#### Abstract

The syntheses of silica-supported oligomeric benzyl phosphates $\left(\mathrm{Si}_{\mathrm{i}}-\mathrm{OBP}_{\mathrm{n}}\right)$ and triazole  alkylating reagents is reported. Ease of synthesis and grafting onto the surface of norbornenyltagged (Nb-tagged) silica particles has been demonstrated for benzyl phosphate and triazole phosphate monomers. It is shown that these silica polymer hybrid reagents, $\mathrm{Si}^{-\mathrm{OBP}_{\mathrm{n}}}$ and $\mathrm{Si}-\mathrm{OTP}_{\mathrm{n}}$, can be used to carry out alkylation reactions with an array of different nucleophiles to afford the corresponding benzylated and (triazolyl)methylated products in good yield and high purity.

## INTRODUCTION

The need to rapidly synthesize a wide variety of small molecules in the desired quantities with high purities and yields is an important challenge facing drug discovery and developmental chemistry. ${ }^{1}$ To help address this need, immobilized reagents and scavengers have been developed to provide ease of synthesis and to eliminate time-consuming chromatographic separation protocols. These reagents have found frequent use in the arena of facilitated synthesis and high-throughput chemistry, ${ }^{2,3}$ as well as in the scale-up of advanced pharmaceutical intermediates. ${ }^{4}$ Given the large range of chemistries and conditions in which they need to be employed as reagents, scavengers, or catalysts, the field has seen a number of new innovations regarding immobilized polystyrene resins, ${ }^{5}$ silicas, ${ }^{6}$

[^0]soluble polyethylene glycol (PEG) polymers, ${ }^{7}$ monolith ${ }^{8}$ and fluorous-tagged compounds ${ }^{9}$ to remove impurities or excess reagents from reaction mixtures. Some of the more recent developments reported include silica-supported isocyanide ligands for scavenging ruthenium, ${ }^{10}$ mesocellular silica-supported boronic acids as direct amidation catalysts, ${ }^{11}$ silica-supported rhodium catalysts, ${ }^{12} \mathrm{~N}$-heterocyclic carbenes, ${ }^{13}$ palladium and copper (I) catalysts, ${ }^{14}$ phosphines, ${ }^{15}$, prolinol and TADDOLs. ${ }^{16}$ However, for all of their advantages immobilized reagents are often limited by several factors, including (i) low load levels (ii) heterogeneous reaction kinetics and non-surface diffusion-controlled processes, (iii) immobilized reagent swelling, and (iv) poor solvent tolerance. While some of these issues have been addressed through the development of technologies such as microgels, Janda-gels and micro-porous resins, ${ }^{3}$ there is still a need for additional materials that can deliver the performance of solution-phase reagents with the ease of removal (via filtration, precipitation, extraction, etc.) afforded by their immobilization.

We have previously examined a variety of soluble, high-load, oligomeric reagents and scavengers derived through the use of ring-opening methathesis polymerization (ROMP) of functionalized norbornene and 7-oxanorbornene monomers. ${ }^{17}$ These materials, known as ROMPgels, build on the pioneering efforts of Barrett, ${ }^{18}$ Buchmeiser, ${ }^{19}$ Bolm ${ }^{20}$ and others; ${ }^{21}$ and they have effectively been used to mediate a number of chemical reactions. However, while these ROMPgel materials have the advantage of behaving equivalently to traditional homogeneous reagents and catalysts, they are generally removed from solution via precipitation, which can limit their use in pharmaceutical applications.

As a result, inspired by the seminal work of Buchmeister and coworkers, ${ }^{22}$ efforts were focused on the synthesis and study of a number of hybrid materials that graft several of the ROMPgel materials onto the surface of silica particles. ${ }^{23}$ Through this grafting process, the resulting immobilized ROMP reagents can be removed from solution by simple filtration, thus eliminating the precipitation step. In this fashion, silica-supported ROMPgel acid chloride, dichlorotriazine, and triphenylphosphine reagents were generated with properties nearly identical to the equivalent soluble ROMPgel oligomeric reagents. ${ }^{23}$

We herein describe our efforts to expand the family oligomeric materials that have been grafted onto silica to include ROMP-derived oligomeric benzyl phosphate $\left(\mathrm{OBP}_{\mathrm{n}}\right)$ and triazole phosphate $\left(\mathrm{OTP}_{\mathrm{n}}\right)$, which we previously reported as soluble alkylating reagents that were used in facilitated library generation. ${ }^{24}$ Benzylation and triazolation are useful diversification reactions in medicinal chemistry, high-throughput chemistry, and diversityoriented synthesis (DOS). ${ }^{25}$ The benzylation of amines and alcohols also serves as one of the most utilized protecting group strategies in organic synthesis due to its easy incorporation and removal. ${ }^{26}$ While these uses have spurred development of a number of alternative approaches to benzylation ${ }^{27}$ and triazolation, we believe the generation of the analogous silica-oligomeric benzyl phosphate $\left(\mathrm{Si}^{-\mathrm{OBP}_{\mathrm{n}}}\right.$ ) and triazole phosphate ( $\mathrm{Si}-\mathrm{OTP}_{\mathrm{n}}$ ) reagents could find efficient, safe, and cost effective applications in chemical synthesis and library production. Key advantages of these reagents, include: (i) their stability at room temperature (ii) safety in handling when compared to commercially available benzyl bromides or iodides, and (iii) ease of purification via simple filtration through Celite ${ }^{\circledR}$.

## RESULTS AND DISCUSSION

Initial efforts centered on the synthesis of the silica-grafted oligomeric benzyl phosphate reagent, as outlined in Scheme 1, using a modification of the procedure reported by Buchmeiser. ${ }^{28}$ The activated silica $1(60 \AA, 20 \mu \mathrm{~m})$ was tagged with commercially available norbornene silyl reagent $\left[(\mathrm{MeO})_{3} \mathrm{Si}-\left(\mathrm{CH}_{2}\right)_{2}-\mathrm{Nb}(2)\right]$ followed by capping with trimethoxymethylsilane and dimethoxydimethylsilane to afford the norbornenefunctionalized silica (Si-Nb) 3 (Scheme 1). It was observed that, the use of ( MeO$)_{3} \mathrm{Si}$ -$\left(\mathrm{CH}_{2}\right)_{2}-\mathrm{Nb}(\mathbf{2})$ dramatically increased the norbornene load of Si-Nb (3), compare to 5-(bicycloheptenyl)-triethoxysilane $\left[\mathrm{Nb}-\mathrm{Si}(\mathrm{OEt})_{3}\right]$, which was previously used for silica tagging. ${ }^{23}$ By this optimized method, we prepared norbornene-functionalized silica 3 (SiNb ) on gram scale with $0.4 \mathrm{mmol} / \mathrm{g}$ loading (determined by modified bromine titration method). ${ }^{29}$ With this Si-tagged nanoparticle (3) in hand, a metathesis catalyst-armed surface-initiated polymerization was established using the C848 [Grubbs $2^{\text {nd }}$ generation catalyst, G-II) $)^{30}(20 \mathrm{~mol} \%$, based on $\mathrm{Si}-\mathrm{Nb}$ load $)$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and toluene as solvents, followed by addition of the Nb -tagged benzyl phosphate monomer $\mathbf{4}$ to rapidly generate the desired hybrid material 5a, silica oligomeric benzyl phosphate ( $\mathrm{Si}_{\mathrm{i}} \mathrm{OBP}_{\mathrm{n}}$ ). The benzyl phosphate monomer 4 was itself easily synthesized in good yield and purity according to previously reported methods. ${ }^{24 \mathrm{a}}$ Norbornene exo-diol 6 was reacted with $\mathrm{POCl}_{3}$ and $\mathrm{Et}_{3} \mathrm{~N}$ in the presence of catalytic DMAP to generate the Nb-tagged monochlorophosphate compound 7 in moderate yields as a white solid (Scheme 1). This material was then reacted with benzyl alcohol in NMI, and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature to yield 4. The scale-up synthesis of the monomeric reagent, as well as $\mathrm{Si}^{-} \mathrm{OBP}_{\mathrm{n}}$ have been carried out on gram scale as stable, freeflowing powders. The SEM images of $\mathrm{Si}-\mathrm{OBP}_{\mathrm{n}}$ and $\mathrm{Si}-\mathrm{OTP}_{\mathrm{n}}$ silica hybrid materials demonstrate the grafting of the corresponding monomer on silica surface and inherent morphology of hybrid materials (Figure 1).

The utilization of silica oligomeric benzyl phosphate $\mathbf{5 a}\left(\mathrm{Si}_{\mathrm{-}}-\mathrm{OBP}_{\mathrm{n}}\right)$ for benzylation with various $N$-, $O$-, $S$ - nucleophiles including anilines, amines, phenols, thiols, and sulfonamides (Table 1), were next examined. The reactions were carried out in a sealed pressure tube with different nucleophiles ( 1 equiv.), $\mathrm{Si}^{-} \mathrm{OBP}_{\mathrm{n}}$ ( 1.5 equiv), $\mathrm{Cs}_{2} \mathrm{CO}_{3}$ ( 3.0 equiv.) and NaI ( 0.2 equiv.) in THF at $80^{\circ} \mathrm{C}$ (oil bath temperature) to yield the products after simple filtration via Celite ${ }^{\circledR}$-SPE to remove Si-phosphate by-product. The corresponding benzylated analogs ( $\mathbf{8 a}-\mathbf{8 h}$ ) were isolated in excellent purities ( $>90 \%$, determined by LC-MS) and yields. We have screened wide varieties of nucleophile for benzylation. Initially, a variety of amines and phenols (Table 1, entry 1-4) were utilized and then extended to thiophenols and sulfonamides (Table 1, entry 5-8) to yield (>90\%) of the benzylated products.

With these results in hand, an expanded set of $\mathrm{Si}_{\mathrm{-}} \mathrm{OBP}_{\mathrm{n}}$ derivatives was next examined (Figure 2). These high load reagents ( $\mathbf{5 b} \mathbf{- 5 d}$ ) were synthesized in an analogous fashion to the $\mathrm{Si}_{\mathrm{-}} \mathrm{OBP}_{\mathrm{n}}$ reagent in Scheme 1 and were also obtained on gram scales as free-flowing powders. Utilization of these reagents in substitution reaction with $O$ - and $S$-nucleophiles were next carried out to afford benzylated products ( $\mathbf{8 i} \mathbf{i} \mathbf{8 n}$ ) in good yield ( $>90 \%$ ) and excellent purity after Celite ${ }^{\circledR}$-SPE filtration (Table 2). Diversification of the $\mathrm{Si}^{-} \mathrm{OBP}_{\mathrm{n}}$ reagents via substituting electron withdrawing groups, as well as electron donating groups,
on the aryl moiety were next examined, and in all cases, analogous results to Table 1 were obtained (see Table 2).

Attention was next placed on the gram-scale generation of silica oligomeric triazole phosphate hybrid reagents $\left(\mathrm{Si}-\mathrm{OTP}_{\mathrm{n}}\right)$. Triazoles and their derivatives have demonstrated a wide variety of biological activity, with many reports focusing on antifungal activity. ${ }^{31} \mathrm{We}$ previously reported soluble oligomeric triazole phosphates to construct a wide array of triazole-containing compounds. Silica-immobilized oligomeric triazole phosphate $\mathbf{1 0 a}(\mathrm{Si}-$ $\mathrm{OTP}_{\mathrm{n}}$ ) was synthesized via grafting of the Nb-tagged benzyl triazole phosphate monomer 9 onto the surface of norbornene-functionalized silica $(\mathrm{Si}-\mathrm{Nb}) 3$ through the same protocol discussed for the synthesis of $\mathrm{Si}-\mathrm{OBP}_{\mathrm{n}}$ in Scheme 1. The product, 10a $\left(\mathrm{Si}-\mathrm{OTP}_{\mathrm{n}}\right)$, was isolated as a free flowing solid in high-load ( $1.15 \mathrm{mmol} / \mathrm{g}$ ) (Scheme 2). The triazole phosphate monomer 9 was synthesized in good yield and purity according to previously reported methods. ${ }^{24}$ Phosphorylation of propargyl alcohol with Nb-tagged phosphonyl chloride 7, followed by a "Click"-capture event of the corresponding azide, yields the desired monomer 9 in an efficient fashion (Scheme 2). The triazole phosphate monomer, as well as silica oligomeric triazole phosphate reagents $\left(\mathrm{Si}_{-}-\mathrm{OTP}_{\mathrm{n}}\right)$ have been synthesized on gram scale as stable, free-flowing solids.

With $\operatorname{Si-OTP} \mathrm{n}_{\mathrm{n}}$ 10a in hand, the hybrid material was evaluated for (triazolyl)methylation on various nucleophiles including amines, phenols, thiophenols and sulfonamides in good yields and high purity with chromatography-free purification. The reaction was carried out in a pressure tube with different nucleophiles ( 1 equiv.), $\mathrm{Si}^{-} \mathrm{OTP}_{\mathrm{n}}$ ( 1.5 equiv.), $\mathrm{Cs}_{2} \mathrm{CO}_{3}$ (3.0 equiv.) and NaI ( 0.2 equiv.) in DMF at $90^{\circ} \mathrm{C}$ for overnight. The reaction mixture was diluted with EtOAc and filtered through a pad of Celite ${ }^{\circledR}$ to give the corresponding (triazolyl)methylated products. Optimal results were achieved in DMF compared to THF. A variety of $N$-, $O-, S$-nucleophiles were utilized for nucleophilic substitution reaction with Si $\mathrm{OTP}_{\mathrm{n}}$ triazolating reagent gave the (triazolyl)methylated products (11a-11g) in excellent yield and high purity ( $>85 \%$, determined by LC-MS) (Table 3). In all cases, similar results (Table 3) were obtained as compared to $\mathrm{Si}-\mathrm{OBP}_{\mathrm{n}}$ in THF in Table 1.

Building on these results, the project was expanded to the synthesis of additional variants of Si-OTP ${ }_{n}$ hybrid reagents ( $\mathbf{1 0 b} \mathbf{- 1 0 d}$, Figure 3 ) on gram scales as free-flowing powders in an analogous fashion to the $\mathrm{Si}^{-} \mathrm{OTP}_{\mathrm{n}}$ reagent in Scheme 2. These $\mathrm{Si}^{2}-\mathrm{OTP}_{\mathrm{n}}$ hybrid reagents were utilized for (triazolyl)methylation of $O$ - and $S$-nucleophiles. In all cases, (triazolyl)methylated products (11h-11m) were isolated in excellent yield and high purity after passing thru a Celite ${ }^{\circledR}$ SPE (Table 4).

In conclusion, the combination of Nb -tagged silica particles and functionalized Nb -tagged monomers efficiently yields high-load, hybrid Si-ROMP benzylating and (triazolyl)methylating reagents. A metathesis catalyst-armed surface (CAS)-initiated polymerization was key to functionalization of units off the silica particle surface. With this technology, we developed Si-immobilized oligomeric benzyl phosphate $\left(\mathrm{Si}_{-} \mathrm{OBP}_{\mathrm{n}}\right)$ as a benzylating reagent and triazole phosphate $\left(\mathrm{Si}_{\mathrm{i}}-\mathrm{OTP}_{\mathrm{n}}\right)$ as a (triazolyl)methylating reagent on gram scale as stable, free-flowing powders in all cases, utilizing ROMP of Nb-tagged phosphate monomers. SEM imaging was utilized to demonstrate the successful grafting of
the corresponding oligomer and the inherent morphology of the hybrid materials. Utilization of these reagents for representative small molecule synthesis, under purification free protocols, was demonstrated to afford corresponding products in excellent yield and with high purity. Since benzylation is a key transformation in many synthetic processes, we are currently working on expanding the scope of nucleophiles (i.e., alcohols, bis-nucleophilic, etc), as well as the scale on which these transformations can be carried out.

## EXPERIMENTAL SECTION

## General Information

All reactions were carried out under argon atmosphere. Stirring was achieved with ovendried magnetic stir bars. $\mathrm{Et}_{2} \mathrm{O}$ and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ were purified by passage through the Solv-Tek purification system employing activated $\mathrm{Al}_{2} \mathrm{O}_{3}$ (Pangborn, A. B.; Giardello, M. A.; Grubbs, R. H.; Rosen, R. K.; Timmers, F. J. Safe and Convenient Procedure for Solvent Purification Organometallics 1996, 15, 1518-1520). $\mathrm{CHCl}_{3}$ was passed through basic alumina and dried over molecular sieves. $\mathrm{Et}_{3} \mathrm{~N}$ was purified by passage through basic alumina or distilled over $\mathrm{CaH}_{2}$ and stored over KOH. For Celite-SPE 6 mL empty cartridges were used. All the solvents for routine isolation of products and chromatography were reagent grade. Flash chromatography was performed using silica gel (300-400 mesh) with the indicated solvents. Melting points were recorded on an Electrothermal digital melting point apparatus and were uncorrected. IR spectra were recorded on a spectrophotometer using KBr optics. ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on 400 or $500 \mathrm{MHz}\left({ }^{1} \mathrm{H}\right.$ NMR) and 100 or 125 MHz $\left({ }^{13} \mathrm{C}\right.$ NMR) spectrometers using $\mathrm{CDCl}_{3}$ as the solvent and TMS as the internal standard. The ${ }^{1} \mathrm{H}$ NMR data are reported as the chemical shift in parts per million, multiplicity (s, singlet; d , doublet; t , triplet; q , quartet; m , multiplet), coupling constant in hertz, and number of protons. High-resolution mass spectra were obtained using a high-resolution ESI-TOF mass spectrometer.

## General Procedure for Silica Oligomeric Benzyl Phosphate (Si-OBP ${ }_{n}$ ) and Triazole Phosphate (Si-OTP ${ }_{\mathrm{n}}$ )

$\mathrm{Si}-\mathrm{Nb}$ (load $\sim 0.4 \mathrm{mmol} / \mathrm{g}, 1$ equiv.) was heated with C 848 (G-II, 0.2 equiv.) at $45{ }^{\circ} \mathrm{C}$ in dichloromethane for 2 hrs under argon. The OBP or OTP monomer was added ( 50 equiv. w/r to cat. G-II) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and toluene to the reaction mixture and heated at $45^{\circ} \mathrm{C}$ for overnight. The reaction mixture was cooled to room temperature and EVE was added, with stirring for an additional 1 hour at room temperature. The reaction mixture was filtered and washed with mixture of toluene: $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1: 1)$, and dried over high vacuo pump.

The mixture was stirred rapidly and then nucleophiles were added. The reaction was sealed under argon and heated to $80^{\circ} \mathrm{C}$ with stirring for 12 h . After such time, the reaction was cooled to rt and the crude mixture was filtered via a Celite ${ }^{\circledR}$-packed SPE and rinsed several times with a mixture of hexanes:EtOAc (1:2). The resulting eluent was concentrated in vacuo to yield the benzylated products in good to excellent yields and purities.

## Procedure B: General procedure for different nucleophilic substitution with $\mathrm{Si}^{-\mathrm{OTP}_{\mathbf{n}}}$

In a pressure tube was added $\mathrm{Si}^{-\mathrm{OTP}_{\mathrm{n}}} \mathbf{1 0 a}$ (1.5 equiv.), followed by addition of $\mathrm{NaI}(0.2$ equiv.), $\mathrm{Cs}_{2} \mathrm{CO}_{3}$ ( 3.0 equiv.), and solvent DMF ( 0.2 M ). The nucleophile was added and the resulting mixture was stirred rapidly. The reaction was sealed under argon and heated to $90^{\circ} \mathrm{C} \mathrm{w} /$ stirring for ( $12-14 \mathrm{hrs}$ ) after which time, DMF was removed in vacuo. The crude mixture was filtered via celite ${ }^{\circledR}-$ SPE and rinsed with EtOAc. The resulting eluent was then concentrated in vacuo to yield the products in good to excellent yields and purities.
