Using the data accumulated in 2002-2004 with the D0 detector in proton-antiproton collisions at the Fermilab Tevatron collider with a center-of-mass energy of 1.96 TeV , the branching fractions of the decays $B \rightarrow \bar{D}_{1}^{0}(2420) \mu^{+} \nu_{\mu} X$ and $B \rightarrow \bar{D}_{2}^{* 0}(2460) \mu^{+} \nu_{\mu} X$ and their ratio have been measured: $\mathcal{B}(\bar{b} \rightarrow B) \times$ $\mathcal{B}\left(B \rightarrow \bar{D}_{1}^{0} \mu^{+} \nu_{\mu} X\right) \times \mathcal{B}\left(\bar{D}_{1}^{0} \rightarrow D^{*-} \pi^{+}\right)=[0.087 \pm 0.007($ stat $) \pm 0.014($ syst $)] \% ; \mathcal{B}(\bar{b} \rightarrow B) \times \mathcal{B}(B \rightarrow$ $\left.\bar{D}_{2}^{* 0} \mu^{+} \nu_{\mu} X\right) \times \mathcal{B}\left(\bar{D}_{2}^{* 0} \rightarrow D^{*-} \pi^{+}\right)=[0.035 \pm 0.007($ stat $) \pm 0.008($ syst $)] \%$ and $\left[\mathcal{B}\left(B \rightarrow \bar{D}_{2}^{* 0} \mu^{+} \nu_{\mu} X\right) \times\right.$ $\left.\mathcal{B}\left(\bar{D}_{2}^{* 0} \rightarrow D^{*-} \pi^{+}\right)\right] /\left[\mathcal{B}\left(B \rightarrow \bar{D}_{1}^{0} \mu^{+} \nu_{\mu} X\right) \times \mathcal{B}\left(\bar{D}_{1}^{0} \rightarrow D^{*-} \pi^{+}\right)\right]=0.39 \pm 0.09$ (stat) $\pm 0.12$ (syst), where the charge conjugated states are always implied.

This Letter describes our investigation of the properties of semileptonic decays of $B$ mesons to orbitally excited states of the $D$ meson that have small decay widths. In the simplest case, these states consist of a charm quark and a light quark in a state with orbital angular momentum equal to one. In the limit of a large charm quark mass $m_{c} \gg$ $\Lambda_{\mathrm{QCD}}$, one doublet of states with $j=3 / 2\left(D_{1}, D_{2}^{*}\right)$ and another doublet with $j=1 / 2\left(D_{0}^{*}, D_{1}^{\prime}\right)$ are predicted to exist, where the angular momentum $j$ is the sum of the light quark spin and orbital angular momentum. Conservation of parity and angular momentum restricts the final states that are allowed in the decays of these particles collectively known as $D^{* *}$ mesons. The states that decay through a $D$ wave, $D_{1}$ and $D_{2}^{*}$, are expected to have small decay widths, $O\left(10 \mathrm{MeV} / \mathrm{c}^{2}\right)$, while the states that decay through an $S$ wave, $D_{0}^{*}$ and $D_{1}^{\prime}$, are expected to be broad, $O\left(100 \mathrm{MeV} / \mathrm{c}^{2}\right)$.

The ratio $R$ of the semileptonic branching fractions of the $B$ meson to $D_{1}$ and $D_{2}^{*}$ :

$$
\begin{equation*}
R=\frac{\mathcal{B}\left(B \rightarrow D_{2}^{*} \ell \bar{\nu}\right)}{\mathcal{B}\left(B \rightarrow D_{1} \ell \bar{\nu}\right)} \tag{1}
\end{equation*}
$$

is one of the least model-dependent predictions of heavy quark effective theory (HQET) [1] for these states. This ratio is expected to be equal to 1.6 in the infinite charm quark mass limit [2], but it can have a lower value once $O\left(1 / m_{c}\right)$ corrections are taken into account [3,4]. Together with the measurement of the corresponding ratio $R_{\pi}$ for the nonleptonic decays $B \rightarrow D^{* *} \pi$, determination of $R$ will provide important tests of HQET and factorization of the nonleptonic decays [3].

The narrow $D^{* *}$ mesons have been previously studied by several experiments, most recently at Belle [5] where the ratio $R_{\pi}$ was measured. The semileptonic decay fractions of $B$ mesons to $D^{* *}$ mesons were reported previously by the ARGUS [6], CLEO [7], OPAL [8], ALEPH [9], and DELPHI (as preliminary) [10] Collaborations, with only the latter measuring the fraction of $B \rightarrow D_{2}^{*} \ell \bar{\nu}$ and the others setting upper limits for this decay mode.

The data set used for this analysis corresponds to $\approx$ $460 \mathrm{pb}^{-1}$ of integrated luminosity accumulated by the D0 detector between April 2002 and September 2004 in proton-antiproton collisions at the Fermilab Tevatron collider at center-of-mass energy 1.96 TeV . The D0 detector has a central tracking system consisting of a silicon microstrip tracker (SMT) and a central fiber tracker (CFT) [11]. Both are located within a 2 T superconducting solenoidal magnet and have designs optimized for tracking and vertexing for $|\eta|<3$ and $|\eta|<2.5$ [12], respectively. The SMT has a six-barrel longitudinal structure, each with a set of four layers arranged axially around the beam pipe, and interspersed with 16 radial disks. Silicon sensors have typical strip pitch of $50-150 \mu \mathrm{~m}$. The CFT has eight thin coaxial barrels, each supporting two doublets of overlapping scintillating fibers of 0.835 mm diameter. The next
layer of detection involves a preshower constructed of scintillator strips and a liquid-argon/uranium calorimeter. An outer muon system, covering $|\eta|<2$, consists of a layer of tracking detectors and scintillation trigger counters in front of 1.8 T iron toroids, followed by two similar layers after the toroids [13]. A suite of single-muon online triggers was used to record the data set while offline only information from the muon and tracking systems was used in this analysis.

Production of narrow $D^{* *}$ mesons in $B \rightarrow$ $D^{*-} \pi^{+} \mu^{+} \nu_{\mu} X$ decay manifests itself as resonance peaks in the $D^{*-} \pi^{+}$[14] invariant mass spectrum. To perform the measurement, the semileptonic branching fractions of $B$ mesons to the $D^{* *}$ mesons were normalized to the $B \rightarrow$ $D^{*-} \mu^{+} \nu_{\mu} X$ process.

Initially, a sample of $\mu^{ \pm} \bar{D}^{0}$ candidates was selected by requiring a muon with transverse momentum $p_{T}^{\mu}>$ $2 \mathrm{GeV} / c$ and $\left|\eta^{\mu}\right|<2$. $\bar{D}^{0}$ mesons were reconstructed through their decays into $K^{+} \pi^{-}$. Two tracks with $p_{T}>$ $0.7 \mathrm{GeV} / c$ and $|\eta|<2$ were required to belong to the same jet and to form a common $\bar{D}^{0}$ vertex following the procedure described in detail in Ref. [15]. To increase the signal yield, the event selections of Ref. [15] were relaxed by removing the explicit requirement that the $p_{T}$ of the $\bar{D}^{0}$ exceeds $5 \mathrm{GeV} / c$. In total $216870 \pm 1280$ (stat) $\mu^{+} \bar{D}^{0}$ candidates were found.
$D^{*-}$ candidates were selected through their decays into $\bar{D}^{0} \pi^{-}$by requiring an additional track with $p_{T}>$ $0.18 \mathrm{GeV} / c$ and the charge opposite to that of the muon. The mass difference $\Delta M=M(K \pi \pi)-M(K \pi)$ for all such tracks with assigned pion mass is shown in Fig. 1 for events with $1.75<M(K \pi)<1.95 \mathrm{GeV} / c^{2}$. The signal was described as the sum of two Gaussian functions and

FIG. 1. Distribution of the mass difference $M(K \pi \pi)-$ $M(K \pi)$ for events with $1.75<M(K \pi)<1.95 \mathrm{GeV} / c^{2}$. The fit function describes the signal as the sum of two Gaussian functions and the background as the sum of exponential and first-order polynomial functions. The signal contribution is also shown separately. The hatched histogram corresponds to the same-sign combination of the muon and pion charges.
the background as the sum of exponential and first-order polynomial functions. The total number of $D^{*-}$ candidates in the peak is $55450 \pm 280$ (stat) and is defined as the number of signal events in the mass difference window between 0.142 and $0.149 \mathrm{GeV} / c^{2}$.

To select a sample of $B \rightarrow D^{*-} \mu^{+} \nu_{\mu} X$ decays used later both for the signal search and for the normalization, $B$ candidates were defined using the $\mu^{+}$and $D^{*-}$ particles. All tracks used for the reconstruction of the $B$ candidate had to have at least two SMT and six CFT hits. The decay length of the $B$ meson, defined in the axial plane [16] as the distance between the primary vertex [15] and the $B$ meson vertex, was restricted to be less than 1 cm , the uncertainty on the $B$-vertex axial position had to be less than 0.5 mm , and the $\chi^{2}$ of the $B$-vertex fit had to be less than 25 for 3 degrees of freedom. The significance of the decay length in the axial plane and the proper decay length of the $B$ meson [15] were required to exceed 3.0 and 0.25 mm , respectively. The significance is defined as the ratio of the decay length to its uncertainty. The last selection, more stringent than in Ref. [15], reduces the $c \bar{c}$ contamination in the $\mu^{+} D^{*-}$ sample to less than $1 \%$. After these selections, the total number of $D^{*-}$ candidates in the invariant mass difference peak is $N_{D^{*}}=31160 \pm 230$ (stat).
$D^{* *}$ decays can be selected by combining the $D^{*}$ candidates with an additional track with assigned pion mass. The track was required to have a charge opposite to that of the $D^{*}, p_{T}>0.3 \mathrm{GeV} / c$, and at least two SMT and six CFT hits. Pions from the $D^{* *}$ decay can also be selected by their topology since the corresponding track originates from the $B$ vertex rather than from the primary vertex. The impact parameters (IP) in the axial plane with respect to the primary and with respect to the $B$ vertex were determined for each track. In order to select tracks belonging to the $B$ vertex, the ratio of IP significances of the track for the primary and $B$ vertices was required to be greater than four and the IP significance with respect to the primary vertex

FIG. 2. The invariant mass $M\left(D^{*} \pi\right)$. Event selection is described in the text. The points correspond to the $D^{*} \pi$ combinations with opposite charges, and the hatched histogram corresponds to the same-charge combinations. The distribution was fit with a sum of two relativistic Breit-Wigner functions corresponding to two narrow $D^{* *}$ states and a second-order polynomial describing the background. The contributions of $D_{1}^{0}$ and $D_{2}^{* 0}$ to the fit are shown separately.
was required to be greater than one. The IP significance is defined as the ratio of the impact parameter to its uncertainty.

The $D^{* *}$ invariant mass distribution after all selections is shown in Fig. 2 where the $D^{*}$ mass from the Particle Data Group (PDG) [17] has been used as a mass constraint. The observed mass peak can be interpreted as two merged narrow $D^{* *}$ states, $D_{1}^{0}$ and $D_{2}^{* 0}$.

The distribution was fit using a sum of two relativistic Breit-Wigner functions $G_{D_{1}}$ and $G_{D_{2}^{*}}$, corresponding to the two narrow $D^{* *}$ states with the numbers of events $N_{D_{1}}$ and $N_{D_{2}^{*}}$, respectively, and a second-order polynomial $f_{b}$ describing the background, see Eq. (2).

$$
\begin{array}{cl}
f(x)=N_{D_{1}} G_{D_{1}}+N_{D_{2}^{*}} G_{D_{2}^{*}}+f_{b}(x) ; & G_{i}=\frac{M_{i} \Gamma(x)}{\left(x^{2}-M_{i}^{2}\right)^{2}+M_{i}^{2} \Gamma(x)^{2}} \otimes \operatorname{Res}_{i} \\
\Gamma(x)=\Gamma_{i} \frac{M_{i}}{x}\left(\frac{k}{k_{0}}\right)^{2 L+1} F^{(L)}\left(k, k_{0}\right) ; & F^{(2)}\left(k, k_{0}\right)=\frac{9+3\left(k_{0} z\right)^{2}+\left(k_{0} z\right)^{4}}{9+3(k z)^{2}+(k z)^{4}}
\end{array}
$$

In the formulas above, $x$ is the $D^{*} \pi$ invariant mass and $M_{i}$ and $\Gamma_{i}$ are the mass and width of the corresponding resonance. The variables $k$ and $k_{0}$ are the pion threemomenta in the $D^{* *}$ rest frame when the $D^{* *}$ has a four-momentum-squared equal to $x^{2}$ and $M_{i}^{2}$, respectively. $F^{(2)}\left(k, k_{0}\right)$ is the Blatt-Weisskopf form factor for $D$ wave ( $L=2$ ) decays of $D^{* *}$ mesons [18], and $z=$ $1.6(\mathrm{GeV} / c)^{-1}$ is a hadron scale corresponding to the case of the charm quark. $\mathrm{Res}_{i}$ is the mass resolution function described by two Gaussian functions with the parametrization determined from Monte Carlo (MC) simulations. The second Gaussian describing the resolution
corresponded to $28 \%$ of events and was wider by a factor of 2.2 than the first one. The standard D0 simulation chain included the EVTGEN [19] generator interfaced to PYTHIA [20] and followed by full GEANT [21] modeling of the detector response and event reconstruction. The MC resolution was scaled up by $20 \%$ to account for the difference between the data and the MC, where the scaling factor was estimated by comparing the $D^{*}$ mass resolution in the data and MC. The mass resolution used for the fit (sigma of the first Gaussian in the resolution function) was $8.2 \mathrm{MeV} / c^{2}$ for $D_{1}^{0}$ and $9.4 \mathrm{MeV} / c^{2}$ for $D_{2}^{* 0}$ after the scaling.

The parameters of the background function were determined by fitting the distribution of the same-charge combinations, fixing the function shape parameters, and allowing the overall normalization of the background to float in the mass fit. The mass difference between $D_{1}^{0}$ and $D_{2}^{* 0}$ and the widths of $D_{1}^{0}$ and $D_{2}^{* 0}$ were fixed in the fit using their corresponding values from the PDG [17]: $36.7 \pm$ $2.7 \mathrm{MeV} / c^{2}, \quad 18.9_{-3.5}^{+4.6} \mathrm{MeV} / c^{2}, \quad 23 \pm 5 \mathrm{MeV} / c^{2}$. The numbers of events in the two narrow states derived from the fit, $N_{D_{1}}=467 \pm 39$ (stat) and $N_{D_{2}^{*}}=176 \pm 37$ (stat),
were used to determine the total number of events $N_{D^{* *}}=$ $643 \pm 38$ (stat), and the ratio $N_{D_{2}^{*}} / N_{D_{1}}=0.378 \pm$ 0.086(stat), where the uncertainties take into account correlation between the variables. The $\chi^{2}$ of the fit at the minimum is 46.9 for 46 degrees of freedom.

The branching fraction for the decays $B \rightarrow \bar{D}^{* *} \mu^{+} \nu_{\mu} X$ can be determined by normalization to the known value of the branching fraction $\mathcal{B}\left(\bar{b} \rightarrow D^{*-} \ell^{+} \nu X\right)=(2.75 \pm$ $0.19) \%$ [18]. The following two formulas were used for the calculations:

$$
\begin{aligned}
\mathcal{B}(\bar{b} \rightarrow B) \times \mathcal{B}\left(B \rightarrow \bar{D}^{* *} \mu^{+} \nu_{\mu} X\right) \times \mathcal{B}\left(\bar{D}^{* *} \rightarrow D^{*-} \pi^{+}\right)=\mathcal{B}\left(\bar{b} \rightarrow D^{*-} \ell^{+} \nu X\right) \frac{N_{D^{* *}}}{N_{D^{*}}} \frac{1}{\epsilon_{D^{* *}}} \\
\frac{\mathcal{B}\left(B \rightarrow \bar{D}_{2}^{* 0} \mu^{+} \nu_{\mu} X\right) \times \mathcal{B}\left(\bar{D}_{2}^{* 0} \rightarrow D^{*-} \pi^{+}\right)}{\mathcal{B}\left(B \rightarrow \bar{D}_{1}^{0} \mu^{+} \nu_{\mu} X\right) \times \mathcal{B}\left(\bar{D}_{1}^{0} \rightarrow D^{*-} \pi^{+}\right)}=\frac{N_{D_{2}^{*}}}{N_{D_{1}}} \frac{\epsilon_{D_{1}}}{\epsilon_{D_{2}^{*}}}
\end{aligned}
$$

$N_{D^{* *}}$ and $N_{D^{*}}$ are the numbers of $D^{* *}$ and $D^{*}$ candidates as defined above. The $D^{* *}$ notation stands for $D_{1}^{0}$ or $D_{2}^{* 0}$ or both of them, $\left(D_{1}^{0}, D_{2}^{* 0}\right) . \epsilon_{D^{* * *}}$ is the efficiency to reconstruct the charged pion from the $D^{* *}$ decay determined from the MC and equal to $[47.2 \pm 1.0(\mathrm{stat})] \%$ for the $D_{1}^{0}$ meson and $[45.4 \pm 1.2($ stat $)] \%$ for the $D_{2}^{* 0}$ meson. Contributions from $B_{s}$ mesons, $\Lambda_{b}$ baryons, and $B \rightarrow$ $D_{(s)}^{(*)} D^{*-} X$ decays to the sample were found to be small and have been neglected [16].

The relative systematic uncertainties on the branching fractions and of their ratio are summarized in Table I. The contribution due to uncertainty in $\mathcal{B}\left(\bar{b} \rightarrow D^{*-} \ell^{+} \nu X\right)$ was determined from the uncertainty on this branching fraction. The systematic uncertainty caused by the MC mass resolution was estimated by varying the resolution by $\pm 20 \%$. Contributions due to limited knowledge of the $D^{* *}$ masses and widths were computed by refitting the mass distribution after varying these parameters within their uncertainties. The systematic uncertainty due to efficiency modeling accounts for the variation caused by a possible mismatch
between the $p_{T}$ spectra of reconstructed particles in the data and MC.

There are predictions and possibly observations [6] of a wide resonance $\bar{D}_{1}^{\prime 0}$ with a mass of $2430 \mathrm{MeV} / c^{2}$ and a width of $380 \mathrm{MeV} / c^{2}$ predominantly decaying to $D^{*-} \pi^{+}$. This resonance is not apparent in our data, and it was not used in the fits. The systematic uncertainty caused by a possible contribution of this resonance was evaluated allowing for another Breit-Wigner function in the fit, with the mass and width fixed to the wide resonance parameters.

Any interference effects between the $D_{1}^{0}$ and $D_{2}^{* 0}$ must average to zero after integration over all angles under the assumption of equal acceptances. The validity of this assumption has been checked and the corresponding uncertainty assigned. The systematic uncertainty due to the fitting procedure was estimated by varying the functions describing the backgrounds for the $D^{*}$ and $D^{* *}$ mass distributions and also the function describing the $D^{*}$ mass peak. The total systematic uncertainty was found by summing all the above sources in quadrature.

TABLE I. Relative systematic uncertainties on the semileptonic branching fraction to both narrow states, $\mathcal{B}_{D^{* *}}$; the semileptonic branching fractions to $D_{1}^{0}$ and to $D_{2}^{* 0}, \mathcal{B}_{D_{1}}$ and $\mathcal{B}_{D_{2}^{*}}$; and their ratio $\mathcal{B}_{D_{2}^{*}} / \mathcal{B}_{D_{1}}$.

| Source | $\mathcal{B}_{D^{* *}}$ | $\mathcal{B}_{D_{1}}$ | $\mathcal{B}_{D_{2}^{*}}$ | $\mathcal{B}_{D_{2}^{*}} / \mathcal{B}_{D_{1}}$ |
| :--- | ---: | ---: | ---: | ---: |
| $\mathcal{B}\left(\bar{b} \rightarrow D^{*-} \ell^{+} \nu X\right)$ | $7 \%$ | $7 \%$ | $7 \%$ | - |
| Mass resolution | $2 \%$ | $4 \%$ | $5 \%$ | $8 \%$ |
| $\Gamma_{D_{1}}$ | $3 \%$ | $11 \%$ | $16 \%$ | $24 \%$ |
| $\Gamma_{D_{2}^{*}}$ | $2 \%$ | $2 \%$ | $11 \%$ | $13 \%$ |
| $\Delta M$ | $1 \%$ | $3 \%$ | $6 \%$ | $9 \%$ |
| MC statistics | $2 \%$ | $2 \%$ | $2 \%$ | $3 \%$ |
| $\epsilon_{D^{* *}}$ modeling | $3 \%$ | $3 \%$ | $3 \%$ | $2 \%$ |
| Wide resonance | $5 \%$ | $5 \%$ | $5 \%$ | $2 \%$ |
| Interference effects | $2 \%$ | $2 \%$ | $2 \%$ | $2 \%$ |
| $D^{*}$ fit and $D^{* *}$ bkg fit | $4 \%$ | $4 \%$ | $4 \%$ | $1 \%$ |
| Total uncertainty | $12 \%$ | $16 \%$ | $24 \%$ | $30 \%$ |

Using the numbers defined above, the semileptonic branching fractions of $B$ mesons to $D^{* *}$ mesons and their ratio are:

$$
\begin{aligned}
\mathcal{B}(\bar{b} \rightarrow B) \times \mathcal{B}\left[B \rightarrow\left(\bar{D}_{1}^{0}, \bar{D}_{2}^{* 0}\right) \mu^{+} \nu_{\mu} X\right] \times \mathcal{B}\left[\left(\bar{D}_{1}^{0}, \bar{D}_{2}^{* 0}\right) \rightarrow D^{*-} \pi^{+}\right] & =[0.122 \pm 0.007(\text { stat }) \pm 0.015(\text { syst })] \% \\
\mathcal{B}(\bar{b} \rightarrow B) \times \mathcal{B}\left(B \rightarrow \bar{D}_{1}^{0} \mu^{+} \nu_{\mu} X\right) \times \mathcal{B}\left(\bar{D}_{1}^{0} \rightarrow D^{*-} \pi^{+}\right) & =[0.087 \pm 0.007(\text { stat }) \pm 0.014(\text { syst })] \% \\
\mathcal{B}(\bar{b} \rightarrow B) \times \mathcal{B}\left(B \rightarrow \bar{D}_{2}^{* 0} \mu^{+} \nu_{\mu} X\right) \times \mathcal{B}\left(\bar{D}_{2}^{* 0} \rightarrow D^{*-} \pi^{+}\right) & =[0.035 \pm 0.007(\text { stat }) \pm 0.008(\text { syst })] \% \\
\frac{\mathcal{B}\left(B \rightarrow \bar{D}_{2}^{* 0} \mu^{+} \nu_{\mu} X\right) \times \mathcal{B}\left(\bar{D}_{2}^{* 0} \rightarrow D^{*-} \pi^{+}\right)}{\mathcal{B}\left(B \rightarrow \bar{D}_{1}^{0} \mu^{+} \nu_{\mu} X\right) \times \mathcal{B}\left(\bar{D}_{1}^{0} \rightarrow D^{*-} \pi^{+}\right)} & =[0.39 \pm 0.09(\text { stat }) \pm 0.12(\text { syst })]
\end{aligned}
$$

Upon using the input $\mathcal{B}(\bar{b} \rightarrow B)=(39.7 \pm 1.0) \%$ [17], assuming isospin conservation and that the $D_{1}$ meson decays only into $D^{*} \pi$ [22], the branching fraction $\mathcal{B}(B \rightarrow$ $\left.\bar{D}_{1}^{0} \ell^{+} \nu X\right)=(0.33 \pm 0.06) \%$ is determined. It is different from the PDG value, $(0.74 \pm 0.16) \%$ [17], by 2.5 standard deviations. Similarly the branching fraction $\mathcal{B}(B \rightarrow$ $\left.\bar{D}_{2}^{* 0} \ell^{+} \nu X\right)=(0.44 \pm 0.16) \%$ is determined assuming that $D_{2}^{*}$ decays into $D^{*} \pi$ in $(30 \pm 6) \%$ of the cases [17]. This result is in agreement with the $95 \%$ C.L. upper limit $0.65 \%$ provided by the PDG.

Using the measured ratio of the branching fractions and the same assumptions for the absolute fractions for $D_{1}$ and $D_{2}^{*}$ as above, the ratio $R=1.31 \pm 0.29$ (stat) $\pm 0.47$ (syst) was computed.

In summary, using $460 \mathrm{pb}^{-1}$ of integrated luminosity accumulated with the D 0 detector, the semileptonic decays $B \rightarrow \bar{D}_{1}^{0} \mu^{+} \nu_{\mu} X$ and $B \rightarrow \bar{D}_{2}^{* 0} \mu^{+} \nu_{\mu} X$ have been observed and the branching fractions measured using statistics more than an order of magnitude better than previous measurements [6-10]. This result represents a significant improvement in the knowledge of $B$ branching fractions to orbitally excited $D$ mesons, and the first direct measurement of their ratio.
