Frauke Kreuter University of Maryland/Mannheim & IAB

The National Survey of Family Growth (NSFG) is conducted by the Centers for Disease Control and Prevention's (CDC's) National Center for Health Statistics (NCHS), under contract # 200-2010-33976 with University of Michigan's Institute for Social Research with funding from several agencies of the U.S. Department of Health and Human Services, including CDC/NCHS, the National Institute of Child Health and Human Development (NICHD), the Office of Population Affairs (OPA), and others listed on the NSFG webpage (see <http://www.cdc.gov/nchs/nsfg/>). The views expressed here do not represent those of NCHS nor the other funding agencies.

# Research Questions

Can interviewers effectively

- **rate the respondent's performance** in surveys?
- be used to derive a **meaningful single indicator of response quality**?
- indicate **where the quality breaks down** but pointing to specific steps in the cognitive response process (comprehension/retrieval/judgement/editing)?

# Past Findings – Use of Interviewer Ratings

- Bennett (1948) implemented questions about the quality of respondent's answers addressed to the interviewer as an **instrument against interviewer cheating**.
- Fisk, G. (1950) evaluation of interviewer observations of the survey response process focused on the **variation of interviewer ratings** of interest **between interviewers**
- Feldman, Hyman, and Hart (1951) multiple interviewer evaluations on the respondent's behavior throughout the interview -> **analyze interviewer variance and interviewer influence**
- Later studies found respondents who received **positive or favorable ratings** tended to provide data of better quality in terms of a variety of indicators.
  - less missing data (Tarnai, J., and Paxson, M.C. 2005; Antoun, C. 2012),
  - less measurement error (Peytchev, A. and Peytcheva, E. 2007),
  - more consistent reports (Antoun, C. 2012), and
  - more codeable answers to open-ended questions (Tarnai, J., and Paxson, M.C. 2005).

# Data - NSFG

- Interviewer observation data from the National Survey of Family Growth, a national survey of sexual and reproductive habits in 15-49 year olds.
- 60 minutes survey with two sections, an in-person computer assisted personal interview (CAPI) and an audio computer-assisted self-interview (ACASI).
- 15,820 interviews over 12 quarters of data collection, 1/2016 – 12/2018.
- 30 post-interview observations, including details about the environment, the respondent's response behaviors, and respondent mood. Here 22 of the 30 observations used to map the survey response process.
- Each observation was classified into one of the four stages of the survey response process. (n=52 excluded due to missingness -- final sample size of 15,768).

# Observations – Comprehension

- Comprehension: include four indicators (yes/ no) of **distractions**:
  - television on,
  - respondent received phone calls,
  - children present and need attention,
  - and other distractions.
- Comprehension of the **ACASI**
  - how much help the respondent needed from the interviewer (none/ a little/ a lot/ or interviewer administered),
  - the respondent's use of headphones (at least some of the time/ never),
  - the respondent's use of text and audio (text only/ text and audio/ audio only/ don't know),
  - and what support was used to hold the laptop (table/ lap/ other).
  - Difficulty using the CAPI application (any/ none)
  - Interviewer's opinion of respondent attentiveness (not at all, some/ very)

# Observations – Retrieval/Estimation/Editing

- Retrieval
  - Was the respondent upset (yes/ no),
  - Tired (yes/ no),
  - How did they act during the interview (hostile, neutral/ friendly).
- Judgement or estimation process was an overall indication of the quality of information provided by the R (excellent/ good/ fair-poor).
- Mapping and editing process
  - Seating arrangement (next to respondent facing the same way/ next to respondent at a right angle/ across from the respondent/ other)
  - Presence of other persons within hearing range (no one else present/ 1+ people present, not able to hear/ 1+ people present, able to hear part of IW/ 1+ present able to hear whole IW).
  - Measures of the respondent's ability to see the computer screen during the CAPI section (yes, all questions/ most, not all questions/ a few questions/ none),

# Observations – cont'd

- Interviewer's ability to see the computer screen during the ACASI section (yes/ no)
- Interviewer's mood (happy/ neutral, sad, unhappy) were also captured.
- Location (on the respondent's property/ in the interviewer's car/ in another public place)
- Atmosphere (chaotic, noisy/ some interruptions/ ideal- quiet and calm)
- Language of the interview (English/ Spanish/ both)

# Method

- Six latent class analysis models that each included the 22 categorical interviewer observations.
- Each model used a different number of latent class groups ranging from 2 to 7.
- Fit statistics (including log likelihood, g-squared, AIC, BIC, and adjusted BIC) and entropy (higher entropy indicators better class separation) compared across the 6 models.
- Focus on the model with 7 latent classes that minimizes the model fit statistics and has an entropy estimate of 0.89.

# Results

- 27% in class 1, private, text ACASI, high quality
- 36% into class 2 most private, high quality

----

- 6% in class 3 distractions with kids, text ACASI, no R problems
- 8% in class 4 distractions, no kids, R problems, iwer assist, iwer unhappy, headphones in ACASI, low quality
- 10% in class 5 distractions with kids, headphones in ACASI, no R problems

---

- 8% in class 6 car interviews, sometimes headphones in ACASI
- 5% in class 7 worst quality across board, no privacy, iwer unhappy

## Judgement Stage

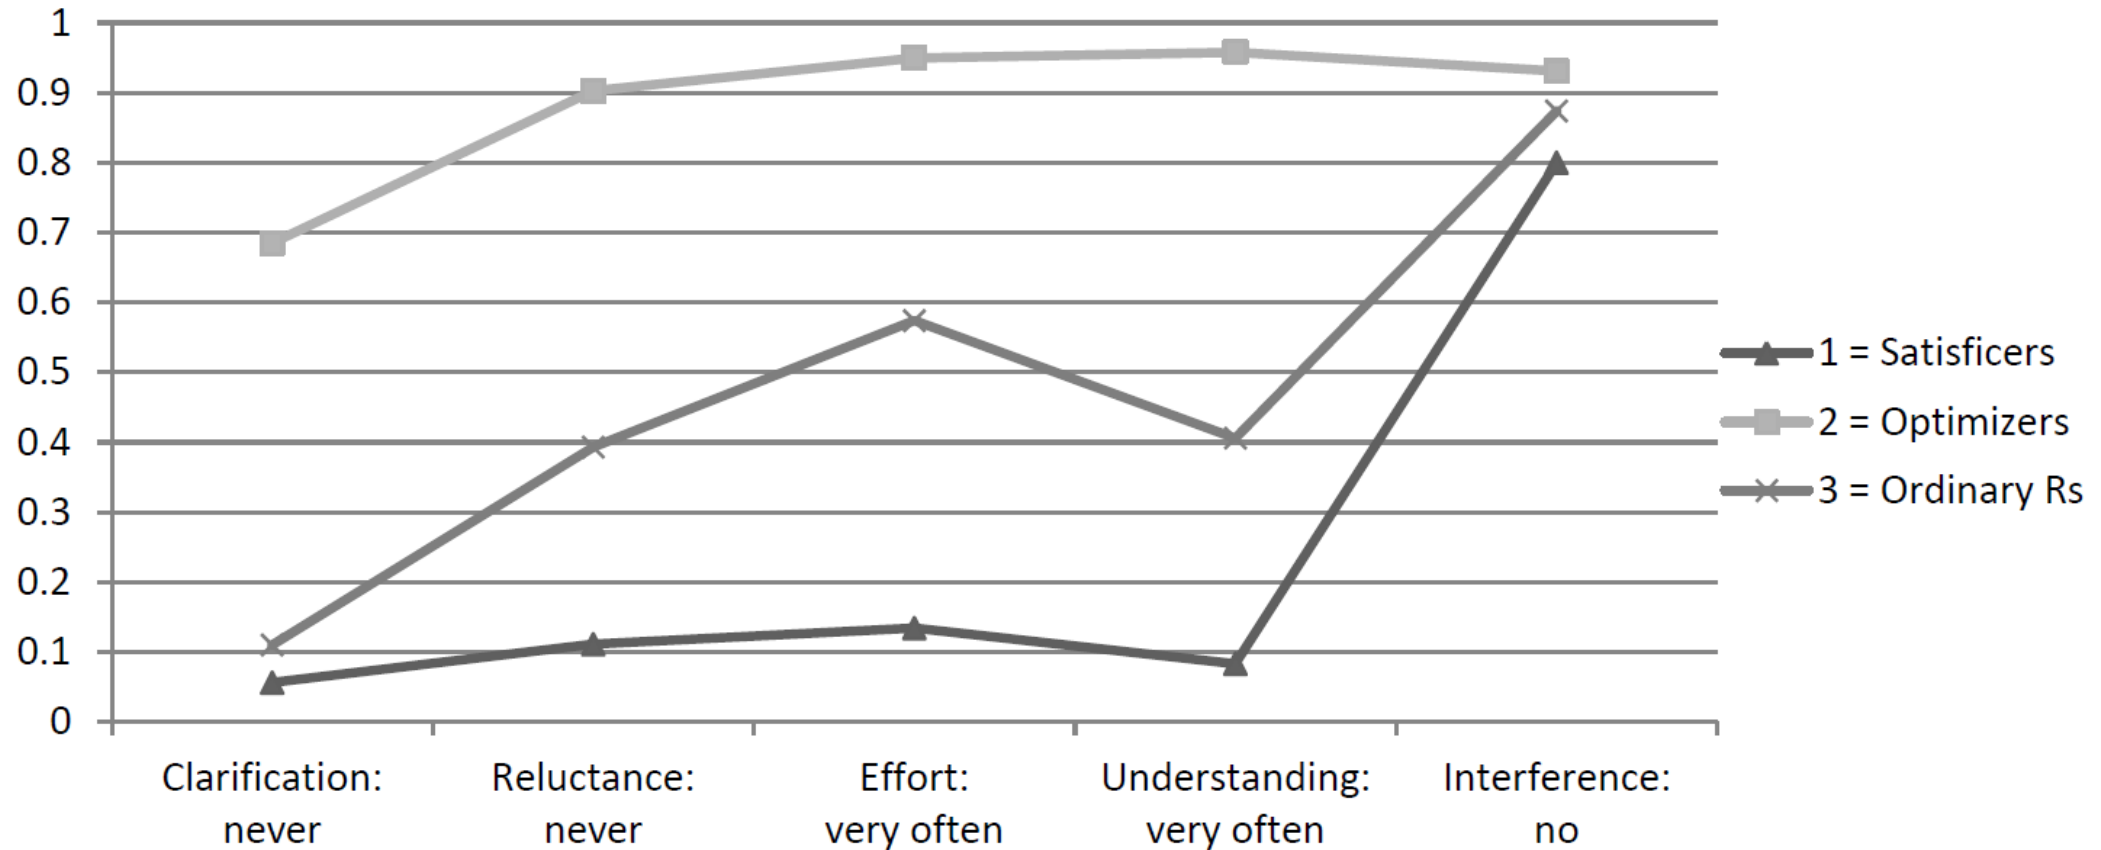

## Retrieval Stage

# Data – ESS

- 5<sup>th</sup> wave of ESS used for this analysis (mostly CAPI)
- 15,820 interviews over 12 quarters of data collection, 1/2016 – 12/2018.
- **Interviewer ratings** (5 point scale; never – very often; don't know):
  - Understanding of the question
  - Clarification of any questions
  - Reluctance in answering
  - Answering with best effort
  - Presence of others with interference
- **Quality indicators**
  - non differentiation (at least 4 same items in matrix question),
  - extreme and middle answers,
  - acquiescence (percentage agreeing in a set of 23 attitudinal items)
  - internal consistency
  - duration

# Conditional Probabilities – highest quality

# Conditional Probabilities – poorest quality

# LCA Rating Results – Quality Indicators

	Freq.	%
Class 1 - Satisficers	1845	11.67
Class 2 - Optimizers	9046	57.20
Class 3 - Ordinary Rs	4923	31.11

	NR-rate	Non-diff.	Extreme	Acqui.	Incon.	Length
Class 1 - Satisficers	6.60 <sup>2,3</sup>	12.94 <sup>2,3</sup>	24.81 <sup>2,3</sup>	54.84	3.85 <sup>2,3</sup>	17.32
Class 2 - Optimizers	2.97	8.30	23.85	59.11 <sup>1,3</sup>	2.86	17.08
Class 3 - Ordinary Rs	4.08 <sup>2</sup>	10.56 <sup>2</sup>	23.51	57.51 <sup>1</sup>	2.60	17.50 <sup>2</sup>
Total	3.74	9.54	23.86	58.12	2.90	17.24

Numbers are percentages, except for interview length which is measured in seconds per item.

Superscript numbers indicate statistically significant differences ( $p < 0.05$ ) against respective class.

# Discussion

- Interviewer observations have the potential to predict data quality and/or response differences.
- Given cost of interviewer observations sensible to investigate
  - which observations are more useful for which types of measures,
  - whether the observations can consistently predict data quality.
- Systematic analysis of observations across different surveys needed
- Observations only recorded at the end – possible that distractions or other events occurred but not in a meaningful way for the entire interview. More mid-stream recording?

# Thank you!
