EXECUTIVE SUMMARY

This report details the chemical and radionuclide contaminant results for the characterization of the 2010 Second Quarter sampling of Tank 50 for the Saltstone Waste Acceptance Criteria (WAC).¹ Information from this characterization will be used by Liquid Waste Operations (LWO) to support the transfer of low-level aqueous waste from Tank 50 to the Salt Feed Tank in the Saltstone Facility in Z-Area, where the waste will be immobilized. This information is also used to update the Tank 50 Waste Characterization System.

The following conclusions are drawn from the analytical results provided in this report:

- The concentrations of the reported chemical and radioactive contaminants were less than their respective WAC targets or limits unless noted in this section.
- The reported detection limits for ⁹⁴Nb and ¹⁴⁴Ce are above both the established and requested limits from References 4 and 6.
- The reported detection limits for ²⁴⁷Cm and ²⁴⁹Cf are above the requested limits from Reference 4. However, they are below the limits established in Reference 6.
- The reported detection limit for Isopar L is greater than the limit from Table 3 of the WAC¹.
- A measurable concentration of Norpar 13 is present in the sample. The reported concentration is greater than the requested limit from Table 4 and Attachment 8.2 of the WAC¹.
- Isopar L and Norpar 13 have limited solubility in aqueous solutions making it difficult to obtain consistent and reliable sub-samples. The values reported in this memo are the concentrations in the sub-sample as detected by the GC/MS; however, the results may not accurately represent the concentrations of the analytes in Tank 50.
- The detection limit for isopropanol has been lowered from 0.5 mg/L to 0.25 mg/L⁷. This revised limit now satisfies the limit in Table 4 of the WAC¹.

1.0 Introduction

The Saltstone Facility is designed and permitted to immobilize and dispose of low-level radioactive and hazardous liquid waste (salt solution) remaining from the processing of radioactive material at the Savannah River Site.¹ Low-level waste (LLW) streams from the Effluent Treatment Project (ETP), H-Canyon, the DDA (Deliquification, Dissolution, and Adjustment) process, and the decontaminated salt solution product from the Actinide Removal Process/Modular Caustic Side Solvent Extraction (CSSX) Unit (ARP/MCU) process are stored in Tank 50 until the LLW can be transferred to the Saltstone Facility for treatment and disposal. The LLW must meet the specified waste acceptance criteria (WAC) before it is processed into saltstone.¹ The specific chemical and radionuclide contaminants and their respective WAC limits are listed in the current Saltstone WAC.¹

SRS Liquid Waste Operations (LWO) requested that Savannah River National Laboratory (SRNL) perform quarterly analysis on saltstone samples.² The concentrations of chemical and radionuclide contaminants are measured to ensure the saltstone produced during each quarter is in compliance with the current WAC.¹⁻⁴ This report documents the concentrations of chemical and radionuclide contaminants for the 2010 Second Quarter samples collected from Tank 50 on April 5, 2010 and discusses those results in further detail than the previously issued results report.⁵

2.0 Experimental Procedure

On April 5, 2010, five 200-mL samplers (HTF-50-10--49, -50, -51, -52, -53) were collected from Tank 50 for Second Quarter 2010 WAC analyses and delivered to the SRNL Shielded Cells (SC).

At SRNL, slurry samples (~12 mL) from HTF-50-10-49 were transferred to glass vials with Teflon-lined caps. The vials were completely filled to minimize the void space and the volatilization of organics. The aliquots were transferred to the Analytical Development (AD) Organic Analysis Laboratory for semi-volatile and volatile organic analysis (SVOA and VOA respectively). An additional a 10-mL aliquot was used for SVOA analysis to more accurately determine the concentration of Isopar L in the sample.

After the samples for organic analyses were obtained, the slurries in the 200-mL samplers were combined into a 2-L high density polyethylene (HDPE) bottle according to the following procedure. Each steel sampler was agitated to disperse any solids in the slurry. After mixing the slurry in the steel sampler, the slurry was transferred to the 2-L HDPE bottle. The transferred slurry was left to settle. A portion of the clear supernate was returned to each steel sampler, mixed to mobilize any remaining solids, and again returned to the 2-L HDPE bottle. Visual inspection of the inside of each 200-mL sampler indicated that all the solids had been removed. The total weight of the transferred slurry was approximately 793 grams.

The 2-L HDPE bottle was agitated to thoroughly mix the solids into the supernate. Aliquots of slurry samples were promptly collected with slurry pipettes to minimize settling effects and placed in HDPE bottles. A three milliliter sample of the slurry was used to determine of the density of the slurry.

Slurry samples were submitted in triplicate to AD laboratories for the following analyses:

• Six-mL aliquots to the AD Ion Chromatography (IC) Laboratory for soluble anion analyses and soluble cation analyses.

- Three-mL aliquots to the AD Organic Analysis Laboratory for measurement of tetraphenlyborate and ethylenediaminetetraacetic acid by high performance liquid chromatography (HPLC).
- Six-mL aliquots to the AD Wet Chemistry Laboratory for Total Inorganic Carbon/ Total Organic Carbon (TIC/TOC) analyses.
- Approximately 70-mL aliquots were removed from the 2-L HDPE bottle. After each 70-mL aliquot was prepared, it was divided into one 50-mL and one 20-mL sample and sent to AD Radiochemistry Laboratory for radiochemical separations and analyses. The subsamples were required in order to stay within the dose limits and hood limits for beta radiation.
- Twelve-mL aliquots of filtered supernate were prepared by filtering aliquots of supernate using a 0.45 micron syringe filter. The filtered supernate samples were then submitted to the AD Wet Chemistry Laboratory for TIC/TOC analyses and Total Base analyses.
- Twelve-mL aliquots were sent to the AD Dissolution Laboratory for digestion using an aqua regia method. Visual inspection of the digested sample by the AD Task Supervisor indicated that all the solids had dissolved. Aliquots of dissolved slurries were analyzed using inductively coupled plasma-(atomic) emission spectroscopy (ICP-ES), inductively coupled plasma-mass spectroscopy (ICP-MS), and atomic absorption spectroscopy (AA) for Hg, As, K, Na, and Se.

3.0 Results and Discussion

The following tables contain the results for the 2010 Second Quarter WAC analyses. Each table provides the analyte of interest, the method used for measuring that analyte, the average concentration of the analyte based on triplicate samples (unless otherwise noted), the %RSD of the average, and, if applicable, the WAC target or limit for the analyte concentration. Several of the contaminants were either not detected in the slurry samples or detected at values below the method reporting limit (MRL). For those analytes, the result is preceded by a "<" which indicates the result is an upper limit based on the sensitivity of the method used to analyze the individual analyte.

Tables 3-1, 3-2, 3-3 and 3-4 are based directly on attachments 8.1, 8.2, 8.3, and 8.4, respectively, of the WAC.¹

Chemical Name	Method	Average Concentration (mg/L)	<u>% RSD</u>	<u>WAC Limit</u> (mg/L)

 Table 3-2. Results for the 2nd Quarter 2010 Tank 50 Slurry Samples for Chemical Contaminants

 Listed in Attachment 8.2 of the Saltstone WAC.

a. Measurement performed on duplicate samples rather than triplicate samples.

b. Currently, a routine method for detecting this species does not exist in AD.

As indicated in Tables 3-1 and 3-2, all of the contaminants are within the WAC limits with the exception of Norpar 13. There is a measurable concentration of Norpar 13 and it is above the WAC limit. Isopar L and Norpar 13 have negligible solubility in aqueous solutions, which makes it difficult to obtain reliable sub-samples of the original sample. The values reported in these tables are the concentrations as detected by the GC/MS but may not necessarily be an accurate representation of the concentrations of these analytes in Tank 50.

Radionuclide	Method	<u>Average</u> <u>Concentration</u> (pCi/mL)	<u>% RSD</u>	WAC LIMIT (pCi/mL)

 Table 3-4 (continued). Results for 2nd Quarter 2010 Tank 50 Slurry Samples and WAC Targets for

 Radionuclide Contaminants Listed in Attachment 8.4 of the Saltstone WAC.

a. Result is the average of two measurements.

As shown in Table 3-4, none of the radionuclide contaminants exceed the targets listed in the latest revision of the WAC. However, in a memo from LWO, the detection limits for several radionuclides were lowered in order to accommodate future inventory reporting requirements.⁴

The reported limits of ⁹⁴Nb and ¹⁴⁴Ce are above the limits requested by LWO (2.00E-03 and 1.00E+01 pCi/mL respectively).⁴ In addition, the reported limits are above the limits set by AD.⁶ The values for ^{93m}Nb and ⁹³Mo in Table 3-4 are estimated from the ICP-MS result for mass 93. The entire signal at mass 93 is assigned to ⁹³Zr, and since it is in secular equilibrium with ^{93m}Nb, the maximum activity of the ^{93m}Nb is equal to that of the ⁹³Zr. The specific activity of ⁹³Zr (2.51E-03 Ci/g) is used when calculating the activity concentration of ^{93m}Nb. Similarly, ⁹³Mo is estimated by assigning all of mass 93 to 93 Mo and using the specific activity of 93 Mo to calculate the concentration. The concentration of ¹³⁵Cs is calculated by assigning all of the mass at 135 to cesium. ¹²⁶Sn and ¹²⁶Sb are in secular equilibrium for this sample; therefore their activities are equal. As a result, the measured activity of ¹²⁶Sb was used for the ¹²⁶Sn concentration since ¹²⁶Sb was detected and ¹²⁶Sn was below the MDL. Since no analyte was detected at mass 229 and because the ²²⁹Th and ²³⁰Th isotopes have identical electronic structures, the MDL measured for ²³⁰Th was used for the MDL for ²²⁹Th. The activity concentrations are then calculated from the specific activities for ²²⁹Th and ²³⁰Th. It is assumed all the mass detected at mass 244 is ²⁴⁴Pu. The Pu alpha Pulse Height Analysis (PHA) method does not resolve the alpha activities of ²³⁹Pu and ²⁴⁰Pu. To determine the maximum concentration of each radionuclide, the total activity is assigned to each radionuclide separately. As shown in Table 3-4, the reported activity is below the WAC limit for each radionuclide.

Tables 3-5 and 3-6 list the chemical contaminants that impact vault flammability. These chemicals must be monitored to ensure flammable gases do not contribute more than 10% of the Composite Lower Flammability Limit (CLFL).¹

 Table 3-5. Results for the 2nd Quarter 2010 Tank 50 Slurry Samples for Acceptance Criteria Limits

 for Chemical Contaminants Impacting Vault Flammability, Listed in Table 3 of the Saltstone WAC.

Methanol	b	b		0.25 mg/L
Norpar 13	SVOA	2.35E-01	21.1	0.1 mg/L

 Table 3-6. Results for the 2nd Quarter 2010 Tank 50 Slurry Samples for Concentrations of "Other Organics" Impacting Vault Flammability, Listed in Table 4 of the Saltstone WAC.

a. Result is from a single value.

b. Currently, a routine method for detecting this species does not exist in AD.

None of the species considered in Tables 3-5 or 3-6 are above the WAC limit with the exception of Isopar L and Norpar 13, respectively. Although the reported detection limit for Isopar L is greater than the WAC limit for vault flammability, it is below the WAC limits for accident analysis as shown in Table 3-1. It should be noted that the value of the detection limit for Isopar L

was expected based on current AD capabilities as documented in the TTQAP.³ The reported concentration of Norpar 13 is above both the accident analysis and vault flammability limits. As previously discussed, the insolubility of Isopar L and Norpar 13 makes sub-sampling difficult, therefore the reported results are not necessarily representative of the concentration of these analytes in the Tank 50 sample received by SRNL. The reported detection limit for isopropanol has been lowered from 0.5 to 0.25 mg/L which now satisfies the WAC limit for vault flammability.⁷

Table 3-7 provides results for the processing criteria for transfers into the Saltstone Facility.

Table 3-7. Results for the 2nd Quarter 2010 Tank 50 Slurry Samples for Saltstone Pro-	cessing
Criteria WAC Limits, Listed in Table 5 of the Saltstone WAC.	

Processing Criterion	Method	od <u>Value</u>	
pH > 10	Calculated	>13	
2.5 M < [Na ⁺] < 7.0 M	AA/ICP-ES	3.96 M	2.69
Total Insoluble Solids <15 wt%	Calculated	0.147 wt%	0.529ª

a. This is the 95% uncertainty calculated from the measured results for the Wt % total solids and Wt % dissolved solids in triplicate samples of the slurry.

All of the results contained in Table 3-7 fall within the general processing criteria. The pH was calculated using the free base concentration (OH⁻). The value for the total insoluble solids was calculated by Engineering Process Development of SRNL from experimentally determined values for total solids and dissolved solids in the slurry supernate.⁸

Table 3-8 provides constituents listed in the Technical Task Request but not contained in the WAC.

Table 3-8. Requests for Constituents for TCLP/UHC Support as well as from the TTR for Tank 50 Output Output
Slurry Samples; Results Not Contained in Previous Tables.

Constituent	Method	<u>Average Value</u> (mg/L, unless stated otherwise) <u>%RS</u>	
Antimony (Sb)	ICP-ES	<8.04E+00	
Beryllium (Be)	ICP-ES	<5.42E-02	
Cyanide (CN)	a.	a.	
Thallium (Tl)	ICP-MS	6.66E-01	17.1
Density (slurry)	Measured (22.0 °C)	1.1804 g/mL	0.00
Total Beta	LSC	SC 9.80E+06 pCi/mL	
Total Solids	Measured	23.75%	0.28

a. Currently, a routine method for detecting this species does not exist in AD.

The results from Table 3-8 are used in a series of calculations performed by the SRNL Engineering Process Development group to support TCLP/UHC testing by a certified laboratory.⁹

The density of the slurry was measured at 22.0 °C. An estimate of the maximum concentration of the natural nonradioactive element Tl in the sample could only be determined by measuring the detection limits for Tl using ICP-MS. Natural Tl is composed of two isotopes, ²⁰³Tl and ²⁰⁵Tl with fraction abundances of 0.295 and 0.705, respectively. The concentration of each isotope was divided by its fractional abundance and the reported concentration of Tl is the average of the two isotopes.

The tank corrosion species listed in Table 3-9 were requested by Waste Solidification Engineering (WSE).^{*} Specific gravity was calculated by dividing the measured density of the slurry (given in Table 3-8 at 22.0 °C) by the density of water at the same temperature.¹⁰

 Table 3-9. Requests from the WSE for Corrosion Species from Tank 50 Slurry Samples; Results Not Contained in Previous Tables.

Constituent	Method	Average Value	<u>%RSD</u>
Specific Gravity	а	1.1830	
Ba-137m	b	6.97E+06 pCi/mL	1.87
Total Gamma	с	6.98E+06 pCi/mL	

a. Calculated from the measured density of slurry and density of water at 22.0 °C¹⁰.

b. Calculated from the measured concentration of Cs-137.

c. Calculated from the sum of measured gamma emitters.

The radionuclide ^{137m}Ba is the radioactive daughter of 94.6% of the beta decay of ¹³⁷Cs. 5.3% of the ¹³⁷Cs decays to stable ^{137m}Ba. The half-life the parent radionuclide, ¹³⁷Cs, is 5x that of the daughter, ^{137m}Ba, therefore the two radionuclides are in secular equilibrium. Radionuclides in secular equilibrium have the same activity associated with decay. Thus the activity of ^{137m}Ba is 94.6% of the activity of the ¹³⁷Cs or 6.97E+06 pCi/mL. The activities calculated for total gamma and ^{137m}Ba are expected to be close for this sample because the total gamma activity is dominated by ^{137m}Ba, the radioactive daughter of ¹³⁷Cs. The total gamma activity was calculated by summing the measured gamma activity of the major gamma emitters: ⁶⁰Co, ¹²⁵Sb, ¹²⁶Sn, ¹³⁷Cs (via ^{137m}Ba), ¹⁵⁴Eu, and ²⁴¹Am.

^{*} Requested in an electronic mail message from S. D. Hevel on December 20, 2007. (See page 30 of WSRC-NB-2007-00189.)

Table 3-10 provides results for additional radionuclides not listed in the WAC but which now require quantification in order to support inventory reporting requirements.

Radionuclide	Method	<u>Average Concentration</u> (pCi/mL)	<u>%RSD</u>	<u>REQUESTED</u> <u>TARGET</u> (pCi/mL)
Potassium-40 (⁴⁰ K)	Gamma scan (Cs removed)	<1.96E+00		1.00E+04
Silver-108m (^{108m} Ag)	Gamma scan (Cs removed)	<9.86E-01		1.00E+04
Barium-133 (¹³³ Ba)	Gamma scan (Cs removed)	<2.34E+00		1.00E+04
Bismuth-207 (²⁰⁷ Bi)	Gamma scan (Cs removed)	<1.03E+00		1.00E+04
Actinium-227 (²²⁷ Ac)	Gamma scan (Cs removed)	<2.24E+01		1.00E+04
Radium-228 (²²⁸ Ra)	Gamma scan (Cs removed)	<2.70E+00		1.00E+04
Thorium-228 (²²⁸ Th)	Gamma scan (Cs removed)	<3.58E+01		1.00E+04
Protactinium-231 (²³¹ Pa)	Gamma scan (Cs removed)	<5.68E+01		1.00E+04
Curium-247 (²⁴⁷ Cm)	Am/Cm	<3.69E+00		1.43E-11
Californium-249 (²⁴⁹ Cf)	Am/Cm	<3.76E+00		1.33E-10
Californium-251 (²⁵¹ Cf)	Am/Cm	<2.73E+00		1.00E+02

 Table 3-10. Additional Radionuclides Requested for Inventory Reporting Requirements.

As shown in Table 3-10, ²⁴⁷Cm and ²⁴⁹Cf surpass the LWO requested targets.⁴ However, the reported detection limits are below the detection limits established by AD. ^{3,6}

4.0 Conclusions

The following conclusions are drawn from the analytical results provided in this report:

- The concentrations of the reported chemical and radioactive contaminants were less than their respective WAC targets or limits unless noted in this section.
- The reported detection limits for ⁹⁴Nb and ¹⁴⁴Ce are above both the established and requested limits from References 4 and 6.
- The reported detection limits for ²⁴⁷Cm and ²⁴⁹Cf are above the requested limits from Reference 4. However, they are below the limits established in Reference 6.
- The reported detection limit for Isopar L is greater than the limit from Table 3 of the WAC¹.
- A measurable concentration of Norpar 13 is present in the sample. The reported concentration is greater than the requested limit from Table 4 and Attachment 8.2 of the WAC¹.
- Isopar L and Norpar 13 have limited solubility in aqueous solutions making it difficult to obtain consistent and reliable sub-samples. The values reported in this memo are the concentrations in the sub-sample as detected by the GC/MS; however, the results may not accurately represent the concentrations of the analytes in Tank 50.
- The detection limit for isopropanol has been lowered from 0.5 mg/L to 0.25 mg/L⁷. This revised limit now satisfies the limit in Table 4 of the WAC¹.
