THE VOLCANISM ONTOLOGY (VO): SEMANTIC MODELING OF VOLCANIC ERUPTIONS
AND VOLCANOES

By

JOHN MYER

Under the Direction of Hassan Babaie, PhD

ABSTRACT

We have modeled the complex material and process entities and properties of volcanic eruptions and structures in the Volcanism Ontology (VO) applying several top-level ontologies such as Basic Formal Ontology (BFO), SWEET, and Ontology of Physics for Biology (OPB) within a single framework. The upper level framework separates the entities into investigative and volcanism entities, and each further separated into their own BFO framework. This allows for VO to be one of the best steps towards a domain ontology to cover the complexity found in volcanology. When deployed on the web, VO will be used to explicitly and formally annotate data and information collected by volcanologists based on domain knowledge. This will enable the integration of global volcanic data and improve the interoperability of software that deal with such data.

DEDICATION

With love and appreciation to my family, parents Deborah McCarty and John Rea Myer, and brothers, Peter, Benjamin, and Patrick. Additional appreciation to friends, both within and outside the graduate program circle, who have continued to support me with their love and encouragement.

ACKNOWLEDGEMENTS

I would like to thank Dr. Hassan Babaie for acting as my faculty advisor, whose assistance, guidance, and expertise in his field allowed for this research to be as possible and as thoroughly complete as it currently stands. This thesis would not have been completed without his continued support.

I would also like to thank the members of my thesis committee, Dr. Rajshekhar Sunderraman and Dr. Brian Meyer, for their guidance and assistance toward the completion of this thesis and the completion of my Master's Degree

Special thanks also to the Department of Geosciences at Georgia State University for providing the opportunity to pursue this research and creating an environment where learning and critical thinking may thrive.

This work was conducted using the Protégé resource, which is supported by grant GM10331601 from the National Institute of General Medical Sciences of the United States National Institutes of Health.

Figure 6-8: Detail on the relations of the class PeleanEruption. Note the appropriate VEI classes listed with the relation 'hasVEIValue.' 33

CHAPTER 1 INTRODUCTION

The collection of observations and measurements known as data is one of the major foundational components of science. The collection, size, storage, and processing of data have expanded with new technology, leading to the concept of big data. The size, rate of production, and type of data have become so large and diverse that the ability to efficiently interpret data into new, useful knowledge is potentially beyond the limits of human capabilities (Sinha et al., 2010). To develop new knowledge, an agreed-upon semantics for terminology needs to be established so that the processing of data into information may be streamlined utilizing digital and network processing and interpretation. Inspired by its philosophical metaphysical counterpart, ontologies fulfill the role of defining terminology and inferring the connections between concepts that make up reality (Arp et al., 2015).

The goal of this thesis is the development of Volcanism Ontology (VO) that would include both material and process concepts utilizing the framework from Basic Formal Ontology as the foundation. The resulting framework is designed to be open-source and non-proprietary. The goal of building this ontology is to allow integration and annotation of volcanic data.

CHAPTER 2 LITERATURE REVIEW

2.1 Introduction to Ontology

Ontologies are computer-based artifacts that are designed to model a domain of knowledge in an attempt to represent reality. Ontologies are organized into a hierarchal taxonomy design with nodes of clearly defined concepts, known as classes, connected by relationships to other classes (Arp et al., 2015; Smith & Ceusters, 2010). Classes or “entities” (hereafter, all classes and properties mentioned in this thesis shall be marked as **Class** and **hasProperty**) are the representations of concepts within ontologies. Top-level concepts are the most generalized entities and terms (e.g., **Rock**, **Lava**) from which more specialized entities extend (e.g. **IgneousRock**, **RhyoliticLava**). Classes are the abstract ideas that are fundamental to the understanding of scientific knowledge and assumptions within the domain of knowledge, without which other terms could not be properly described (Smith, 2004). More specialized concepts and terms are typically broken down into subclasses (Arp et al., 2015) (e.g., the class **Olivine** is a subclass of the class **Mineral**). This may include tangible instances (objects) of the entities that may be described through observation and experimentation (e.g. Mt. St. Helens, a specific hand sample) (Smith & Ceusters, 2010). Association and relationships between entities are represented within ontologies as properties and subproperties. The most common relationship found in ontologies is the **isA** relation, which bridges classes, but many properties and relationships can be created to be used for all sorts of connections (Arp et al., 2015). For example, basalt is a type of igneous rock, which is a type of rock, so in the ontology, the class **Basalt** is related to the class **IgneousRock** and the **IgneousRock** class is related to the **Rock** class through the **isA** property (Figure 2.1).

2.2 Types of Ontologies and the Semantic Web

Since domains have few limits in terms of expansiveness and complexity of their nature, well-designed ontologies can serve as effective representations of the world (Horrocks, 2008). What’s more, ontologies can be built upon one another, creating extensible ontology libraries that may function together with other ontologies, or developed independently that may connect back to similar ontologies.

Figure 2-1: Class hierarchy showing the relationships between Basalt, IgneousRock, and Rock through the isA relation.

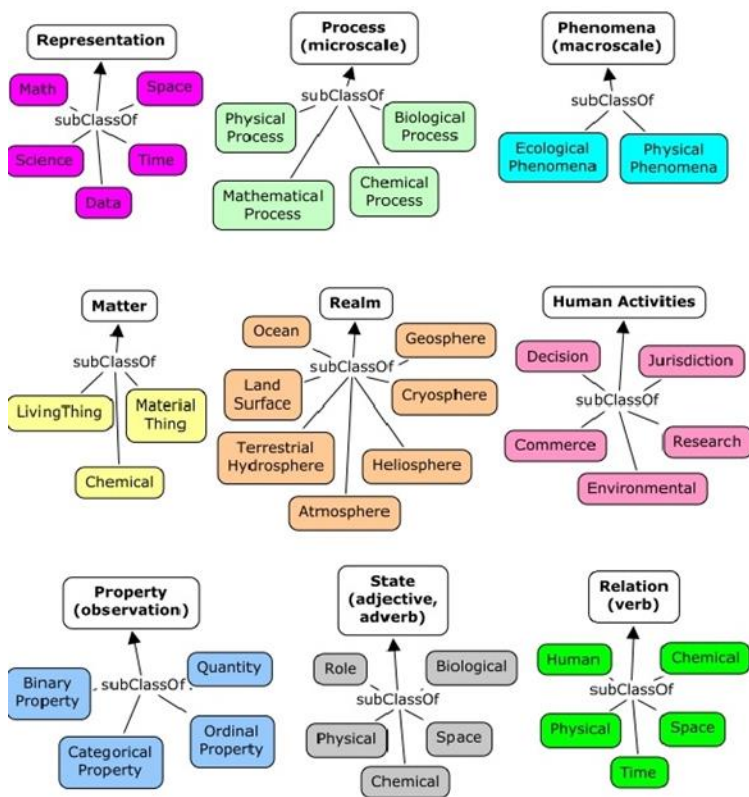

Figure 2-2: Various domains within the upper-level SWEET ontology (from Jet Propulsion Laboratory, 2010).

Ontologies are often broken down based on the broadness of their knowledge base. Upper-level ontologies cover broad terms and concepts, with less detail given to specific terms and concepts. An

example of an upper-level ontology would be the Semantic Web for Earth and Environmental Terminology (SWEET), upper level ontology, designed to cover a large range of terminology and concepts utilized within earth and environmental science disciplines (Figure 2.2) (Raskin & Pan, 2005). Given its broad basis, many of the concepts are undefined and have only basic relationships setup, often leading SWEET acting as a starting point for the creation of more specialized domain ontologies (Tripathi & Babaie, 2008). Domain ontologies cover a specific realm of knowledge, and are more detailed and thorough in their description than upper-level ontologies (Arp et al., 2015). An example of a more specialized domain is the hydrogeology ontology created by Tripathi & Babaie, which originally developed from SWEET and focusing specifically within the domain of hydrogeography (Tripathi & Babaie, 2008)

The most utilized ontologies are designed to be open-sourced and non-proprietary, allowing usage by developers and researchers to suit their needs, with the ability to work with other ontologies. In an effort to ensure that these knowledge bases are easily accessible, most of them are stored and manipulated online through the Semantic Web, a continually developing extension of the World Wide Web, where concepts are stored, accessed and shared with other computer systems and scientists, providing either new data or integrating with other geoinformatic systems (Berners-Lee, Hendler, & Lassila, 2001). The inference capabilities of ontologies and other knowledge bases make them efficient and reliable query systems that may provide important reasoning checks that can find inconsistencies, or reveal new connections between concepts that remained undiscovered (Horrocks, 2008).

2.3 Geoinformatics Ontology Development

Geoinformatics, the geoscience-branch of informatics, is the use of computer-aided knowledge engineering and schemas to create a truthful representation of reality related to Earth. The main concepts involved in the discipline include utilizing new digital tools and methods to collect data and developing web-assessable portals collecting wide range and variety of data points for easy access and sharing of knowledge from multiple disciplines to create and discover new knowledge. For the latter goal, ontologies

serve as the main way of collecting, sharing, and discovering knowledge, acting as a template for knowledge bases in specific domains (Sinha et al., 2010).

Within the span of several years, many disciplines in geosciences have developed or are in the process of developing their own ontologies, representing broad and narrow fields and domains (Babaie et al., 2013; DiGiuseppe et al., 2014; Scheuer et al., 2013; Tripathi & Babaie, 2008). Many of these are domain ontologies, focusing within a particular discipline or subdiscipline in sufficient detail (Arp et al., 2015). Projects such as San Andreas Fault Observatory at Depth (SAFOD) present brittle microstructural and rock mechanics data collected from cores of samples across the San Andreas Fault (Babaie et al., 2013). Utilizing their ability to define relations between ideas and terms, some ontologies have been developed solely for searching and finding GI services and related data catalogues across multiple brokers and heterogeneous datasets (Klien et al., 2006). As mentioned previously, SWEET has become the de-facto ontology library within the realm of geoinformatics given its broad range of topics and sufficient detail in concepts and relations (DiGiuseppe et al., 2014). Overall, Earth science has a strictly low number of ontologies developed compared to other fields, such as biomedicine (Arp et al., 2015).

2.4 Volcanology and Knowledge Engineering

Volcanology, like the rest of the geosciences, has just begun to make its knowledge represented into ontologies (Figure 2-3) (Pshenichny, 2014). Even with its early start, there have already been several developmental ontologies created for the field. McGuinness and colleagues have already established the groundwork for a reference ontology for volcano systems as one of the first detailed branches designed off of the Semantically-Enabled Scientific Data Integration (SESDI), one of the larger Earth science ontology libraries (Fox et al., 2006; McGuinness et al., 2007). Other ontologies have been done solely focusing on the volcanic hazards (Faaziati & Wantanabe, 2010).

One of the unique challenges developing ontologies and knowledge engineering of volcanology is the focus on events as well as objects. By their nature, ontologies are generally designed to describe objects that are static in their nature. Volcanology, however, also heavily relies on more event-based

knowledge, changing events that occur periodically or concurrently leading or preceding other events. To be useful, ontologies need to model both static material and structures as well as varied dynamic volcanic processes that occur during eruptions (Pshenichny, 2014). Given the larger focus on the development of static object-based ontologies, work is being done to develop classifications and methods that better describe dynamic event-based ontologies (Pshenichny & Mouromtsev, 2015). Opportunities to develop ontologies to cover static and dynamic knowledge (Babaie, 2011) are present and have a wide range of potential uses within volcanology, as well as other disciplines of science (Pshenichny, 2014).

Figure 2-3: (a): Conceptual drawing of a caldera setting; (b): semantic graphic network of the same setting (from Pshenichny, 2014).

2.5 Basic Formal Ontology

Basic Formal Ontology (BFO) is an upper-level ontology created as a starting point for developing more specialized domain ontologies (IFOMIS, 2010). Being small and un-descriptive, BFO provides the beginning framework for expressing knowledge within the specialists' domain of interest (Figure 2-4). One of the unique aspects of BFO is that the ontology starts by dividing entities into "continuants" and "occurrents." Continuants cover entities that continue to exist as a whole through time, while occurrents cover entities which unfold over time, whether by occurrence or happening. Like other ontologies, terminology from an upper level ontology can be referenced and extended into other domain specific ontologies, allowing compatibility across multi disciplines and subdisciplines (Arp et al., 2015). BFO has been used extensively as a framework among many domains of science, both for upper-level ontologies and domain-specific (Figure 2-5). BFO is used extensively in bioinformatics, for example in upper level Ontology for General Medical Science (OGMS), that model continuant and occurrent concepts for the medical field (Scheuermann et al., 2009). From OGMS, many domain specific ontologies have been built as extensions, in particular the Infection Disease Ontology (IDO) that covers processes and concepts for infectious diseases (Cowell and Smith, 2010).

2.6 Terminology

The following are definitions for terms that are used throughout this paper as related to this ontology.

Basic Formal Ontology (BFO): A top-level ontology based on the continuants and occurrents concepts.

Class: A term to describe the type of an entity within an ontology.

Continuant: an entity that persists (or continues) through time without changing into another entity. One of the main categories of BFO.

Domain: An area of knowledge within a scientific discipline that is modeled in an ontology.

Entity: Anything that exists; represented as a class within an ontology.

Individual: Instance of a universal entity. Within an ontology, they are related to a particular class.

Occurrent: an entity that changes (or occurs) over time. One of the main categories of BFO.

Ontology: A computer-based representation of knowledge, using a taxonomy of universals, defined classes, and relations between said classes to provide a model of reality.

Particular: A instance of a particular universal entity, e.g., Amazon river.

Property: representation of a relation within the ontology framework. Connects two or more classes together (Arp et al., 2015) (Amazon rivers drains water from South America to Atlantic Ocean).

Protégé: the main editing software program utilized to build and test ontology frameworks (Musen, 2015).

Relation: the manner for how two or more entities are connected.

Resource Description Framework (RDF): A programming language that allows relationships between entities to exist through a subject-predicate-object “triple” structure.

RDF Schema: (RDFS): An enhanced version of RDF that allows for properties to exist as the main relations between entities.

Semantic Web: an interconnected system that makes up the content of data and information from World Wide Web (WWW) pages. Allows machines to respond to complex queries.

Term: the word used to describe any concept that will be represented as classes within an ontology.

Top-level ontology: An ontology of highly general categories that are build more for specific domain ontologies.

Universal: A independent repeatable feature of reality (i.e. rock, olivine). A particular is an instance of a universal (a sample of rock, a sample of olivine).

Web Ontology Language (OWL): the major family of languages used for the Semantic Web; the main family of programming languages for ontologies (Arp et al., 2015).

CHAPTER 3 METHODOLOGY

The Volcanism Ontology (VO) was primarily developed utilizing the Protégé ontology development software, version 5.2.0 (Musen, 2015). The open-source software is the standard integrated development environment (IDE) used for developing domain ontologies, allowing other similar ontologies built with the program to be able to incorporate with this ontology (Figure 3-1) (Arp et al., 2015).

The resulting ontologies are designed based on Extensible Markup Language (XML), Resource Description Framework (RDF), RDF Schema (RDFS), and the Semantic Web's Web Ontology Language (OWL). These ontology languages are the formal languages for developing ontologies. XML is a basic machine readable format that has gained wide usage on the World Wide Web (WWW) and offers a basic schema and tagging system that is utilized in ontologies (W3C, 2016). RDF was created as a unifying language that could merge and create metadata regardless of the schema. Written in XML, RDF consists of a basic structure of subject-predicate-object (SPO), each of which is assigned a unique Internationalized Resource Identifier (IRI) (W3C Consortium, 2014a). The subject may be a concept or entity with an IRI (e.g., *Andesite*) or a blank node (an entity with no label). The object may be another entity, a blank node, or an actual instance or value (e.g. *ExtrusiveIgneousRock*). The subject is connected to the object through the predicate, representing the property sought to model (e.g., the 'isAnIntermediate' in the 'Andesite isAnIntermediate ExtrusiveIgneousRock' statement) (Horrocks, 2008). As another example, the subject, predicate, and object in the "Volcano erupts Lava" SPO statement are Volcano, erupts, and Lava, respectively. RDF Schema is a more vocabulary-focused extension of RDF that allows for more hierarchical structure of classes found in ontologies (W3C Consortium, 2014b). The Web Ontology Language (OWL) was developed as the standard for ontologies, focusing on processing the information content without the need to present information for human consumption (W3C Consortium, 2009). OWL achieves this by integrating similar frameworks and languages, including RDF and RDFS, and building upon them with its own framework (W3C OWL Working Group, 2012). Specifically, OWL has its logic basis in descriptive logic (DL), which allows

more flexibility by providing more information on concepts compared to languages like RDF and RDFS. This allows OWL to express universal and existential statements, cardinality, Boolean operators, equivalence assertions, and relational properties. An example of this in use are the equivalent classes *VolcanicArc* and *VolcanicChain*, which are both terms use to describe the same concept just within slightly different circumstances, with *VolcanicArc* being a subclass of *Arc*, and *VolcanicChain* being the more general class under '*VolcanicFeature*,' although both are subclasses of '*VolcanicFeature*' (Figure 3-2). Ontologies built in OWL have the advantages of being untethered to specific data or assumptions, and can run complex queries and inferences much easier than general relational databases (Arp et al., 2015).

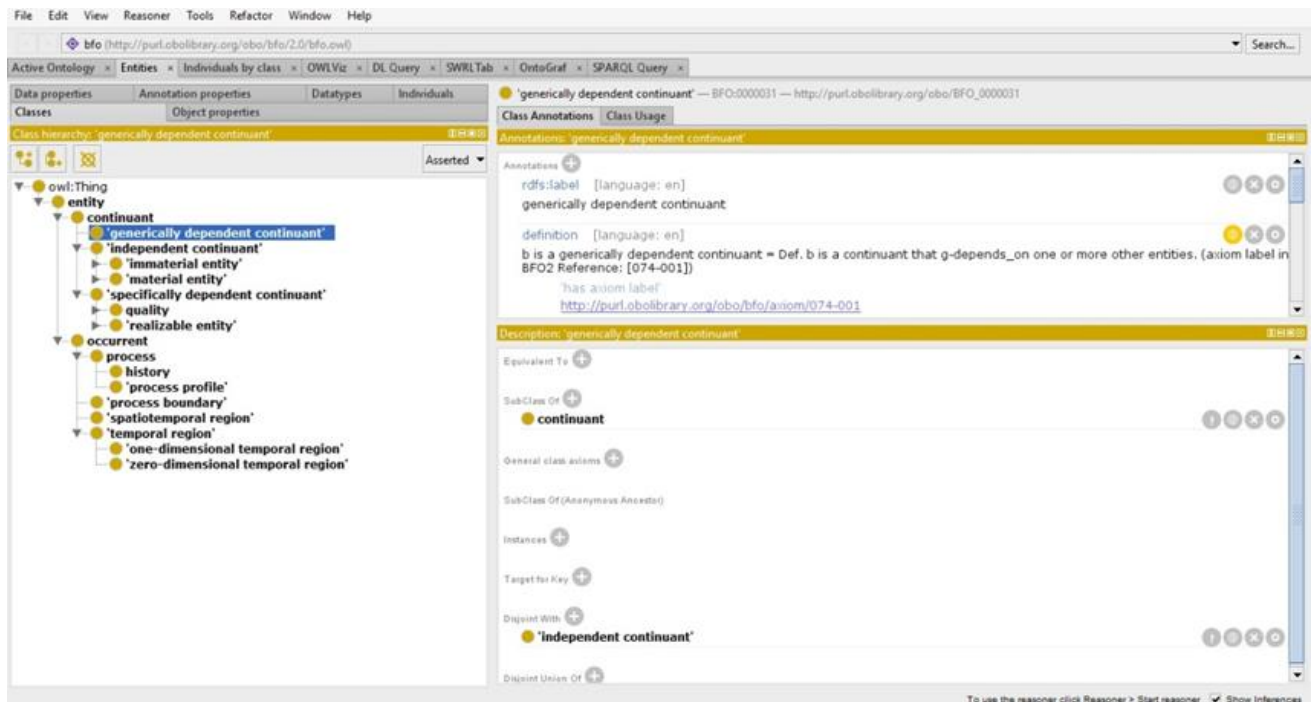

Figure 3-1: Screenshot of the Protégé software window showing the BFO class hierarchy.

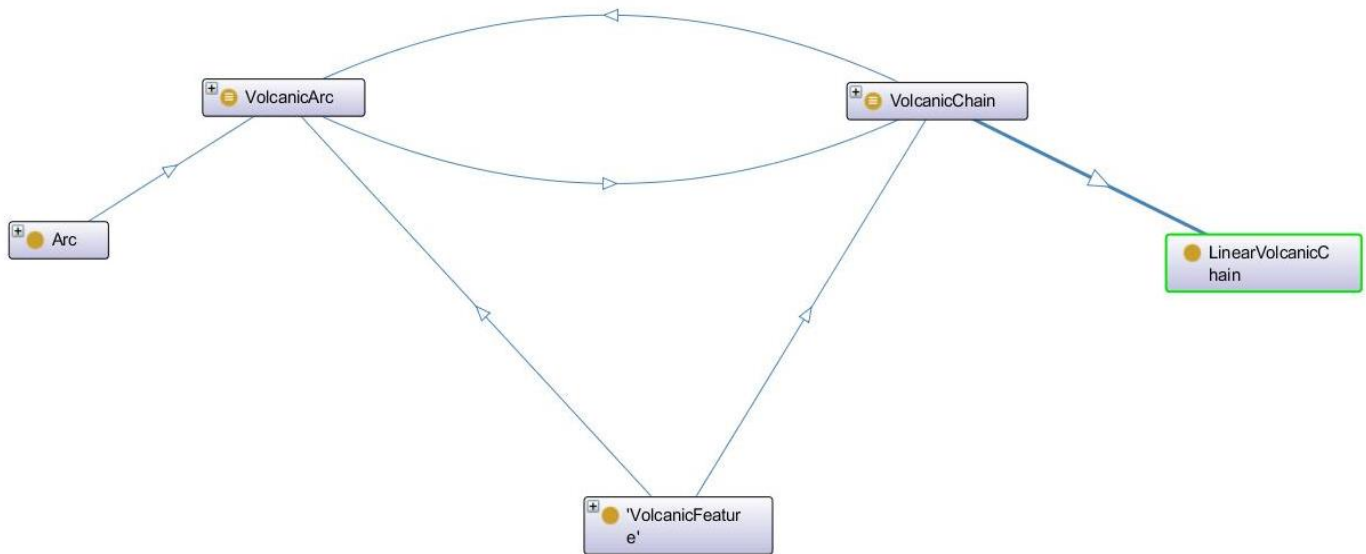

Figure 3-2: Screenshot of VolcanicArc and VolcanicChain classes, showcasing the OWL equivalence classes, visualized here as a pair of circular blue lines, which represent isA object properties, as well as the small golden equal symbol next to the term .

CHAPTER 4 ONTOLOGY FRAMEWORK DEVELOPMENT

4.1 Ontology workflow

The framework development for the volcanism ontology follows the guidelines set out by Arp and others (2015) applying BFO. The first step involved the determination of the most general terms and relationships that are essential for representation. To ease initial development and acquisition, already established concepts from existing ontologies were reused; a practice common in the ontology development community (Arp et al., 2015). For Earth, atmospheric, and other related sciences, concepts from SWEET Ontology version 2.3 were reused (Raskin & Pan, 2005). Statistical concepts were derived from the Statistics Ontology (STATO), a BFO-based ontology (“Statistics Ontology - Summary | NCBO BioPortal,” 2016). Physics concepts were brought in from the Ontology of Physics for Biology (OPB), another ontology based on BFO (Cook, Bookstein, & Gennari, 2011). Supplementing the existing concepts, any remaining undescribed but essential terms and relationships were gathered from textbooks within the field of volcanology and igneous petrology (Neuendorf et al., 2011; Raymond, 2002; Simkin & Siebert, 2010; Spellman & Stoudt, 2013) (Table 4-1). Classes imported from other ontologies that have no description are provided with correct and domain-specific descriptions, following the example of SWEET (Jet Propulsion Laboratory, 2010), using Wikipedia as a source for descriptions.

4.2 Concept development

Classes irrelevant to the knowledge domain were removed to streamline the development process. With terms and relationships collected, the regimentation of these terms using BFO began by organizing types as classes, and relationships as properties, using Protégé. As a best practice, the entities were hierarchically organized under the BFO’s orthogonal occurrents and continuant types, split between volcanism and investigative entities (Figure 4-1).

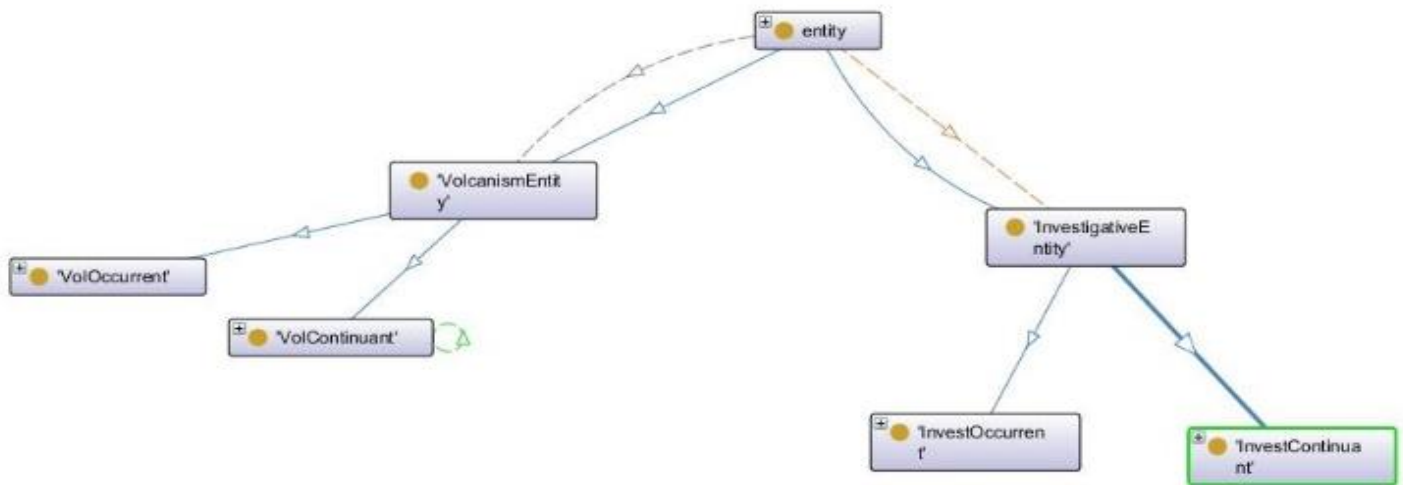

Figure 4-1: Volcanism Ontology showcasing split between 'InvestigativeEntity' and 'VolcanismEntity', each with their own continuant and occurrent entities. Solid blue lines indicate isA object property. Dashed tan line indicates 'hasInvestigativeEntity' object property with Range set for 'InvestigativeEntity,' while dashed brown line represents 'hasVolcanismEntity' with Range set for 'VolcanismEntity.'

4.2.1 Continuant concepts

The continuant classes; entities that persist through time as wholes, include volcano types, deposits, structures, measurements, rocks, and composition, among others. The continuants are broken down into further subcategories into Independent and Dependent entities (Arp et al., 2015). Dependent categories have classes that are dependent or reliant on other classes. This is further broken down into generically dependent entities and specifically dependent entities.

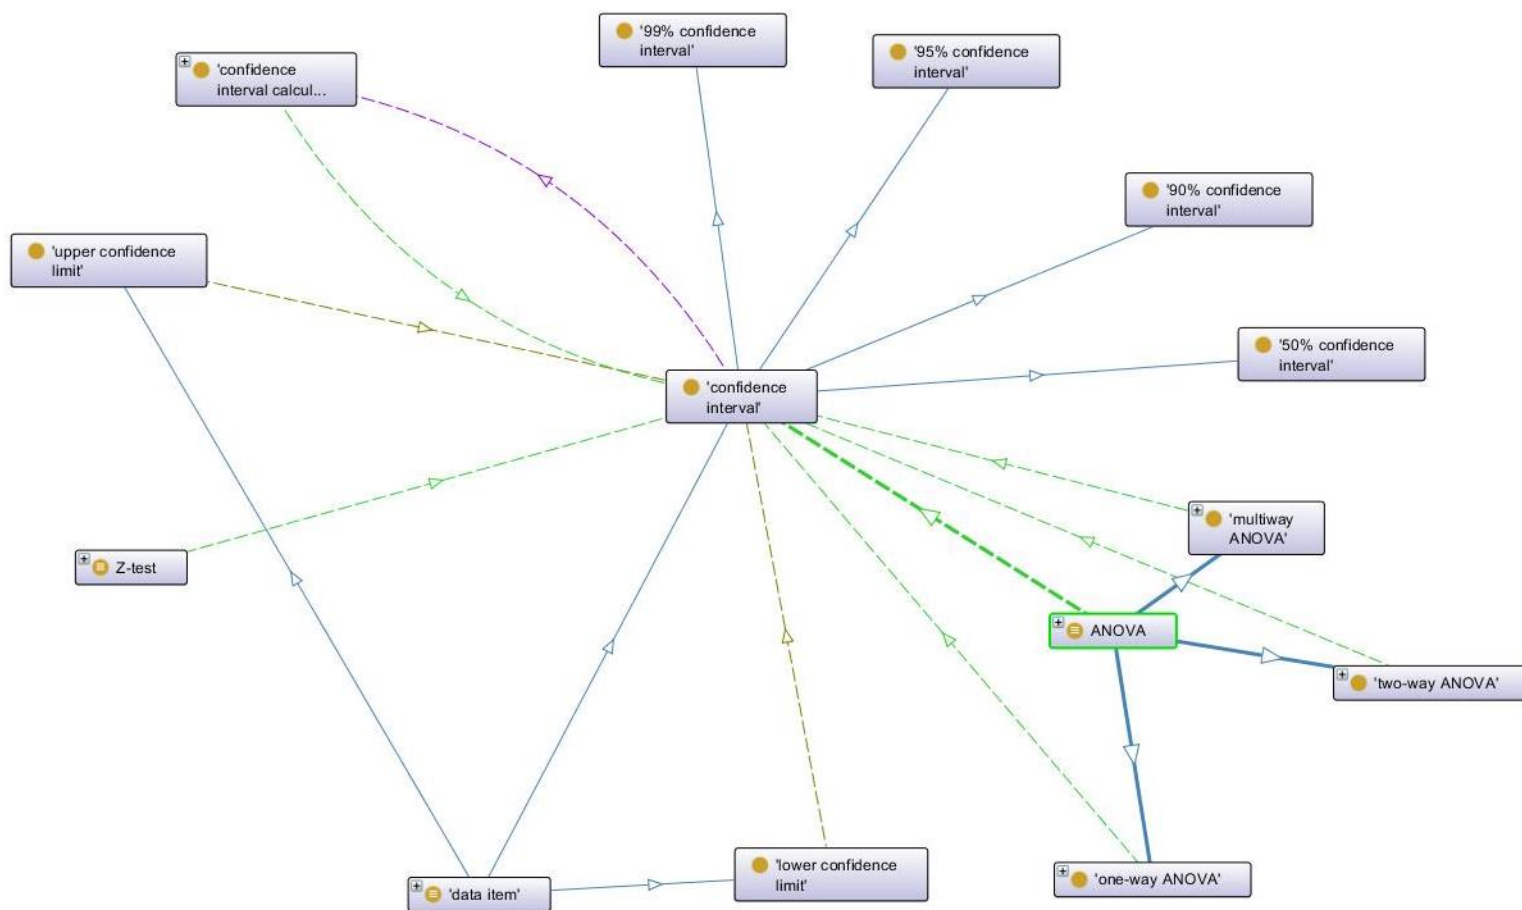

Figure 4-2: Classes related to the generically dependent continuant 'confidence interval.' Solid blue lines indicate isA object property, while green-dashed lines represent 'has_specified_output' property, purple-dashed line indicates 'is_specified_output_of' object property, and yellow-dashed lines represent 'is part of' object property. These classes were imported from STATO Ontology ("Statistics Ontology - Summary | NCBO BioPortal," 2016).

Generically dependent entities are those classes that are wholly dependent on other independent classes. In the case of the Volcanism Ontology, they are primarily useful for providing classes for statistics and investigative classes. This includes scientific investigative concepts such as hypothesis, and conclusions, presentation concepts such as graphs and figures, as well as statistical concepts such as mean standard deviation, and confidence intervals (Figure 4-2). Specifically dependent entities are those that

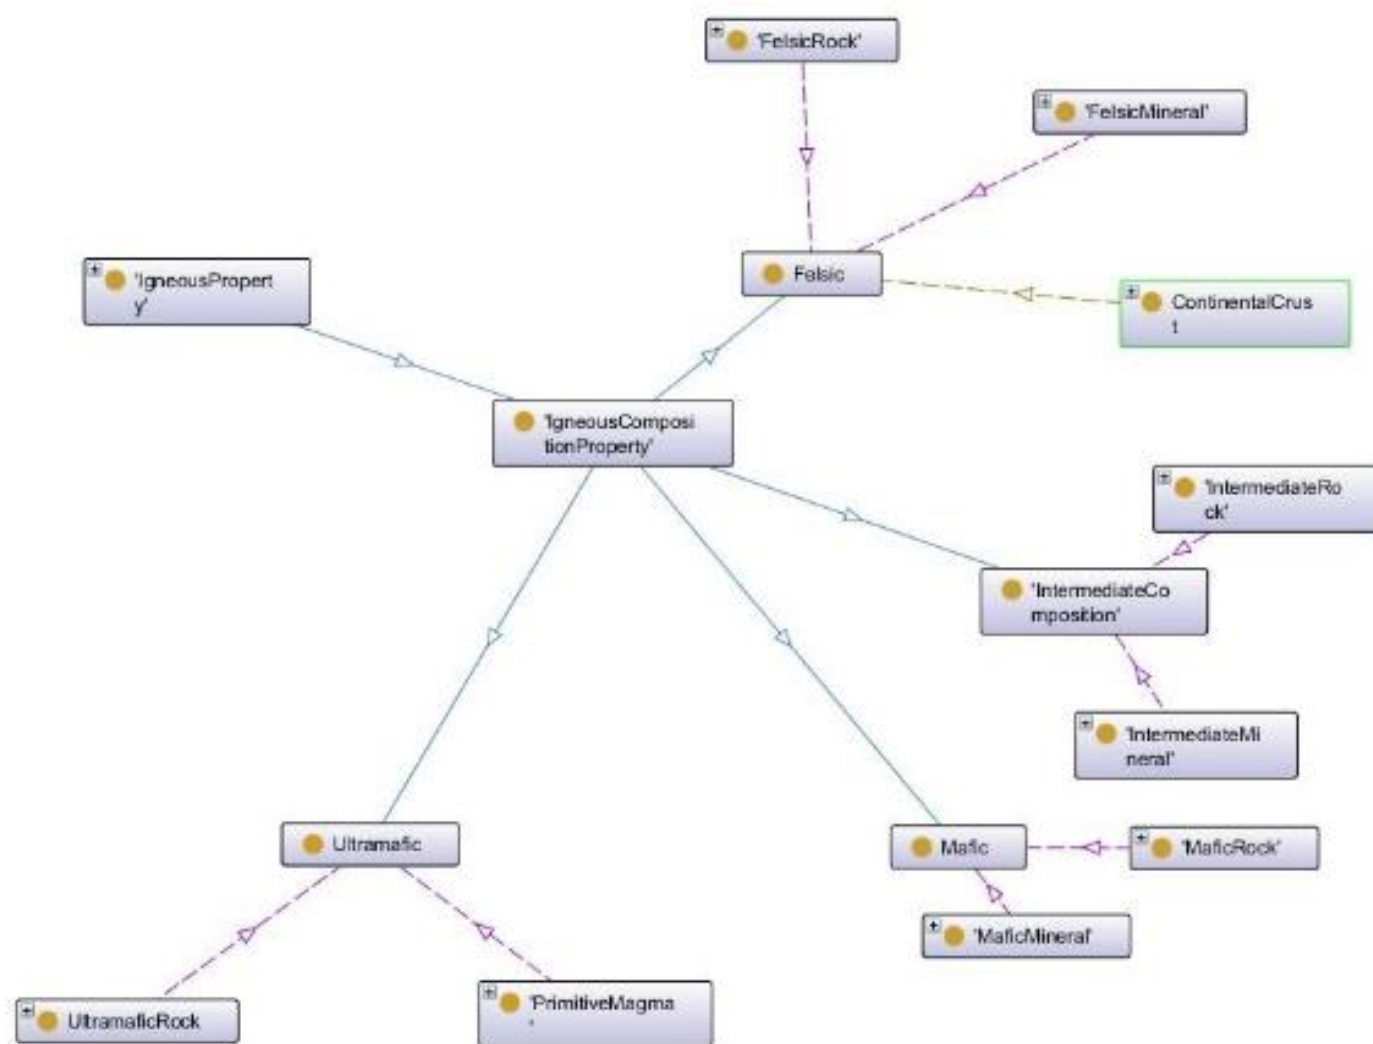

Figure 4-3: Classes related to the specifically dependent 'IgneousCompositionProperty' class. Solid blue lines indicate isA object property. Purple dashed lines indicate the hasProperty object property, while dashed yellow line represents hasRock object property.

describe or adhere to other classes. This includes qualitative entities such as properties for describing rocks by silica content and the roles and functions taken by some investigators (Figure 4-3).

Independent entities are entities that are reliant into and of themselves, that can be independent of other entities. This is where we find most of the classes for rocks, volcanic features as well as investigative devices such as seismometers (Figure 4-4). This also includes spatial regions such as the layers of the Earth and boundaries such as faults and seismic zones (Arp et al., 2015; Smith, 2004).

4.2.2 Occurrent concepts

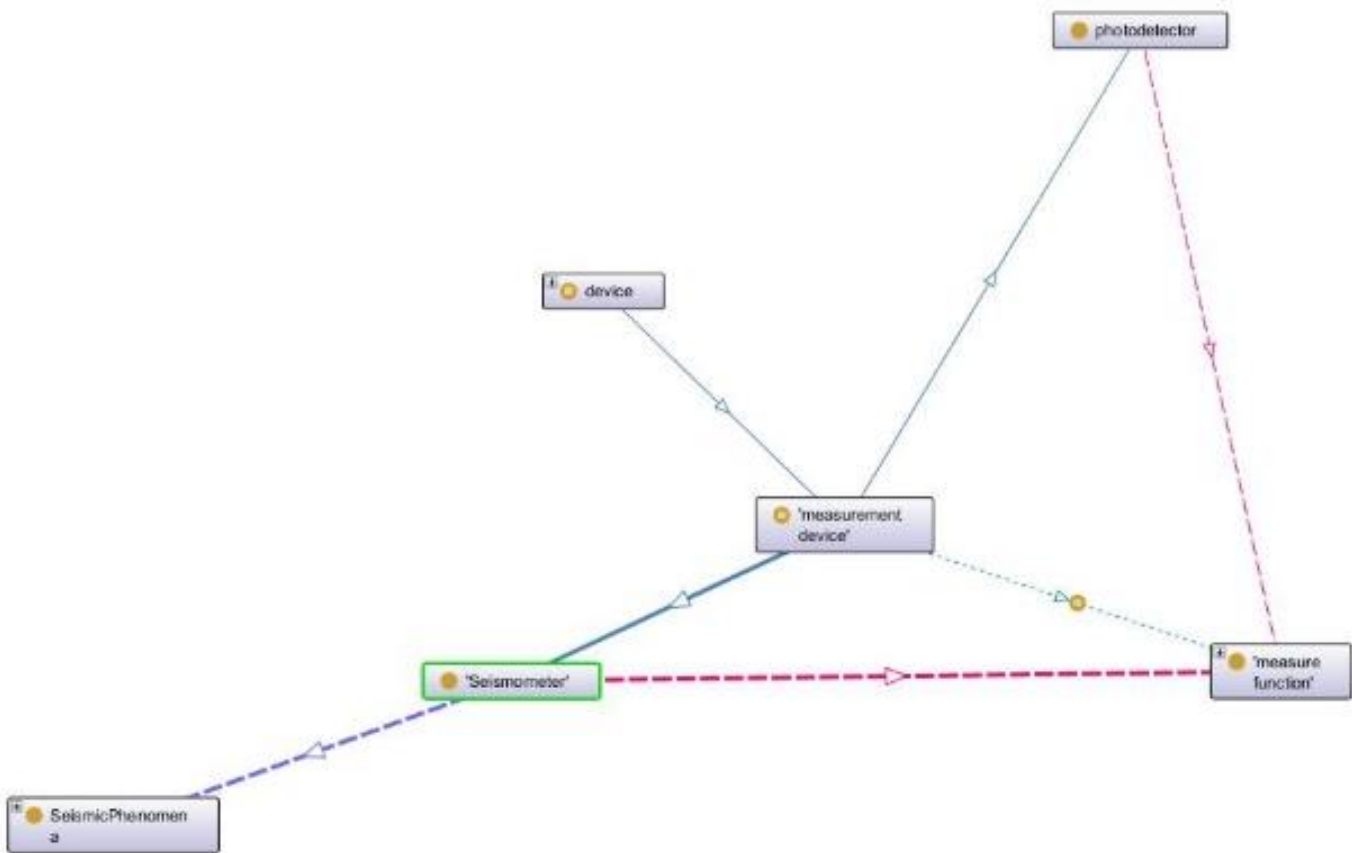

Figure 4-4: Classes related to the class 'Seismometer.' Solid blue lines indicate isA object property. Purple dashed line represents measures property, while pink lines represent "has function" property. The dotted light blue line with equal symbol indicates that 'measurement device' is equivalent to device class that connects to 'measure function' by 'has function' object property.

Entities that require a change over an extent of time are categorized under BFO's occurrent class. Occurrent classes include those that are related to eruption processes such as lava flow, ejection of ash, debris flow, and cooling of lava, and data collection, among others. Process is the main category for occurrents, ranging from numerous physical processes such as volcanic eruptions themselves to the processes related to research and data transformation (Figure 4-5). Occurrent entities also include temporal and historical entities such as TimeInterval and classes representing a range of time (Arp et al., 2015).

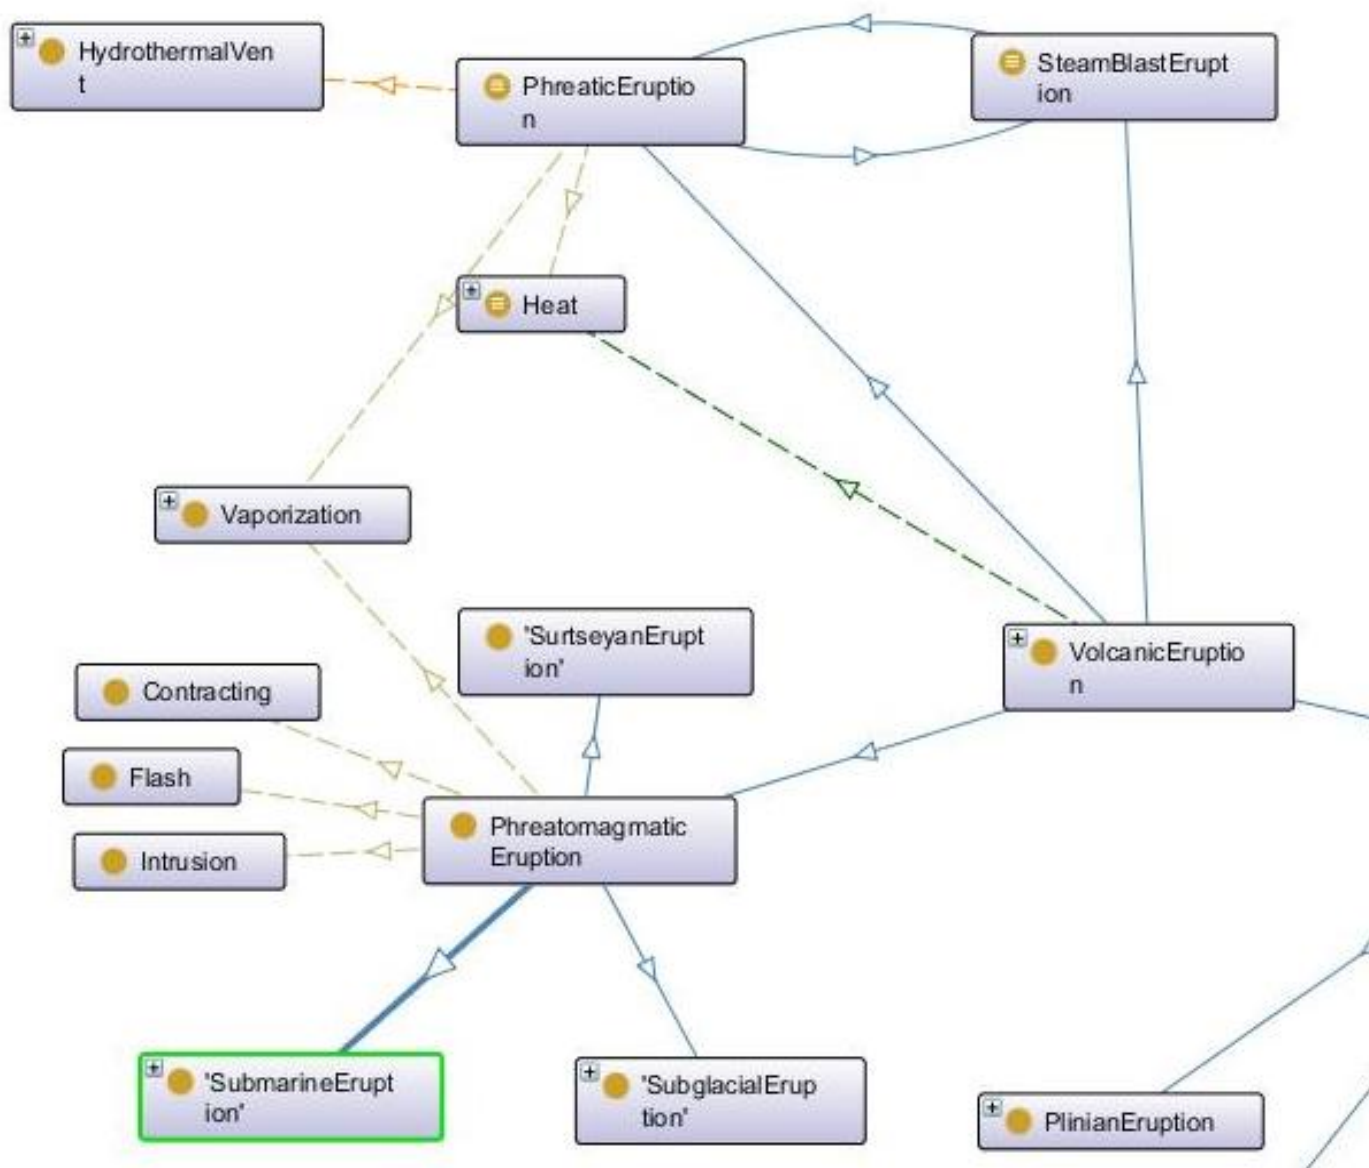

Figure 4-5: Classes related to VolcanicEruption. Yellow dashed lines represent the processOf property, while green dashed line represents hasTransport property, and the dashed orange line indicates 'associatedWith' property.

CHAPTER 5 RESULTS: VOLCANISM ONTOLOGY (VO)

5.1 Classes

To help distinguish classes, and all other new entries created just for the Volcanism Ontology, the names of new classes are given in single quotation marks and notated as such in this thesis. Between the single quotation marks, nomenclature for Volcanism Ontology entries follows similar nomenclature pattern found in the SWEET Ontology, which labels classes with no spaces between words and proper capitalization (Jet Propulsion Laboratory, 2010). Examples of VO's nomenclature are as follows: 'ExampleName' an example of a class in VO; 'hasExampleProperty' an example of a property in VO. While imported SWEET classes and properties Imported classes and properties from other ontologies such as BFO, STATO, and OPB ontologies do have single quotation marks in their nomenclature, but have lower case letters, and have spaces or dashes between words (Figure 5-1). Definitions were sourced

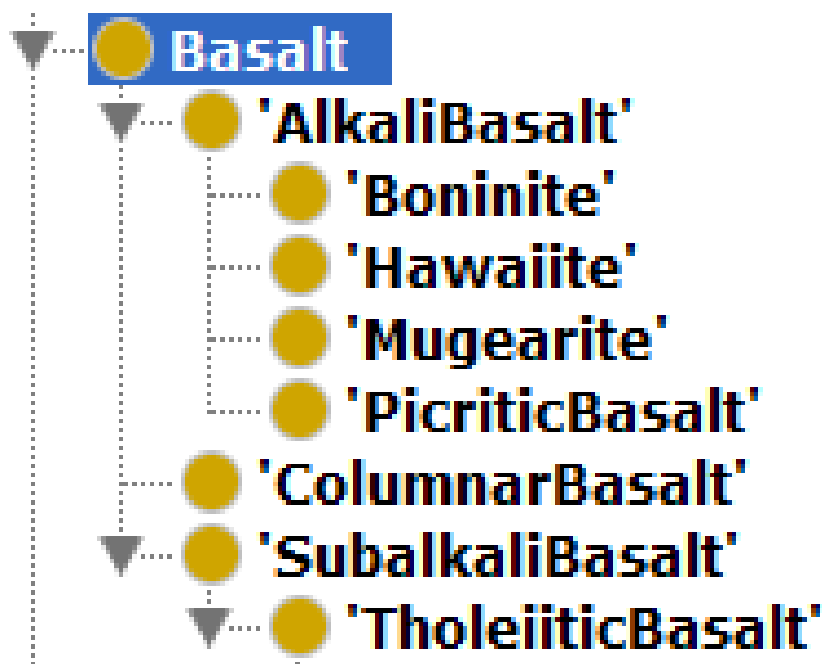

Figure 5-1: Screenshot of the class hierarchy of Basalt in Protégé. The class Basalt is imported from SWEET, while classes such as 'AlkaliBasalt,' 'ColumnarBasalt,' and 'SubalkaliBasalt' the new classes to the right created for the Volcanism Ontology, and therefore, marked with ' ' within the name of the class.

mainly from Wikipedia, following the schema utilized in SWEET's classes, with additional definitions provided by Raymond (2002) as needed (Jet Propulsion Laboratory, 2010).

5.2 Object Properties

Figure 5-2: Screenshot of the object property 'createdFrom,' showing that this is a subproperty of 'derives from' object property and the inverse property of 'creates' property. 'VoObject' is the domain for the property, representing the "subject" of RDF triple, while the range of the property, 'VolProcess,' represents the "object of the RDF triple.

Object properties allow for classes of concepts to bridge (relate to) one another. Object relationships are established for both occurrent and continuant classes. For example, instances of the continuant 'VoObject' class can be created by the 'VolProcess' occurrent class, through the 'createdFrom' object property (Figure 5-2). Some object properties were utilized from other ontologies, often modified to include new subproperties or to create inverse properties of existing properties (Figure 5-3).

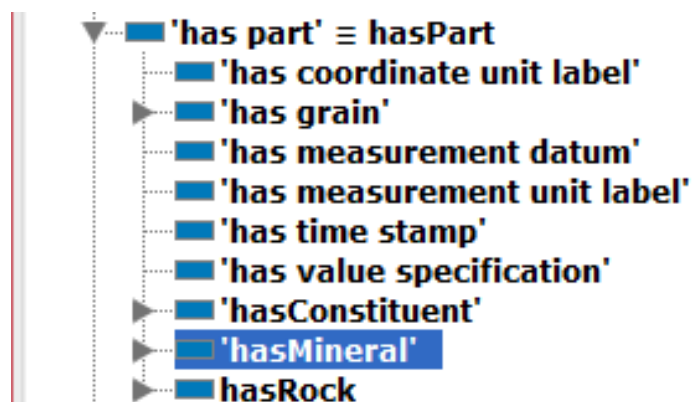

Figure 5-3: Hierarchy of a few of the VolOnt subproperties structured under BFO's 'has part' property. Note that 'hasConstituent,' 'hasMineral,' are newly created properties for VO, while hasRock comes from SWEET, and the others are native subproperties from BFO.

5.3 Data Properties

Data properties work with classes that required data or input information. For example, in Figure 5-4, samples are typically listed with people collected them. The property 'collectedBy' therefore would have a domain of 'SampleName' and a range of `xsd:string`, which allows the user to input the name of the person. Additionally, when considering classifications based on numerical ranges, such as QAPF (Quartz, Alkali Feldspar, Plagioclase, Feldspathoid) and TAS (Total Alkali Silica) percentage classifications schemes for rock names, data properties were utilized to provide the proper percentage ranges for the rock class in question (Figure 5-5).

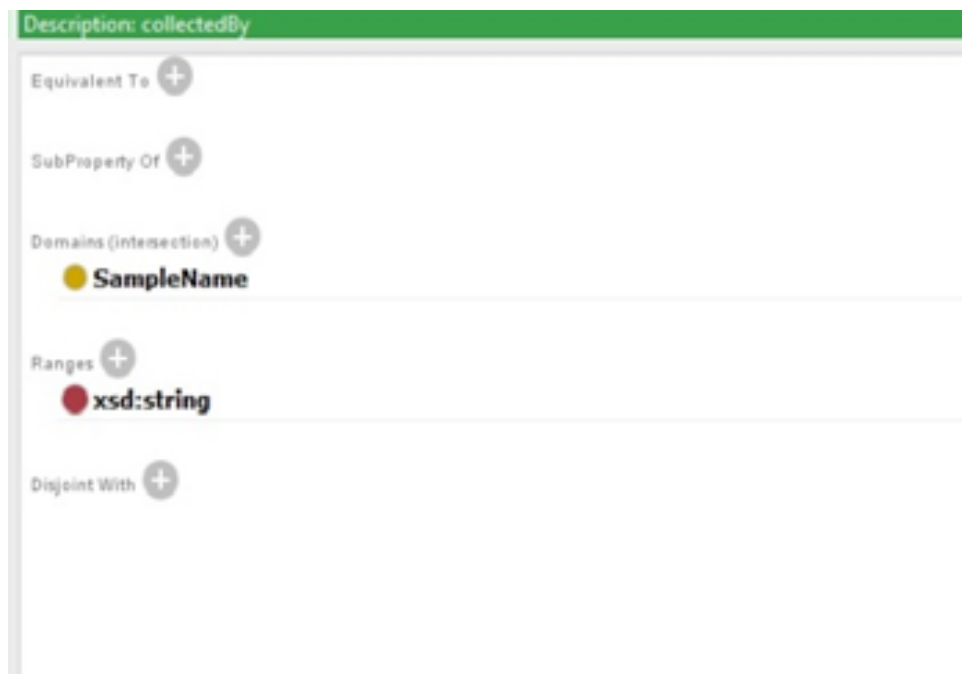

Figure 5-4: Screenshot of the 'collectedBy' data property with the domain connected to the class 'SampleName' and range to a string-based class (xsd:string), allowing user input.

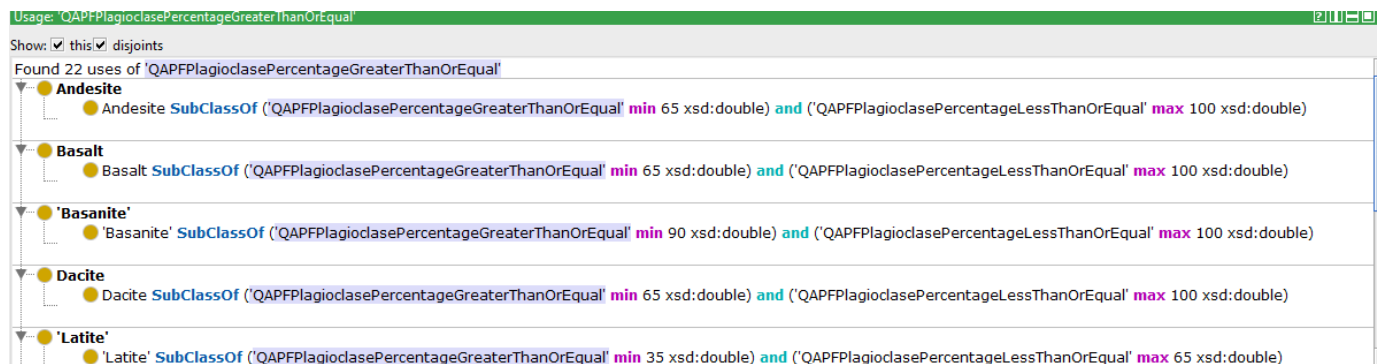

Figure 5-5: Instances of the use of the data properties of represent the limits of minerals using the QAPF classification of rock schemes. In these instances, each rock indicates the numerical limits of percentage of plagioclase based on QAPF classification, with 'QAPFPlagioclaseGreaterThanOrEqualTo' representing the lower limit for percentage of plagioclase feldspar, while 'QAPFPlagioclaseLessThanOrEqualTo' representing the upper limit for plagioclase feldspar.

5.4 OWL Reasoner assessment

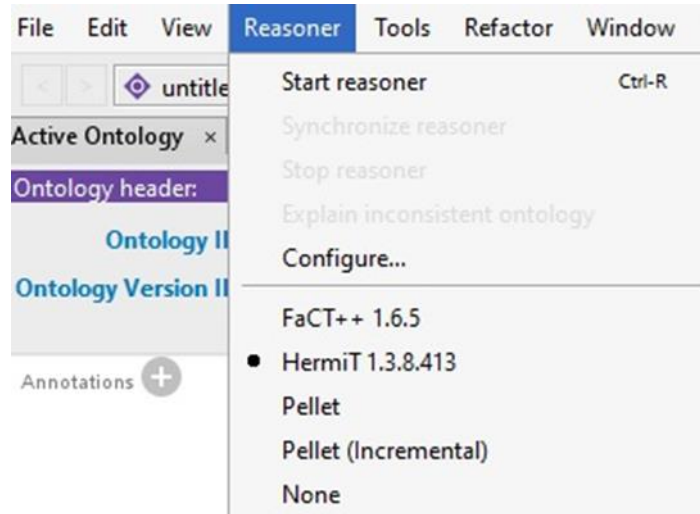

Figure 5-6: Screenshot of reasoners available through Protégé.

For ensuring that the completed ontology will cover the knowledge of the domain effectively and thoroughly, a reasoner software will be utilized. Reasoners are software designed to look at the inferences created by the established assertions (Arp et al., 2015). Protégé 5.2.0 comes preinstalled with HermiT OWL Reasoner, a reasoner implemented with Java (Information System Group, 2016). Other reasoners, including Pellet and FaCT++ that are downloaded and installed automatically through Protégé installation (Figure 5-6). Pellet, like HermiT is another Java-based OWL Reasoner (W3C Consortium, 2011). FaCT++, unlike Pellet, and HermiT, was implemented using C++ (Tsarkov, 2014). After each test, the inferred relations were compared to the actual relations. Once this is completed, simple querying tests were done using the SPARQL Query software, already integrated within Protégé (Figure 5-7) (W3C SPARQL Working Group, 2013).

| subject | object |
|------------------------------------|---|
| Sand | Sediment |
| 'State Change' | ● from only StateOfMatter |
| Kimberlite | ● hasMaterial value 'Diamond' |
| q-value | 'quantitative confidence value' |
| 'Benmoreite' | Trachyandesite |
| 'HawaiianEruption' | ● not (hasProcess some Explosion) |
| 'absence of enrichment hypothesis' | 'absence of positive difference hypothesis' |
| Unstable | SystemState |
| Peridotite | UltramaficRock |
| 'CrystalTexture' | 'Texture' |
| HeightRange | ● rangeOf some Height |
| PolarWander | EarthOscillation |
| Moho | GeologicBoundary |
| Constituent | ConsistenceProperty |
| 'study design' | ● denotes some 'study group population' |
| Set | Bag |
| SpatialDistribution | SpatialConfiguration |

*Figure 5-7: Screenshot of the SPARQL Query for Volcanism Ontology within Protégé, using RDF triple (subject-predicate-object) format to find relationships between subject and object. Object classes without a yellow circle are direct **isA** relationship. Those with yellow circles indicate a special predicate connecting the object class to the subject class.*

CHAPTER 6 DISCUSSION, CONCLUSIONS AND FUTURE WORK

6.1 Discussion

Figure 6-1: the continuant investigative object class 'Seismometer' is related to the occurrent volcanism process class SeismicPhenomena by the object property measures.

Initial versions of the Volcanism Ontology had all classes organized under the single base framework of BFO. Continued development showed that the initial organization was too convoluted and confusing to be able to easily navigate and understand how the entities relate. Taking inspiration from other ontological development, the decision was made to separate the investigative entities and the volcanism entities into their own frameworks, each still organized using BFO (Babaie et al., 2013). This change reduced the confusion and allowed for easier organization of entities. Properties were utilized to connect investigative entities with volcanism entities, such as the continuant object class 'Seismometer' found under the 'InvestigativeEntity' framework, connects to the occurrent process class SeismicPhenomena in the 'VolcanismEntity' framework, by the property measures (Figure 6-1).

Figure 6-2: The class 'data item,' which is imported from STATO ontology is set as an equivalent class to the class Data, which is imported from SWEET Ontology.

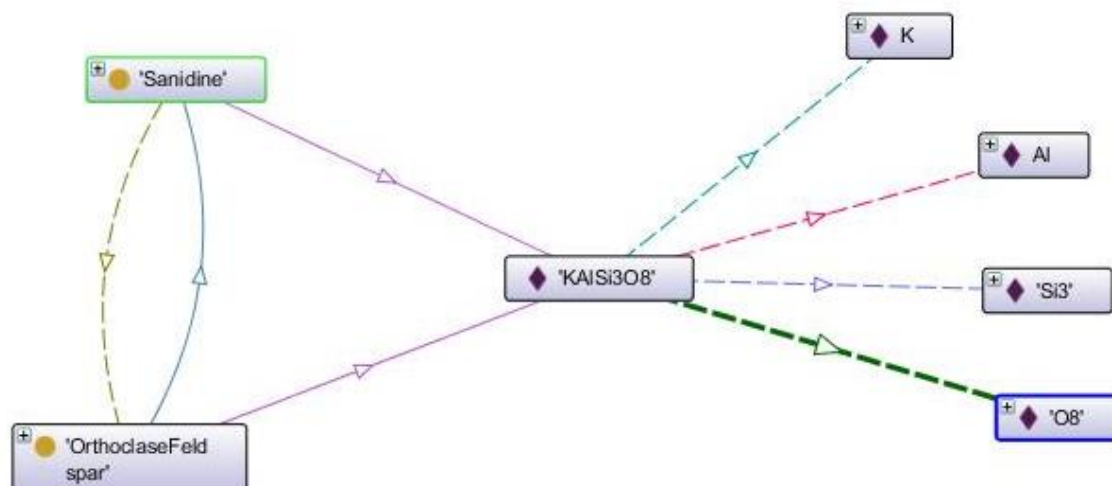

Figure 6-3: The classes 'OrthoclaseFeldspar' and 'Sanidine' and their associated element individuals. Note the construction of the chemical formula instance 'KAISI3O8,' which utilizes an approach from SWEET ontology and uses object properties (hasChemical_1, hasChemical_2, hasChemical_3, hasChemical_4) to connect to other elemental and molecular individuals. Solid blue line represents isA object property, solid purple lines indicate hasIndividual object property, dashed green line represents 'formOf' object property, and the remaining dashed lines indicate the previously mentioned hasChemical object properties.

Given that multiple ontologies were imported, identical entities were connected between these entities via equivalence relations (Figure 6-2). For assistance in mineral classification, instances of those minerals and their chemical formulas were created (Figure 6-3). These chemical formulas followed similar formula construction found in SWEET ontology utilizing object and data properties (Jet Propulsion Laboratory, 2010). Classes of minerals were modeled in mineral reaction series such as Bowen's Reaction Series (Figure 6-4). As mentioned previously, classification of rocks was assisted by data properties to provide mineral percentage ranges based on TAS and QAPF rock classifications (Figure 6-5). Minerals and rocks were further organized by silica content with property classes referring to Felsic, 'IntermediateComposition,' Mafic, and Ultramafic (Figure 6-6).

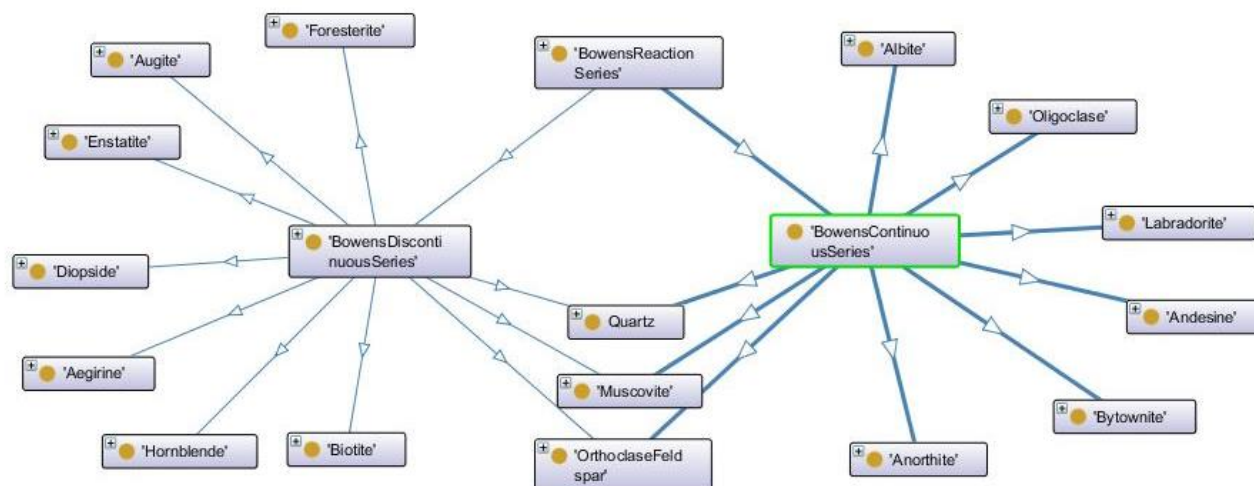

Figure 6-5: The class 'BowensReactionSeries,' broken down into subclasses 'BowensDiscontinuousSeries' and 'BowensContinuousSeries' and their associated mineral classes. Note that the minerals 'Muscovite,' 'OrthoclaseFeldspar,' and 'Quartz' are found in both series, since they occur at the end of these reaction series. Blue solid lines represent isA object property.

Description: Basalt

Equivalent To

SubClass Of

- 'hasMineral' some 'MaficMineral'
- 'MaficRock'
- ('hasGrainSize' value 'FineGrained') or ('hasGrainSize' value 'VeryFineGrained')
- ('hasTexture' some 'Aphanitic') or ('hasTexture' some 'IntergranularTexture') or ('hasTexture' some 'PorphyriticTexture')
- ('QAPFAlkaliPercentageGreaterThanOrEqualTo' min 0 xsd:double) and ('QAPFAlkaliPercentageLessThanOrEqualTo' max 35 xsd:double)
- ('QAPFFeldspathoidPercentageGreaterThanOrEqualTo' min 0 xsd:double) and ('QAPFFeldspathoidPercentageLessThanOrEqualTo' max 10 xsd:double)
- ('QAPFPlagioclasePercentageGreaterThanOrEqualTo' min 65 xsd:double) and ('QAPFPlagioclasePercentageLessThanOrEqualTo' max 100 xsd:double)
- ('QAPFQuartzPercentageGreaterThanOrEqualTo' min 0 xsd:double) and ('QAPFQuartzPercentageLessThanOrEqualTo' max 20 xsd:double)
- ('silicaPercentageGreaterThanOrEqualTo' min 45 xsd:double) and ('silicaPercentageLessThanOrEqualTo' max 52 xsd:double)
- ('TASAlkaliPercentageGreaterThanOrEqualTo' min 0 xsd:double) and ('TASAlkaliPercentageLessThanOrEqualTo' max 5 xsd:double)
- VolcanicRock
- wasDerivedFrom some UpperMantle

Figure 6-4: Detail on some of the relations for the class Basalt. Note several data properties used to indicate the percentage limits for minerals used in QAPF and TAS rock classification schemes. (The data properties 'silicaPercentage...' represent the silica aspect of the TAS classification)

Similar approaches were done also when it comes to occurrent entities. A notable example being the class 'VolcanicExplosivityIndex,' an index used to measure the explosiveness of volcanic eruptions (Neuendorf et al., 2011). Classes were created for each classification of VEI with their volume limits included as part of data properties (Figure 6-7). These VEI level classes were connected to eruption type classes using the object property 'hasVEIValue' (Figure 6-8).

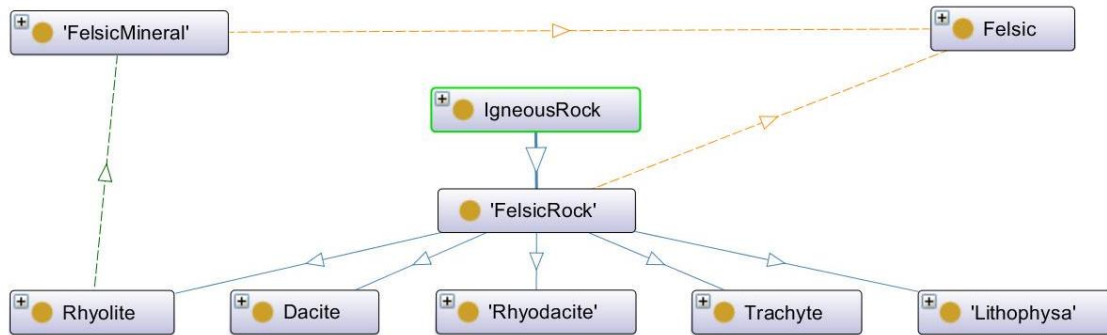

Figure 6-7: Classes connected to class 'FelsicRock' with the subclasses being different felsic rocks. The blue solid lines represent isA object property, dashed yellow lines indicate hasProperty object property, and green dashed line represents 'hasMineral' object property.

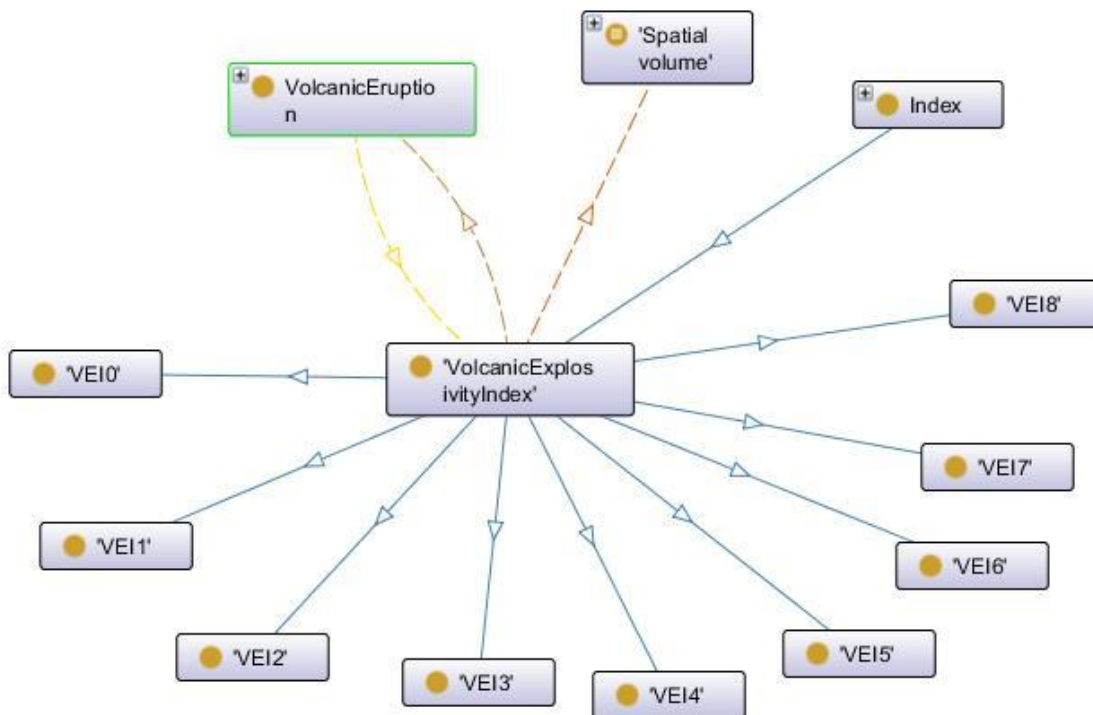

Figure 6-6: Classes related to the class 'VolcanicExplosivityIndex.' Solid blue line indicates isA object property, dashed orange line indicates measures object property, dashed brown line represents 'measureOf' object property, and dashed yellow line indicates the range class for the object property 'hasVEIValue.'

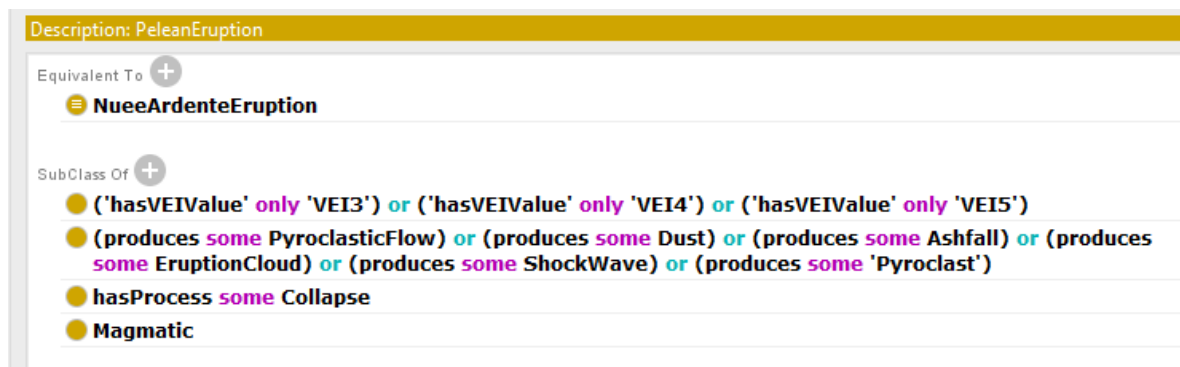

Figure 6-8: Detail on the relations of the class PeleanEruption. Note the appropriate VEI classes listed with the relation 'hasVEIValue.'

6.2 Conclusions

As previously mentioned, work within the realm of geosciences is fast growing, leading to the use of ontologies and the semantic integration of data processing, filtering, and long-term knowledge management (Sinha et al., 2010). Much of this work in the field has been focused more on the development of top-level domain ontologies such as SWEET and SESDI, with less work on more specialized domain ontologies (Barahmand et al., 2010; McGuinness et al., 2007). Within the domain of volcanology, the need for knowledge representation has been noted (C. A. Pshenichny, 2014).

The Volcanism Ontology (VO) is the first major attempt to consolidate and cover the continuant and occurrent entities found within volcanology within a single framework thanks to BFO (Arp et al., 2015). Thanks to BFO, VO has been demonstrated to be a potential domain ontology needed for volcanologists (C. A. Pshenichny, 2014). The ontology may be of practical use, for example, for volcanic hazard assessments. Given the high-intensity environments during any geological hazard, including volcanic eruption, clear communication, familiarity with the terminology, and sharing of accurate information and data is key for successful management and mitigation (Sinha et al., 2010). The works of ontologies such as IDO within the realm of bioinformatics show that these same capabilities could be applied for volcanic hazards mitigation, particularly given the need for the communication of accurate information in a short period of time (Arp et al., 2015; C. A. Pshenichny, 2014).

With the work created here within of BFO, there forgoes the need of using more ontologies for proper filtering and analyzing of data to commence. Given that the work also utilizes concepts from other existing upper-level ontologies, this allows this ontology framework to work as extension of other upper-level ontologies (DiGiuseppe et al., 2014). This allows the integration of other ontologies developed to create a much larger, more precise filtering and analysis of data as needed, given that the ontology would eventually be stored on the Semantic Web for use by any researcher needing its capabilities (Horrocks, 2008).

6.2.1 Future Work

This thesis focuses only on the development of the ontology, and not on the building of the web user interface for data input into its knowledge base. Future work would focus on helping those to ensure that this framework can work easily with a web interface. Further work would need to help the ontology better provide straightforward and clear connections to assist in making sure web interface development is smooth and with few major issues of compatibility. Once connected to a web interface, efforts can be made to ensure that there is proper connections with the Semantic Web and allow recognition and usage of the ontology (Horrocks, 2008). More work can also be done into looking into the refining and finding the blind spots in the ontology and including more rare minerals and rock varieties as sample are provided into a database. Areas of particular refinement would be the development of volcanoclastic deposits and the realm of petrogenesis of certain magmas of the rare variety such as calc-alkaline volcanism (Raymond, 2002). As the domain of volcanology is a complex tapestry of continuant and occurrent concepts intertwining with one another, the Volcanism Ontology will continue to grow in its own complexity to be a better representation of reality (C. A. Pshenichny, 2014).
