  <AnnotationProperty IRI="http://bhi.washington.edu/OPB#discussion"/>
  <IRI>http://bhi.washington.edu/OPB#OPB_00002</IRI>
  <Literal datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">Rate properties
represent the FORCE DIFFERENTIAL or the RATE OF FLOW of material, charge, energy, or
information across a boundary separating one physical entity from another via some pathway. Examples:

```

- 1) fluid flow rate through a tube or vessel (dimensions of volume/time)
- 2) charge flow rate of an electrical current through an ion channel or wire (dimensions of charge/time or current)
- 3) chemical flux through a reaction kinetic pathway (dimensions of amount/time typically moles/sec or concentration/time)
- 4) the force in a spring as applied by entities at either end and as transmitted through the length of the spring.

Rate properties can be properly attributed to entities in two mathematically equivalent, but logically different, ways.

1) Representing the source/sink of a process where the rate properties are attributed to participants in a process. For example, a fluid flow process has a fluid-source entity and a fluid-sink entity so that the fluid rate is expressed as flow from source-to-sink. Similarly, mechanical process is due to forces exerted by "entity A" upon "entity B". This kind of formulation asserts that the flow/force properties are so-called "cross properties" because they describe how energy is transmitted across a process in which entities participate.

2) Representing rates as “through” properties as attributes of a “mediator” that is an entity through which the process occurs. For a fluid flow process, the fluid flow rate is thus attributed to the flow conduit (or more properly, the lumen of the conduit) that mediates the source-to-sink flow. Or, in the case of the transmission of mechanical force, across the interface or boundary between two mechanical solid entities.

These different approaches yield mathematically equivalent results yet their semantic-logical representations differ ways that is a burden for the reasoning required to detect and resolve their equivalence. In the “cross” representation, source/sink entities are represented as source/sink participants in a process. In the “through” representation, source/sink entities are represented as parts of an entity that “mediates” the process.

The distinction between “through” and “cross” properties (variables in math models) is commonly used in engineering analyses such the PhysSys ontology; see:

```

By rights, a conductance (or its inverse, resistance) is a constitutive property of an electrochemical flow process (see: OPB:Electrical conductance). However, we classify ionic conductances as dynamical amounts because they are, ultimately, determined by the aggregates of the molecular conformational states of the ionic channels mediating the electropotential ion transport. Thus, these classes are suitable for representing the conductance ion channels at a moment in time, as well as the conductance of ion channel as characterized for standard conditions and by which the channel is named (e.g., "250 pS Ca-dependent K-channel");</Literal>

<Literal datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">Constitutive proportionalities apply only to those constitutive dependencies that can be expressed by which the dependent property is proportional to the independent property. Any other algebraic form of the dependency may have specially-defined parameters (e.g., offsets, rate parameters). Given the creativity and license of modelers for creating the best fit to constitutive dependencies, the parameters of such non-proportional dependencies must be annotated by some local mechanism that does not depend on OPB classifications.

Constitutive proportionalities are approximations to dependencies for which a first-order, linear approximation is sufficient for the purposes of analysis. Piecewise linear approximations may apply over a limited range of dynamical property values. In general, various algebraic functions may be required using one or more parameters to fit observed dependency relationships. Given the range of possible constitutive dependencies, OPB defers representing such possibilities on a case-by-case basis for specific use-cases.

Non-proportionality constants include coefficients and parameters required to characterize linear and nonlinear dependencies that are not simple proportionalities. Some may constitutive dependencies may include dynamic modeling schemes with internal dynamic states (e.g., the "gating variable" of Hodgkin-Huxley ion gating equations). We will treat such properties as "internal" to the constitutive dependency, shielded from other entities in the system and known solely as hypothetical constructs derived as constitutively observed dynamic phenomena. Thus, HH gating variables will be classified as properties of constitutive dependencies which are also subclasses of Dynamical property without, however, declaring a Dynamical entity of which it is a property.

Important to realize that MM params, HH params, etc. are all derived and asserted by virtue of curve-fits to the directly observed attributes of a system; number of gating particles and their respective states is entirely inferential by best fits and, so, are no more physically real than any other coefficient or parameter.</Literal>

temperature is an objective comparative measurement of hotness or coldness.&quot;;

```

<https://en.wikipedia.org/wiki/Temperature>

Because temperature is an intensive property that properly only applies to a single point in an entity, assigning a "temperature" as a property of a discretized physical entity that extends its space presents problems. If temperature is constant over the spatial extent of an entity (i.e., it is "isothermic") then it is fair to say that the entity has a single value of temperature. Such an assumption is quite often made for homeothermic biological organisms and their parts. However, it is not meaningful to calculate a spatial integral of temperature to derive an "average" temperature because such integrals have meaning only for extensive properties like mass density or current density. However, some analyses do aim to account explicitly for temperature gradients that drive heat transfers between entities or parts of entities. In such cases it is useful to define, for continuum modeling, a spatial distribution for temperature and heat fluxes.

However, for discrete modeling, the temperature of an entity can be assigned a value while its parts are assigned different temperatures – the discrete analogue of a continuum temperature distribution. For example, the temperature of mitochondria is likely to be higher than the surrounding portion of cytosol. That being said, there is utility in expressing that a discrete, dynamical entity can have a discrete temperature property with one value while allowing one or more of its parts to have separate temperature properties with different values. For computational purposes one can make the assumption that all parts of an entity share the same temperature property instance as the (whole) entity while parts that have a different temperature will have their own temperature property with a value that may differ from the temperature value of the whole entity (and the other parts).</Literal>

    <Literal datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">Dynamical state
properties are the CONSERVED amount or the CONSERVED momentum within the boundary of a
physical entity. State property values are changed during a span of time according to the temporal
integration of flow rates or forces according, respectively, to Stokes's law.

```

Differentials of state property values between physical entity process participants are the drivers for flows between entities as expressed in the constitutive dependencies according to the (linear, proportional) laws of Ohm, Hooke, and Newton.

State properties are termed "across" or "cross" variables to express the idea that the value differential exists across the path to which a rate property applies. In PhysSys ontology [1] and Karnopp [2], they are classified as "forces" variables (f).

has the dimension of force per unit length, or of energy per unit area. The two are equivalent&acirc"but when
referring to energy per unit of area, people use the term surface energy&acirc"which is a more general term in
the sense that it applies also to solids and not just liquids.

Surface tension, usually represented by the symbol  $\hat{I}^3$ , is measured in forces per unit length. Its SI unit is
newton per meter but the cgs unit of dyne per cm is also used.

```

No physical difference has been found between gravitational and inertial mass in a given inertial frame.

Inertial mass is found by applying a known net force to an unknown mass, measuring the resulting acceleration, and applying Newton's Second Law, $m = F/a$.

Gravitational mass is measured by comparing the force of gravity of an unknown mass to the force of gravity of a known mass.</Literal>

property that assigns a class of &quot;SI-unit&quot; to OPB:Physical property classes. Multiple instances
of hasSI-unit and hasReciprocal-SI-unit may be assigned to a given property class to express, as factors
and reciprocals, compound units such as for a velocity (distance/time) or density (mass / volume).

```

SI-units are the only system of units to be represented in OPB and is implemented according to the globally-adopted system as described in:

https://en.wikipedia.org/wiki/International_System_of_Units. SI-unit classes.

Accordingly and by fiat, some are "base units" that are irreducible and some are "derived units" that are derived from base units by multiplication or division. In other formal systems or conventional usages, other allocations between base/derived units may be encountered.

SI-unit classes map, non-exclusively to classes of OPB:PropertyDimension either as single classes, or as multiples/quotients of base units

<AnnotationProperty IRI="http://bhi.washington.edu/OPB#discussion"/>
 <IRI>http://bhi.washington.edu/OPB#OPB_01502</IRI>
 <Literal datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">Constitutive dynamical properties ultimately depend on an empirically determined material property (e.g., density, resistivity) of a participant in the process. For example, mass density depends on both the spatial distribution of atoms and the atomic weight of each. Resistance of a conductor depends on the resistivity of the material in the wire which is only defined and determinable empirically.

There are two conflicting views of constitutive properties as properties of processes or of continuant entities:

1. The definition of constitutive property as a "ratio or partial derivative" of physical property values necessarily implicates a measurement process whereby values of two or more physical properties are varying and are measured and computed. However...
2. Constitutive properties are conventionally viewed as inherent attributes of a continuant or a process:
 - . mass density is the ratio of a material amount to the extent of the spatial region that it occupies.
 - . resistivity is the ratio of a potential difference to current flow rate for an electrical flow process
 - .
- 3) what is common to each case is that "constitutive properties" are defined in the context of a specific entity or process in a manner that depends on the material and structural composition of the entities participating in the measurement process.

Any other algebraic form of the dependency may have specially-defined parameters (e.g., offsets, rate parameters). Given the creativity and license of modelers for creating the best fit to constitutive dependencies, the parameters of such non-proportional dependencies must be annotated by some local mechanism that does not depend on OPB classifications.

Constitutive proportionalities are approximations to dependencies for which a first-order, linear approximation is sufficient for the purposes of analysis. Piecewise linear approximations may apply over a limited range of dynamical property values. In general, various algebraic functions may be required using one or more parameters to fit observed dependency relationships. Given the range of possible constitutive dependencies, OPB defers representing such possibilities on a case-by-case basis for specific use-cases.

Non-proportionality constants include coefficients and parameters required to characterize linear and nonlinear dependencies that are not simple proportionalities. Some constitutive dependencies may include dynamic modeling schemes with internal dynamic states (e.g., the "gating variable" of Hodgkin-Huxley ion gating equations). We will treat such properties as "internal" to the constitutive dependency, shielded from other entities in the system and known solely as hypothetical constructs derived as constitutively observed dynamic phenomena. Thus, HH gating variables will be classified as properties of constitutive dependencies which are also subclasses of Dynamical property without, however, declaring a Dynamical entity of which it is a property.

Important to realize that MM params, HH params, etc. are all derived and asserted by virtue of curve-fits to the directly observed attributes of a system; number of gating particles and their respective states is entirely inferential by best fits and, so, are no more physically real than any other coefficient or parameter.</Literal>

      <Literal datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">Simons uses
different terminology for relations of occurrents to regions: Denote the spatio-temporal location of a given
occurent e by 'span[e]'; and call this region its span. We may say an occurrent is at its span, in
any larger region, and covers any smaller region. Now suppose we have fixed a frame of reference so that
we can speak not merely of spatio-temporal but also of spatial regions (places) and temporal regions
(times). The spread of an occurrent, (relative to a frame of reference) is the space it exactly occupies, and
its spell is likewise the time it exactly occupies. We write 'spr[e]'; and 'spl[e]';
respectively for the spread and spell of e, omitting mention of the frame.</Literal>

  <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">BFO 2 Reference: The realm of occurrents is less pervasively marked by the presence of
natural units than is the case in the realm of independent continuants. Thus there is here no counterpart of
â€˜objectâ€™. In BFO 1.0 â€˜processâ€™ served as such a counterpart. In BFO 2.0 â€˜processâ€™ is,
rather, the occurrent counterpart of â€˜material entityâ€™. Those natural â€˜ as contrasted with
engineered, which here means: deliberately executed â€˜ units which do exist in the realm of occurrents
are typically either parasitic on the existence of natural units on the continuant side, or they are fiat in
nature. Thus we can count lives; we can count football games; we can count chemical reactions
performed in experiments or in chemical manufacturing. We cannot count the processes taking place, for
instance, in an episode of insect mating behavior. Even where natural units are identifiable, for example
cycles in a cyclical process such as the beating of a heart or an organismâ€™s sleep/wake cycle, the
processes in question form a sequence with no discontinuities (temporal gaps) of the sort that we find for
instance where billiard balls or zebrafish or planets are separated by clear spatial gaps. Lives of organisms
are process units, but they too unfold in a continuous series from other, prior processes such as
fertilization, and they unfold in turn in continuous series of post-life processes such as post-mortem
decay. Clear examples of boundaries of processes are almost always of the fiat sort (midnight, a time of
death as declared in an operating theater or on a death certificate, the initiation of a state of war)</Literal>

  <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">BFO 2 Reference: One major family of examples of non-rigid universals involves roles,
and ontologies developed for corresponding administrative purposes may consist entirely of
representatives of entities of this sort. Thus  $\hat{\sim}$ professor $\hat{\in}$ TM, defined as follows, b instance_of professor
at t =Def. there is some c, c instance_of professor role & c inheres_in b at t.denotes a non-rigid
universal and so also do  $\hat{\sim}$ nurse $\hat{\in}$ TM,  $\hat{\sim}$ student $\hat{\in}$ TM,  $\hat{\sim}$ colonel $\hat{\in}$ TM,  $\hat{\sim}$ taxpayer $\hat{\in}$ TM, and so forth.
(These terms are all, in the jargon of philosophy, phase sortals.) By using role terms in definitions, we can
create a BFO conformant treatment of such entities drawing on the fact that, while an instance of
professor may be simultaneously an instance of trade union member, no instance of the type professor
role is also (at any time) an instance of the type trade union member role (any more than any instance of
the type color is at any time an instance of the type length).If an ontology of employment positions should
be defined in terms of roles following the above pattern, this enables the ontology to do justice to the fact
that individuals instantiate the corresponding universals  $\hat{\in}$  professor, sergeant, nurse  $\hat{\in}$  only during
certain phases in their lives.</Literal>

```

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">or with divisions drawn by cognitive subjects for practical reasons, such as the division of a cake (before slicing) into (what will become) slices (and thus member parts of an object aggregate). However, this does not mean that fiat object parts are dependent for their existence on divisions or delineations effected by cognitive subjects. If, for example, it is correct to conceive geological layers of the Earth as fiat object parts of the Earth, then even though these layers were first delineated in recent times, still existed long before such delineation and what holds of these layers (for example that the oldest layers are also the lowest layers) did not begin to hold because of our acts of delineation. Treatment of material entity in BFO Examples viewed by some as problematic cases for the trichotomy of fiat object part, object, and object aggregate include: a mussel on (and attached to) a rock, a slime mold, a pizza, a cloud, a galaxy, a railway train with engine and multiple carriages, a clonal stand of quaking aspen, a bacterial community (biofilm), a broken femur. Note that, as Aristotle already clearly recognized, such problematic cases "need not invalidate these categories. The existence of grey objects does not prove that there are not objects which are black and objects which are white; the existence of mules does not prove that there are not objects which are donkeys and objects which are horses. It does, however, show that the examples in question need to be addressed carefully in order to show how they can be fitted into the proposed scheme, for example by recognizing additional subdivisions [29</Literal>

    <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">BFO 2 Reference: BFO rests on the presupposition that at multiple micro-, meso- and
macroscopic scales reality exhibits certain stable, spatially separated or separable material units,

```

combined or combinable into aggregates of various sorts (for example organisms into what are called "populations"). Such units play a central role in almost all domains of natural science from particle physics to cosmology. Many scientific laws govern the units in question, employing general terms (such as "molecule" or "planet") referring to the types and subtypes of units, and also to the types and subtypes of the processes through which such units develop and interact. The division of reality into such natural units is at the heart of biological science, as also is the fact that these units may form higher-level units (as cells form multicellular organisms) and that they may also form aggregates of units, for example as cells form portions of tissue and organs form families, herds, breeds, species, and so on. At the same time, the division of certain portions of reality into engineered units (manufactured artifacts) is the basis of modern industrial technology, which rests on the distributed mass production of engineered parts through division of labor and on their assembly into larger, compound units such as cars and laptops. The division of portions of reality into units is one starting point for the phenomenon of counting.

<IRI>http://purl.obolibrary.org/obo/BFO_0000030</IRI>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">BFO 2 Reference: Each object is such that there are entities of which we can assert unproblematically that they lie in its interior, and other entities of which we can assert unproblematically that they lie in its exterior. This may not be so for entities lying at or near the boundary between the interior and exterior. This means that two objects " for example the two cells depicted in Figure 3 " may be such that there are material entities crossing their boundaries which belong determinately to neither cell. Something similar obtains in certain cases of conjoined twins (see below).

</AnnotationAssertion>

<AnnotationAssertion>

<AnnotationProperty IRI="http://purl.obolibrary.org/obo/IAO_0000116"/>

<IRI>http://purl.obolibrary.org/obo/BFO_0000030</IRI>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">BFO 2 Reference: To say that b is causally unified means: b is a material entity which is such that its material parts are tied together in such a way that, in environments typical for entities of the type in question, if c, a continuant part of b that is in the interior of b at t, is larger than a certain threshold size (which will be determined differently from case to case, depending on factors such as porosity of external cover) and is moved in space to be at t at a location on the exterior of the spatial region that had been occupied by b at t, then either b's other parts will be moved in coordinated fashion or b will be damaged (be affected, for example, by breakage or tearing) in the interval between t and t. causal changes in one part of b can have consequences for other parts of b without the mediation of any entity that lies on the exterior of b. Material entities with no proper material parts would satisfy these conditions trivially. Candidate examples of types of causal unity for material entities of more complex sorts are as follows (this is not intended to be an exhaustive list): CU1: Causal unity via physical covering Here the parts in the interior of the unified entity are combined together causally through a common membrane or other physical covering. The latter points outwards toward and may serve a protective function in relation to what lies on the exterior of the entity [13, 47

  <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">BFO 2 Reference: "Matter"™ is intended to encompass both mass and energy (we
will address the ontological treatment of portions of energy in a later version of BFO). A portion of matter
is anything that includes elementary particles among its proper or improper parts: quarks and leptons,
including electrons, as the smallest particles thus far discovered; baryons (including protons and neutrons)
at a higher level of granularity; atoms and molecules at still higher levels, forming the cells, organs,
organisms and other material entities studied by biologists, the portions of rock studied by geologists, the
fossils studied by paleontologists, and so on. Material entities are three-dimensional entities (entities
extended in three spatial dimensions), as contrasted with the processes in which they participate, which
are four-dimensional entities (entities extended also along the dimension of time). According to the FMA,
material entities may have immaterial entities as parts " including the entities identified below as sites;
for example the interior (or "lumen"™) of your small intestine is a part of your body. BFO 2.0
embodies a decision to follow the FMA here.</Literal>

  <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">One important sub-family of rate process profiles is illustrated by the beat or frequency
profiles of cyclical processes, illustrated by the 60 beats per minute beating process of Johnâ€™s heart, or
the 120 beats per minute drumming process involved in one of Johnâ€™s performances in a rock band,
and so on. Each such process includes what we shall call a beat process profile instance as part, a subtype
of rate process profile in which the salient ratio is not distance covered but rather number of beat cycles
per unit of time. Each beat process profile instance instantiates the determinable universal beat process
profile. But it also instantiates multiple more specialized universals at lower levels of generality, selected
from rate process profilebeat process profileregular beat process profile3 bpm beat process profile4 bpm
beat process profileirregular beat process profileincreasing beat process profileand so on.In the case of a
regular beat process profile, a rate can be assigned in the simplest possible fashion by dividing the number
of cycles by the length of the temporal region occupied by the beating process profile as a whole.
Irregular process profiles of this sort, for example as identified in the clinic, or in the readings on an
aircraft instrument panel, are often of diagnostic significance.</Literal>

  <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">A
light source is an optical subsystem that provides light for use in a distant area using a delivery system
(e.g., fiber optics). Light sources may include one of a variety of lamps (e.g., xenon, halogen, mercury).
Most light sources are operated from line power, but some may be powered from batteries. They are
mostly used in endoscopic, microscopic, and other examination and/or in surgical procedures. The light
source is part of the optical subsystem. In a flow cytometer the light source directs high intensity light at
particles at the interrogation point. The light source in a flow cytometer is usually a laser.</Literal>

    <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">PMID: 17408389-Purpose: Proliferative vitreoretinopathy (PVR) is the most important
reason for blindness following retinal detachment. Presently, vitreous tamponades such as gas or silicone
oil cannot contact the lower part of the retina. A heavier-than-water tamponade displaces the
inflammatory and PVR-stimulating environment from the inferior area of the retina. The Heavy Silicone
Oil versus Standard Silicone Oil Study (HSO Study) is designed to answer the question of whether a
heavier-than-water tamponade improves the prognosis of eyes with PVR of the lower retina. Methods:
The HSO Study is a multicentre, randomized, prospective controlled clinical trial comparing two
endotamponades within a two-arm parallel group design. Patients with inferiorly and posteriorly located
PVR are randomized to either heavy silicone oil or standard silicone oil as a tamponading agent. Three
hundred and fifty consecutive patients are recruited per group. After intraoperative re-attachment, patients
are randomized to either standard silicone oil (1000 cSt or 5000 cSt) or Densiron((R)) as a tamponading
agent. The main endpoint criteria are complete retinal attachment at 12 months and change of visual
acuity (VA) 12 months postoperatively compared with the preoperative VA. Secondary endpoints include
complete retinal attachment before endotamponade removal, quality of life analysis and the number of

```

retina affecting re-operation within 1 year of follow-up. Results: The design and early recruitment phase of the study are described. Conclusions: The results of this study will uncover whether or not heavy silicone oil improves the prognosis of eyes with PVR.</Literal>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">PMID: 14744830-Microarrays are powerful tools for surveying the expression levels of many thousands of genes simultaneously. They belong to the new genomics technologies which have important applications in the biological, agricultural and pharmaceutical sciences. There are myriad sources of uncertainty in microarray experiments, and rigorous experimental design is essential for fully realizing the potential of these valuable resources. Two questions frequently asked by biologists on the brink of conducting cDNA or two-colour, spotted microarray experiments are 'Which mRNA samples should be competitively hybridized together on the same slide?' and 'How many times should each slide be replicated?' Early experience has shown that whilst the field of classical experimental design has much to offer this emerging multi-disciplinary area, new approaches which accommodate features specific to the microarray context are needed. In this paper, we propose optimal designs for factorial and time course experiments, which are special designs arising quite frequently in microarray experimentation. Our criterion for optimality is statistical efficiency based on a new notion of admissible designs; our approach enables efficient designs to be selected subject to the information available on the effects of most interest to biologists, the number of arrays available for the experiment, and other resource or practical constraints, including limitations on the amount of mRNA probe. We show that our designs are superior to both the popular reference designs, which are highly inefficient, and to designs incorporating all possible direct pairwise comparisons. Moreover, our proposed designs represent a substantial practical improvement over classical experimental designs which work in terms of standard interactions and main effects. The latter do not provide a basis for meaningful inference on the effects of most interest to biologists, nor make the most efficient use of valuable and limited resources.</Literal>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">Yate&apos;s corrected Chi-Squared test is a statistical test which is used to test the
association/linkage/independence of 2 dichotomous variables while introducing a correction for using the
continous Chi-squared distribution for the test.
To reduce the error in approximation, Frank Yates, an English statistician, suggested a correction for
continuity that adjusts the formula for Pearson&apos;s chi-squared test by subtracting 0.5 from the
difference between each observed value and its expected value in a 2 Å— 2 contingency table. This
reduces the chi-squared value obtained and thus increases its p-value.</Literal>

ns#PlainLiteral">The Wilcoxon signed rank test is a statistical test which tests the null hypothesis that the
median difference between pairs of observations is zero. This is the non-parametric analogue to the paired
t-test, and should be used if the distribution of differences between pairs may be non-normally distributed.

```

The procedure involves a ranking, hence the name. The absolute value of the differences between observations are ranked from smallest to largest, with the smallest difference getting a rank of 1, then next larger difference getting a rank of 2, etc. Ties are given average ranks. The ranks of all differences in one direction are summed, and the ranks of all differences in the other direction are summed. The smaller of these two sums is the test statistic, *W* (sometimes symbolized *T*_s). Unlike most test statistics, smaller values of *W* are less likely under the null hypothesis.</Literal>

  <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">Hotelling T squared distribution is a probability distribution used in multivariate
hypothesis testing, which is a univariate distribution proportional to the F-distribution and arises
importantly as the distribution of a set of statistics which are natural generalizations of the statistics
underlying Student&apos;s t-distribution.
In particular, the distribution arises in multivariate statistics in undertaking tests of the differences
between the (multivariate) means of different populations, where tests for univariate problems would
make use of a t-test.
The distribution is named for Harold Hotelling, who developed it[1] as a generalization of
Student&apos;s t-distribution.
This distribution is commonly used to describe the sample Mahalanobis distance between two
populations.</Literal>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">strictly standardized mean difference (SSMS) is a standardized mean difference which
corresponds to the ratio of mean to the standard deviation of the difference between two groups.
SSMD directly measures the magnitude of difference between two groups.
SSMD is widely used in High Content Screen for hit selection and quality control.

```

When the data is preprocessed using log-transformation as normally done in HTS experiments, SSMD is the mean of log fold change divided by the standard deviation of log fold change with respect to a negative reference.

In other words, SSMD is the average fold change (on the log scale) penalized by the variability of fold change (on the log scale).

For quality control, one index for the quality of an HTS assay is the magnitude of difference between a positive control and a negative reference in an assay plate. For hit selection, the size of effects of a compound (i.e., a small molecule or an siRNA) is represented by the magnitude of difference between the compound and a negative reference. SSMD directly measures the magnitude of difference between two groups. Therefore, SSMD can be used for both quality control and hit selection in HTS experiments.</Literal>

contingency table is a data item which displays the (multivariate) frequency distribution of the possible values of categorical variables.

The first row of the table corresponds to categories of one categorical variable, the first column of the table corresponds to categories of the other categorical variable, the cells corresponding to each combination of categories is filled with the observed occurrences in the sample being considered.

The table also contains marginal total (marginal sums) and grand total of the occurrences

The term contingency table was first used by Karl Pearson in "On the Theory of Contingency and Its Relation to Association and Normal Correlation", part of the Drapers' Company Research Memoirs Biometric Series I published in 1904.</Literal>

  <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">the geometric distribution is a negative binomial distribution where r is 1.
It is useful for modeling the runs of consecutive successes (or failures) in repeated independent trials of a
system.

```

The geometric distribution models the number of successes before one failure in an independent succession of tests where each test results in success or failure.

The geometric distribution with prob = p has density

$$p(x) = p (1-p)^x$$

for $x = 0, 1, 2, \dots$; $0 < p < 1$.

If an element of x is not integer, the result of dgeom is zero, with a warning.

The quantile is defined as the smallest value x such that $F(x) \geq p$, where F is the distribution function.</Literal>

  <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">ANCOVA or analysis of covariance is a data transformation which evaluates if
population means of a dependent variable are equal across levels of a categorical independent variables
while controlling for the effects of other continuous variable s, known as covariates. Therefore, when
performing ANCOVA, we are adjusting the dependent variable means to what they would be if all groups
were equal on the covariates.
It augments the ANOVA model with one or more additional quantitative variables, called covariates,
which are related to the response variable. The covariates are included to reduce the variance in the error
terms and provide more precise measurement of the treatment effects. ANCOVA is used to test the main
and interaction effects of the factors, while controlling for the effects of the covariate</Literal>

ns#PlainLiteral">Spearman&apos;s rank correlation coefficient is a correlation coefficient which is a
nonparametric measure of statistical dependence between two ranked variables. It assesses how well the
relationship between two variables can be described using a monotonic function. If there are no repeated
data values, a perfect Spearman correlation of +1 or  $\hat{1}$  occurs when each of the variables is a perfect
monotone function of the other.
Spearman&apos;s coefficient may be used when the conditions for computing Pearson&apos;s
correlation are not met (e.g linearity, normality of the 2 continuous variables) but may require a ranking
transformation of the variables</Literal>

ns#PlainLiteral">The binomial distribution is a discrete probability distribution which describes the
probability of k successes in n draws with replacement from a finite population of size N.

```

The binomial distribution is frequently used to model the number of successes in a sample of size n drawn with replacement from a population of size N.

The binomial distribution gives the discrete probability distribution of obtaining exactly n successes out of N Bernoulli trials (where the result of each Bernoulli trial is true with probability p and false with probability q=1-p)

notation: B(n,p)

The mean is $N \cdot p$

The variance is $N \cdot p \cdot q$

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">a design matrix is an information content entity which denotes a study design. The design matrix is a n by m matrix where n the number of rows, corresponds to the number of observations (4 rows if quadruplicates) and where m, the number of columns corresponds to the number of independent variables. Each element in the matrix correspond to a discretized value representing one of the factor levels for a given factor.

A design matrix can be used as input to statistical modeling or statistical analysis.

The design matrix contains data on the independent variables (also called explanatory variables) in statistical models which attempt to explain observed data on a response variable (often called a dependent variable) in terms of the explanatory variables. The theory relating to such models makes substantial use of matrix manipulations involving the design matrix: see for example linear regression. A notable feature of the concept of a design matrix is that it is able to represent a number of different experimental designs and statistical models, e.g., ANOVA, ANCOVA, and linear regression</Literal>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">The covariance is a measurement data item about the strength of correlation between a
set (2 or more) of random variables.
The covariance is obtained by forming:

$$\text{cov}(X,Y)=E([X-E(X)][Y-E(Y)])$$

where  $E(X)$ ,  $E(Y)$  is the expected value (mean) of variable  $X$  and  $Y$ 
respectively.

```

covariance is symmetric so $\text{cov}(X,Y)=\text{cov}(Y,X)$.

The covariance is usefull when looking at the variance of the sum of the 2 random variables since:
 $\text{var}(X+Y) = \text{var}(X) + \text{var}(Y) + 2\text{cov}(X,Y)$

The covariance $\text{cov}(x,y)$ is used to obtain the coefficient of correlation $\text{cor}(x,y)$ by normalizing (dividing) $\text{cov}(x,y)$ but the product of the standard deviations of x and y .

    <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">The Akaike information criterion (AIC) is a measure of the relative quality of a
statistical model for a given set of data. As such, AIC provides a means for model selection. AIC is
defined as:

```

$$\text{AIC} = 2K - 2\log(L)$$

where K is the number of predictors and L is the maximized likelihood value.

AIC deals with the trade-off between the goodness of fit of the model and the complexity of the model. It is founded on information theory: it offers a relative estimate of the information lost when a given model is used to represent the process that generates the data. AIC does not provide a test of a model in the sense of testing a null hypothesis; i.e. AIC can tell nothing about the quality of the model in an absolute sense. If all the candidate models fit poorly, AIC will not give any warning of that.

```

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">The deviance information criterion (DIC) is a hierarchical modeling generalization of the AIC (Akaike information criterion) and BIC (Bayesian information criterion, also known as the Schwarz criterion). It is particularly useful in Bayesian model selection problems where the posterior distributions of the models have been obtained by Markov chain Monte Carlo (MCMC) simulation. Like AIC and BIC it is an asymptotic approximation as the sample size becomes large. It is only valid when the posterior distribution is approximately multivariate normal.

The deviance information criterion was published in 2002 by Spiegelhalter et al.

Spiegelhalter, D. J., N. G. Best, B. P. Carlin, and A. van der Linde, 2002. Bayesian measures of model complexity and fit. *Journal of the Royal Statistical Society, B*, 64, 583-639.</Literal>

<AnnotationAssertion>

<AnnotationProperty abbreviatedIRI="rdfs:comment"/>

<IRI>http://sweet.jpl.nasa.gov/2.3/matrRockIgneous.owl#Mafic</IRI>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">Mafic is an adjective describing a silicate mineral or rock that is rich in magnesium and iron; the term was derived by contracting "magnesium" and "ferric". Most mafic minerals are dark in color and the specific gravity is greater than 3. Common rock-forming mafic minerals include olivine, pyroxene, amphibole, and biotite. Common mafic rocks include basalt and gabbro. In terms of chemistry, mafic rocks are on the other side of the rock spectrum from the felsic rocks. The term roughly corresponds to the older basic rock class. Mafic lava, before cooling, has a low viscosity, in comparison to felsic lava, due to the lower silica content in mafic magma. Water and other volatiles can more easily and gradually escape from mafic lava, so eruptions of volcanoes made of mafic lavas are less explosively violent than felsic lava eruptions. Most mafic lava volcanoes are oceanic volcanoes, like Hawaii. [Wikipedia]</Literal>

These changes happen at relatively low temperatures and pressures and result in changes to the rock's original mineralogy and texture. The boundary between diagenesis and metamorphism, which occurs under conditions of higher temperature and pressure, is gradational. After deposition, sediments are compacted as they are buried beneath successive layers of sediment and cemented by minerals that precipitate from solution. Grains of sediment, rock fragments and fossils can be replaced by other minerals during diagenesis. Porosity usually decreases during diagenesis, except in rare cases such as dissolution of minerals and dolomitization.</Literal>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">Rayleigh waves, also called ground roll, are surface waves that travel as ripples similar to those on the surface of water. The existence of these waves was predicted by John William Strutt, Lord Rayleigh, in 1885. They are slower than body waves, roughly 70% of the velocity of S waves, and have been asserted to be visible during an earthquake in an open space like a parking lot where the cars move up and down with the waves. Reports among seismologists suggest that the apparent motion may be due to distortion of the human eye during shaking. Anecdotally, placing people on shake tables causes the room to appear to ripple. In any case, waves of the reported amplitude, wavelength, and velocity of the visible waves have never been recorded instrumentally.</Literal>

The mineral assembly is usually abundant feldspathoids (nepheline or leucite), plagioclase, and augite,

```

together with olivine and lesser iron-titanium oxides such as ilmenite and magnetite-ulvospinel; minor alkali feldspar may be present. Clinopyroxene (augite) and olivine are common as phenocrysts and in the matrix. The augite contains significantly greater titanium, aluminium and sodium than that in typical tholeiitic basalt. Quartz is absent, as are orthopyroxene and pigeonite. Chemically, basanites are low in silica (42 to 45% SiO₂) and high in alkalis (3 to 5.5% Na₂O and K₂O) compared to basalt, which typically contains more SiO₂, as evident on the diagram used for TAS classification. Nephelinite is yet richer in Na₂O plus K₂O compared to SiO₂. Basanites occur both on continents and on ocean islands. For example, together with basalts, they are produced by hotspot volcanism in the Hawaiian and the Comoros Islands [Wikipedia].</Literal>

Hawaiian eruption is a type of volcanic eruption where lava flows from the vent in a relatively gentle, low
level eruption; it is so named because it is characteristic of Hawaiian volcanoes. Typically they are
effusive eruptions, with basaltic magmas of low viscosity, low content of gases, and high temperature at
the vent. Very little amounts of volcanic ash are produced. This type of eruption occurs most often at
hotspot volcanoes such as K  lauea on Hawaii&apos;s big island and in Iceland, though it can occur
near subduction zones (e.g. Medicine Lake Volcano in California, United States) and rift zones.</Literal>

ns#PlainLiteral">BFO 2 Reference: "Matter"™ is intended to encompass both mass and energy (we
will address the ontological treatment of portions of energy in a later version of BFO). A portion of matter
is anything that includes elementary particles among its proper or improper parts: quarks and leptons,
including electrons, as the smallest particles thus far discovered; baryons (including protons and neutrons)
at a higher level of granularity; atoms and molecules at still higher levels, forming the cells, organs,
organisms and other material entities studied by biologists, the portions of rock studied by geologists, the
fossils studied by paleontologists, and so on. Material entities are three-dimensional entities (entities
extended in three spatial dimensions), as contrasted with the processes in which they participate, which
are four-dimensional entities (entities extended also along the dimension of time). According to the FMA,
material entities may have immaterial entities as parts " including the entities identified below as sites;
for example the interior (or "lumen"™) of your small intestine is a part of your body. BFO 2.0
embodies a decision to follow the FMA here.</Literal>

  <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">BFO 2 Reference: BFO rests on the presupposition that at multiple micro-, meso- and
macroscopic scales reality exhibits certain stable, spatially separated or separable material units,
combined or combinable into aggregates of various sorts (for example organisms into what are called
&acirc~populations&acirc~TM). Such units play a central role in almost all domains of natural science from particle
physics to cosmology. Many scientific laws govern the units in question, employing general terms (such
as &acirc~molecule&acirc~TM or &acirc~planet&acirc~TM) referring to the types and subtypes of units, and also to the types
and subtypes of the processes through which such units develop and interact. The division of reality into

```

such natural units is at the heart of biological science, as also is the fact that these units may form higher-level units (as cells form multicellular organisms) and that they may also form aggregates of units, for example as cells form portions of tissue and organs form families, herds, breeds, species, and so on. At the same time, the division of certain portions of reality into engineered units (manufactured artifacts) is the basis of modern industrial technology, which rests on the distributed mass production of engineered parts through division of labor and on their assembly into larger, compound units such as cars and laptops. The division of portions of reality into units is one starting point for the phenomenon of counting.</Literal>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">BFO 2 Reference: To say that b is causally unified means: b is a material entity which is such that its material parts are tied together in such a way that, in environments typical for entities of the type in question, if c, a continuant part of b that is in the interior of b at t, is larger than a certain threshold size (which will be determined differently from case to case, depending on factors such as porosity of external cover) and is moved in space to be at t at a location on the exterior of the spatial region that had been occupied by b at t, then either b’s other parts will be moved in coordinated fashion or b will be damaged (be affected, for example, by breakage or tearing) in the interval between t and t. causal changes in one part of b can have consequences for other parts of b without the mediation of any entity that lies on the exterior of b. Material entities with no proper material parts would satisfy these conditions trivially. Candidate examples of types of causal unity for material entities of more complex sorts are as follows (this is not intended to be an exhaustive list): CU1: Causal unity via physical covering Here the parts in the interior of the unified entity are combined together causally through a common membrane or other physical covering\). The latter points outwards toward and may serve a protective function in relation to what lies on the exterior of the entity [13, 47</Literal>

ns#PlainLiteral">BFO 2 Reference: The realm of occurrents is less pervasively marked by the presence of
natural units than is the case in the realm of independent continuants. Thus there is here no counterpart of
&acirc~object&acirc~TM. In BFO 1.0 &acirc~process&acirc~TM served as such a counterpart. In BFO 2.0 &acirc~process&acirc~TM is,
rather, the occurrent counterpart of &acirc~material entity&acirc~TM. Those natural &acirc~ as contrasted with
engineered, which here means: deliberately executed &acirc~ units which do exist in the realm of occurrents
are typically either parasitic on the existence of natural units on the continuant side, or they are fiat in
nature. Thus we can count lives; we can count football games; we can count chemical reactions
performed in experiments or in chemical manufacturing. We cannot count the processes taking place, for
instance, in an episode of insect mating behavior. Even where natural units are identifiable, for example
cycles in a cyclical process such as the beating of a heart or an organism&acirc~TMs sleep/wake cycle, the
processes in question form a sequence with no discontinuities (temporal gaps) of the sort that we find for
instance where billiard balls or zebrafish or planets are separated by clear spatial gaps. Lives of organisms
are process units, but they too unfold in a continuous series from other, prior processes such as
fertilization, and they unfold in turn in continuous series of post-life processes such as post-mortem
decay. Clear examples of boundaries of processes are almost always of the fiat sort (midnight, a time of
death as declared in an operating theater or on a death certificate, the initiation of a state of war)</Literal>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">BFO 2 Reference: One major family of examples of non-rigid universals involves roles, and ontologies developed for corresponding administrative purposes may consist entirely of representatives of entities of this sort. Thus "professor"TM, defined as follows, b instance_of professor at t =Def. there is some c, c instance_of professor role & c inheres_in b at t.denotes a non-rigid universal and so also do "nurse"TM, "student"TM, "colonel"TM, "taxpayer"TM, and so forth. (These terms are all, in the jargon of philosophy, phase sortals.) By using role terms in definitions, we can create a BFO conformant treatment of such entities drawing on the fact that, while an instance of professor may be simultaneously an instance of trade union member, no instance of the type professor role is also (at any time) an instance of the type trade union member role (any more than any instance of the type color is at any time an instance of the type length).If an ontology of employment positions should be defined in terms of roles following the above pattern, this enables the ontology to do justice to the fact that individuals instantiate the corresponding universals " professor, sergeant, nurse " only during certain phases in their lives.</Literal>

<IRI>#'Komatiite'</IRI>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">Komatiite is a type of ultramafic mantle-derived volcanic rock. Komatiites have low silicon, potassium and aluminium, and high to extremely high magnesium content. Komatiite was named for its type locality along the Komati River in South Africa. True komatiites are very rare and essentially restricted to rocks of Archean age, with few Proterozoic or Phanerozoic komatiites known (although high-magnesian lamprophyres are known from the Mesozoic). This restriction in age is thought to be due to cooling of the mantle, which may have been up to 500 Å°C hotter during the early to middle Archean (3.8 to 2.8 billion years ago). The early Earth had much higher heat production, due to the residual heat from planetary accretion, as well as the greater abundance of radioactive elements [Wikipedia].</Literal>

 <IRI>#'Leucite'</IRI>
 <Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">Leucite or leucite rock is an igneous rock containing leucite. It is scarce, many countries such as England being entirely without them. However, they are of wide distribution, occurring in every quarter of the globe. Taken collectively, they exhibit a considerable variety of types and are of great interest petrographically. For the presence of this mineral it is necessary that the silica percentage of the rock should be low, since leucite is incompatible with free quartz and reacts with it to form potassium feldspar. Because it weathers rapidly, leucite is most common in lavas of recent and Tertiary age, which have a fair amount of potassium, or at any rate have potassium equal to or greater than sodium; if sodium is abundant nepheline occurs rather than leucite [Wikipedia].</Literal>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-
ns#PlainLiteral">Normative mineralogy is a calculation of the composition of a rock sample that
estimates the idealised mineralogy of a rock according to the principles of geochemistry. Normative
mineral calculations can be achieved via either the CIPW Norm or the Barth-Niggli Norm (also known as
the Cation Norm). Normative calculations are used to produce an idealised mineralogy of a crystallized
melt. First, a rock is chemically analysed to determine the elemental constituents. Results of the chemical
analysis traditionally are expressed as oxides (e.g., weight percent Mg is expressed as weight percent
MgO). The normative mineralogy of the rock then is calculated, based upon assumptions about the order
of mineral formation and known phase relationships of rocks and minerals, and using simplified mineral
formulas. The calculated mineralogy can be used to assess concepts such as silica saturation of melts.

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">A Surtseyan eruption (or hydrovolcanic) is a type of volcanic eruption caused by shallow-water interactions between water and lava, named so after its most famous example, the eruption and formation of the island of Surtsey off the coast of Iceland in 1963. Surtseyan eruptions are the "wet" equivalent of ground-based Strombolian eruptions, but because of where they are taking place they are much more explosive. This is because as water is heated by lava, it flashes in steam and expands violently, fragmenting the magma it is in contact with into fine-grained ash. Surtseyan eruptions are the hallmark of shallow-water volcanic oceanic islands, however they are not specifically confined to them. Surtseyan eruptions can happen on land as well, and are caused by rising magma that comes into contact with an aquifer (water-bearing rock formation) at shallow levels under the volcano. The products of Surtseyan

eruptions are generally oxidized palagonite basalts (though andesitic eruptions do occur, albeit rarely), and like Strombolian eruptions Surtseyan eruptions are generally continuous or otherwise rhythmic.</Literal>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">Volcanic pipes are subterranean geological structures formed by the violent, supersonic eruption of deep-origin volcanoes. They are considered to be a type of diatrema. Volcanic pipes are composed of a deep, narrow cone of solidified magma (described as "carrot-shaped"), and are

usually largely composed of one of two characteristic rock types – kimberlite or lamproite. These rocks reflect the composition of the volcanoes’ deep magma sources, where the Earth is rich in magnesium. Volcanic pipes are relatively rare. They are well known as the primary source of diamonds, and are mined for this purpose [Wikipedia].</Literal>

<IRI>#'VulcanianEruption'</IRI>

<Literal xml:lang="en" datatypeIRI="http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral">Vulcanian eruptions are a type of volcanic eruption, named after the volcano Vulcano. It was named so following Giuseppe Mercalli’s observations of its 1888–1890 eruptions. In Vulcanian eruptions, intermediate viscous magma within the volcano make it difficult for vesiculate gases to escape. Similar to Strombolian eruptions, this leads to the buildup of high gas pressure, eventually popping the cap holding the magma down and resulting in an explosive eruption. However, unlike Strombolian eruptions, ejected lava fragments are not aerodynamic; this is due to the higher viscosity of Vulcanian magma and the greater incorporation of crystalline material broken off from the former cap. They are also more explosive than their Strombolian counterparts, with eruptive columns often reaching between 5 and 10 km (3 and 6 mi) high. Lastly, Vulcanian deposits are andesitic to dacitic rather than basaltic.</Literal>
