**Chemical Composition of Emissions from
Urban Sources of Fine Organic Aerosol**Lynn M. Hildemann¹, Gregory R. Markowski and Glen R. Cass*Environmental Engineering Science Department and Environmental Quality Laboratory
California Institute of Technology, Pasadena, California 91125**Bulk Chemical Analysis Results for Individual Source Tests**

The following tables contain the results of the bulk chemical analyses for each of the experiments performed for each source type. The values (except for the fine mass emission rates) are expressed as percent of the total fine particulate mass collected. The measurements have been corrected for the contribution of any trace species present in the dilution air, and as a result, negative values occasionally occur.

The standard deviation values listed with the individual measurements reflect the accuracy of the analytical methods. On the right side of each table, the mean of the multiple experimental values is calculated, along with the standard deviation of the mean of the sample population (designated as "S.D. of MEAN"). An asterisk (*) is used to mark those species with mean values that are greater than zero by at least twice the standard deviation of the mean of the sample population. A plus sign (+) is used to mark those species where the concentrations measured in at least half of the experiments are greater than zero by at least twice the standard deviation of the analytical method.
