## FOREWARD

Thirteen Agricultural Experiment Stations in the Midwest joined in a research project entitled, "Adjustments in Livestock Marketing in the North Central States to Changing Patterns of Production and Consumption." Agricultural economists, whose names appear on the preceding page have made extensive analyses of data on the geographical movement of livestock and meat in the United States in 1955 and 1960 and have made projections for future years. This publication is one of a series eminating from these studies.

Because of the large number of farms and businesses engaged in providing the Nation's meat supply and the importance of meat in the American diet, this study should have widespread significance. In a dynamic society in which the human population is migrating from rural to metropolitan areas and in which some metropolitan areas grow more rapidly than others, there must be a continuous change in the ultimate destination of the meat supply. Likewise, as farm technology and production patterns change there is a continuous change in the sources of supply. Businesses and industries engaged in the marketing, processing, and distribution of livestock and meat must continuously adjust to these changing conditions. Studies that throw light on these changes can provide valuable information to those who must make decisions in these business operations. It is to those farmers and ranchers, marketing and transportation agencies, processors, wholesalers and retailers who are engaged in the complex livestock and meat industry that the study is addressed.

# II. Spatial Analyses of the Flows of Slaughter Livestock in 1955 and 1960* 

J. Havlicek, R. L. Rizek and G. G. Judge $\dagger$

## I. INTRODUCTION

The livestock economy is a complex of production, marketing, slaughtering, processing, distribution, and consumption of livestock and meat products. Changes are taking place in the livestock economy of the U.S. which affect the various components of this complex in a different manner. In some areas the changes are occurring more rapidly and are of greater magnitude than in other areas. The more prominent of these changes are the regional shifts in the locations of production, slaughter and consumption. Changes of this nature directly affect the activities of the various components of the livestock complex.

In this study attention is focused on the spatial aspects of slaughter livestock movements from production to slaughtering. Given the regional levels of production, slaughtering and the costs of moving one unit of various types of slaughter livestock from any one region to another region, this study is concerned with ascertaining the regional price differentials, and the volume and direction of regional imports and exports that are consistent with minimizing the total cost of moving the livestock from production to slaughter. In addition, questions about the consequences of changes in the existing structure of the livestock economy may be evaluated with regard to their impact on regional prices and slaughter livestock flows.

In particular, the problems with which the current research is concerned are as follows: (1) estimating annual and quarterly live weight quantities of slaughter production of cattle, calves, hogs, and sheep and lambs for 1955 and 1960 for 26 regions of the U.S., (2) estimating the set of transportation costs for moving each type of slaughter livestock among each of the 26 regions in 1955 and 1960, (3) determining annual and quarterly optimum flows of slaughter cattle, calves, hogs, and sheep
and lambs from production to slaughter for 1955 and 1960 for 26 regions of the U.S., (4) determining the competitive price differentials for each of the four types of slaughter livestock for 1955 and 1960, (5) determining the total transportation costs and regional transportation costs of optimum slaughter livestock movements for 1955 and 1960, (6) investigating the differences between the 1955 and 1960 optimum flows, (7) identifying and evaluating divergences between actual flows and optimum flows, and (8) examining what impact disturbances such as changes in transportation costs, geographical location of production, and geographical location of slaughtering have on optimum regional flows and the regional price pattern of each of the types of slaughter livestock. It is hoped that the information generated by these analyses will be useful in making decisions and policies concerning slaughter livestock.

## II. THE BASIC DATA

Given the particular problems being considered and the specification of the type of data needed, the basic data used in describing the spatial structure of the livestock sector in 1955 and 1960 are presented in this section.

[^0]
## A. Regional Demarcation

The delineation of regions considered in this study was conditioned by availability of data and the computational burden associated with larger numbers of regions. As a compromise between the need to portray reality and at the same time to limit the number of regions used, the United States was partitioned into 26 geographical contiguous regions (Table 1). Each region consists of one or more states since the basic data used are not available for smaller regions. Homogeneity in terms of production of livestock played an important role in suggesting the aggregation of states into regions. Major slaughter livestock-producing states each constitute a region whereas other regions are composed of two to six states.

A centrally located city was chosen as a market and supply point for each region. The regional demarcation and basing point cities are presented in Table 1.

## B. Transportation Rates

The market and supply sources as formulated in the model are assumed to be designated by a single point in each region. Since transportation costs are a major determinant in the spatial interpretation, it is necessary to obtain costs or estimates of the transfer costs between the points that represent each pair of regions.

While it might be desirable to use actual point-to-point rates, the data problem hindered this approach. ${ }^{1}$ In addition, the basing cities were chosen in some instances because of their proximity to the geographical center of the regions. Consequently, it is possible there has not been a sufficient number of livestock shipped between the alternative regions to establish representative rates. In view of these restrictions, a series of models were developed to estimate the point-to-point transport costs.

The model postulated to reflect truck rates for livestock between market and supply source points was:

$$
\begin{aligned}
& C_{\mathrm{ij}}=b_{0}+b_{1} D_{\mathrm{ij}}+ b_{2} \sqrt{D_{\mathrm{ij}}}+b_{3} W_{\mathrm{ij}}+b_{4} \\
& \frac{D_{\mathrm{ij}}}{T_{i j}}
\end{aligned}
$$

where $C_{\mathrm{ij}}$ represents the cost in dollars of shipping 100 pounds of live animals from point $i$ to point $j$ by truck, $D_{\mathrm{ij}}$ is the highway mileage between $i$ and $j, W_{\mathrm{ij}}$ is the total weight of the livestock per shipment from region $i$ to region $j, T_{i \mathrm{j}}$ is the time in hours required to haul livestock from point $i$ to point $j, D_{\mathrm{ij}} \div T_{\mathrm{ij}}$ is the average speed of the haul, and the bi's are estimated regression coefficients.

[^1]Table 1. Regional Demarcation and Demand and Supply Points

| Regions | s State(s) D | Demand and Supply Points |
| :---: | :---: | :---: |
| 1 | Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, Vermont | Boston, Mass. |
| $2$ | Delaware, District of Columbia, Maryland, New Jersey, New York, Pennsylvania | Philadelphia, Pa. |
| 3 | North Carolina, Virginia, West Virginia | Richmond, Va. |
| 4 | Florida | Orlando, Fla. |
| 5 | Georgia and South Carolina | a Atlanta, Ga. |
| 6 | Alabama and Mississippi | Columbus, Miss. |
| 7 | Kentucky and Tennessee | Nashville, Tenn. |
| 8 | Ohio | Columbus, Ohio |
| 9 | Indiana | Indianapolis, Ind. |
| 10 | Michigan | Detroit, Mich. |
| 11 | Illinois | Chicago |
| 12 | Wisconsin | Milwaukee |
| 13 | Arkansas and Louisina | Alexandria, La. |
| 14 | Missouri | Columbia, Mo. |
| 15 | Iowa | Des Moines |
| 16 | Minnesota | St. Paul |
| 17 | Texas and Oklahoma | Fort Worth, Texas |
| 18 | Kansas | Kansas City |
| 19 | Nebraska | Lincoln |
| 20 | North Dakota and South |  |
|  | Dakota | Bismarck, N. D. |
| 21 | Colorado | Denver |
| 22 | Montana and Wyoming | Billings, Mont. |
| 23 | Arizona and New Mexico | Phoenix, Ariz. |
| 24 | Idaho, Nevada, and Utah | Salt Lake City, Utah |
| 25 | California | Fresno |
| 26 | Oregon and Washington | Portland, Ore. |

The above model was postulated on the basis that truck rates are an increasing function of mileage; however, the relationship is not necessarily linear. As specified by the model, rates may increase as a function of distance at a decreasing or increasing rate as a result of the supply of transportation facilities available and demand for such facilities. The effective load density, load size, and size of truck were measured by the weight of livestock transported, while road conditions were accounted for by the average speed of the trip.

Since livestock are shipped by rail as well as by truck, an additional model was constructed to represent rail rates within and between the alternative freight territories.

$$
C_{\mathrm{ij}}=b_{0}+b_{1} M_{\mathrm{ij}}+b_{2} \sqrt{M_{\mathrm{ij}}}
$$

where $C_{i j}$ is the cost in dollars of shipping 100 pounds of live animals from point $i$ to point $j, M_{i j}$ is the rail mileage between $i$ and $j$, and the $b$ ''s are the estimated regression coefficients. Since livestock is generally not moved short distances by rail, the truck and rail transportation costs were combined to provide a realistic rate over all distances.

| 16 | 1,471,513 | 1,492,524 | 98,291 | 49,391 | 1,456,455 | 1,350,452 | 96,006 | 108,446 |
| 17 | 1,719,319 | 1,598,624 | 567,434 | 468,752 | 618,693 | 561,001 | 95,168 | 116,901 |
| 18 | 1,143,787 | 1,159,452 | 76,822 | 40,396 | 638,367 | 698,822 | 51,586 | 29,004 |
| 19 | 1,880,087 | 2,204,856 | 18,370 | 4,248 | 979,525 | 1,021,768 | 116,395 | 111,238 |
| 20 | 467,578 | 463,670 | 9,816 | 274 | 634,048 | 565,712 | 69,582 | 58,584 |
| 21 | 851,552 | 1,079,853 | 21,809 | 5,044 | 157,989 | 151,205 | 87,955 | 153,636 |
| 22 | 88,204 | 120,951 | 3,418 | 1,455 | 55,576 | 68,666 | 1,325 | 1,879 |
| 23 | 143,544 | 203,694 | 13,308 | 7,041 | 43,988 | 56,984 | 4,160 | 5,233 |
| 24 | 318,069 | 446,788 | 12,884 | 6,745 | 92,698 | 108,686 | 44,800 | 40,162 |
| 25 | 2,415,814 | 2,540,572 | 153,861 | 99,047 | 517,754 | 391,941 | 233,212 | 251,902 |
| 26 | 680,723 | 705,884 | 35,543 | 16,202 | 259,616 | 274,571 | 38,861 | 39,647 |
| U. S. Total | 24,200,821 | 25,330,994 | 2,688,626 | 1,825,494 | 17,603,394 | 18,658,000 | 1,555,746 | 1,567,492 |

The data for estimating the coefficients of the models were obtained from a survey of truckers and from the ICC 1 percent waybill sample data." Least square regression techniques were used in obtaining estimates of parameters for both the truck and rail models. Due to the institutional peculiarities that exist in the rate structure between the alternative freight territories, separate functions were estimated for each freight territory. Since comparable data on truck transportation costs were not available for 1955 , the 1960 truck rates were adjusted by the changes that occurred in rail rates for the different species between 1955 and 1960. The estimated 1955 and 1960 transport cost data are presented in appendix A, Tables 1-6. ${ }^{3}$

## C. Regional Livestock Slaughter

Regional slaughter data for cattle, calves, hogs, and sheep and lambs for 1955 and 1960 consist of commercial slaughter estimates published by the USDA and estimates of farm slaughter based on reported numbers of animals slaughtered on farms. The annual estimates of commercial slaughter in each region consist of the sum of the reported annual commercial slaughter of the states included in the region. In each of the 26 regions of the U.S. the slaughtering is assumed to occur at the centrally located cities designated as market and supply points
of the regions in the previous section on regional demarcation. Annual estimates of regional commercial slaughter of cattle, calves, hogs, and sheep and lambs are presented in Table 2.

The number of animals slaughtered on farms weighted by an average adjusted farm slaughter weight was used to estimate farm slaughter live weight by states. ${ }^{4}$ Individual state live weights were summed for states included in a region to obtain the regional quantity. The adjusted average farm slaughter live weight is the state average commercial slaughter live weight adjusted by the difference between the U.S. average commercial slaughter live weight and the U.S. average farm slaughter

[^2]live weight. An iterative procedure was used in adjusting the state farm slaughter live weight so that the product of reported numbers slaughtered on farms in each state and adjusted farm slaughter live weight when aggregated into regions and summed over the 26 regions is equal to the total live weight of farm slaughter reported for the U.S. The regional estimates of farm slaughter live weight for 1955 and 1960 are presented in Appendix B, Table 1.

For each of the 26 regions quarterly data of commercial slaughter live weight consist of the sum of the three monthly quantities included in each quarter. In each region within the year distribution of farm slaughter live weight is assumed to be the same as commercial slaughter live weight and the quarterly proportions of commercial slaughter live weight in each region were used to obtain the quarterly quantities of farm slaughter live weight. Quarterly estimates of regional commercial slaughter live weight for 1955 and 1960 are presented in Appendix B, Tables 2-9.
D. Regional Production of Livestock for Slaughter

## 1. Procedure for Estimating Production

Production in this study refers to the live weight quantity of livestock production for slaughter purposes. Two components of this production are farm production and commercial production for slaughter and on a national basis these two components are farm slaughter and commercial slaughter. However, production data for slaughter are not available for regions or states of the United States. If regional contributions to the total U.S. slaughter are to be identified, regional productions for farm and commercial slaughter need to be estimated.

## a. Farm slaughter

Estimates of annual live weight quantities of farm production for slaughter are the same as those of farm slaughter. Regional live weights of farm production were assumed to be geographically located in the regions in which the number of animals slaughtered on farms was reported. Regional estimates of farm production for 1955 and 1960 are presented in Appendix B, Table 1.

## b. Commercial production

Commercial production for slaughter is viewed as the live weight production which is commercially slaughtered during a given calendar year. For the U.S. as a whole, total commercial production for slaughter is synonymous with reported commercial slaughter live weight. Since data were not available for states or regions of the United States, estimates of cattle, calf, hog, and sheep and lamb commercial production were developed for each of the 26 regions of the United States.

The commercial production of a region was assumed to consist of three components: (1) live weight of inshipments and weight added to inshipments, (2) live weight of a decrease in inventory numbers, and (3) live weight resulting from production that has occurred entirely within the region during the current year. The latter is a portion of the reported production for the region. The quantities attributable to each of these three components were identified for each of the 26 regions. The sum of the quantities from each of the three components was considered the commercial production of the region and the sum of the commercial productions for the 26 regions was restricted to equal the live weight of commercial slaughter of the U.S. for that year. In allocating commercial production to regions, the quantities attributable to (1) and (2) above were known with the greatest certainty to exist in particular geographical locations and were allocated first. The geographical location of quantities accounted for by (3) was less certain and the quantities were allocated last as residuals.

## (1) Cattle and calves

In each region the contribution of an inventory decrease to production for slaughter consists of the number of head weighted by the average marketing weight of cattle. It was assumed that an inventory decrease within a region consisted of mature cattle which were commercially slaughtered during the year." The live weight quantity due to an inventory decrease was assumed to be geographically located in the region which reported the decrease in number. Increasing or stable inventory numbers were assumed to provide no quantity for commercial slaughter and therefore make no contribution to commercial production.

The regional quantities of commercial production arising from inshipments were calculated by taking 95 percent ${ }^{1 i}$ of the reported inshipments of the previous year times the current year regional average marketing weight. ${ }^{7}$ Both the live weight of inshipments and the weight added to inshipments were credited as the commercial production of the region that received the inshipments. Although the inshipment weight portion was produced in some other region, at the time these animals were avail-

[^3]able for slaughter both the inshipment weight and weight added were spatially located in the region which received the animals. All inshipments were assumed to remain to be finished in the region which initially received them and all of the marketing live weight of inshipments was considered to be a part of the commercial production of cattle for slaughter.

In order to avoid double counting the live weight of inshipments, the production of regions supplying feeder animals had to be adjusted by the outshipment live weight. In estimating outshipments, the 26 regions were classified on the basis of judgment and historical patterns into supplying and finishing areas. Regions receiving large numbers of inshipments and traditionally referred to as feeding areas were considered to be finishing areas and it was assumed that these regions had no outshipments. The Texas and Oklahoma, North and South Dakota, and New Mexico and Arizona regions were considered to be both supplying and finishing areas and were treated accordingly. These three regions, the Corn Belt, California, and Colorado were considered to be the feeding areas of the United States and the rest of the regions, except for the New England area, were considered to be the supplying regions.

In estimating the live weight of outshipments it was assumed that the total weight of inshipments into the finishing regions was equal to the total outshipment live weight of the supplying regions. In the supplying regions the base from which outshipments could come was considered to be (calves on hand January 1 plus births during the current year) less (deaths of calves plus calves slaughtered on farms plus calves slaughtered commercially). It was assumed that calves slaughtered commercially in a feeder animal supplying region were produced in that region. The base of each region was expressed as a proportion of the base of all of the supplying regions combined. The regional outshipments were obtained by allowing each region to account for a relative proportion of the total number of inshipments into the finishing area equal to its relative proportion of the base. The live weight of total outshipments of each region was obtained by weighting the numbers shipped out by the average inshipment weight of the finishing area. In each region outshipments were allocated between cattle outshipments and calf outshipments according to the proportion of marketing live weight of the region accounted for by each.

The procedure for estimating commercial production can be expressed symbolically as follows:

$$
\begin{gathered}
{\left[\left(R P_{1}-W A_{1}\right)\left(R_{1}\right)-\left(F S_{1}+O_{1}\right)\right] \bullet} \\
\left(C S R_{1}\right)+I D_{1}+I M_{1}=C S P_{1}
\end{gathered}
$$

where:
$R P_{1}=$ reported live weight of cattle and calf production (USDA)
$W A_{1}=$ weight added to inshipments
$R_{1}=$ proportion that the live weight of cattle marketings is of the total live weight of cattle and calf marketings in each region.
$F S_{1}=$ estimate of the live weight of cattle farm slaughter
$0_{1}=$ estimate of the live weight of cattle outshipments from the supplying regions
$\operatorname{CSR} R_{1}=$ ratio of the portion of total U . S. commercial slaughter production of cattle after weight added to inshipments, farm slaughter weight, and outshipment weight were accounted for to reported total U.S. commercial cattle slaughter not accounted for by inventory decrease and inshipment marketings.
$I D_{1}=$ live weight production accounted for by a decrease in inventory
$I M_{1}=$ live weight production accounted for by inshipment marketings
CSP $P_{1}=$ live weight commercial slaughter production of cattle
After the proportion of live weight of commercial ${ }^{1}$ production accounted for by inventory change and inshipment marketings are identified spatially, the remaining proportion is obtained from reported production after adjusting for farm slaughter, outshipments of feeder animals, and weight added to feeder animals received in the region.

A similar procedure was used for estimating the regional commercial production of calves for slaughter. However, live weight production due to inventory decrease and inshipments of the previous year marketed during the current year were assumed not to make any contribution to calf production. Symbolically, the expression for commercial production of calves is as follows:

$$
\begin{gathered}
{\left[\left(R P_{1}-W A_{1}\right)\left(1-R_{1}\right)-(F S 2+0 \because)\right] \cdot} \\
C S R_{2}=C S P_{2}
\end{gathered}
$$

where:
$R P_{1}$ and $W A_{1}$ are the same as defined previously $\left(1-R_{1}\right)=$ proportion that the live weight of calf marketings is of the total live weight of cattle and calf marketings in each region
$F S_{2}=$ estimate of the live weight of calf farm slaughter
$0_{2}=$ estimate of the live weight of calf outshipments from the supplying regions

CSR: $=$ ratio of the portion of total U.S. commercial slaughter production of calves after weight and outshipment weight were accounted for to the total U.S. reported commercial calf slaughter
CSP $2=$ live weight commercial slaughter production of calves
In developing the production estimates for cattle and calves, the calves were viewed as a residual production.

## (2) Hogs

The procedure used in estimating commercial production of hogs is similar to that used for cattle and calves. The relationship which expresses regional commercial hog production is as follows:

$$
\begin{gathered}
\left(R P_{3}-W A_{3}-F S_{3}-O_{3}\right) \bullet \\
C S R_{3}+I D_{3}+I M_{3}=C S P_{3}
\end{gathered}
$$

where:
$R P_{3}=$ reported live weight production of hogs (USDA)
$W A:=$ weight added to inshipments
$F S_{3}=$ estimate of the live weight of hog farm slaughter
$0: 3=$ estimates of the live weight of hog outshipments from the supplying regions
$C S R_{3}=$ ratio of the portion of total U.S. commercial slaughter production of hogs after weight added to inshipments, farm slaughter weight, and outshipment weight were accounted for to the total reported U.S. commercial hog slaughter not accounted for by inventory decrease and inshipment marketings
$I D_{3}=$ live weight production accounted for by a decrease in inventory
$I M_{3}=$ live weight production accounted for by inshipment marketings
$C S P_{3}=$ live weight commercial slaughter production of hogs
For each region the contribution to live weight commercial production of inventory decrease and inshipments was obtained by weighting the number of head involved by the regional average marketing weight per head. Ninety-five percent of the current year inshipments was assumed to enter commercial slaughter channels and was used to estimate the liveweight attributable to inshipments.

In estimating the live weight of outshipments again the regions were categorized into finishing regions and feeder pig supplying regions ${ }^{8}$ on the basis

[^4]of judgment and number of inshipments received. For each region the proportion of the number of net births minus numbers slaughtered on farms relative to the total number of net births minus numbers slaughtered on farms for the entire feeder pig supplying area (eight regions combined) was computed. The outshipments of each region were obtained by allowing each region to account for a relative proportion of total numbers received in the finishing area equal to the region proportion relative to the total supplying area of the number of net births less number slaughtered on farms. The number of outshipments for regions 7 and 12 were modified slightly to conform with unpublished information about the feeder pig outshipments of these two regions. Outshipment numbers were weighted by the average inshipment weight of the finishing area to obtain the live weight of outshipments.

## (3) Sheep and lambs

Sheep and lambs were combined to estimate the sheep and lamb commercial production for slaughter. The regional sheep and lamb commercial production may be expressed as follows:

$$
\begin{gathered}
{\left[R P_{4}-\left(W A_{4}+W A_{5}+F S_{4}-F S_{\overline{3}}+O_{4}+O_{\overline{5}}\right)\right]:} \\
C S R_{4}+I D_{4}+I M_{4}=C S P_{4}
\end{gathered}
$$

where:
$R P_{ \pm}=$reported live weight production of sheep and lambs (USDA)
$W A_{+}=$weight added to inshipment of sheep
$W A_{5}=$ weight added to inshipments of lambs
$F S_{4}=$ estimate of the live weight of sheep slaughtered on farms
$F S_{\bar{i}}=$ estimate of the live weight of lambs slaughtered on farms
$0_{4}=$ estimate of the live weight of sheep outshipments from the supplying regions
$0:=$ estimate of the live weight of lamb outshipments from the supplying regions
$\operatorname{CSR}_{4}=$ ratio of the portion of total U.S. commercial slaughter production of sheep and lambs after weight added to inshipments, farm slaughter weight and outshipment weight were accounted for to the total reportted U.S. commercial sheep and lamb slaughtter not accounted for by inventory decrease and inshipment marketings
$I D_{4}=$ live weight production accounted for by a decrease in the inventory number of sheep
$I M^{+}=$live weight production accounted for by sheep and lamb inshipment marketings
CSP $P_{4}=$ live weight commercial slaughter production of sheep and lambs

Table 3. Estimated Commercial Slaughter Production of Cattle, Calves, Hogs, and Sheep and Lambs, 26 Regions of the United State, 1955 and 1960.

| Total | 24,200,821 | 25,330,994 | 2,688,626 | 1,825,494 | 17,603,394 | 18,658,000 | 1,555,746 | 1,567,492 |

For each region the contributions to live weight commercial production of an inventory decrease and inshipments were obtained by weighting the number of head involved by the regional average marketing weight per head. In estimating the live weight accounted for by inshipments, 95 percent of the sheep and lamb inshipments of the previous year was assumed to enter commercial slaughter channels in the current year.

In estimating regional outshipments of sheep and lambs, 13 regions were considered finishing regions, seven regions were considered supplying regions of feeder sheep and lambs, and six regions were not considered in estimating outshipments. ${ }^{9}$ The number of inshipments of sheep and lambs of the finishing area times the regional average inshipment weights of sheep and lambs respectively was assumed to be the total live weight which had to be accounted for by the supplying area. The live weight of inshipments of sheep and lambs was considered separately. In each of the supplying regions

[^5]a base from which outshipments could come was estimated for sheep and lambs separately. Ewes on hand January 1 formed the base for the outshipments of sheep and a relative proportion that each supplying region had of the total supplying area was computed. Each supplying region was assumed to account for the proportion of total number of sheep inshipments received in the finishing area equal to its relative proportion of the number of ewes on hand January 1. The live weight of sheep outshipments for each region is the number of head of sheep times the average inshipment weight of sheep in the finishing area.

In each supplying region the base for lambs was obtained by subtracting from the regional net births the number of lambs slaughtered on farms and the regional commercial lamb slaughter. Each supplying region's base was expressed as a proportion of the lamb base for the total supplying area and each supplying region was assumed to account for the proportion of the number of lamb inshipments received in the finishing area equal to its relative proportion of the lamb base. The live weight of lamb outshipments for each supplying region was obtained as the product of the number of head shipped out and the average inshipment weight of lambs in the finishing area.

## 2. Estimates of Production for Slaughter

The 1955 and 1960 commercial production estimates of cattle, calves, hogs, and sheep and lambs for each of the 26 regions are presented in Table 3. Regional commercial production is the live weight which during the year is slaughtered in the region where it is located or in some other region to which part of it may have been shipped. Also, the part of the regional commercial production accounted for by feeder animals was in reality produced in some feeder animal supplying area but the live weight was credited to the region in which the animals were located immediately prior to shipment for slaughter.

Quarterly estimates of 1955 and 1960 farm and commercial production of cattle, calves, hogs, and sheep and lambs for each of the 26 regions are presented in Appendix C, Table 1-16. The quarterly production of each region was estimated by allocating the annual regional production among quarters of the year on the basis of the quarterly proportional distribution of total regional commercial slaughter.

## III. THE EMPIRICAL RESULTS

A linear-programming transportation model is used to determine the minimum cost flows of slaughter livestock from location of production to location of slaughtering. The regional live weight quantities of slaughter production, regional live weight quantities of slaughter, and the transportation costs of moving one unit of slaughter livestock from each region to every other region are taken as given. The regional live weight quantities of production and transportation costs are estimated by procedures discussed in previous sections. Regional quantities of slaughter are reported amounts that were actually slaughtered in each of the regions. Instead of using regional surplus and deficit quantities in the programming framework, total regional commercial production and total regional live weight slaughtered commercially are used. The details of the formal model used in this study are presented in the first of this series of bulletins entitled "Spatial Analyses of the Flows of Meat in 1955 and 1960."

The analyses presented in this report include the optimum price differentials and the minimum cost shipment patterns as derived by the formal model for the four species of slaughter livestock. The 1955 analysis discussed in the text refers to the optimum flows when only truck transportation rates are considered. The 1960 analysis utilizes a combination truck-rail rate as well as the truck transportation rates. Quarterly analyses for 1960 utilize only the combination truck-rail rates.

The flow solutions are optimum only in that they minimize the costs of shipping livestock, given the regional supplies and demands of slaughter live-stock-where demand for slaughter livestock in any given region is the amount that was actually slaughtered during the year. No consideration was given to the regional slaughter capacities or the final meat consuming areas.

## A. Annual Spatial Analyses <br> 1. Slaughter Cattle

The results of the spatial analyses for 1955 and 1960 are presented in Tables 4 and 5, respectively. The numbers at the left side of these tables and in the tables for other species refer to the surplus or deficit of slaughter livestock in each region. The underlined numbers appearing in the body of the tables represent the live weight amounts of slaughter cattle shipped interregionally to satisfy regional demands and to minimize total transportation costs. The resulting $U_{i}$ and $V_{j}$ of the final solution refer to the live animal price differentials relative to the base region (region 1). For example, under 1955 equilibrium conditions (Table 4), the estimated cost of live animals is $\$ 1.64$ per hundred pounds less in Missouri (region 14) than in the New England area (region 1). The numbers not underlined in the body of Table 4 are the result of the difference between direct and indirect costs of shipping from one region to another. They are calculated by subtracting ( $\mathrm{U}_{\mathrm{i}}$ $\mathrm{V}_{\mathrm{j}}$ ) from $\mathrm{C}_{\mathrm{ij}}$, the cost of shipping 100 pounds of live weight from region $i$ to region $j$. For example, the element .42 which appears in the cell common to deficit region 1 and surplus region 19 indicates that if region 19 shipped to region 1 the shipment cost between regions 1 and 19 would be increased by 42 cents per hundred pounds.

The estimates of total quantities of slaughter cattle shipped and the total transportation costs appear directly below the table. These estimates have meaning only for the regional demarcation used in these analyses. However, since all subsequent analyses in this publication as well as other publications in this series use the same regional breakdown, comparisons of estimates of total costs and shipments may be made.

Optimum flows of live weights of slaughter cattle for 1955 and 1960 are presented graphically in Figures 1 and 2. The unshaded regions in Figures 1 and 2 and in figures for other species of slaughter livestock denote deficit regions. Conversely, shaded areas denote regions with surplus livestock production for slaughter. Lines originating from the shaded regions represent the optimum movement of slaughter cattle and the numbers appearing in the breaks indicate the quantities shipped between the regions.

As indicated in Table 4, an estimated total of

Table 4. Regional Price Differences, Surpluses and Deficits, and Optimum Flows of Cattle for Slaughter, 26 Regions of the U. S., 1955.*

*Based on 1960 combination truck-rail transportation rates. Regions and basing points are identified in Table 1.
Total shipments $4,552,600,000$ pounds.
Total cost $\$ 57,065,896$.
4.5 billion pounds live weight of slaughter cattle would have been shipped at a total cost of 58.0 million dollars in 1955. The shipments of slaughter cattle from surplus to deficit regions would have accounted for approximately 18.6 percent of the total supply of slaughter cattle. In 1960 approximately 4.6 billion pounds of slaughter cattle, or 18.0 percent of the total supply of slaughter cattle, would have been shipped at a cost of 58.5 million dollars. ${ }^{10}$

It is interesting to note that in 1955 the average cost of shipping slaughter cattle was $\$ 1.29$ per hundred, while in 1960 the average cost was $\$ 1.28$ per hundred even though transportation rates had increased approximately 13 percent. This suggests that the average length of haul in 1960 was less than that of 1955.

The main deficit regions in both 1955 and 1960 were regions 2 and 25, of which region 2 (New York, Pennsylvania, etc.) received slightly more than onefourth of the total shipments. In both years the large surplus areas of slaughter cattle were Iowa and Kansas.

The primary differences between the optimum flows estimated for 1955 and 1960 occurred because some areas changed from surplus to deficit and vice versa. For example, in 1955 regions 6, 13, and 24 were all surplus areas of slaughter cattle production, while in 1960 these areas became deficit. Conversely, regions 11 and 16, Illinois and Minnesota, respectively, were deficit regions in 1955 but surplus regions in 1960. One reason for the change in Illi-

[^7]nois is the large exit of slaughtering facilities from this region during this period. Consequently, there was a decrease in the demand for slaughter cattle from 2.0 billion pounds in 1955 to approximately 1.5 billion pounds in 1960. Although the demand for slaughter livestock remained relatively stable in Minnesota (region 16), there was a substantial increase in production of slaughter cattle so that this region became a surplus area in 1960 . The changing structure of the meat packing industry is further exemplified by the optimum flow patterns derived for 1955 and 1960 with reference to Nebraska, region 19. In 1955, Nebraska would have shipped out approximately 500 million pounds of slaughter cattle; however, in 1960 Nebraska exported only 9.4 million pounds. While there was a slight decrease in production from 1955 to 1960 in Nebraska the demand for slaughter cattle was increased over 300 million pounds as a result of packing facilities moving to the areas of production. This is illustrated further by the increase in demand of 550 million pounds in Iowa.

The spatial analyses for 1955 and 1960 illustrate the potential ability of the Plains States and Colorado to ship either east or west, depending on demand and supply conditions. In 1955 regions 17 and 21 would have moved their cattle east while region 20 would have moved cattle in both directions. However, in 1960 regions 20 and 21 would optimally have shipped only west, while cattle from region 17 would have moved in both directions.

The optimum shipment pattern estimated for slaughter cattle in 1960 based on the combination truck-rail transportation rates is presented in Table 6 and the optimum flows are presented graphically in Figure 3. Since the combination rate was lower on longer distances, the estimated total transportation

cost would have been reduced from approximately 58.5 million dollars to 57.1 million dollars and the average cost would be $\$ 1.25$ per hundred. In addition, longer hauls would have resulted particularly from regions bordering and regions west of the Mississippi River.

In terms of the directional flows, only slight differences would have occurred between the two alternative optimums. Under the combination rate, Nebraska would have shipped west, and North and South Dakota would have shipped both east and west. However, when truck rates were utilized, Nebraska's slaughter cattle would have moved east and slaughter cattle from North and South Dakotawould have gone west.

Some cross- and back-hauling can be expected to exist in reality. This is partly due to the location of market and slaughtering facilities in adjoining states. A second factor not accounted for in the optimum models that might result in some cross- and backhauling is the demand and supply for a specific grade and quality of animal in a specific region. However, even if account had been taken of these factors, it appears as if a considerable amount of inefficiency exists in the movement of slaughter cattle.

## 2. Slaughter Calves

The results of the spatial analyses for slaughter calves for 1955 and 1960 are presented in Tables 7
and 8 and Figures 4 and 5. In 1955, an estimated total of 584.3 million pounds of slaughter calves, or 21.7 percent of the total commercial production would have been shipped interregionally, at a cost of approximately 7.8 million dollars. In 1960, 523.7 million pounds, or 28.7 percent of the total calf production for slaughter would have moved at a cost of 6.3 million dollars.

As shown in Figure 4 and 5, there was a considerable divergence between the optimum flow patterns derived for 1955 and 1960. To a large degree this is due to the large decrease of over 860 million pounds from 1955 to 1960 in the U.S. aggregate supply and regions changing from surplus to deficit areas and vice versa. In the 1955 solution, all regions west of the Mississippi River except Kansas (region 18 ) and Texas and Oklahoma (region 17) were surplus producers of slaughter calves. The major deficit areas were regions 2,10 , and 11 which received 67 percent of the total shipments. As a result, most of the surplus slaughter calves of the Mountain States would have moved east into the Corn Belt and the Northeastern States. Surpluses of the Southeastern States would have moved into the eastern Corn Belt as well as the northeastern areas (regions 1 and 2). With the large decrease in aggregate supply in 1960, Texas and Oklahoma (region 17), became a large deficit area, approximately 226 million pounds. Con-

Total cost $\$ 5,699,141$.
sequently, in 1960 the surplus of slaughter calves of the Mountain States would have moved into region 17. In addition, Florida and Georgia and Alabama became deficit regions and the only shipments out of the southeast, as determined by the optimum flows, were from region 3 to region 2.

With the changes in the location of the major deficit areas and changes in the relative magnitudes of the deficits, the average cost of moving slaughter calves decreased from $\$ 1.33$ per hundred pounds in 1955 to $\$ 1.21$ per hundred pounds in 1960 even
though transportation rates had increased approximately 13 percent during this period. In addition, there were considerable changes in equilibrium price differentials.

Only slight modifications occurred in the optimum flow patterns when the alternative rate (truckrail) for 1960 was used (Table 9 and Figure 6). Due to the lower truck-rail transportation rates on the longer distances, the total transportation cost would have been reduced by $\$ 624,380$. In addition, there were slight differences in the magnitude and sign of

18
the price differentials. For example, when the truck rate was used, the equilibrium prices of the western regions ( 21 to 26) would have ranged from .02 cents to $\$ 1.72$ less than region 1 . However, when the combination rate was used, the equilibrium prices for these regions ranged from .52 cents to $\$ 1.80$ less than that of region 1. Some of the major differences in the optimum flow patterns based on truck rates indicate shipment from region 26 to region 2, whereas, the optimum flows based on truck-rail rates indicate that a major proportion of the Oregon-Washington surplus would have been shipped to region 17 and the remainder to California. Based on truck rates alone, Nebraska would have shipped all of its surplus slaughter calves to region 17 . However, the optimum flow patterns based on truck-rail rates show Nebraska shipping to Kansas and Iowa in addition to the Texas and Oklahoma region. Conversely, Missouri would have shipped both east and west in the analysis based on truck rates, while in the alternative analysis, the optimum flows were northeast to other Corn Belt States and to regions in the southeast.

## 3. Slaughter Hogs

The spatial analyses for slaughter hogs for 1955 and 1960 are presented in Tables 10 and 11 and Figures 7 and 8.

In 1955, an estimated 3.4 billion pounds, or 19.4 percent of commercial slaughter hog production would have been. shipped interregionally at a cost of approximately 40.3 million dollars. In 1960, 3.5 billion pounds of slaughter hogs, approximately 18.6 percent, were estimated to have been shipped interregionally at a cost of 39.4 million dollars. In 1955, the average cost of shipping slaughter hogs optimally was $\$ 1.18$ per hundred. In 1960 the average cost decreased to approximately $\$ 1.14$ per hundred, even though rates were about 7 percent higher in 1960 than in 1955.

In 1955 only seven regions were surplus producers of slaughter hogs while in 1960 eight were surplus. Of these regions, Iowa, Illinois, and Indiana accounted for 83 percent of the surplus in 1955 and 86 percent in 1960. One of the important aspects of the surplus of slaughter hogs is the change that occurred between Illinois and Iowa. In 1955 Iowa had a surplus of 1.5 billion pounds while the surplus in Illinois was 710 million pounds. However, in 1960, Iowa's surplus decreased to 929 million pounds while the surplus in Illinois increased to 1.4 million pounds. This change is in part a result of two factors. The production of slaughter hogs in Illinois increased approximately 400 million pounds between 1955 and 1960. Also, as was the situation with cattle slaughtering, hog slaughter decreased by 340 million pounds in Illinois and increased over 500 million pounds in Iowa.

The optimum directional flows for 1955 and 1960 in Figures 7 and 8 are quite similar. This is primarily the result of the stability in the surplus and deficit regions between the two years. One of the major changes indicated by the optimum flows was that in 1955 region 15 (Iowa) showed shipments both east and west, whereas in 1960 there were no shipments eastward. This change in the shipping patterns of Iowa was a consequence of the smaller surplus in this region and the increased surplus of Illinois. These changes in the relative surpluses of these two regions ( 15 and 11) also had an effect on the shipment pattern of Missouri. In 1955 Missouri would have shipped mostly to the Southeastern States (regions 3, 5 and 7) and to Texas and Oklahoma. However, in 1960 Missouri would have shipped to the West Coast, Texas and Oklahoma and only to the Kentucky-Tennessee region of the Southeastern States.

Although the surplus of slaughter hogs in Indiana decreased slightly from 1955 to 1960, the number of regions receiving the surplus production of Indiana under an optimum flow pattern increased. In 1955 Indiana would have shipped only to region 2, but in 1960 the spatial analysis indicated flows to region 3,7 , and 8 in addition to region 2.

The least-cost flows for slaughter hogs for 1960 based on the combination truck-rail transportation rates are presented in Table 12 and Figure 9. A considerable divergence exists between the optimum flows based on the combination rate as compared to those based on truck rates only. With the combination rate, both Illinois and Iowa would ship both east and west, while with truck rates Illinois would ship east and Iowa would ship west. Consequently, when the combination rates are considered instead of truck rates, the deficit regions in the East would receive slaughter hogs from regions located further west while western deficit regions would receive slaughter hogs from regions located farther east. This change is due to lower transportation cost for longer length of shipments when rail transport rates are used.

The estimated minimum cost for the truck-rail combination in terms of total cost was 39.5 million dollars which is slightly higher than that incurred when truck rates were used. The average cost increased only $\$ 0.004$ per hundred, from $\$ 1.136$ to $\$ 1.14$ per hundred.

As was the situation with slaughter cattle, considerable cross-hauling occurred in the actual movements of slaughter hogs in 1960 when compared to the optimum flows in this analysis. For Minnesota and Iowa, the available data, though incomplete, indicated that approximately 1.7 million pounds of slaughter hogs were moved in excess of the movement estimated by the optimum solution. In these

Total cost $\$ 39,538,094$.
two states alone, the excess movement of slaughter hogs was approximately 50 percent of the total interregional movement in the optimum solution.

## 4. Slaughter Sheep and Lambs

For both 1955 and 1960 approximately 29 percent of the sheep and lambs slaughtered was estimated to
have been shipped interregionally (Tables 13 and 14). As determined by the optimum solution for 1955, a total of 450 million pounds of live slaughter sheep and lambswere shipped at a cost of 7.8 million dollars. Average shipment costs were approximately $\$ 1.73$ per hundred pounds. In 1960, 436 million

[^11]
pounds), 1960.
pounds of slaughter sheep and lambs were shipped to the nine deficit regions at a total cost of 7.6 million dollars. The average cost per hundred pounds in 1960 was $\$ 1.74$.

The main deficit regions in both years were region 2 (New York-Pennsylvania, etc.), Michigan, and California, while the major surplus slaughter sheep and lamb regions were the Mountain States. Between the years of analysis, Illinois shifted from a deficit to a surplus region, while Wisconsin and Colorado shifted from surplus to deficit regions. During this period, Illinois decreased its slaughter of sheep and lambs byapproximately 35 million pounds while Colorado increased its slaughter by 66 million pounds.

As shown in Figures 10 and 11, the 1955 optimum flows from the Montana-Wyoming regionwere all eastward (Michigan, New England, and New York-Pennsylvania, etc). The Nevada, Utah, Idaho region shipped to the California region and eastward to Nebraska. Region 23 (Arizona and New Mexico) shipped both to California and to region 2. However, in 1960 the optimum flows indicate that regions 23 and 24 would ship only to California. Although the Montana-Wyoming region continued to ship a large proportion of their surplus to regions 1 and 2, they also shipped surplus slaughter sheep and lambs into California and Colorado.

The optimum shipment pattern in 1960 for slaughter sheep and lambs when the combination truck-rail rates were used is presented in Table 15 and Figure 12. The optimum flows for the two major producing areas (region 22 and 24) were similar for the two alternative rates. In the optimum flow based on truck rates, the North and South Dakota region shipped only to the Lake States and Nebraska. However, with the combination truck-rail rate, this region shipped slaughter sheep and lambs into regions 1 and 2. Based on the combination rate, Michigan, which was the largest deficit state of the Lake States, obtained its slaughter sheep and lambs from the Illinois, Indiana and Ohio regions.

The estimated total cost associated with the optimum flows based on the truck-rail combination was 6.0 million dollars as compared to 7.6 million dollars when truck rates were used. Average cost per hundred pounds decreased from $\$ 1.74$ to $\$ 1.38$.

## B. Quarterly Spatial Analyses ${ }^{11}$

In an effort to assess the degree of distortion present in the annual models due to the aggregation over time, spatial equilibrium analyses were performed for each of the species for each of the four quarters

[^12]of 1955 and 1960. The 1955 quarterly analyses used truck transportation rates, while the 1960 analyses were based on the combination truck-rail rates. To facilitate the presentation, only the 1960 analyses will be discussed except when major differences occurred between the annual and quarterly results for 1955.

## 1. Slaughter Cattle

In the quarterly models for 1960, all regions retained the same classification with regard to being a surplus or deficit region as in the annual model. Because of the magnitudes involved, slight differences in the shipping patterns occurred between the annual and quarterly models (Tables 6 and 16). In the quarterly models region 20 (North and South Dakota) would have shipped to region 2 (New York, Pennsylvania, etc.). Region 18 (Kansas) would have shipped to region 6 (Mississippi and Alabama), and region 15 (Iowa) would have shipped to region 8 (Ohio). Under no conditions could the annual analysis have yielded the shipment pattern presented in Table 16. This is due to the restriction that only $n$ $+m-1$ or in this case 25 activities may enter in a minimum shipment pattern. In addition to the inclusion of the three additional shipment patterns (those in parenthesis) that would have occurred in the quarterly models, small differences occurred in the proportions shipped to deficit regions when there were two or more supplying regions.

One of the major findings provided by the quarterly analysis is that the quantities shipped to a deficit region from any given surplus producing area may vary considerably from quarter to quarter, even though the deficits of the deficit region and the surpluses of the supplying regions remain relatively stable. For example, the deficit in region 5 varied from a low of 53.6 million pounds in the first quarter to 63.3 million pounds in the third quarter. The optimum solution indicated that regions 14 and 18 would have supplied this deficit. However, the quantity supplied by region 14 varied from zero shipments in the third quarter to 19.0 million pounds in the first quarter, while the shipments from region 18 varied from 34.5 million pounds in the first quarter to 63.3 million pounds in the third quarter. Although variation existed in the quantity shipped between quarters, the estimated regional price differential remained the same for each quarter, as well as between the annual and quarterly models.

Total cost for all four quarterly programs was 57.1 million dollars and summing the total shipments for the four quarters yielded an estimate of 4,552 million pounds (Table 17). Both of these estimates were the same as those obtained for the annual analysis (Table 6). In general, there is a consistency between the quarterly and annual estimates in regard

*Based on 1960 combination truck-rail transportation rates. Regions and basing points are identified in Table 1.

to the magnitudes of total shipments and cost. While quarterly models provide some additional information about the variability of shipments from any given region during the four quarters and include additional shipping routes, the alternative analysis suggests that for live cattle, minimum-cost flows based on the aggregative annual model differ only slightly from those based on the quarterly models.

Except for the inclusion of three additional shipping routes, the results of the 1955 quarterly analyses were approximately the same as those of the annual
solution, with respect to quantities shipped and total cost of shipments (Table 4).

## 2. Slaughter Calves

A summation of the four quarterly shipments for 1960 is presented in Table 18. Except for region 1, which was a deficit region in the second quarter, the classification of regions remained the same in the first, third and fourth quarters as in the annual model. However, because of the magnitudes involved, slight differences occurred in the shipping patterns between the annual and quarterly models. The major

| 9 |  |  |  |  |  | 2,098 |  |  |  |  |  |  |  |  |
| 10 |  |  |  |  | 6,253 | 23,785 | $(3,472)$ |  |  |  |  |  |  |  |
| 11 |  |  |  |  |  | 46,084 |  |  |  |  |  |  |  |  |
| 12 |  |  |  |  |  |  | 23,116 |  | 7,005 |  |  |  |  |  |
| 13 |  |  | 13,060 |  |  |  |  |  | (846) |  |  |  |  |  |
| 15 |  |  |  |  |  |  |  | 26,925 |  |  |  |  |  |  |
| 17 |  |  | (993) |  |  |  |  | 20,052 | 16,599 | 43,748 | 76,413 | 18,783 | 26,796 | 22,360 |
| 18 |  |  |  |  |  | $(7,028)$ |  | 11,620 |  |  |  |  |  |  |
| 25 |  |  |  |  |  |  |  |  |  |  |  |  |  | 4,365 |

[^13]difference was that six more additional flows were included in the quarterly models than were in the annual model: region 20 (North and South Dakota) shipped to regions 1, 4 and 13 (New England, Florida, Arkansas and Louisiana); region 6 (Mississippi and Alabama) shipped to region 17 (Texas and Oklahoma) ; region 14 (Missouri) shipped to region 18 (Kansas); and region 16 (Minnesota) shipped to region 10 (Michigan). Due to the restriction on the number of activities that can enter in the programming analysis, the shipping patterns as shown in Table 18 would not have been possible in the annual model. As a result of the additional flows and the varying magnitudes of the surpluses and deficits between quarters, there were slight variations in the quantities shipped to the alternative deficit regions.

The price differentials between the alternative regions were the same for the first, third, and fourth quarters as for the annual model. However, in the second quarter with the base region (region 1) changing from a surplus to a deficit area, the alternative price differentials all became negative with respect to the base region. In general, most of the price differentials decreased by approximately $80-85$ cents in comparison with the base region.

As shown in Table 19, the average cost of $\$ 1.09$ per hundred pounds was the same as that of the annual model. However, the average cost per hundred pounds did vary from a low of $\$ 1.06$ in the first quarter to a high of $\$ 1.12$ in the second quarter.

In the 1955 quarterly analyses, the classifications of surplus and deficit regions remained the same as

Table 19. Quantity and Cost of Optimum Shipments of Calves for Slaughter, Quarterly and Annual, for Truck-Rail Transport Costs, 26 Regions of the U. S., 1960.

| Time <br> Period | Quantity Shipped <br> (1,000 lbs.) <br> (Percent) | Total <br> Cost <br> (Dollars) | Average <br> Cost per <br> 100 Pounds <br> (Dollars) |  |
| :--- | :---: | :---: | :---: | :---: |
| Jan. - March | 108,867 | 21 | $1,1533,564$ | 1.06 |
| Apr. - June | 130,372 | 25 | $1,461,574$ | 1.12 |
| July - Sept. | 143,109 | 27 | $1,568,833$ | 1.10 |

| Quarterly Total | 522,657 |  | $5,697,945$ | 1.09 |
| Annual | 523,720 |  | $5,699,141$ | 1.09 |

in the annual model. Except for the inclusion of nine additional flows which produced changes in the magnitudes of shipments, the results of the quarterly analyses were quite similar to those of the annual model.

## 3. Slaughter Hogs

The summation of the four quarterly shipments of live hogs in 1960 is presented in Table 20. Even though hog slaughter and production varied considerably from quarter to quarter, all regions retained the same surplus or deficit classification in the quarterly models as in the annual model. As shown in Tables 12 and 20, no additional flows were included in the quarterly models, nor were there any changes in the patterns derived by the annual model or changes in the quantities shipped between the alternative surplus and deficit regions. In addition, the regional price differentials were approximately the same for all five models.

Total cost for all four quarterly models was 39.5

Table 20. Summation of Optimum Quarterly Shipments of Slaughter Hogs, 26 Regions of the U. S., 1960.*

| 24 |  |  |  |  |  |  |  | 5,142 |
| 25 |  |  |  | 29,113 |  |  |  |  |
| 26 |  |  |  | 18,405 |  |  |  |  |

[^14]million dollars and summing the total shipments for the four quarters yielded a total of 3,468 million pounds. Both of these estimates were approximately the same as those of the annual estimates. Although the average costs per hundred pounds varied from $\$ 1.12$ in the second quarter to $\$ 1.15$ in the third and fourth quarters, the average for the four quarters was the same as for the annual model (Table 21). Since the results between the quarterly and annual models were the same, this suggests that the annual model for the hog sector for 1960 affords a satisfactory approximation to quarterly time periods within the year.

| Jan. - March | 953,600 | 27 | $10,852,178$ | 1.14 |
| Apr. - June | 854,900 | 25 | $9,591,199$ | 1.12 |
| July - Sept. | 780,400 | 23 | $8,954,277$ | 1.15 |
| Oct. - Dec. | 879,200 | 25 | $10,141,875$ | 1.15 |
| Quarterly Total | $3,468,100$ |  | $39,539,529$ | 1.14 |
| Annual | $3,468,100$ |  | $39,538,094$ | 1.14 |

Except for one additional flow, region 9 shipping to region 8 in the third quarter, the 1955 quarterly analyses did not reveal any information in addition to that provided by the annual model.

## 4. Slaughter Sheep and Lambs

The optimum quarterly shipment pattern is presented in Table 22 and is given to facilitate comparisons with the annual shipment pattern for sheep and lambs (Table 15). Except for regions 17 (Texas and Oklahoma), 21 (Colorado), and 26 (Oregon and Washington) the classification of the regions with respect to surplus and deficit remained the same in all four quarters as in the annual model. Regions 17 and 26 were surplus for the year but deficit in the third and fourth quarters while region 21 was deficit for the year but surplus in both the first and second quarters. These changes in classification between the quarters of the year represent an obscurity that would not have been detected in the annual model. As shown in Table 22, 13 more additional shipping activities (those in parenthesis) were included in the quarterly models than were in the annual model. Because one of the requisites for a minimum solution for a given problem is that only $n+m-1$ shipments occur, the annual analysis could not have yielded the set of flows that appear in Table 22.

The changes in classification from surplus to deficit area between quarters in regions 17,21 , and 26 had considerable effect on the price differentials of these regions as well as those in adjoining regions
Table 22. Summation of Optimum Quarterly Shipments of Slaughter Sheep and Lambs, 26 Regions of the U. S., 1960.*
(regions 23, 24, and 25). For example, regions 17 and 26 which were surplus areas for the year were deficit in the third and fourth quarters. The equilibrium prices in these regions were estimated to be $\$ 2.22$ and $\$ 1.69$ less than that of the base region in the annual model as well as the first and second quarters. However, when these regions became deficit areas in the third and fourth quarters, the equilibrium price in region 17 was only 93 cents less than the base region in the third quarter and 79 cents less in the fourth quarter. For region 26 , the equilibrium price changed to 85 and 67 cents less than the base region in the third and fourth quarters respectively.

Total cost for all four quarterly models was 6.08 million dollars and summing the total shipments for the four quarters yielded an estimate of $439 \mathrm{mil}-$ lion pounds (Table 23). Both of these estimates were slightly higher than those estimated by the annual

Table 23. Quantity and Cost of Optimum Shipments of Sheep and Lambs for Slaughter, Quarterly and Annual, for Truck-Rail Transport Costs, 26 Regions of the U. S., 1960.

| Time <br> Period | Quantity Shipped <br> (1,000 lbs.) <br> (Percent) | Total <br> Cost <br> (Dollars) | Average <br> Cost per <br> 100 Pounds <br> (Dollars) |  |
| :--- | ---: | :---: | :---: | :---: |
| Jan. - March | 105,694 | 24 | $1,488,848$ | 1.41 |
| Apr. - June | 98,210 | 22 | $1,368,055$ | 1.39 |
| July - Sept. | 111,776 | 26 | $1,497,791$ | 1.34 |
| Oct. - Dec. | 123,538 | 28 | $1,726,577$ | 1.40 |
| Quarterly Total | 439,118 |  | $6,081,271$ | 1.38 |
| Annual | 436,008 |  | $6,029,356$ | 1.38 |

solution. However, in terms of average cost per hundred pounds, the average for the four quarters was the same as that obtained for the annual model. While there is a general consistency between the quarterly and annual estimates with regard to total quantity shipped and costs, it appears that the quarterly models do provide additional information relative to the time assumption, price differential, and additional shipping activities.

As in the 1960 quarterly analyses, the 1955 quarterly analyses indicated that three regions changed from surplus to deficit and vice versa during the year. Region 14 was surplus during the first quarter and deficit during the remaining quarters; region 15 was surplus the first two quarters and deficit during the last two; while region 18 had slight deficit in the third quarter. Otherwise, except for the inclusion of eight additional shipping activities, the 1955 quarterly analyses were quite similar to the more aggregative annual analysis.

## IV SUMMARY

Minimum-cost flows of slaughter cattle, calves, hogs, and sheep and lambs from production to slaughtering among 26 component regions of the
U.S. were determined by a linear-programming transportation model for 1955 and 1960. Annual and quarterly spatial and price equilibrium analyses were performed for each of the four types of slaughter livestock. Truck transportation rates were used for all of the 1955 analyses. Both truck and truck-rail combination transportation rates were used in the 1960 annual models and only the truck-rail combination rates were used in the 1960 quarterly analyses.

Estimates of regional production which reflect a region's production contribution to total commercial slaughter of the U.S. were generated for each of the four types of livestock for 1955 and 1960. The estimates of regional production for commercial slaughter consist of three major components: (a) live weight of inshipments and weight added to inshipments, (b) live weight of a decrease in inventory numbers, and (c) live weight of production occurring in the region during the calendar year.

Optimum shipment patterns of slaughter animals from location of production to slaughter were estimated for cattle, calves, hogs, and sheep and lambs for 1955 and 1960. About 18-20 percent of slaughter cattle and slaughter hogs and approximately 29 percent of slaughter sheep and lambs would have moved interregionally in both 1955 and 1960. In 1955 approximately 22 percent and in 1960 about 29 percent of calf production for slaughter would have entered into interregional trade while concurrently calf production for slaughter dropped substantially.

Major surplus regions of slaughter cattle in 1955 and 1960 were located in the western part of the Corn Belt and in addition to these in 1960 the Ari-zona-New Mexico region was one of the major surplus regions. In both years region 2 (New York, Pennsylvania, etc.), California, Ohio, Wisconsin, and Michigan were major deficit areas. In 1955 region 3 (North Carolina, Virginia, West Virginia), AlabamaMississippi, Indiana, and Arkansas-Louisiana were surplus regions with the greatest comparative price advantage for slaughter cattle while regions in the Plains area tended to have the least comparative price advantage. In 1960 region 3, Indiana, ArkansasLousiana, and Arizona-New Mexico were regions with the greatest comparative price advantage. From 1955 to 1960 surplus regions with the least comparative price advantage changed from regions in the Plains area to regions in the western portion of the Corn Belt. Regions located along the Atlantic Coast and in 1960, also California and Oregon-Washington were deficit regions with the highest relative prices. Regions with the lowest relative cattle prices were located adjacent to the surplus regions of the Corn Belt.

There were rather marked differences between the 1955 and the 1960 estimated optimum flow pat-
terns for slaughter calves. This can be largely attributed to the large decrease in the U.S. aggregate production and in different rates of decrease among regions. In 1955 the Dakotas, Missouri and the Mon-tana-Wyoming regions continued to be major surplus areas and the North Carolina-Virginia-West Virginia region became a major surplus region. For the two years considered, surplus regions with the greatest comparative price advantage were located in the South and Southeast while regions with the least comparative price advantage were located in the Plains area and in the West. In 1955 the deficit regions with the highest relative prices were in the Northeast (regions 1 and 2) and region 2 continued to have high relative prices in 1960. Also, in 1960 the Florida and Georgia-South Carolina regions were deficit regions with high relative prices.

Major surplus regions of live slaughter hogs were Iowa, Illinois, Indiana, and Missouri and major deficit regions were region 2 (New York, Pennsylvania, etc.), California, and Kansas in both 1955 and 1960. Surplus regions with the greatest comparative price advantage in 1955 were Mississippi-Alabama, Indiana, and the Dakotas, and in 1960 they were the Dakotas, Georgia-South Carolina, Arkansas-Louisiana, and Indiana. Iowa and Missouri in 1955 and Iowa, Illinois, and Missouri in 1960 were surplus regions with the least comparative price advantage. In 1955 and 1960 deficit regions with the highest relative prices of live slaughter hogs were regions along the West Coast, Arizona-New Mexico and the New England area while deficit regions with the lowest relative prices were Nebraska, Kansas, Minnesota, and Wisconsin.

The four major surplus regions of live slaughter sheep and lambs in 1955 and 1960 were MontanaWyoming, Idaho-Utah-Nevada, North Dakota-South Dakota, and Ohio. In both 1955 and 1960 Ohio, Indiana, and North Carolina-Virginia-West Virginia were surplus regions with the greatest price advantage while the Idaho-Utah-Nevada, Arizona-New Mexico, and Montana-Wyoming in 1955 and Mon-tana-Wyoming, Dakotas, and Idaho-Utah-Nevada regions in 1960 had the least comparative price advantage.

In general, the quarterly analyses performed did provide some seasonal information over and above the annual analysis, particularly with respect to calves and sheep and lambs. In all species the quantities shipped from any one region to another varied considerably from quarter to quarter even though the relative supplies and demands remained quite stable. With respect to calves and sheep and lambs, the quarterly analyses indicated that some regions changed from surplus to deficit regions between quarters of the year. These changes in the demand and sup-
ply positions were not revealed by the annual analysis. However, the results of the quarterly analyses suggested that only slight distortion was induced by aggregation over time.

Except for slaughter calves, only moderate changes occurred in the flow patterns between the two years analyzed. The changes which occurred were due mainly to regional shifts in the location of production and slaughter facilities moving closer to areas of production. For the time period considered, relative increases in production occurred in the western part of the Corn Belt and in some of the regions in southwestern United States. Although actual slaughter and not slaughter capacities were restrictions in the spatial models, the structural change in the location of meat packing facilities is exemplified by the westward shift in the regional demand for slaughter livestock. The demand for slaughter livestock between 1955 and 1960 decreased in eastern United States and in the central and eastern parts of the Corn Belt. The magnitude of the changes was not the same in all major livestock producing areas. These changes resulted in a slight reduction in the total quantites which entered interregional trade and in the percent of total commercial production shipped interregionally. Also the average length of haul tended to be shorter. If these kinds of changes in the location of production and location of slaughtering facilities continue, then the changes in the flow patterns and relative price patterns among regions suggested by this study will be more pronounced in the future.

Truck-rail combination transportation rates were lower for longer hauls than were truck transportation rates. Use of truck-rail combination rates affected the spatial flows of slaughter calves the least. These lower rates for longer hauls resulted in an increased average length of haul, a change in the magnitude and directional flows of livestock from some regions, and a lower total transportation cost for all species except hogs. The greatest impact occurred in the western part of the Corn Belt and regions further west. The lower rates for longer hauls made it feasible for these regions to ship slaughter livestock both east and west whereas with truck rates alone these regions shipped in only one direction. These results suggest that changes in the transportation rate structure, particularly a decrease, would alter the direction of shipments and competitive position of surplus producing regions. The greatest impact would probably occur in the western part of the Corn Belt and Western States in terms of east and west shipments and length of haul.

The spatial analyses provide information for
decision making at various structural levels. In particular, the results from these analyses suggest how changes in transportation costs of live animals, geographical location of slaughtering facilities, and regional location of production might alter the regional flows and prices of live slaughter animals. Also, information is provided about competitive price position for slaughter livestock of one region relative to another. From the standpoint of processing firms the information provided by these analyses should be helpful in assessing the consequences
of alternative geographical locations of processing facilities.

The results of these analyses provide one standard for judging the efficiency of the pricing and distribution system for slaughter livestock. Until more complete data become available on regional production and interregional flows of slaughter livestock, analyses of this type provide an operational way of ascertaining the probable consequences of alternative courses of action or disturbances in the slaughter livestock sector of the economy.

[^0]:    * This is the second in a series of three North Central regional bulletins concerned with the spatial structure of the livestock marketing system. This report is concerned with estimating the regional productien of cattle, veal, calves, hogs, and sheep and lambs and determining the optimum geographical flows and competitive price differentials from production to slaughtering. The first bulletin in this series is entitled "Spatial Analyses of the Meat Marketing Sector in 1955 and 1960" and is concerned with estimating the regional consumption of beef, veal, pork, and lamb and mutton and deriving least-cost flows and competitive price differentials for these products. The third bulletin is entitled "Joint Spatial Analyses of Regional Slạughter and the Flows and Pricing of Livestock and Meat" and is concerned with estimating regional slaughterng capacities for each type of livestock and analyzing jointly the optimum location and level of livestock slaughtering and the geographical flows of each type of livestock and meat from production through slaughter to consumption.
    $\dagger$ Associate professor of agricultural economics, Purdue University; regional Coordinator of NCM-25, MED-ERS USDA, Iowa State University; and professor of agricultural economics, University of Illinois.

[^1]:    ${ }^{1}$ Data for 26 regions would require 650 rates for each species for each means of transportation.

[^2]:    "The waybill data used in this study consist of a 1 percent sample of all full carloads of livestock shipped by rail in 1960 as reported by the railroads to the Interstate Commerce Commission. The state of origin and destination are specified for each carload. In estimating the transportation cost functions, the data were stratified according to freight regions. Transportation charges used were developed from total revenue, including costs of feeding and layover derived from shipments.
    "The analysis for these estimated transport cost data and the other alternatives considered will be presented in two forthcoming North Central regional publications: Transportation Patterns and Cost of Livestock Movements, Brewer, D. and Rizek, R.L. and Interregional Transportation and Intersectional Adjustments in the Livestock Economy, Maki, W. R.
    "Agricultural Marketing Service, "Livestock and Meat Statistics," U.S. Department of Agriculture, Statistical Bulletin No. 230, Supplement for 1961 and Statistical Reporting Service, "Meat Animals," U.S. Department of Agriculture, Statistical Bulletin No. 284, May 1961.

[^3]:    ${ }^{5}$ Part of the inventory decrease may be due to normal death loss; however there was no satisfactory basis for taking account of this.
    ${ }^{6}$ Five percent of inshipment were assumed to never enter slaughtering channels largely because of death loss and diversion to other uses.
    Average inshipment weights and average marketing weights by states were provided as a special release by the Livestock and Poultry Statistics Branch, Agricultural Estimates Division, Statistical Reporting Service, U. S. Department of Agriculture.

[^4]:    ${ }^{8}$ Regions $2,4,8,9,11,15,16,17,18,19$, and 20 were considered finishing areas; 10, 12, and 13 were considered to be areas supplying feeder pigs. Missouri, region 14 , was considered to be both a supplying and finishing area and was handled accordingly. Other regions account for sinall numbers of feeder pig movements and were not considered in developing outshipment estimates.

[^5]:    ${ }^{9}$ Regions $8,9,10,11,12,14,15,16,18,19,20,21$, and 25 were considered inshipment receiving or finishing regions; regions 3, 7, 17, 22, 23, 24, and 26 were considered exporters of feeder sheep and lambs; and regions $1,2,4,5,6$, and 13 account for small numbers of feeder sheep and lambs and were not considered in estimating outshipment live weight of feeder sheep and lambs.

[^6]:    *Based on 1960 truck transportation rates. Regions and basing points are identified in Table 1.
    Total shipments $4,552,600,000$ pounds.
    Total cost \$58,454,120.

[^7]:    ${ }^{10}$ Due to the structure of the transportation rates used in this analysis, (rates were developed separately for the different regions) cross-hauling occurred in two regions (regions 3 and 13) in 1955 and in region 13 in 1960. Consequently, in 1960 the total shipments of 4.6 billion pounds include a double counting of 138 million pounds.

[^8]:    *Based on 1960 truck transportation rates. Regions and basing points are identified in Table 1. Total shipments $523,720,000$ pounds.
    Total costs $\$ 46,323,521$.

[^9]:    *Based on 1960 truck transportation rates. Regions and basing points are identified in Table 1. Total shipments $3,468,100,000$.
    Total costs $\$ 39,405,920$.

[^10]:    *Based on 1955 truck transportation rates. Regions and basing points are identified in Table 1.
    Total shipments 449,719,000 pounds.
    Total costs $\$ 7,799,437$.

[^11]:    *Based on 1960 truck transportation rates. Regions and basing points are identified in Table 1.
    Total shipments $436,008,000$ pounds.
    Total costs \$7,603,035.

[^12]:    ${ }^{11}$ Tables giving the results of the 1955 and 1960 quarterly models are not given in this bulletin but may be obtained by writing to the Department of Agricultural Economics, Purdue University, Lafayette, Indiana.

[^13]:    *Based on 1960 combination truck-rail transportation rates. Regions and basing points are identified in Table 1.

[^14]:    *Based on 1960 combination truck-rail transportation rate. Regions and basing points are identified in Table 1.
