  
37 like observation or interviews. Also, while observations and interviews requires specific times and prior  
38 arrangements, respondents can reply to questionnaires at their own leisure. Moreover, because questionnaires  
39 ensure the anonymity of its respondents, they feel free to express their own point of views without having to  
40 worry about being identified or questioned for giving their honest feedback. Questionnaire is also considered  
41 an easy method. It does not require much knowledge or technical skill to plan, design and manage.  
42 Moreover, questionnaires do not allow much of data variation because it is distributed in a written form  
43 which will help the respondents to focus on the significant aspects and will standardize the process to record  
44 responses and therefore ensure uniformity. Another important advantage of using questionnaires for data  
45 collection that it can be used as an initial tool for performing a more in-depth research by any other method  
46 afterward. In addition, questionnaires have a unique advantage in regards to the validity of its information. In  
47 the questionnaire respondents provide their written responses using their own language which does not allow  
48 for any miss interpretation by the researcher while with other methods like observations and interviews the  
49 validity and reliability of the information depends on how the researcher interpret them which may be  
50 influenced by their own opinions and prejudice (Choudhury, 2015).  
51

### 52 **4.2 Measurements:** 53

54 Measurements are defined as a concept for linking the research model to the real world by using observations  
55 that are expressed in terms of steps to measure (Vogt, 2007). Given the amount of papers published in the  
56 area of this research, current measures were adopted to operationalize the variables. For Example the  
57 dependent variable value chain agility was measured using four dimensions of agility adopted from Yusuf et  
58 al. (2014), supply disruption was measured using two items adopted from Urciuoli et al. (2014), Outsourcing  
59 was measured using three items adopted from Modarress, Ansari & Thies (2016), and the last independent  
60

1 variable which is implementing management strategies was measured using two items adopted from Urciuoli  
2 et al. (2014). Table (2) below includes all measurements adopted for each variable and their references.  
3  
4

5 [Table 1: Measurement Items]  
6

### 7 **4.3 Questionnaire Design**

8 The questionnaire in this research thesis was designed to provide the input needed to answer the research  
9 question. The above measurement items were included and then analyzed to fulfil the research objectives.  
10 Moreover, formal procedures of questionnaire design, distribution, administration and analysis was applied  
11 to improve the validity of the data and reduce error.  
12  
13

14 The questionnaire used a “5-Point Likert Scale” to scale the answers of the survey research respondents.  
15 From a statistical point of view, the results of the questionnaire should have a normal distribution around a  
16 good percentage of points at the middle. Using a five point scale will allow the respondents to answer at  
17 either side of the middle point (3) and will result in the desired distribution.  
18  
19

20 The questionnaire started with a short introduction to brief the respondents on the researcher, research aims  
21 and the purpose of the study. Also to ensure participants that their participation is voluntary and all personal  
22 details will be kept confidential and anonymous. In addition, brief definitions of Value Chain and Agility  
23 was stated at the beginning to acquaint respondents with the study.  
24

25 The questionnaire had six sections, the first section (A) aimed to gather some information about the  
26 company, including type of company, company legal structure, number of employees in company, type of  
27 workflow process and the average procurement / contracted expenditure per annum. The second section (B)  
28 intended to collect market / industry information including respondents’ opinion on size of their main  
29 competitor and which companies control the oil and gas industry. Other questions aimed to specify the main  
30 aspects on which the companies compete or consider for oil and gas projects and oil & gas company’s  
31 competitive priorities.  
32  
33

34 The third, fourth and fifth sections were designed so that answers are used to proof the proposed hypothesis.  
35 The third section (C) started with a brief definition of supply disruption, then a question on supply disruption  
36 strategies was incorporated with the below scale:  
37  
38

- 39 1: Not Used
- 40 2: Very Limited
- 41 3: Limited
- 42 4: Extensive
- 43 5: Very Extensive
- 44

45 The forth section (D) started with a brief definition of outsourcing, then a question on outsourcing strategies  
46 and their effect on company’s profitability was included. Both negative and positive values scale was used to  
47 determine if implementing such strategies have a positive or negative effect or no effect at all (Zero). This  
48 scale was later converted to (1 to 5) scale for the purpose of data analysis.  
49  
50  
51

- 52 2: Highly Positive
- 53 1: Positive
- 54 0: No effect
- 55 -1: Negative
- 56 -2: Highly negative
- 57  
58  
59  
60

1 The fifth section (E) was designed to determine the degree to which company's use management strategies  
2 within the value chain, the below scale was adopted:  
3

- 4  
5 1: Not Used  
6 2: Very Limited  
7 3: Limited  
8 4: Extensive  
9 5: Very Extensive  
10

11 As for the dependent variable, Value Chain Agility, a question linking the four dimensions of agility with  
12 each of supply disruption, outsourcing and management strategies was included in all three sections (C, D &  
13 E) with the following scale:  
14

- 15  
16 1: Very Low  
17 2: Low  
18 3: Moderate  
19 4: High  
20 5: Very High  
21  
22

23 The last section (F) was added to gather personal information on the participants including department, job  
24 role, name, contact number and email address. This part was pushed to the end to raise confidence level of  
25 the respondents.  
26

#### 27 **4.4 Sample Profile**

28 The population targeted by this questionnaire was initially those in the designation of supply chain manager,  
29 supply chain director, purchasing manager, purchasing officer, director, managing director (MD) and chief  
30 executive officer. After starting the data collection the researcher found the response rate to be very low  
31 therefore the target audience was expanded to include more departments such as logistics, engineering,  
32 services and finance. The questionnaire was sent to respondents working in large, medium and small  
33 enterprises in the field of oil and gas explorations and production, logistics services, engineering services and  
34 offshore construction. This is supported by the view that oil and gas value chains are served by companies  
35 from different industrial sectors and different sizes (Cumbers *et al.*, 2003). Moreover, the questionnaires was  
36 sent out to respondents in companies that the researcher have no investment in nor direct relationship with  
37 (van der Vaart and van Donk, 2008).  
38  
39  
40

#### 41 **4.5 Oil & gas companies in the UAE**

42 Oil and gas companies in the UAE spread through the seven emirates. However, most of the companies are  
43 located in Abu Dhabi, the emirate with the biggest deposits of oil. Followed by Dubai, the next largest oil  
44 producer in the UAE. Its important status is reinforced by the presence of JAFZA where most of the oil and  
45 gas supporting companies exists. In fact, there are hundreds of companies under the oil and gas industry  
46 classification in both Abu Dhabi and Dubai chambers' commercial directory. And since it is difficult to send  
47 a survey to the whole population, the non-probability sampling method was followed and the questionnaire  
48 was sent to the people that are most conveniently available. Some of the companies that were contacted  
49 include: GE Oil & Gas, ABB, Siemens, Silvertch Middle East, Delta Controls FZCO, Abu Dhabi Marine  
50 Operating Company (ADMA-OPCO), Abu Dhabi National Oil Company (ADNOC), Abu Dhabi Oil  
51 Refining Company (TAKREER), Abu Dhabi Gas Industries Company (GASCO), Zakum Development  
52 Company (ZADCO), Abu Dhabi Company for Onshore Oil Operations (ADCO), Emirates National Oil  
53 Company (ENOC), and Dubai Petroleum Company (DPC).  
54  
55  
56  
57  
58  
59  
60

#### 4.6 Sample size

In this research, there are three independent variables (3IVs) and one dependent variable (1DV) that constitutes a total of 4 variables. As per Hair *et al.* (2010) standard response of quantitative research must be equal to or greater than 10 times the number of variables. Therefore a total of 40 responses or more will be sufficient enough to proceed with the statistical testing. For the survey participants, totally 400 participants were invited with a target to get a minimum of 40 responses to meet Hair *et al.* (2010) recommendation of 10 times or more observations per variable.

#### 4.7 Data Collection

Once the questionnaire was designed and validated the researcher started the data collection process. The participants were required to complete an online questionnaire using an online questionnaire tool named “Survey Monkey”. An online survey tool is employed because it is more convenient, cost effective and the responses can be easily exported to the data analysis application for statistical testing. The survey was created on 26<sup>th</sup> of October and closed 42 days later on the 6<sup>th</sup> of December, 2016. A total of 108 responses were received representing 27% response rate, nevertheless, two of them were incomplete. Therefore, 106 responses were used as input for IBM SPSS Statistics software package to conduct data analysis.

### 5 Results

The statistical analysis of the data gathered through the questionnaires was performed using IBM SPSS Statistics (v.23).

#### 5.1 Respondents and Responding firms characteristics

Table (3) below represents the characteristics of the respondents and their firms; first are the demographic and personal characteristics of the respondents to the questionnaire which include: participants’ position / job role in the organization and participants department. Second are companies’ information which include type of the company, company legal structure, size of the company, type of workflow process and value of procurement / contracted expenditure per annum. Finally are industry information that include size of the competition, control over the oil and gas Industry, main aspects for project consideration and the frequency of obtaining new contracts.

[Table 3: Characteristics of Respondents and Responding Firms]

#### 5.2 Validity and reliability

Content validity is a tool used to make sure that the questions in the questionnaire have some relationship with the variables and they are quantifying the concepts that are planned to be tested (Sekaran, 2003). For this purpose the survey was sent for a consultant agency by the name “Rapid Action Management Consultancy” in to order to make sure that the questionnaire was designed so that it is capable of providing information that can be analysed to achieve the aim of the research. Second, the survey was shared with an industry expert to get his feedback on the questions and revise accordingly in case of any issues arising. Finally, a pilot test of the survey was also conducted by sharing the questionnaire with a number of individuals for the purpose of testing the understanding of the questions and then making relevant modifications.

Reliability test is conducted on each individual variable to confirm if the results obtained for that particular variable is reliable. Cronbach’s alpha was used to measure internal consistency and the results in table (4) below confirmed that all variables are accepted as all Cronbach’s alpha values are 0.7 and above. (Cronbach, 1951)

[Table 4: Variables Cronbach’s alpha]

1 In addition, Cronbach's alpha was measured for the overall questionnaire (table (5)) and found to be 0.675.  
2 Although alpha values preferably range between (0.7 and 0.9), Nunnally & Bernstein (1994) stated that  
3 figures as low as 0.6 maybe acceptable. Therefore, the alpha value obtained for the overall questionnaire also  
4 ensures the internal consistency and validity of the variables used.  
5  
6

7 [Table 5: Questionnaire Cronbach's alpha]  
8  
9

### 10 **5.3 Descriptive Statistics**

11 Table (6) below shows the descriptive statistics of each variable including minimum, maximum, mean and  
12 standard deviation. All missing entries in the data were replaced with the corresponding mean and since a 5-  
13 Point Likert Scale was adopted, no outliers were detected.  
14

15 [Table 6: Descriptive Statistics]  
16  
17

18 With respect to the independent variables, it is clear that on average, the supply disruption strategies is the  
19 strongest variable (Mean = 4.08, SD = 0.83) followed by outsourcing strategies (Mean = 4.06, SD = 0.84).  
20 The weakest variable is management strategies (Mean = 3.05, SD = 1.19). Therefore, the suggestion is that,  
21 oil and gas companies would pay extra attention to implementing supply disruption strategies to insure  
22 continuous supply. Next is the management strategies that work side by side with supply disruption  
23 strategies to enhance the overall agility of the value chain and therefore increase the responsiveness to  
24 unplanned events.  
25  
26

### 27 **5.4 Factor analysis**

28 Factor analysis is defined as a reliant method and technique that is used to explain the underlying structure  
29 between the variables used in the analysis (Hair *et al.*, 2010). In addition to adequate sample size which  
30 means that number of observations must be equal or more than 10 times the number of variables, three main  
31 items were checked and confirmed before proceeding with factor analysis: first, strong foundational rationale  
32 supporting the existence of a structure; second, an existence of sufficient correlation among the variables  
33 supported by Barlett's test of sphericity with sigma value less than 0.05; and finally, Measure of Sampling  
34 Adequacy (MSA) with values for each variable exceeding 0.5. After carrying out the factor analysis, total  
35 variance explained was examined as well as factor loadings and commonalities which all were within the  
36 acceptable range as per (Nunnally and Vernstein, 1994). Table 7 below displays the output of the factor  
37 analysis conducted.  
38  
39

40 [Table 7: Factor Analysis Output]  
41  
42

43 Bartlett's Test of Sphericity was performed to indorse the statistical significance of the correlation between  
44 the items of the variable. As seen in table (7) above, the probability related to Bartlett's test for all constructs  
45 is < 0.001 which fulfills the requirement and confirms that factor analysis is appropriate for the selected data.  
46 Moreover, the KMO value for all variables is 0.5 or above which also fulfills the requirement of a minimum  
47 value of 0.5 (Kaiser, 1974).  
48

49 The indicators for the "Supply Disruption Strategies" construct explain (90.9%) of the total variance in the  
50 data. The values for the other constructs are as follows: Outsourcing Strategies (70.99%), Management  
51 Strategies (92.7%) and Value Chain Agility is (67.4%). Moreover, Factor loadings for all measurement items  
52 are above 0.7 as shown in the table.  
53  
54

### 55 **5.5 Multiple Linear Regression Analysis (MRA)**

56  
57  
58  
59  
60

1  
2 In order for the researcher to validate the proposed model, statistical techniques has to be employed to  
3 explain and predict the impact of the independent variables on the dependent variable and also to compare  
4 the combined effect of all individual variables on the independent variable. Multiple regression analysis is  
5 used to test the relationship between dependent and independent variables because this approach examines  
6 the relationship between single dependent variable (Value Chain Agility) and several independent variables  
7 (Supply disruption strategies, Outsourcing Strategies and Management Strategies). The significance value  
8 can also be determined through this.

### 9 10 **5.5.1 Model Summary**

11 Table (8) for model summary shows as sig F change value is 0.000 which is less than the limit value of 0.05  
12 therefore the addition of the three independent variables is statistically significant in predicting the dependent  
13 variable . In addition the table shows an R square value of 0.293 which indicates that 29.3% of the variability  
14 in the dependent variable VCA is explained by the independent variables (SD, OS and MS).

15  
16 [Table 8: The model summary]

### 17 18 19 20 **5.5.2 Coefficients table**

21  
22 To measure the contribution of each independent variable to the model we examine the above coefficients  
23 table (9). Based on  $\beta$  values, the value chain agility with respect to supply disruption strategies, outsourcing  
24 strategies and management strategies can be presented as:

$$25 \hat{Y} (VCA) = 3.588 - 0.141 SD_{avg} + 0.099 OS_{avg} + 0.327 MS_{avg} + Error$$

26  
27  
28  
29  
30  
31 [Table 9: VCA Coefficients]

### 32 33 34 35 **5.5.3 ANOVA**

36  
37 ANOVA table (10) shows that as P value = 0.000, the regression model is significantly better at predicting  
38 the relationship between the dependent and independent variables than some random method.

39  
40  
41 [Table 10: ANOVA results]

## 42 43 44 45 **5.6 Hypothesis Testing**

46  
47 The hypothesis testing is performed to confirm the hypothesis that was proposed. In this research the  
48 researcher is interested in quantifying the strength and the direction of an assumed relationship between  
49 numbers of variables. Therefore, correlation is used to determine the nature and features of this relationship.  
50 And since the survey results have a normal distribution and there are no outliers as the Likert scale is  
51 adopted, Pearson's Product-Moment Correlation Coefficient is better suited than others. (Prion & Haerling,  
52 2014)

53  
54  
55  
56  
57  
58  
59  
60 Pearson's Product-Moment Correlation Coefficient, which is commonly known as "Pearson's  $r$ ", usually  
generates an  $r$  value between the values of -1 and 1. The value -1 indicates a strong negative relationship, the  
value 1 indicates a strong positive relationship and "Zero" indicates no relationship at all (Prion & Haerling,

2014). The “rule of thumb” for interpreting Pearson’s  $r$  results are as follows for absolute values: (0 to 0.20) is negligible, (0.21 to 0.35) is weak, (0.36 to 0.67) is moderate, (0.68 to 0.90) is strong, and (0.91 to 1.00) is considered very strong and also very rare in social science research. (Taylor, 1990; Shavelson, 1996).

Puth, Neuhauser & Ruxton (2014) stated that having a positive correlation indicates that both the dependent and independent variables move in same direction. In other words if the value independent variable goes up then the value of the dependent variable will go up as well. Moreover, having a negative correlation indicates that the dependent and independent variables moves in opposite directions. If one variable goes up the second one will go down.

Another outcome that can be determined from the Pearson’s  $r$  value is the coefficient of determination ( $r^2$ ). For example, if the value of  $r^2= 0.7$  then 70% of the variation in the dependent variable (Y) can be explained by the variation in the dependent variable (X). And similarly, 70% of the variation among sampled respondents in their values in the independent variable (X) can be explained by the variation in their values in the dependent variable (Y). (Puth, Neuhauser & Ruxton (2014)). Table 11 below shows the output for Pearson Correlation test.

[Table (11): Output for Pearson Correlation test]

The table shows that there is a positive and significant relationship between implementing supply disruption strategies, outsourcing strategies, management strategies and value chain agility as all Pearson’s  $r$  have a positive value in the range (0.68 to 0.90) which indicates a “moderate positive correlation”. The table also shows sig. values of .000 which indicates that the correlation is significant. Moreover, 18.7% of the variation in the dependent variable (VCA) can be explained by the variation in the dependent variable (SD), 15% of the variation in the dependent variable (VCA) can be explained by the variation in the dependent variable (OS) and 20.9% of the variation in the dependent variable (VCA) can be explained by the variation in the dependent variable (MS).

## 6 Discussions and Conclusions

The analysis of the data confirmed that oil and gas value chains in the UAE have in place a good combination of supply disruption strategies including transport capacity planning and building safety stocks. This is in line with previous research stating that it is essential to plan and implement in advance effective strategies to handle supply disruption (Deane et al., 2009; Krishnan and Ulrich, 2001; Urciuoli et al., 2014). Value chain managers build safety stocks to ensure uninterrupted supply in case of disruption by calibrating inventories to guarantee availability of products (Tomlin, 2006; Sheffi, 2006; Torhaug, 2008; Tang, 2006). Moreover, companies usually seek to set up access to various modes of transportation by dealing with multiple carriers and therefore multiple channels and distribution routes (Tang, 2006; Tomlin, 2006). Some of the other strategies that was mentioned by the respondents to mitigate supply disruption include pre-arranging critical stocks in advance, reduce dependence on key suppliers, better contingency planning, contracts management and supplier engagement. In addition, respondents confirmed that the implementation of such strategies improved the agility of the value chain through a positive impact on various dimensions of agility. Previous researches suggested that such strategies enhanced the resilience competences of the companies by enabling rapid responses to unexpected situations and hence improve competitive advantage which was also confirmed by the questionnaire respondents. (Khan et al., 2012, Urciuoli et al., 2014)

Moreover, the analysis of the data confirmed the importance of diverse management strategies including information sharing and the effective use of risk management tools. Similarly to what is proposed in the current literature (Tomlin, 2006; Blos et al., 2009; Li et al., 2006; Skipper & Hanna, 2009; Christopher et al., 2011). Respondents confirmed that top management should work on implementing the concept of

1 information sharing to build a ground base of data to face supply disruptions and manage outsourcing  
2 activities. Moreover, value chain risk management tools should be implemented to enable supply chain  
3 managers to continuously monitor external threats and re-evaluate their strategies and respond to their clients  
4 accordingly. The output of the data gathered through the questionnaire also confirmed that implementing  
5 such strategies have a positive effect on diverse dimensions of agility and therefore increase the overall value  
6 chain responsiveness.  
7  
8

9  
10 Another issue facing the oil and gas value chain management is to sustain a good economic growth line in  
11 geopolitical zones as required by investors, especially with the unprecedented low oil and gas prices in the  
12 past few years. Therefore, outsourcing has become a significant part of the oil and gas value chain strategy  
13 for cost-saving across all segments of the value chain. Respondents to the questionnaire confirmed that  
14 outsourcing has a positive effect on their companies' profitability in terms of cost savings, which is in line  
15 with previous research stating that reducing cost is one of the major benefits of outsourcing (Modarress,  
16 Ansari & Thies, 2016). Respondents also confirmed that outsourcing has a positive impact on the quality of  
17 product or service as contracting some functions to third parties for cost reduction results in added value to  
18 in-house efficiency. This is also consistent with current literature (Doh et al. 2005; Modarress et al. 2010).  
19 On the other hand, Respondent's to the questionnaire had split views on the effect of outsourcing on  
20 knowledge partnership, some considered that outsourcing has a positive effect on knowledge partnership.  
21 This is supported in the literature by viewing outsourcing as a strategic knowledge partnership with highly  
22 skilled vendors that can bring experience and knowledge to the organization (Roza et al., 2011). Other  
23 respondents considered that outsourcing has no effect on the companies' information security. This view is  
24 also supported in the literature by the fact that knowledge partnership with outsourcing providers is  
25 controlled by laws of intellectual property protection. Oil and gas companies have legal rights to patents its  
26 trademarks and products (Modarress, Ansari & Thies, 2016). Taking into consideration the effect of  
27 outsourcing on companies' profitability the results of the questionnaire confirmed that outsourcing has a  
28 positive effect on different dimensions of agility resulting in a highly responsive and more resilience value  
29 chains. This is consistent with view that the benefits of outsourcing outweigh the potential risks of hidden or  
30 unexpected costs, lack of confidentiality, poor service and late delivery. (Schiederjans & Zukweiler, 2004;  
31 Modarress & Ansari, 2007; Modarress, Ansari & Thies, 2016)  
32  
33  
34  
35

36 From a scientific perspective, this research paper contributes to the ongoing research on the role of agility in  
37 organizational success and the factors that impact and determine this agility in the context of UAE oil and  
38 gas industry. The literature review included in this paper reveals that unlike in the other process industries  
39 where there is a plenty of data on the role of agility in organizational success (Azevedo et al., 2012;  
40 Gunasekaran and Ngai, 2012; Sarkis et al., 2011; Khan and Pillania, 2008; Abdulmalek, and Rajgopal, 2007;  
41 Lin et al., 2006; Yusuf et al., 2004) this issue remains untapped in the area of oil and gas industry especially  
42 in the United Arab Emirates oil and gas value chains. Hence, this research contributes with an overview of  
43 the effect of implementing supply disruption, outsourcing and management strategies on the overall value  
44 chain agility. From a practical perspective, this paper describes relevant strategies that should be taken into  
45 consideration by value chain managers of oil and gas companies in order to improve their companies value  
46 chain's agility. Figure (4) below shows the final theoretical framework with the results of hypothesis testing  
47 using Pearson Product-Moment Correlation Coefficient.  
48  
49  
50

51 [Figure 4: Theoretical Framework with Hypothesis Testing Results]  
52

53 The main limitation of this study is the limitation in geographic accessibility issues since many oil and gas  
54 companies are based in Abu Dhabi and Dubai in the UAE. The researcher recommendation for future  
55 research is to adopt a qualitative approach by conducting interviews with industry experts form different oil  
56 and gas companies across the United Arab Emirates to gain deeper understanding on some outcomes of the  
57 study. Moreover, case studies can be used to understand how oil and gas companies, from a value chain  
58 perspective, are working to increase their overall responsiveness to gain competitive advantage.  
59  
60

1  
2 In conclusion, the oil and gas value chains today are complex networks of sourcing, pre-manufacturing,  
3 manufacturing, marketing, and consumption. Supply chain managers of these companies are more often  
4 being asked to take decisions in complex environments where both technical and social capabilities make the  
5 difference in terms of building agile value chains. The findings indicates that oil and gas value chain  
6 mangers in the United Arab Emirates have in place a good combination of supply disruption and outsourcing  
7 strategies that are synchronized with management strategies. The implementation of these strategies have a  
8 positive and significant effect on the agility of the value chain and therefore the company's competitive  
9 position.  
10

Figure 3: Research Framework  
(Framework developed by Author)

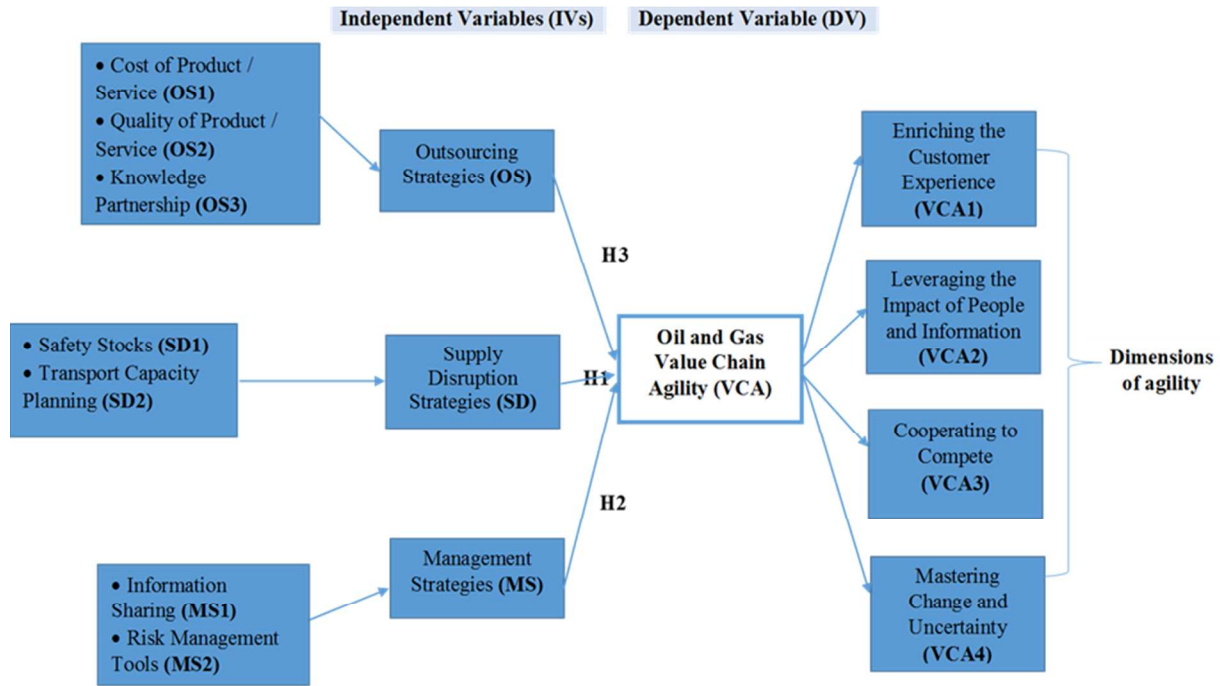

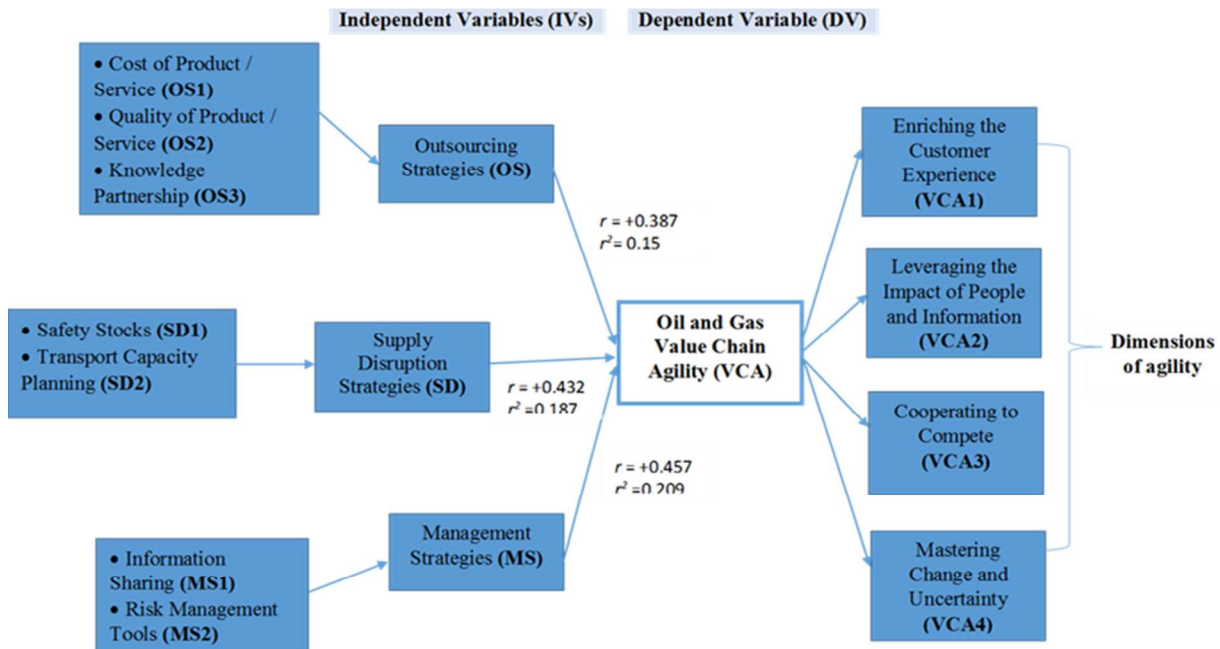

Figure 4: Theoretical Framework with Hypothesis Testing Results

**Table 1: Identification of Research Gap**

Author	Title	Research Method	Major research findings	Identified (potential) research gaps	Research objectives
Modarress, Ansari & Thies 2016	<b>Outsourcing in the Persian Gulf petroleum supply chain</b>	Quantitative + Qualitative	<ol style="list-style-type: none"> <li>1. Challenges, benefits and risks in outsourcing</li> <li>2. The oil and gas exporters have mixed but broad positive view of outsourcing strategy</li> <li>3. While outsourcing could provide savings across the entire supply chain, it also generates a distracting resistance due to the fear of unknown in a complex range of culture</li> <li>4. The results reveal the compromise between the potential benefits in cost reduction and the security of petroleum supply</li> </ol>	undisclosed	Investigate the implementation of outsourcing strategy
Uraiuoli et. al. 2014	<b>The resilience of energy supply chains: a multiple case study approach on oil and gas supply chains to Europe</b>	Case study	<ol style="list-style-type: none"> <li>1. Disruption strategies that companies are using include: portfolio diversification, flexible contracts, transport capacity planning and safety stocks</li> <li>2. Security threats companies fear, include hijacking of vessels (sea piracy), terrorism, and wars</li> <li>3. European Union has built a comprehensive portfolio of strategies to deal with scarcity of oil and gas resources</li> </ol>	<ol style="list-style-type: none"> <li>1. New supply chain risk management tools need to be developed to enable supply chain managers to continuously monitor and assess policies and foreign political conflicts and then align their strategies accordingly</li> <li>2. Surveys could be used to collect data from a wider sample of companies and also to demonstrate and validate causal relationships among the structures identified</li> </ol>	Supply disruption & management strategies to build resilience
Yusuf et. al. 2014	<b>A relational study of supply chain agility, competitiveness and business performance in the oil and gas industry</b>	questionnaire based survey	<ol style="list-style-type: none"> <li>1. The paper identifies the most important dimensions and attributes of supply chain agility and provides a deeper insight into those characteristics of agility that are most relevant within the oil and gas industry</li> <li>2. Agility has a significant influence on competitive objectives and business performance</li> <li>3. Where supply chains are considered as long-term partnerships, they lead to enhanced customer loyalty</li> <li>4. Prosperity in a dynamic business environment can be attained only through innovation and risk taking</li> <li>5. Statistical evidence was found to support the impact of capturing demand information on both financial and non-financial business performance measures</li> </ol>	There is a need to look in-depth at each of the streams of the industry (i.e., operators, contractors and suppliers) to determine the critical factors that impact and determine the agility of their respective supply sub-chains	How agile are the oil and gas supply chains in the oil and gas industry?

		SD2 Transport Capacity Planning			0.953	
	Outsourcing Strategies	OS1 Cost of Product / Service	0.691	0.000	0.794	70.985
		OS2 Quality of Product / Service			0.866	
		OS3 Knowledge Partnership			0.865	
	Management Strategies	MS1 Information Sharing	0.500	0.000	0.963	92.696
MS2 Risk Management Tools		0.963				
Dependent	Value Chain Agility	VCA1 Enriching the Customer Experience	0.750	0.000	0.864	67.353
		VCA2 Leveraging the Impact of People and Information			0.793	
		VCA3 Cooperating to Compete			0.774	
		VCA4 Mastering Change and Uncertainty			0.848	

**Table 8: VCA Model Summary**

Model Summary <sup>b</sup>										
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics					Durbin-Watson
					R Square Change	F Change	df1	df2	Sig. F Change	
1	.541 <sup>a</sup>	.293	.272	.35209	.293	14.069	3	102	.000	1.962

a. Predictors: (Constant), MS\_Average, OS\_Average, SD\_Average

b. Dependent Variable: VCA\_Average

**Table 9: VCA Coefficients**

Coefficients <sup>a</sup>													
Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	95.0% Confidence Interval for B		Correlations			Collinearity Statistics	
		$\beta$	Std. Error	Beta			Lower Bound	Upper Bound	Zero-order	Partial	Part	Tolerance	MF
1	(Constant)	<b>3.588</b>	.180		19.919	<b>.000</b>	3.231	3.946					
	SD_Average	<b>-.141</b>	.219	-.284	-.644	<b>.521</b>	-.576	.293	.432	-.064	-.054	.036	28.096
	OS_Average	<b>.099</b>	.030	.286	3.295	<b>.001</b>	.039	.159	.387	.310	.274	.923	1.083
	MS_Average	<b>.327</b>	.218	.666	1.499	<b>.137</b>	-.106	.760	.457	.147	.125	.035	28.495

a. Dependent Variable: VCA\_Average

**Table 10: ANOVA**

ANOVA <sup>a</sup>						
Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	5.232	3	1.744	14.069	<b>.000<sup>b</sup></b>
	Residual	12.645	102	.124		
	Total	17.877	105			

a. Dependent Variable: VCA\_Average

b. Predictors: (Constant), MS\_Average, OS\_Average, SD\_Average

Table (11): Output for Pearson Correlation test

Correlations					
		<b>SD<sub>avg</sub></b>	<b>OS<sub>avg</sub></b>	<b>MS<sub>avg</sub></b>	<b>VCA<sub>avg</sub></b>
<b>SD<sub>avg</sub></b>	Pearson Correlation	1			
	Sig. (2-tailed)				
	N	106			
<b>OS<sub>avg</sub></b>	Pearson Correlation	.216 <sup>*</sup>	1		
	Sig. (2-tailed)	.026			
	N	106	106		
<b>MS<sub>avg</sub></b>	Pearson Correlation	.982 <sup>**</sup>	.245 <sup>*</sup>	1	
	Sig. (2-tailed)	.000	.011		
	N	106	106	106	
<b>VCA<sub>avg</sub></b>	Pearson Correlation	.432 <sup>**</sup>	.387 <sup>**</sup>	.457 <sup>**</sup>	1
	Sig. (2-tailed)	.000	.000	.000	
	N	106	106	106	106

\*. Correlation is significant at the 0.05 level (2-tailed).

\*\*. Correlation is significant at the 0.01 level (2-tailed).
