### **About Argonne National Laboratory**

Argonne is a U.S. Department of Energy laboratory managed by UChicago Argonne, LLC under contract DE-AC02-06CH11357. The Laboratory's main facility is outside Chicago, at 9700 South Cass Avenue, Argonne, Illinois 60439. For information about Argonne and its pioneering science and technology programs, see [www.anl.gov](http://www.anl.gov).

## **Final Work Plan: Phase II Investigation of Potential Contamination at the Former CCC/USDA Grain Storage Facility in Savannah, Missouri**

### **1 Introduction**

From approximately 1949 until 1970, the Commodity Credit Corporation of the U.S. Department of Agriculture (CCC/USDA) operated a grain storage facility on federally owned property approximately 0.25 mi northwest of Savannah, Missouri (Figure 1.1). During this time, commercial grain fumigants containing carbon tetrachloride were commonly used by the CCC/USDA and the private grain storage industry to preserve grain in their facilities. In November 1998, carbon tetrachloride was detected in a private well (Morgan) roughly 50 ft south of the former CCC/USDA facility, as a result of statewide screening of private wells near former CCC/USDA facilities, conducted in Missouri by the U.S. Environmental Protection Agency (EPA 1999).

The 1998 and subsequent investigations by the EPA and the Missouri Department of Natural Resources (MoDNR) confirmed the presence of carbon tetrachloride in the Morgan well, as well as in a second well (on property currently occupied by the Missouri Department of Transportation [MoDOT]) described as being approximately 400 ft east of the former CCC/USDA facility. The identified concentrations in these two wells were above the EPA maximum contaminant level (MCL) and the Missouri risk-based corrective action default target level (MRBCA DTL) values of 5.0 µg/L for carbon tetrachloride in water used for domestic purposes (EPA 1999; MoDNR 2000a,b, 2006).

Because the observed contamination in the Morgan and MoDOT wells might be linked to the past use of carbon tetrachloride-based fumigants at its former grain storage facility, the CCC/USDA is conducting an investigation to (1) characterize the source(s), extent, and factors controlling the subsurface distribution and movement of carbon tetrachloride at Savannah and (2) evaluate the potential risks to human health, public welfare, and the environment posed by the contamination. This work is being performed in accord with the Intergovernmental Agreement established between the Farm Service Agency of the USDA and the MoDNR, to address carbon tetrachloride contamination potentially associated with a number of former CCC/USDA grain storage facilities in Missouri. The site characterization at Savannah is being conducted on behalf of the CCC/USDA by the Environmental Science Division of Argonne National Laboratory.

The investigation at Savannah is being conducted in phases. This approach is being used by the CCC/USDA and Argonne, with the approval of the MoDNR, so that information obtained and interpretations developed during each incremental stage of the investigation can be used most effectively to guide subsequent phases of the program. Phase I of the Savannah program was conducted in October-November 2007 and January 2008 (Argonne 2007a, 2008). This site-specific *Work Plan* provides a brief summary of the Phase I findings and the results of groundwater level monitoring that has been ongoing since completion of the Phase I study and also outlines technical objectives, investigation tasks, and investigation methods for Phase II of the site characterization at Savannah.

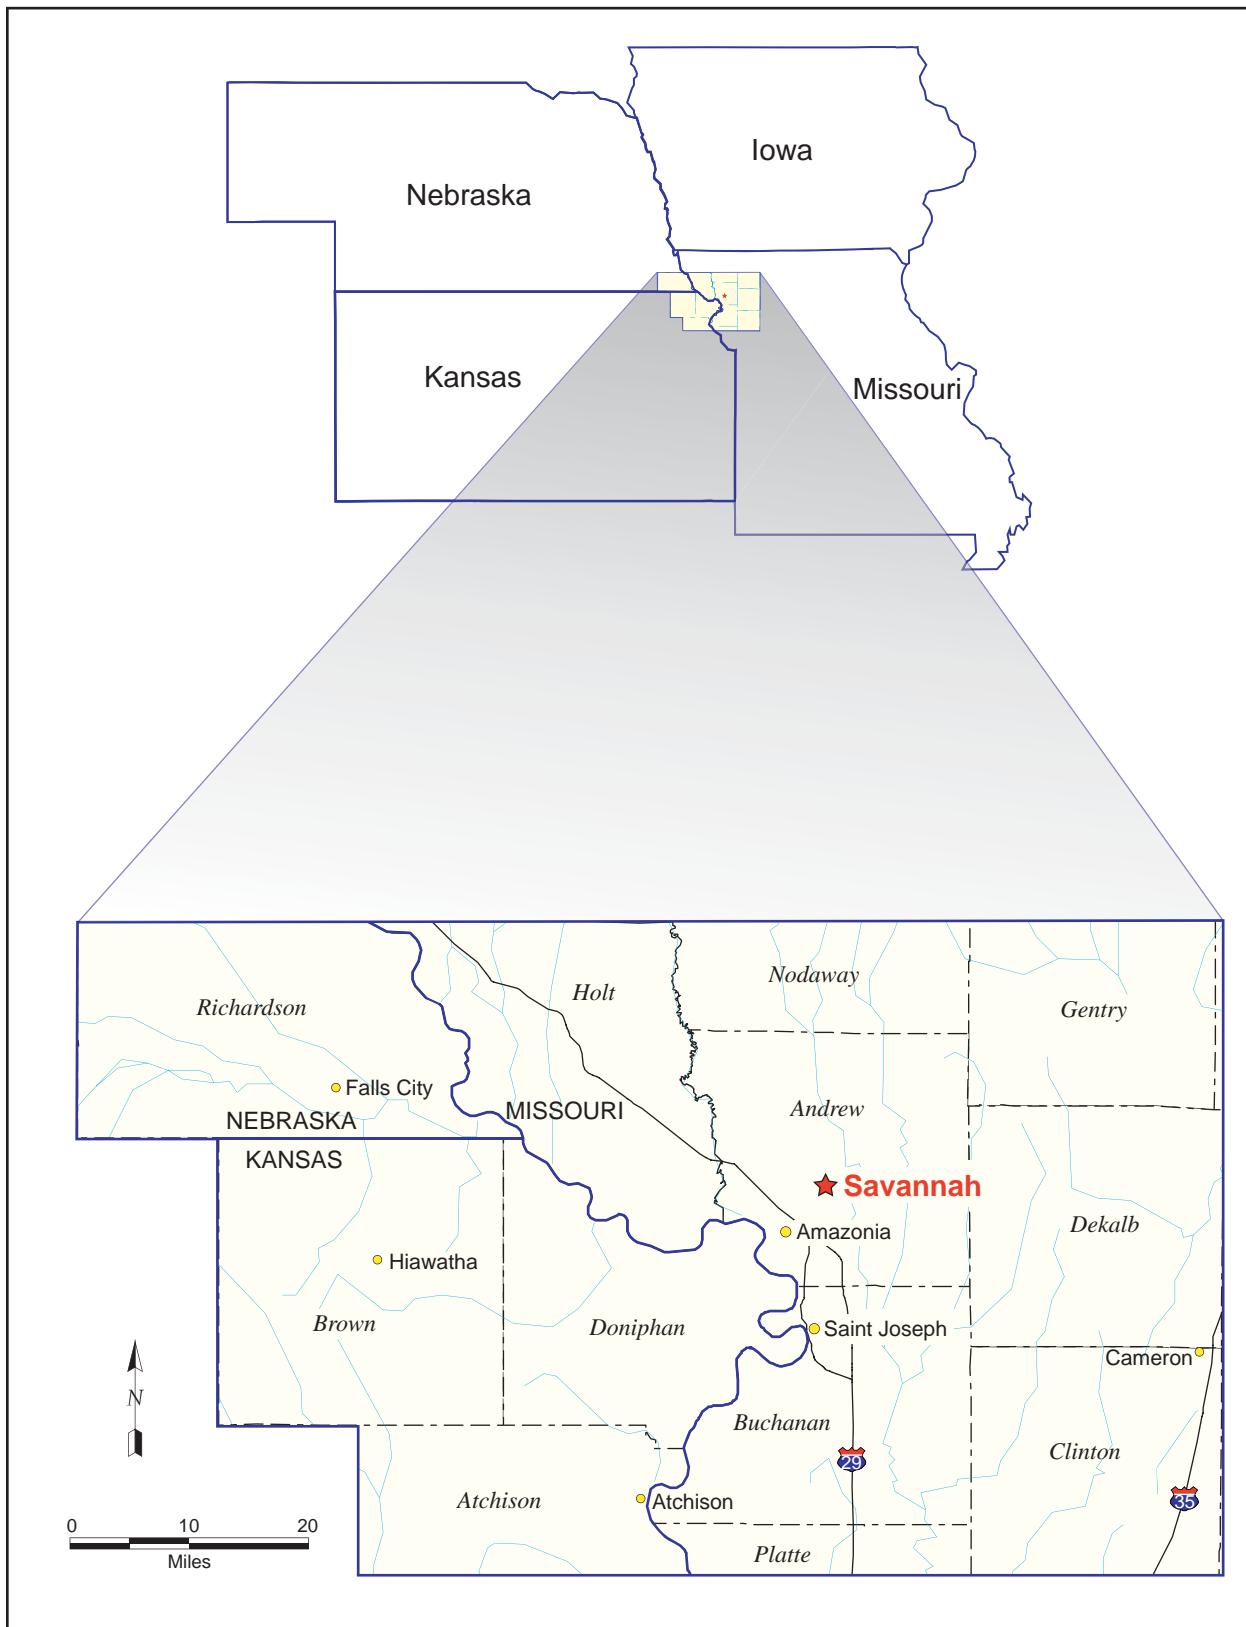

FIGURE 1.1 Location of Savannah, Missouri.

## 2 Results of the Phase I Work and Continuing Monitoring Studies at Savannah

### 2.1 Summary of the Phase I Investigation Program

With the approval of the MoDNR, Phase I of the Savannah investigation was undertaken to address four primary technical objectives (Argonne 2007a), as follows:

- Update the previous (MoDNR 2000a,b) inventory and status of private wells in the immediate vicinity of the former CCC/USDA grain storage facility, and sample the identified wells for analyses for volatile organic compounds (VOCs) and geochemical constituents.
- Investigate for possible evidence of a soil source of carbon tetrachloride contamination to groundwater beneath the former CCC/USDA facility.
- Obtain preliminary information on the site-specific lithologies and hydrostratigraphy at the former CCC/USDA grain storage location.
- Establish preliminary groundwater monitoring points, to investigate the patterns of groundwater movement affecting possible contaminant migration near the former CCC/USDA facility.

The Phase I program was conducted in two primary field sessions, on October 24-November 3, 2007, and January 28-31, 2008. The activities included the following:

- Location, identification, and sampling of private wells (plus the Savannah public water system) for VOCs and geochemical analyses.
- Collection of surficial, shallow subsurface, and deeper subsurface soils for lithologic characterization and for VOCs analyses.
- Installation of temporary and permanent piezometers to facilitate groundwater sampling and measurement of groundwater levels.

- Use of automatic data recorders to initiate groundwater level monitoring in a preliminary network of private wells and piezometers.

Soil sampling, groundwater sampling, and piezometer installation on the property formerly occupied by the CCC/USDA storage facility were conducted in Phase I primarily by using the direct-push capabilities of the Argonne 22-ton, track-mounted crawler cone penetrometer (CPT) vehicle. The Phase I locations investigated within the limits of the former CCC/USDA facility are shown in Figure 2.1. Phase I study locations lying outside the former CCC/USDA facility are shown in Figure 2.2.

The results of the Phase I studies were interpreted and integrated to develop a preliminary conceptual model of the factors controlling the distribution, possible movement, and potential risks associated with the carbon tetrachloride contamination identified at Savannah (Argonne 2008). The key findings of the Phase I investigation are summarized as follows:

- Depths to bedrock, inferred to coincide with the depths of refusal encountered during vertical probing with the Argonne CPT, ranged from 91.8 ft below ground level (BGL) to 96.3 ft BGL, suggesting a relatively consistent bedrock surface elevation beneath the former CCC/USDA facility. The observed refusal depths were comparable to depths to bedrock reported previously for the Savannah area.
- Two predominantly fine-grained lithologic units were identified at the former CCC/USDA facility. The uppermost of these units consists of approximately 58-65 ft of generally dense, stiff to slightly softer, non-plastic and non-calcareous silty clay to clayey silt, with possible traces of very fine sand. The second, deeper lithologic unit consists of approximately 26-30 ft of generally firm and dense, uniformly light gray silty clay till with some fine to medium sand.
- Thin zones (up to approximately 1.1 ft in thickness) of damp-to-dry, coarser-grained sediments were identified directly above the refusal depth at three locations on the former CCC/USDA property, in borings SB24, SB38, and SB42 (Figure 2.1). These zones appeared most extensively developed at the SB38 location. No other distinctly coarse-grained intervals were identified in

the overlying silty clay and till units at the locations investigated during Phase I.

- Groundwater levels measured in nearby private wells located immediately to the north (McPike) and south (Morgan) of the former CCC/USDA facility property (Figure 2.2) were 18.53 ft BGL and 32.71 ft BGL, respectively, at the time of the Phase I field activities. The depth to groundwater beneath the former CCC/USDA facility could not be determined with certainty, however, on the basis of the Phase I study results.
- The observed physical, textural, and water-producing characteristics of the silty clay to clayey silt and till units suggest that the ability of these deposits to transmit groundwater is limited. Occasional thin, discontinuous intervals of relatively softer and lighter-colored materials, observed most commonly at depths of 50-70 ft BGL, might suggest the presence of preferred pathways for horizontal groundwater movement in these units. Locally enhanced porosity and/or permeability might occur in association with calcareous nodules and patches observed in the till, if hydraulic communication among these features is sufficient. Basal coarse-grained deposits similar to those observed at borings SB24, SB38, and SB42 might also provide pathways for enhanced groundwater migration in the Savannah study area, if these materials are locally saturated.
- Groundwater levels measured in private wells in the vicinity of the former CCC/USDA facility indicated that the apparent patterns of groundwater flow in this area mirror the predominant local topographic trends (Figure 2.3). The data suggested groundwater flow toward the south or southeast beneath the former CCC/USDA facility during the Phase I investigation period.
- No carbon tetrachloride contamination was identified in surficial and shallow subsurface soils collected at the former CCC/USDA grain storage facility, at depths of 1 ft, 4 ft, 8 ft, and 12 ft BGL, at concentrations at or above either the MRBCA DTL of 79.6 µg/kg or the quantitation limit of 10 µg/kg for analyses according to EPA Methods 5030B and 8260B (purge-and-trap sample

preparation with analysis on a gas chromatograph-mass spectrometer [GC-MS] system).

- With the approval of the MoDNR, four locations at the former CCC/USDA facility (SB24, SB29, SB38, SB42; Figure 2.1) were chosen for sampling of deeper subsurface soils for VOCs analyses. Traces of carbon tetrachloride contamination (below the purge-and-trap method quantitation limit of 10 µg/kg) were detected at each location; however, quantifiable levels of carbon tetrachloride were identified only at SB38 and SB42. Carbon tetrachloride concentrations of 10-42 µg/kg were identified at SB38. Concentrations of 15-171 µg/kg were identified at SB42, with the highest of these levels (126 µg/kg and 171 µg/kg) occurring in the zone of saturated soils at 48 ft and 44 ft BGL, respectively (Figure 2.4).
- Only the two highest carbon tetrachloride concentrations in soil samples identified during the Phase I investigation, at SB42 (126 µg/kg and 171 µg/kg), were greater than the MRBCA DTL for carbon tetrachloride in soils (79.6 µg/kg). No concentrations detected in the subsurface (vadose) zone as defined by MoDNR (2006) exceeded the DTL. For carbon tetrachloride in soils, the DTL reflects risk that might be associated with the indoor inhalation pathway. Because the former CCC/USDA property has been used only for non-residential purposes since the CCC/USDA grain storage operations were terminated (by 1974), the indoor inhalation pathway is incomplete at the former facility, and no receptors have historically been, or presently are, at risk of exposure by this route.
- Samples of groundwater recovered at two locations at the former CCC/USDA facility, SB24 and SB38 (Figure 2.1), contained carbon tetrachloride at concentrations of 3.8-6.4 µg/L. The identified concentrations are either slightly below or slightly above the EPA MCL and the MRBCA DTL values for carbon tetrachloride (5.0 µg/L) in groundwater used for domestic purposes.
- Both the surface water samples obtained by the city of Savannah from a municipal reservoir approximately 0.75 mi southwest of the former

CCC/USDA facility (Figure 2.2) and the water samples from the Savannah public distribution system were confirmed to be free of carbon tetrachloride contamination.

- Sixteen private wells were identified within approximately 0.5 mi of the former CCC/USDA facility (Figure 2.2). Three of these wells were confirmed to be damaged or otherwise inaccessible, and nine of the wells are not used for any purpose. Two wells (Morgan and Clizer “old”) are currently used for lawn and garden watering, and two (Moore and Clizer “new”) are used for domestic purposes. Access for sampling was denied for one well (Vanschoiack) identified as not in use.
- Except for the Moore residence, all other occupied residential and commercial properties within approximately 0.5 mi of the former CCC/USDA facility have confirmed access to and obtain water for domestic purposes from a public water supply. (The Clizer “new” private well is used to supplement the water obtained from the public supply at this residence.)
- Only two of the private wells tested in Phase I (Figure 2.5) contained carbon tetrachloride: the Morgan well (13 µg/L) and the MoDOT well (150 µg/L). The carbon tetrachloride levels at these locations have decreased since the wells were originally sampled in 1998 and 2000, respectively. The Moore well and the Clizer “new” well (used for domestic purposes) were confirmed to be free of carbon tetrachloride contamination.
- The carbon tetrachloride concentration identified in the Morgan well, to the south of the former CCC/USDA facility, is generally comparable to the levels detected in the groundwater at the former facility. The identified carbon tetrachloride concentration in the MoDOT well, to the east of the former CCC/USDA facility, is greater by approximately an order of magnitude than the levels at the former facility.

## 2.2 Ongoing Groundwater Level Monitoring at Savannah

A groundwater monitoring network consisting of eight private wells and two permanent piezometers was established during the Phase I investigation at Savannah (Table 2.1). The private wells and piezometers are not constructed with a common depth of penetration or screened intervals, and hence the water levels measured in these wells might not reflect the hydraulic heads controlling groundwater movement (vertical, lateral, or both) at any one specific depth or horizon within the saturated zone. The identified wells and piezometers were selected to obtain preliminary information on the distribution of groundwater levels, and hence potential influences on the direction(s) of groundwater flow, in the area surrounding the former CCC/USDA facility. Automatic water level sensors and data loggers were initially installed in the McPike, Burks, Barr, Hughes, Potter, and MoDOT private wells in October 2007. These locations were supplemented in March 2008 by the addition of sensors and data loggers in the Morgan well and the Clizer “old” well, as well as at SB38 (upon accumulation of sufficient groundwater for monitoring in the piezometer) (Figures 2.1 and 2.2). The sensors and data loggers are used to measure and record water levels continuously at 4-hr intervals.

Water level data for the period October 28, 2007, to April 30, 2008, were reported for the monitored points as part of the Phase I investigation (Argonne 2008). These results suggested that groundwater flow near the former CCC/USDA facility is influenced by both the local land surface topography (Figure 2.3) and rainfall events. In accord with recommendations presented at the conclusion of the Phase I investigation (Argonne 2008), automatic monitoring has continued at the observation points noted above to document the potential effects of seasonal or longer-term influences on the local groundwater levels and apparent flow pattern(s). On April 30, 2008, a water level recording unit was also installed at location SB24 at the former CCC/USDA facility (Figure 2.1), upon accumulation of sufficient groundwater for monitoring in this piezometer.

The results of the continued monitoring program are summarized in Figures 2.6-2.8. Complete data for the period April 30, 2008, to May 8, 2009, are in Supplement 1, Table S1.1 (on the compact disc [CD] inside the back cover of this report). The hydrographs are shown in conjunction with daily rainfall data recorded at the Saint Joseph, Missouri, weather monitoring station (MU Extension 2009; Supplement 1, Table S1.2 [on CD]), approximately 7 mi south of Savannah. Water levels measured manually at Savannah in association with each retrieval of data from the water level recorders (performed approximately quarterly since completion of the

Phase I investigation) are in Table 2.2. The hand-measured levels were the primary data used to construct the water level contour maps in this report.

The hydrographs (Figure 2.6) indicate that, with one exception, groundwater levels at the monitored points on and around the former CCC/USDA facility reached a transient maximum in May 2008, in apparent response to relatively frequent rainfall events from late 2007 through spring 2008. Groundwater levels then declined slowly across the study area during the summer (June-August) of 2008, before becoming relatively stable throughout the fall and winter of 2008 and the early spring of 2009. Figure 2.6 indicates that groundwater levels rose again from early April to early May 2009, in response to spring rainfall events.

The hydrograph for monitoring point SB24 (Figure 2.6) is distinct from those outlined above, in depicting a continuous rise in water level throughout the spring and early summer of 2008, before reaching apparent stability in August 2008. The SB24 piezometer is screened at 50-60 ft below ground level (BGL), near the interpreted base of the silty-clay to clayey-silt lithologic unit, across a zone (53-58 ft BGL) that yielded small quantities of groundwater (sufficient for VOCs analysis) at this location during the Phase I field program (Argonne 2008). Very slow groundwater accumulation was observed, however, in the permanent piezometer constructed at this location (Argonne 2008), and the rising trend documented in Figure 2.6 reflects the initial influx of groundwater to the SB24 piezometer after its installation.

Table 2.1 indicates that SB24 penetrates the subsurface to a stratigraphic level (elevation above mean sea level [AMSL]) that is comparable to the levels reached in the nearby McPike, Morgan, and MoDOT private wells (Figure 2.2). In contrast to SB24, however, these wells are constructed with segmented concrete casings that allow groundwater entry into the wells from the full thickness of the saturated interval penetrated by each well. Despite these construction differences, the monitoring data obtained to date suggest that the groundwater elevations observed at SB24 are generally consistent with those in the McPike, Morgan, and MoDOT wells.

Piezometer SB38 was installed with a long screened interval (from 50 ft to 90 ft BGL) to approximate the construction approach identified in the nearby private wells. Table 2.1 indicates, however, that the screened interval at SB38 intersects a lower stratigraphic interval than is penetrated in the McPike, Morgan, and MoDOT wells and SB24. The hydrographs for these monitoring points together suggest the existence of both vertical (downward) and lateral

hydraulic gradients within the saturated zone in the vicinity of the former CCC/USDA facility that might influence the potential migration of carbon tetrachloride in this area.

Water level measurements obtained manually on November 4, 2008, and February 6, 2009 (Table 2.2), during the observed period of relatively stable winter groundwater levels, were used to generate estimates of the configuration of the potentiometric surface near the former CCC/USDA facility, as shown in Figures 2.7 and 2.8. The resulting diagrams suggest a general pattern of semi-radial lateral groundwater flow in the study area, from a relative high west-northwest of the former CCC/USDA facility. The flow pattern qualitatively mirrors the dominant local topographic trends (Argonne 2008). These observations are consistent with the preliminary interpretation of groundwater flow toward the south or southeast beneath the former CCC/USDA facility (Figure 2.3) developed during the Phase I investigation (Argonne 2008). Additional groundwater monitoring is warranted, however, to investigate the influence of both vertical and horizontal hydraulic gradients on the three-dimensional movement of groundwater (and possible carbon tetrachloride contamination) in the vicinity of the former CCC/USDA facility.

### 3 Investigation Objectives and Tasks

#### 3.1 Technical Objectives of the Phase II Studies

Phase II of the CCC/USDA investigations at Savannah will focus on three primary technical objectives that are designed to increase understanding of the local hydrogeologic system and its influence on the distribution of carbon tetrachloride contamination associated with the former CCC/USDA facility. The objectives incorporate recommendations for the Phase II program provided by the MoDNR (2008, 2009), the CCC/USDA, and Argonne. The proposed technical objectives for the Phase II program are as follows:

- Investigate the more detailed characteristics of groundwater flow in the vicinity of the former CCC/USDA facility and the contaminated Morgan and MoDOT private wells.
- Obtain additional information on the vertical and lateral distribution and concentrations of carbon tetrachloride contamination in groundwater in the vicinity of the former CCC/USDA facility and the contaminated Morgan and MoDOT private wells.
- Investigate further for possible evidence of carbon tetrachloride contamination in the subsurface (vadose zone) and deeper soils beneath the former CCC/USDA facility, as well as in the vicinity of the contaminated MoDOT private well.

#### 3.2 Phase II Investigation Tasks

To address the technical objectives proposed in Section 3.1, the activities described below are recommended. Site-specific elements of the investigative approach and methods that will be used to implement the proposed Phase II program at Savannah are discussed in Section 4. Detailed information on the investigative technologies, field procedures, and analysis procedures that are pertinent to the CCC/USDA's planned characterization efforts at this site are in the *Provisional Master Work Plan (PMWP; Argonne 2007b)* that was reviewed by the MoDNR and approved for current use by the CCC/USDA for environmental investigations in Missouri.

### **3.2.1 Investigate the More Detailed Characteristics of Groundwater Flow in the Vicinity of the Former CCC/USDA Facility and the Contaminated Morgan and MoDOT Private Wells**

As noted in Section 2.2 and Table 2.1, the private wells and piezometers that compose the preliminary groundwater monitoring network established at Savannah vary in method of construction, depth of penetration, and depth interval over which groundwater may enter the casing of each well (or piezometer). The water level data obtained under these conditions have therefore been used to develop an initial interpretation of the hydrologic setting at this site, in conjunction with lithologic data obtained from the Phase I investigative boreholes. This initial interpretation suggests that the local topography and predominant surface drainage features exert a significant influence on the apparent patterns of groundwater flow in the vicinity of the former CCC/USDA facility. The water level relationships observed at piezometers SB24 and SB38 (outlined in Section 2.2) further suggest, however, that both vertical and horizontal hydraulic gradients exist in the predominantly fine-grained soils of the saturated zone beneath the former CCC/USDA facility. The potential impact of these gradients on the three-dimensional movement of groundwater — and possible carbon tetrachloride migration — in the vicinity of the former facility and the contaminated Morgan and MoDOT private wells cannot be discerned from the existing monitoring points.

To obtain more detailed information on the hydrogeology of the Savannah investigation area, additional investigative borings are recommended at seven locations. The currently proposed locations, shown in Figures 3.1 and 3.2, are intended to help in further constraining the hydrostratigraphy and the apparent patterns of groundwater flow in the vicinity of the former CCC/USDA facility and the contaminated Morgan and MoDOT private wells, as interpreted from the Phase I studies (Sections 2.1 and 2.2). The recommended locations were chosen to address the multiple technical objectives of the Phase II study (see also Sections 3.2.2 and 3.2.3), subject to the logistic limitations imposed by local site conditions and to the receipt of access approvals from the indicated property owners. The actual locations to be investigated might be modified (subject to the approval of the CCC/USDA and MoDNR project managers), however, if technically warranted on the basis of the data acquired and the revised site interpretations developed as the Phase II investigation proceeds.

The recommended Phase II boring locations are as follows:

- Boring locations 1 and 2 (Figures 3.1 and 3.2) are in the inferred portion of the groundwater flow system lying generally upgradient from the former

CCC/USDA facility. The points are sited to help define the apparent flow of groundwater toward the former CCC/USDA facility along the topographic high that extends from northwest to southeast beneath the former CCC/USDA facility and the adjacent MoDOT property (Figure 2.3). Location 1 is proposed in the northwest corner of the former CCC/USDA facility (currently owned by Reorganized School District III of Savannah); location 2 lies along the eastern edge of the McPike commercial property (currently owned by Joan Whitlock), north of the former CCC/USDA facility. These locations are presently grass covered, with no apparent physical obstructions that would impede the proposed investigative activities.

- Location 3 is expected to lie downgradient of the former CCC/USDA facility and upgradient of the contaminated MoDOT well. The proposed well location (Figures 3.1 and 3.2) is on the MoDOT property, in a parking area northwest of the MoDOT well on the east side of Business Hwy. 71. Argonne's observations during the Phase I field sessions suggest that this location should not interfere with the frequent heavy-vehicle traffic that enters and leaves the vehicle maintenance building in which the MoDOT well is located. Proposed monitoring well location 4 is also on the MoDOT property, at a position that is both topographically downslope and hydraulically downgradient from the contaminated MoDOT well.
- Proposed boring locations 5 and 6 (Figures 3.1 and 3.2) lie downgradient from the contaminated Morgan private well and the former CCC/USDA facility, on the Charles Morgan property. This property is well maintained and landscaped, particularly in the immediate vicinity of the main house and outbuildings. The suggested well locations are in a grassed area along the southern margin of the property, slightly downslope and relatively removed from the Morgan home.
- Boring location 7 was selected at the request of the MoDNR. This location is expected to lie downgradient of Phase I boring location SB42, which returned the highest concentrations of carbon tetrachloride in soils (126 µg/kg at 48 ft BGL and 171 µg/kg at 44 ft BGL) identified during the Phase I investigation

at Savannah. The proposed well location is in a grass-covered area in the northeast corner of the former CCC/USDA facility.

The two primary investigative activities described below will be conducted at the proposed locations, to address the present Phase II technical objective.

### **3.2.1.1 Characterization of the Hydrogeologic Section**

The findings of the Phase I investigations at Savannah (Argonne 2008) identified two principal lithologic units underlying the former CCC/USDA facility, consisting of (1) approximately 58-65 ft of silty clay to clayey silt overlying (2) approximately 26-30 ft of silty clay till, which in turn rests on Pennsylvanian bedrock. A relatively consistent elevation for the bedrock surface was suggested beneath the former CCC/USDA facility, ranging from approximately 1,062.5 ft to 1,066 ft AMSL (approximately 91.8-96.3 ft BGL). Thin zones of coarser-grained sediments — locally identified directly above the bedrock surface at several locations — appeared to be dry to damp (at most). No other distinctly coarser-grained intervals were identified in the overlying silty clay and till units during Phase I.

At each of the proposed Phase II locations, conventional drilling techniques will be used to obtain continuous cores of the soil profile from the surface to the top of bedrock. The hydrogeologic sequence will be characterized in detail, to determine the range of lithologies and types of sedimentary units present and to identify potential water-bearing and confining intervals. Samples of the soil materials penetrated at each location might also be collected (at selected depths to be determined in the field) for the laboratory measurement of soil properties including particle size distribution, moisture content, porosity, bulk density, permeability, and total organic carbon. These parameters would facilitate subsequent quantitative estimation of (1) the state of saturation of the penetrated soils and (2) the potential rates of groundwater flow and contaminant migration through these soils. If the results of these analyses (see also Sections 3.2.2 and 3.2.3) suggest that further investigation of the hydraulic properties of the saturated soils is warranted, the proposed installation of monitoring wells (Section 3.2.1.2) would provide (subject to the approval of the CCC/USDA and MoDNR project managers) a basis for conducting *in situ* single-well response (“slug”) testing to obtain an estimate of the local horizontal hydraulic conductivity ( $K_h$ ) at one or more of the locations and depth intervals outlined below.

### **3.2.1.2 Installation of Permanent Groundwater Monitoring Wells**

The contaminated Morgan and MoDOT private wells penetrate to subsurface elevations of approximately 1,097 ft AMSL (60.6 ft BGL) and 1,108 ft AMSL (44 ft BGL), respectively, and are constructed to intercept groundwater from throughout the overlying saturated zone. Piezometer SB24, installed at the former CCC/USDA facility during the Phase I investigation program, is screened over the 10-ft interval at approximately 1,099-1,109 ft AMSL (50-60 ft BGL), near the base of the unit of silty clay to clayey silt, and thus corresponds roughly to the completion depths of the contaminated private wells. Piezometer SB38 is screened at approximately 1,069-1,109 ft AMSL (50-90 ft BGL), in the lower portion of the unit of silty clay to clayey silt and the underlying silty clay till unit (Table 2.1).

At each proposed Phase II location, the installation of paired shallow and deep monitoring wells is recommended. The wells will be installed by using conventional drilling methods (Section 4.2). Proposed construction of each well will employ nominal 2-in.-diameter polyvinyl chloride (PVC) casing and a standard 10-ft screen, in accord with MoDNR recommendations (MoDNR 2008, 2009) and applicable regulations for the installation of groundwater monitoring wells (MoDNR 2005). The exact depths for installation of the shallow and deep well screens at each location will be determined as part of the Phase II investigation activities. On the basis of the existing Phase I findings, however, screening of the shallow monitoring wells is tentatively recommended at an elevation of approximately 1,099-1,109 ft AMSL, to correspond with the screen interval of the SB24 piezometer and thus facilitate the determination and mapping of groundwater levels at a consistent horizon near the base of the saturated silty-clay unit (as identified beneath the former CCC/USDA facility). Because of topographic elevation differences, the 10-ft screens in the shallow wells will be set at depth intervals ranging from 32-42 ft BGL to 44-54 ft BGL. Screening of the deep monitoring wells is recommended over the 10-ft interval directly above bedrock at each proposed location (Figures 3.1 and 3.2).

The CCC/USDA-Argonne experience during the Phase I investigation and subsequent continued water level monitoring suggest that the initial infiltration of groundwater into the proposed new monitoring wells might be relatively slow. At each selected monitoring point, Argonne therefore proposes to use automatic water level sensors and data loggers to acquire continuous records of the water level fluctuations over a minimum period of one year, to

document the infiltration and possible subsequent variations in the resulting groundwater levels (Section 4.6).

### **3.2.2 Obtain Additional Information on the Vertical and Lateral Distribution and Concentrations of Carbon Tetrachloride Contamination in Groundwater in the Vicinity of the Former CCC/USDA Facility and the Contaminated Morgan and MoDOT Private Wells**

Phase I of the site characterization studies at Savannah (Argonne 2008) identified carbon tetrachloride contamination in groundwater at only four locations in the vicinity of the former CCC/USDA facility. Carbon tetrachloride levels of 3.8-6.4 µg/L were detected at locations SB24 and SB38 at the former CCC/USDA facility, as well as at 13 µg/L in the Morgan private well and 150 µg/L in the MoDOT well, located to the south and east, respectively, of the former facility.

To obtain additional information on the possible occurrence of a soil source of carbon tetrachloride contamination to the groundwater in the vicinity of the former CCC/USDA facility, the soils penetrated at proposed boring locations 1 and 7 (on the former CCC/USDA facility property) and 3 and 4 (on the MoDOT property; Figures 3.1 and 3.2) will be sampled for VOCs analyses in a vertical profile, at 4-ft intervals, from 4 ft BGL to the top of bedrock. The VOCs in the soils will be quantified through purge-and-trap sample preparation with analysis by GC-MS (discussed in Section 4.3). Boring locations 1 and 7 (Figures 3.1 and 3.2) are interpreted to lie upgradient of the carbon tetrachloride contamination in groundwater identified beneath the former CCC/USDA facility at SB24 and SB38, the Morgan private well, and possibly the MoDOT well. Boring location 3 is inferred to lie upgradient of the contaminated MoDOT well only. Boring location 4 is inferred to lie downgradient of the MoDOT well; soil sampling for VOCs analysis at this location was specifically requested by the MoDNR.

As noted in Section 3.2.1, experience during the Phase I investigation suggests that an extended time period (days to weeks) might be required for the infiltration of sufficient groundwater into the proposed new (2-in.-diameter) monitoring wells to permit their sampling for VOCs analyses. These slow accumulation rates might preclude the use of conventional well-volume purging and sampling techniques. Because of the large-diameter well casings employed in the construction of the Morgan and MoDOT private wells (Table 2.1), the volumetric purging (and subsequent disposal) of large quantities of wastewater from these wells during the Phase I field program posed logistic difficulties. In view of these conditions, Argonne is investigating

and developing alternative sampling methodologies that are more amenable to use in low-yield wells, including low-flow and “passive” (no-purge) sampling technologies. The collection and analysis of groundwater samples during Phase II of the investigation at Savannah are discussed further in Section 4.5.

**3.2.3 Investigate Further for Possible Evidence of Carbon Tetrachloride Contamination in the Subsurface (Vadose Zone) and Deeper Soils beneath the Former CCC/USDA Facility and in the Vicinity of the Contaminated MoDOT Private Well**

No carbon tetrachloride contamination was identified during Phase I in surficial or shallow subsurface soils (to a depth of 12 ft BGL) collected at 41 locations across the former CCC/USDA facility (SB01-SB41; Figure 2.1), at concentrations at or above the MRBCA DTL of 79.6 µg/kg or the quantitation limit of 10 µg/kg for analyses according to EPA Methods 5030B and 8260 B (purge-and-trap sample preparation with analysis by GC-MS). Carbon tetrachloride concentrations greater than the MRBCA DTL were identified in only two samples of deeper soils (171 µg/kg and 126 µg/kg, at 44 ft and 48 ft BGL, respectively, within the saturated zone at SB42) collected from 12 ft BGL to bedrock at four Phase I investigation locations (SB24, SB29, SB38, SB42; Figures 2.1 and 2.4).

To obtain additional information on the possible occurrence of a soil source of carbon tetrachloride contamination to the groundwater in the vicinity of the former CCC/USDA facility, the soils penetrated at proposed boring locations 1 (on the former CCC/USDA facility property) and 3 (on the MoDOT property; Figures 3.1 and 3.2) will be sampled for VOCs analyses in a vertical profile, at 4-ft intervals from 4 ft BGL to the top of bedrock. The VOCs in the soils will be quantified through purge-and-trap sample preparation with analysis by GC-MS (discussed in Section 4.3). Boring location 1 (Figures 3.1 and 3.2) is interpreted to lie upgradient of the carbon tetrachloride contamination in groundwater identified beneath the former CCC/USDA facility at SB24 and SB38, the Morgan private well, and possibly the MoDOT well. Boring location 3 is inferred to lie upgradient of the contaminated MoDOT well only.

## 4 Investigative Methods

The *PMWP* (Argonne 2007b) summarizes the anticipated range of investigative technologies, field procedures, and analytical methods that might be employed by Argonne in the characterization of former CCC/USDA grain storage facilities in Missouri. During each phase of the characterization process at a site, specific technologies and methodologies are recommended (for the approval of the CCC/USDA and MoDNR project managers) to address the identified technical objectives of the investigation program. The approved elements will then be implemented in accord with the standard operating procedures, quality assurance/quality control measures, and general health and safety policies outlined in the *PMWP*.

The proposed technical objectives and investigation tasks for Phase II of the site characterization at Savannah are in Section 3. Section 4 summarizes the site-specific approach, technologies, and methods recommended for the Phase II program. Detailed, site-specific community relations procedures and site-specific health and safety information for use throughout the CCC/USDA-Argonne program at Savannah were provided in the *Phase I Work Plan* (Argonne 2007a) approved by the MoDNR. Brief updates to these procedures and information are in Sections 5 and 6.

### 4.1 Proposed Field Sessions and Scheduling

The Phase II investigation will be conducted in one primary field session. The activities to be performed in this session will include drilling and coring of sediments for hydrogeologic characterization, installation of permanent monitoring wells, installation of automated groundwater level monitoring units at six locations, and collection of soil samples for VOCs analyses at two locations, as outlined in Sections 3.2.1 and 3.2.3. Field work during this session will be conducted on a 10-days-on, 4-days-off cycle, until the required tasks are completed.

Efforts will also be made during the field session to recover groundwater samples for VOCs analyses from the investigative borings, the proposed new monitoring wells, existing piezometers SB24 and SB34, and the Morgan and MoDOT private wells (Section 3.2.2). If the identified conditions at the investigation site preclude groundwater sampling at these points in a timely manner, however, alternative groundwater sampling technologies might be implemented (subject to the approval of the CCC/USDA and MoDOT project managers). In that case, one or more additional field sessions might be needed to complete the groundwater sampling tasks.

Groundwater level data accumulated by the automatic water level sensors and data loggers installed during both the Phase I and Phase II investigations at Savannah will be retrieved quarterly.

## **4.2 Methods for Drilling and for Collecting and Logging Soil Core Samples**

At each boring location identified in Section 3.2.1.1, core samples will be obtained (to the extent possible) for determination of the lithologies present and their stratigraphic distribution, identification of potential hydrostratigraphic zones, and possible sampling for VOCs or physical property analyses. The soil boring and coring tasks will be performed by using a sonic drilling rig and a crew licensed for operation in Missouri per state requirements (*PMWP*, Argonne 2007b, Section 6.4.1.3). All cores will be logged in accord with the *PMWP* (Argonne 2007b, Sections 4.3.1.3 and 6.4.1.5) and will be archived upon completion of the Phase II field program at an Argonne facility for future reference.

## **4.3 Sampling and Analysis Methods for Soils**

At proposed boring locations 1 and 3 (Section 3.2.1), soils will be sampled for VOCs analyses at 4-ft depth intervals, in a vertical profile from an initial depth of 4 ft BGL to the top of bedrock. Samples from additional depths within the cored interval at each boring location will be collected, if necessary, to adequately represent any significant variations observed in the lithologies penetrated.

Soil samples for the determination of VOCs will be placed immediately in jars, sealed, preserved on dry ice, and shipped by overnight service to the Applied Geosciences and Environmental Management (AGEM) Laboratory at Argonne National Laboratory for analysis by the purge-and-trap sample preparation method with analysis by GC-MS (EPA Methods 5030B and 8260B; *PMWP*, Argonne 2007b, Sections 6.1.1, 6.2, and 6.3.1). At selected locations and depth intervals to be determined in the field, soil materials will also be collected from the cores for the laboratory measurement of soil properties including particle size distribution, moisture content, porosity, bulk density, permeability, and total organic carbon (*PMWP*, Argonne 2007b, Sections 6.1.1 and 6.3.1).

If the results of these analyses (see also Sections 3.2.2 and 3.2.3) suggest that further investigation of the hydraulic properties of the saturated soils is warranted, *in situ* single-well response (slug) tests might be performed (subject to the approval of the CCC/USDA and MoDNR project managers) at one or more of the proposed new monitoring wells to obtain an estimate of the local  $K_h$  value. If required, well response testing will be conducted in accord with the *PMWP* (Argonne 2007b, Section 6.7.3) by using either the casing air pressurization method or a physical slug of appropriate size to perturb the initial static groundwater level within each well under investigation.

#### **4.4 Methods for the Construction of Monitoring Wells**

Monitoring wells will be installed and developed in accord with the procedures in the *PMWP* (Argonne 2007b, Sections 6.4.3 and 6.4.5) and MoDNR regulatory requirements (MoDNR 2005). Each well will be constructed by using 2-in.-diameter, Schedule 40 PVC casing with a maximum screened interval of 10 ft. The installation of the monitoring wells as nested pairs of shallow and deep wells is anticipated. The wells will be constructed as either flush-mount or aboveground completions, as requested by individual property owners.

Any boreholes advanced during the Phase II investigation that are not completed as monitoring points will be abandoned in accord with MoDNR requirements (MoDNR 2005; *PMWP*, Argonne 2007b, Section 6.4.7).

#### **4.5 Sampling and Analysis Methods for Groundwater**

Groundwater samples collected from the Morgan and MoDOT private wells (and other private wells at Savannah) during the Phase I investigation were obtained by the use of a conventional, well-volume purge technique in accord with the *PMWP* (Argonne 2007b, Section 6.1.2). This approach generated very large quantities of wastewater (several thousand gallons) because of the large-diameter construction employed for private wells in the Savannah area. Furthermore, the recovery to static groundwater levels in several of the wells was very slow, taking days to weeks (Argonne 2008). The conventional well-volume purge technique could not be used effectively for sampling of piezometers SB24 and SB38 because of the very slow rates of groundwater accumulation observed in the (1-in.-diameter) casings at these locations. In responding to these Phase I findings, the MoDNR has therefore recommended that

alternative purging and sampling techniques be considered for the (existing and potential) low-yielding wells at this site during the Phase II study (MoDNR 2008).

Since completion of the Savannah Phase I program, Argonne has developed a standard operating procedure (SOP) for the collection of groundwater samples for geochemical and VOCs analyses through use of a low-flow purging and sampling technique. The SOP (attached as Appendix A) was developed in accord with guidance for the use of this approach promulgated by the EPA and the Kansas Department of Health and Environment and is now the required method for use by the CCC/USDA and Argonne for routine groundwater sampling in Kansas. Argonne's analytical results for groundwater samples collected with this approach have met applicable Argonne and Kansas quality assurance/quality control standards (*PMWP*; Argonne 2007b, Section 4.2), while greatly reducing purge volume requirements in comparison to the traditional well-volume purge technique.

The CCC/USDA and Argonne therefore recommend that the low-flow purging and sampling technique be considered for the collection of groundwater samples in Phase II of the investigation at Savannah. To provide a quantitative basis for evaluation of this technique, we propose to sample the Morgan and MoDOT wells and piezometer SB38 initially by using both the low-flow and well-volume purge methods. The results of these comparative tests will be discussed with the CCC/USDA and MoDNR project managers; if the results of the analyses prove acceptable on the basis of the existing quality criteria established for Argonne's investigations (*PMWP*; Argonne 2007b, Section 4.2), Argonne will attempt to use the low-flow methodology for the remainder of the proposed groundwater sampling effort at Savannah.

If groundwater accumulation rates in the proposed new Phase II monitoring wells are insufficient to facilitate use of either the well-volume purge or low-flow sampling techniques in an effective and timely manner, Argonne will present a supplemental recommendation to the CCC/USDA and MoDNR project managers for the possible use of an alternative, passive (no-purge) sampling methodology to address the identified Phase II sampling objectives. Argonne is presently conducting an internal technical review of passive technologies that are suited for use in low-yield wells (ITRC 2006, 2007).

Measurements of pH, temperature, specific conductivity, dissolved oxygen, oxidation-reduction potential, and reduced iron ( $\text{Fe}^{2+}$ ) will be made for all groundwater samples collected during the Phase II investigation by using calibrated field instruments and appropriate field test

kits in accord with the manufacturers' instructions. Water samples collected for the determination of VOCs will be preserved and shipped (on ice at 4°C) by overnight service to the AGEM Laboratory for quantitation by the purge-and-trap sample preparation method and analysis by GC-MS (EPA Methods 5030B and 8260B; *PMWP*, Argonne 2007b, Section 6.3.2). To ensure reproducibility, a minimum of 10% of the water samples will also be selected for verification analysis by a second laboratory (TestAmerica Laboratories, South Burlington, Vermont) with the EPA's Contract Laboratory Program methods. An index of the EPA methods is online (<http://www.epa.gov/epahome/index/>).

## **4.6 Water Level Monitoring**

Groundwater levels will be monitored continuously in the proposed new monitoring wells by using programmable downhole pressure sensor and data logging units (Instrumentation Northwest PT2X™ devices). The new data loggers will be programmed to record one measurement every 4 hr, to coincide with the measurements currently being collected in the Phase I water level monitoring network (Section 2.2). The data loggers in the new wells will initially be downloaded after approximately one month to verify their operation; data will then be retrieved quarterly from the complete network of Phase I and Phase II monitoring points. Automated monitoring is recommended for a minimum of one year in the combined Phase I and Phase II well network, to document the initial accumulation of groundwater at each new (Phase II) monitoring point and any subsequent seasonal or longer-term variations in the water levels (*PMWP*, Argonne 2007b, Section 6.4.6.3).

## **5 Community Relations Plan**

The detailed community relations plan in the MoDNR-approved Phase I *Work Plan* (Argonne 2007a) describes the background of the Savannah community and outlines the site-specific community relations objectives and activities to be implemented by the CCC/USDA and Argonne throughout all phases of the site investigation program at Savannah.

An updated contact list of key officials for use during execution of this work plan for the Phase II investigation at Savannah is in Table 5.1.

## **6 Health and Safety Plan**

The general health and safety plan for use at Savannah is in Section 3 of the *PMWP* (Argonne 2007b). The general plan addresses all anticipated safety issues for the activities to be conducted. Specific emergency information for use at Savannah is in Figure 6.1 and Table 6.1.

**Andrew County has 911 service for all emergency responses.** The Andrew County Ambulance District office, which responds to 911 calls, is located in Savannah. Major medical services are provided by the Heartland Regional Medical Center in St. Joseph, Missouri, approximately 16 mi south of Savannah (Figure 6.1).

Savannah has a local medical clinic, located within 2 mi of the former CCC/USDA grain storage facility, that is open from 8 a.m. to 5 p.m. on weekdays. The city is also served by municipal police and fire departments and is the site of the Andrew County Sheriff's Office.

## 1.0 Scope and Applicability

The purpose of this SOP is to establish a method for low-flow groundwater purging and sampling of monitoring wells. The objective of groundwater sampling is to generate reproducible, representative, verifiable, legally defensible data for concentrations of chemicals in groundwater. Monitoring wells are purged before sampling because water in the well casing is not considered representative of formation water in the aquifer (Puls and Barcelona 1996; Yeskis and Zavala 2002).

Purging a large volume or an arbitrary number of “well volumes” increases the pumping radius of influence in the aquifer and leads to analytical results for a sample that represents an average value in a large volume of water. Purging at rates in excess of site hydrogeologic conditions (1) causes excessive drawdown in the well; (2) pulls stagnant water into the screened interval; (3) mixes chemically distinct waters; and (4) causes aeration, turbulence, and redevelopment of the well. In thin or narrow contaminant plumes (which are common), the mixing of chemically distinct waters can result in dilution and yield misleading data concerning contaminant concentrations and concentration gradients. High-volume purging is time-consuming and costly, and it results in the generation of large volumes of potentially contaminated water that must be managed as investigation-derived waste.

Low-flow (also called low-stress) purging and sampling addresses the problems associated with historical large-volume well purging practices. “Low-flow” refers to the velocity at which water enters the pump intake from the formation water in the immediate vicinity of the well screen. The major objective of low-flow purging is to minimize stress by keeping the pumping rate consistent with the natural flow rate of groundwater in the aquifer or water-bearing zone.

## 2.0 Responsibilities

The field project manager, or another designee of the AGEM program manager, is responsible for

- Verifying that the personnel implementing this SOP understand the procedure and are capable of implementing it correctly and
- Overseeing all groundwater sampling and ensuring that it is performed in accordance with the *Master Work Plan*, the project-specific sampling plan, and this and other SOPs.

Personnel conducting the field sampling are responsible for

- Implementing this SOP as directed;
- Collecting, handling, and shipping samples in accordance with applicable SOPs; and
- Recording all pertinent data on the AGEM Low-Flow Groundwater Purging and Sampling Record (Attachment 1).

### **3.0 Health and Safety**

General health and safety guidelines are in the *Master Work Plan*, Section 3. Site-specific health and safety information is issued in a site-specific health and safety plan for each field project.

Low-flow groundwater sampling requires Level D personal protection. Specific health and safety hazards include the following:

- Slips, trips, and falls at well locations.
- Dermal exposure to potentially contaminated groundwater.
- Possible injuries to arms, shoulders, and back resulting from transport of equipment to and from well locations with insufficient attention to good ergonomic practice.
- Weather-related heat or cold stress.

### **4.0 Method Summary**

Before sampling, measure the groundwater level in each well and the well depth.

Implement low-flow groundwater sampling techniques according to U.S. Environmental Protection Agency guidelines (Puls and Barcelona 1996; Yeskis and Zavala 2002) by using a bladder pump and appropriate field equipment to determine when representative formation water is entering the well casing during pumping.

Periodically measure static water levels and monitor the levels of pH, temperature, specific conductivity, oxidation-reduction potential (ORP), and dissolved oxygen (DO), in order to determine when a sample representative of formation water can be collected.

### **5.0 Procedure**

#### **5.1 Supplies Needed**

- Electronic water level indicator and weighted tape with marked intervals of 0.01 ft for measuring the depth to water.
- Submersible or bladder pump with adjustable rate control.
- Generator and extension cord.
- Polyethylene tubing.

- Multi-parameter meter with flow-through cell, graduated container, stop watch, and calculator for measuring flow.
- AGEM Low-Flow Groundwater Purgung and Sampling Record (Attachment 1) and indelible pen.
- Sample containers, sample labels, and chain-of-custody forms.
- Decontamination equipment and supplies.
- Disposable gloves, resealable bags, and garbage bags.
- Shipping container and ice packs.
- Drum or container for purged water.
- Well keys.
- Map of well locations and summary of well construction details.

## **5.2 Preparations before Sampling**

1. Assemble all equipment and supplies; ensure that they are clean and in working order. Calibrate field meters. Load vehicle with equipment and supplies needed for the planned sampling event.
2. Prepare and organize sample containers for each well site. Prepare waterproof sample labels containing the following information:
  - a. Site identifier
  - b. Well location identifier
  - c. Date and time of collection
  - d. Type of analysis
  - e. Unique sample identification number
3. If necessary, place plastic sheeting on the ground around the well to keep the sampling equipment clean.
4. Position sampling equipment and field instruments.

5. Check the condition of the well for damage or evidence of tampering. Unlock the wellhead. Record location, time, date, and other appropriate information on the AGEM Low-Flow Groundwater Purgung and Sampling Record (Attachment 1).
6. Check the known well construction data to determine the screen interval and to calculate the volume of water in the well casing.

### **5.3 Step-by-Step Implementation**

1. Measure the static water level in the well with an electronic water level meter.
2. Measure the total depth of the well.
3. Slowly insert the bladder pump into the well to a depth midway between the top and bottom of the screen. Keep the pump above the bottom of the casing to minimize disturbance of the solids that are typically present at the bottom of a well. If the water depth in a well is inadequate to cover the screen interval, then the AGEM program manager will determine a suitable depth for the bladder pump intake.
4. Set the pumping rate for the bladder pump to minimize drawdown during pumping. Monitor the rate by measuring the static water level periodically throughout pumping.
5. Use polyethylene tubing to connect the bladder pump to an in-line flow cell that continuously measures formation parameters including pH, temperature, specific conductivity, ORP, and DO in the in-line flow cell during pumping. Record measurements every 4 min, until three successive measurements for each parameter are within a range indicating that the formation water is stable. The ranges for formation stabilization for the specific parameters are as follows:
  - a. pH, within 0.1
  - b. Temperature, within 3%
  - c. Specific conductivity, within 3%
  - d. ORP, within  $\pm 10$  mV
  - e. DO, within  $\pm 0.3$  mg/L
6. After stabilization of the formation water parameters occurs, disconnect the polyethylene tubing from the in-line flow cell, and pump the representative groundwater sample through the tubing and into laboratory-approved containers.

7. Keep the polyethylene tubing for each well and dedicate it for reuse at that well. Record pumping rate data for each well as a reference for subsequent sampling events.

#### **5.4 Field Quality Control**

1. Begin sampling at well locations with the least contamination; proceed systematically to the wells with the most contamination.
2. Fill the sample containers for volatile organic compounds (VOCs) analysis first. Visually check these containers to ensure that no bubbles are present.
3. Fill sample containers for additional analytes, as required by the site-specific sampling plan, in the following order:
  - a. Methane
  - b. Semivolatile organic compounds
  - c. Inorganics and water quality parameters
4. Temporarily place all samples in a cooler with ice immediately after collection. Verify that all sample types required for the well are present.
5. Verify that all information required on sample labels and field forms is complete and that the well is locked and secured, before proceeding to the next well location.
6. Decontaminate sampling equipment between wells.
7. Collect quality control samples as appropriate, including field blank, equipment rinsates, trip blanks, replicates, and verification samples.
8. Document adherence to this SOP by completing the AGEM Low-Flow Groundwater Purging and Sampling Record (Attachment 1).
