Water Supply at Los Alamos During 1977

William D. Purtyman

WATER SUPPLY AT LOS ALAMOS DURING 1977

by

William D. Purtyman

NOTICE

This report was prepared by the Los Alamos Scientific Laboratory, a Division of the University of California, for the U.S. Department of Energy. This work was performed under the auspices of the U.S. Department of Energy by the Los Alamos Scientific Laboratory, a Division of the University of California. The views expressed herein do not necessarily represent the position or policies of the U.S. Department of Energy or the University of California. Mention of trade names or commercial products does not constitute endorsement by the U.S. Department of Energy or the University of California.

ABSTRACT

The Los Alamos water supply for 1977 consisted of 1474×10^6 gal from wells in three fields and 57×10^6 gal from the gallery in Water Canyon. The production from the well fields was at its lowest volume since 1970. Water-level trends were as anticipated under current production practices. Well rehabilitation should be continued to ensure an adequate and reliable supply from wells that are 10 to over 25 yr old.

I. INTRODUCTION

This report summarizes pumpage and aquifer conditions for wells in the Los Alamos, Guaje, and Pajarito well fields (Fig. 1). These wells supply most of the water used for municipal and industrial purposes in Los Alamos. The gallery in Water Canyon that supplies the balance to the system is also discussed. This report is a joint effort between Group H-8 of the Los Alamos Scientific Laboratory (LASL) and the Utilities and Engineering Division of the Zia Company (Zia U/E). Its purpose is to ensure a continuing historical record and to provide guidance for management of water resources and long-range planning for the water supply system. One summary report and six annual reports have been issued as the result of these studies.¹⁻⁷ The eighth report extrapolates water-level trends in the well fields to 1983 under current production.⁸

The Zia U/E, the Department of Energy (DOE) support contractor at Los Alamos, maintains and operates the water supply system. Water is pumped from wells, through transmission lines, and lifted by booster pumps into reservoirs for storage and distribution to the community and Laboratory areas

(Fig. 1). Water from the gallery flows by gravity through a microfilter station and is pumped into one of the system reservoirs for distribution. Zia U/E maintains monthly records of hours of operation on each well, along with daily and monthly production records. Monthly average nonpumping and pumping water levels are computed from air-line pressure data recorded continuously at each well. These data provide input for calculating pumping rates, drawdown (difference between nonpumping and pumping water levels), specific capacity (pump rate per unit drawdown), and other well-field statistics included in this report.

Hydrographs have been prepared for one observation well, one standby supply well, 15 supply wells, and the gallery in Water Canyon. The hydrographs for the wells show annual average nonpumping and pumping water levels, specific capacity, and annual pumpage for the years during which the wells have been in production. The hydrograph for the gallery presents annual production and the annual average discharge rate. Appendixes A and B contain basic pumping and production information for each supply well, monthly for 1977 and annually for the period of record.

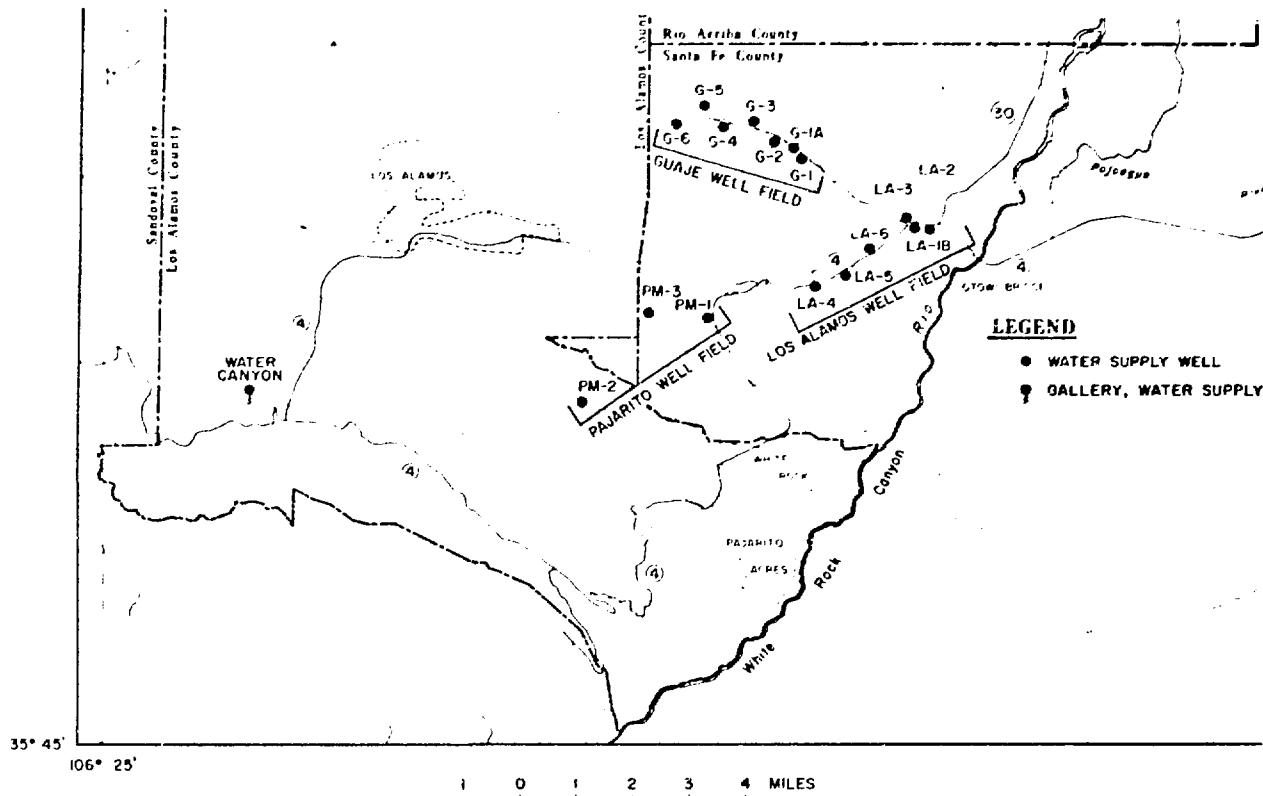

Fig. 1.
Location of well fields, supply wells, and gallery water supply.

II. WELL-FIELD CHARACTERISTICS

Production from the three well fields decreased 217×10^6 gal from 1691×10^6 gal in 1976 to 1474×10^6 gal in 1977 (Table I). The production declined to its lowest point since 1970 in spite of a larger number of residents, as represented by the completion of 140 housing units in Los Alamos and 117 units in White Rock. This decline was partly because of early summer rains, which reduced demand for lawn irrigation, and partly because of conservation by residents of Los Alamos County, possibly encouraged by increased water rates. The decline was accompanied by a relative shift in area of demand. Production into Los Alamos from the Los Alamos and Guaje Fields decreased only 14×10^6 gal, whereas that in White Rock from the Pajarito Field decreased 203×10^6 gal. Water production in 1977 fell below the projected demand by 620×10^6 gal (Fig. 2).*

The peak demand period in 1977 was for the 19 day period of May 31 through June 18 when pumping was about 149×10^6 gal, or 7.8×10^6 gal/day. Voluntary reduction of water use by the residents ended the peak demand period during the La Mesa fire, in order to maintain maximum storage for fire protection. The production decreased 4×10^6 gal/day when the emergency was announced. Daily production during the 19 day period exceeded 10×10^6 gal for 2 days, 9×10^6 gal for 4 days, and 8×10^6 gal for 4 days. During the remaining 9 days, production was less than 8×10^6 gal/day. In comparison, the peak demand period in 1976 was for 32 days when production was 299×10^6 gal for an average of 9.4×10^6 gal/day. During this period, the production exceeded 10×10^6 gal/day for 14 days, 9×10^6 gal/day for 9 days, and 8×10^6 gal/day for 4 days. During the remaining 5 days, production was less than 8×10^6 gal/day.

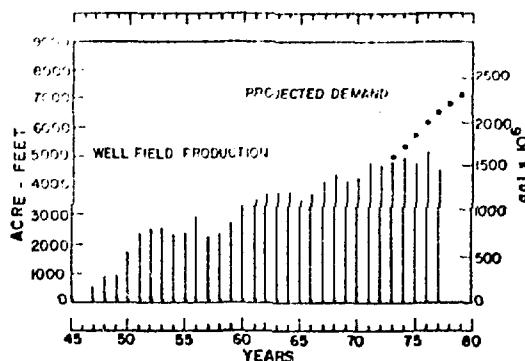

Fig. 2
Well-field production 1947-77 and projected demand 1973-79.

The heaviest demand for water in 1977 was in May, June, and July, when about 578×10^6 gal were used, representing about 38% of the total production of 1977. The months of least demand were December, January, and February, when production was 260×10^6 gal, representing about 17% of the total production. Water levels in the wells fluctuated with pumpage. The highest water levels were during the months of least pumpage (December, January, and February), whereas lowest water levels were during months of greatest pumpage (May, June, and July).

Total production from the well fields and gallery since 1947 has been $34\ 765 \times 10^6$ gal. Of this, the wells have produced $33\ 076 \times 10^6$ gal, or 95% (Table I). The annual production, per cent pumpage by field, and per cent of pumpage of individual wells are given in Table II. The average annual pumping rate for individual wells for the period 1973 through 1977 is shown in Table III.

A. Los Alamos Field

The Los Alamos well field is composed of six supply wells and one observation well. The production in 1977 was from five supply wells; the sixth is on standby status for emergency use only.¹⁰ Pumpage from the field increased by 2×10^6 gal, from 343×10^6 gal in 1976 to 345×10^6 gal in 1977. The field produced about 22% of the total for the year (Table II).

Pumpage from the individual wells increased only slightly above the 1976 productions. The water levels in wells LA-1, LA-1B, LA-2, LA-3, LA-4, and LA-5 varied slightly, but did not change significantly (Figs. 3 through 8, respectively).

Well LA-6, on standby status, was pumped only three times during the year for testing and maintenance of the pump. About 1.7×10^6 gal of water was pumped to waste during the year. The restricted use of the well has resulted in higher water levels in 1977 than in 1975 or 1976 (Fig. 9). The water levels in LA-6 rose about 14 ft during the year, whereas in the upper portion of the field (LA-4 and -5) there was no significant change (Fig. 1). In the lower part of the field (LA-1, -1B, -2, and -3), the average water level decline was about 2 ft.

The average annual pumping rate from the five producing wells in the field declined about 27 gpm from 2124 gpm in 1976 to 2097 gpm in 1977. The largest decline occurred at Well LA-1B (Table III). It appears that the meter may have been reading 3 to 5% low, which would account for the decreased pumping rate. If this is so, production for the year would be about 4×10^6 gal greater than reported. The specific capacities of the five producing wells also showed no significant change in 1977 from 1976 data.

B. Guaje Well-Field

The Guaje well field is composed of seven wells (Fig. 1). The pumpage from the field decreased 16×10^6 gal from 531×10^6 gal in 1976 to 515×10^6 gal in 1977 (Table I). The field produced 34% of the total production (Table II). The pumpage declined in all wells except G-4 where pumpage increased 15×10^6 gal above the pumpage of 1976.

There was no significant change in annual average nonpumping levels in wells G-1, -1A, -2, -3, -4, -5, and -6 (Figs. 10 through 16, respectively) when compared to 1976 water levels. The pumping level in well G-1 shows a continuing decline accompanied by a continuing decrease in specific capacity (Fig. 10). Rehabilitation of the pump and well was performed in early 1977. The intake of the pump was set 20 ft higher at 500 ft, about 4 ft above the reduction of the casing from 12 to 10 in., to allow free intake of water to the pump. Cleaning the casing and removal of

sediments from the well did not improve the specific capacity. The decline in the nonpumping water level and specific capacity results from interference by the nearby well G-1A.

The pumping level in well G-4 declined with increased pumpage, whereas the nonpumping level remained about the same (Fig. 14). As the pumping rate was decreased, the specific capacity did not change significantly.

The average annual pumping rate from the field decreased about 42 gpm from 2991 gpm in 1976 to

2949 gpm in 1977. The rates from individual wells during 1977 were only slightly different than in 1976 (Table III). The pumping rate of well G-6 has been reduced to keep the pumping level above the top of the pump. The specific capacity of the well has remained about the same; however, inspection of sand samples indicates some metal, line shaft, or pump wear.

C. Pajarito Well Field

The Pajarito well field is composed of three wells (Fig. 1). The pumpage from the wells decreased 203×10^6 gal from 817×10^6 in 1976 to 614×10^6 gal in 1977. The decreases in individual wells were 1.4×10^6 gal from PM-1, 169.2×10^6 gal from PM-2, and 32.8×10^6 gal from PM-3. The field produced 40% of total production (Table II).

Water levels remained about the same as in 1976 in wells PM-1, -2, and -3 (Figs. 17 through 19, respectively) in spite of the decrease in pumpage. The average annual pumping rate from the field declined about 13 gpm from 3386 gpm in 1976 to 3373 gpm in 1977. This change was not considered significant, as the largest decrease (15 gpm) occurred at PM-1 and was the result of a change in back pressure in the transmission line when PM-3 was

pumping. The pumping rate of PM-2 increased slightly, while the rate of PM-3 decreased (Table III). There were no significant changes in specific capacities in the three wells.

III. WATER CANYON GALLERY

Production from the gallery in Water Canyon increased 16×10^6 gal from 41×10^6 gal in 1976 to 57×10^6 gal in 1977 (Table I). The production for 1977 was the highest since 1970 (Fig. 20). The discharge from the gallery was over 100 gpm during 1977. Recharge to the gallery is from precipitation on the flanks of the mountains west of the gallery. The gallery produced about 4% of the total supply to Los Alamos during 1977.

The gallery was rehabilitated in late 1977. Retaining walls were built outside the tunnel and the tunnel support was strengthened. The collection basin was rebuilt to collect all of the ground water discharge.

IV. SUMMARY AND RECOMMENDATIONS

Well-field operations in 1977 were very satisfactory. Production from the three well fields declined about 217×10^6 gal from 1976 to 1977. Water levels in wells in the Los Alamos, Guaje, and Pajarito fields were as expected under current production.

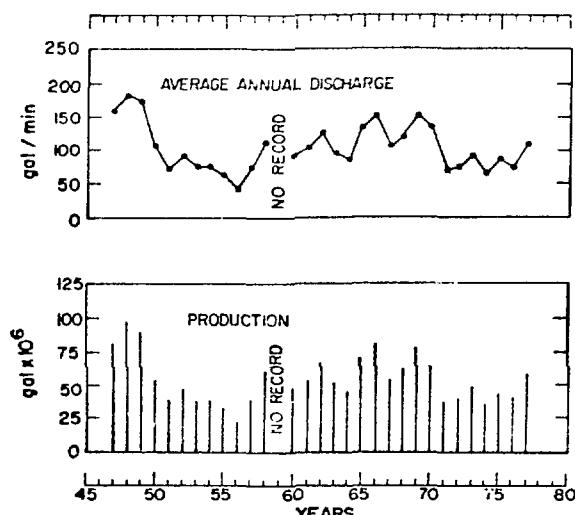

Fig. 20.

Annual average discharge and annual production from the gallery in Water Canyon.

The production from the well fields fell to the lowest level since 1970. This was a unique year in terms of timing of precipitation and other factors and should not be construed to mean that additional wells are not needed for the system. There has been, and will continue to be, expansions of LASL facilities and increases in population and housing in the county that will require additional water. Even at the present time an exceedingly dry year or loss of a high yield well during peak demand period could result in a shortage of water. In planning, consideration must be given to the 18–24 month delay between the start of construction of a well and the time when it is complete and can be added to the system.

Rehabilitation of wells by removing sediment accumulation, additional development, and repair of casing and pumps should be continued. Ten of the 15 wells in use are more than 25 yr old; thus rehabilitation of these wells is necessary to maintain the already established system.

Wells that should be considered for rehabilitation are G-6, PM-2, and LA-5. The pump was pulled from well G-6 in 1972 and about 45 ft of sediments were removed from the well. The pumping rate has been reduced from about 378 gpm in 1972 to 307 gpm to control the entry of sand into the well. Metal collected in the sand sampler indicates wear on line shaft or pump. About 6×10^6 gal of water is pumped to waste at the start of the pumping period to keep the sand out of the main transmission line. Consideration should be given to installation of a filter or line to the sand trap at Booster Station 1 to utilize the water pumped to waste.

Well PM-2 is a high yield well that has been in operation since 1966. The pumping characteristics indicate no problems with the pump; however, the period of operation (35 000 h), as recommended life of pump by the manufacturer, has been exceeded. As the well is a high-yield producer ($\approx 18\%$ of total production), the pump should be pulled for inspection.

Well LA-5 was pulled for inspection in 1962. Pumping rates have declined from about 480 gpm to 468 gpm since that period, with only a slight change in specific capacity. Zia U/E reports that a larger line shaft is needed to keep the pump in adjustment and that the motor needs to be rewound from 125 to 150 hp, as the motor is presently drawing 152 to 155A on a 150A rating.

Zia U. E recommends the following: (1) the motor on well G-1A should be rewound from 150 to 175 hp, as the motor is drawing 170A on a 170A rating, (2) electric starters on pump motors on wells in the Los Alamos and Game Fields and on pump motors in the Los Alamos booster stations should be replaced as they have had extended service, are obsolete, and when repairs are needed, parts are not available.

ACKNOWLEDGMENTS

Pumping statistics were compiled by Glenn Bryant (Zia U.E), Max Maes (H-S), and Charlene Wardlow (H-S). Computer processing of data was handled by Ron Griego (H-12).
