ABSTRACT

A selected annotated bibliography of 521 references was prepared as a part of a feasibility study of the extraction of uranium from seawater. For the most part, these references are related to the chemical processes whereby the uranium is removed from the seawater. A companion document contains a similar bibliography of 471 references related to oceanographic and uranium extraction plant siting considerations, although some of the references are in common.

The bibliography was prepared by computer retrieval from Chemical Abstracts, Nuclear Science Abstracts, Energy Data Base, NTIS, and Oceanic Abstracts.

References are listed by author, country of author, and selected keywords.

CHAPTER 1

INTRODUCTION

1.1 PURPOSE AND SCOPE

This document contains results obtained in a U. S. Department of Energy (DOE) project sponsored through Bendix Field Engineering Corporation (BFEC). The project was a joint effort between Exxon Nuclear Company, Inc. (ENC) and Oregon State University (OSU).

This document, the second of two volumes, contains selected bibliographic information used in the preparation of Volume I of XN-RT-15 and OSU-NE-7901, "Extraction of Uranium from Seawater: Chemical Process and Plant Design Feasibility Study." Both of these documents are closely related to two other documents, which were also an important part of the same study:

XN-RT-14, Volume I:

"Extraction of Uranium from Seawater: Evaluation of Uranium Resources and Plant Siting" by Michael R. Rodman, Louis I. Gordon, and Arthur C-T. Chen.

XN-RT-14, Volume II:

"Selected Bibliography for the Extraction of Uranium from Seawater: Evaluation of Uranium Resources and Plant Siting" by Arthur C-T. Chen, Louis I. Gordon, Michael R. Rodman, and Stephen E. Binney.

These documents constitute part of the low-level uranium resource study conducted by DOE/BFEC as part of the National Uranium Resource Evaluation (NURE) program.

1.2 COMPILATION METHODOLOGY

A total of 521 references from various countries are included in this bibliography. For the most part, these citations are related to the chemical processes which have been investigated to extract uranium from seawater.

The literature search for this project was performed mainly through the OSU Library Information Retrieval Service (LIRS) and the USDOE Technical Information Center RECON system at Oak Ridge, Tennessee.

LIRS provides on-line bibliographic searching through remote access terminals. These terminals connect with information retailers such as Lockheed Information Systems and Systems Development Corporation. LIRS directly retrieves information from a number of indices and directories specially programmed for retrieval by computer. These data bases cover agriculture, the biological sciences, business, chemistry, education, engineering, the earth science, physics, psychology, and the social sciences. Computer search has the advantages of specificity and comprehensiveness. Through text-searching and Boolean logic, the searcher may specify search parameters by coordinating subjects, authors, time periods to be covered, etc. Also, direct access to data bases allows the search to interact with the system to augment or alter the search strategy. Another advantage of this search is the immediate retrieval of information, typically from 10 to 20 minutes, as opposed to a number of days of equivalent manual searching. The printout consists of a computer-produced bibliography with citations which can be displayed in various formats on-line, or printed off-line.

The RECON system was accessed off-line to information in a similar fashion to that obtained from LIRS.

The search may be comprehensive or specific, and it may involve several data bases. Many of the data bases in LIRS cover only the last four to five years of the literature. The data bases considered most appropriate for the LIRS search were Chemical Abstracts, Oceanic Abstracts and the National Technical Information Service (NTIS). Chemical Abstracts were searched for three data bases arranged according to year, namely, 1970-71, 1972-76, 1977-78. The Oceanic Abstracts and NTIS searches included information from 1964 to 1977 and 1964 to 1978, respectively. In the RECON search, the data bases accessed were Nuclear Science Abstracts (1966-1976) and Energy Data Base, including Atomindex (1976-1978).

As mentioned above, text searching was done by Boolean logic. Search parameters were specified by combining keywords or descriptors that are related to the subject of interest. The computer searched through the title words, corporate sources, index terms and sometimes abstracts of the articles in the different data bases selected, retrieved

and printed out according to the format chosen those articles containing the specified search parameters.

In the LIRS search, information was retrieved from Oceanic Abstracts and NTIS by using the following combinations of keywords:

(uranium or titanium) and (seawater or ocean- or river water(s) or estuar- or algae or kelp or sewage or phytoplankton or plankton or marine organism(s)) and (234 or 235 or 238 or isotope(s) or reactor(s) or U234 or U235 or U238) but not (corrod- or corrosion).

The Chemical Abstracts 1977-78 data base was searched using the same descriptors together with the Chemical Abstracts' sections on extractive metallurgy (CA054) or water [reviews (CA061000), source (CA061001), and analysis (CA061002)], but without (234 or 235 or 238 or U234 or U235 or U238 or reactor(s) or isotop- or corrod- or corrosion).

The keywords used to search the other two Chemical Abstracts data bases were limited to:

(uranium or U or U308 or U02) and (seawater or ocean- or river water(s) or estuar- or algae or kelp or sewage or phytoplankton or plankton or marine organism(s) but without (234 or 235 or 238 or U234 or U235 or U238 or reactor(s) or isotop- or corrod- or corrosion or sediment(s)).

The word titanium was excluded to be more specific about the main subject of the literature search.

As bibliographic information and actual reprints and copies of articles were acquired, the appropriate bibliographic data were entered into the FAMULUS bibliographic data management system available through the Oregon State University Computer Center. This system provided the capacity for entry and storage of the bibliographic data, editing capability, listing and numbering after sorting (in this case by alphabetical order of authors), indexing according to keywords and other descriptors, and finally printing out in useable format the data list and indices which comprise Chapters 2 and 3 of this report. A sample of one bibliographic entry and listing by FAMULUS is shown and described in Section 1.3.

1.3 EXPLANATION OF FORMAT

Included below is a sample bibliographic entry found in Chapter 2:

107 AUTH Davies,R.V.; Kennedy,J.; McIlroy,R.W.; Spence,R.; and
Hill,K.M.
DATE 1964

TITL Extraction of uranium from sea water.
 CITA Nature 203: 1110-1115 (1964).
 COUN UK
 AREA Menai Straits, Portland Harbour
 ABST A summary of the program to separate uranium from sea water by continuous counter-current extraction is presented.
 KEY extraction, uranium, seawater, plant design, concentration, chemical species

Each reference has an identification number (107 in the example above) internal to this bibliography. Each reference is further identified by eight field descriptors as follows:

AUTH The authors of the reference are listed as cited (in this example, Davies, Kennedy, McIlroy, Spence, and Hill). Section 3.1 contains an index which sorts all of the bibliographic entries alphabetically by the last name of all the authors of each of the references.

DATE This field descriptor refers to the year in which the reference was published (1964, for this citation).

TITL This refers to the title of the bibliographic entry as published.

CITA Listed in this entry is the journal or technical report citation. For example, the article entitled "Extraction of Uranium from Sea Water" was published in Nature, volume 203, pages 1110 to 1115, in 1964. If the citation was in a language other than English, it is so indicated.

COUN The country listed refers to the country of the authors. This entry was included because so much of the work on the extraction of uranium from seawater has been performed in countries other than the United States. Section 3.2 contains a sorting of the bibliographic entries by country of the author.

AREA The geographical area in which the work was performed is included, if it pertains specifically to a certain oceanic region. In the example shown, reference was made to studies in the Menai Straits of Wales and Portland Harbour, England.

ABST An annotation is included for each reference. Often this is the abstract as found in the particular abstracting source from which the citation was obtained.

KEY Keywords are included in order to provide sortings of the bibliographic entries according to subject material. If not already listed in the abstracting source, keywords were added

to represent the important topics covered in the reference. A sorting of the bibliographic entries according to keyword is included in Section 3.3.

1.4 ACKNOWLEDGEMENTS

This work was performed for DOE/BFEC with Mr. Owen Kingman, BFEC, serving as Contract Manager and providing many helpful suggestions during the course of this work.

The authors would also like to extend special thanks for the valuable assistance given them by the following individuals: Mr. Paul Oman and Mr. Robert Baker, for their assistance in running the FAMULUS program; Ms. Kris Brooks, for performing the computerized literature searches at OSU; Dr. Arthur Chen and Dr. Louis Gordon, for their overall collaboration on this project as consulting investigators; and Ms. Mary Knower, for her assistance in entering the bibliographic data into FAMULUS.

CHAPTER 2

BIBLIOGRAPHIC LISTING

The selected bibliography for this portion of the project is listed in this section in alphabetical order according to the last name of the first author of each entry. A sample format is shown in Section 1.3.

- 1 AUTH Abrao, A.; Franca, J.M.Jr.
DATE 1970
TITL Pilot plant for purification of uranium by ion exchange in IEA operations.
CITA Instituto de Energia Atomica Report IEA-219: 94p (1970). (Portuguese).
COUN Brazil
ABST The installation and operation of a pilot plant for uranium purification based on an ion-exchange process are described. The preparation of uranyl nitrate solution, used to feed the ion-exchanger columns, is performed by fractional dissolution of raw sodium diuranate. The decontamination of thorium plus rare earth elements is achieved by oxalic acid precipitation directly in the bulk of uranyl nitrate. The decontamination of various impurities is enhanced by an EDTA-complex formation before the uranyl load on the strong cationic resin bed. The uranyl sulfate obtained by eluting the resin column with ammonium sulfate is reverse precipitated to avoid sulfate coprecipitation in the nuclear grade ammonium diuranate obtained.

DATE 1972
TITL Silica of high pore volume.
CITA Ger. Offen. 2,145,090 (Cl. C 01b, B 01j, C 09c), US Appl. 71,966, 14 Sep 1970: 26p (1972).
COUN W Germany
ABST SiO₂ of pore vol. 1.2-3.0 cm³/g and particle size ≤ 0.1 or 1-20 μ , useful as thickening or delustering agents, resp., was manufd. from Na silicate soln. by adding NH₃ as coacervating agent for redn. of the soly. of the silicic acid and acidification to pH 10.6-11.2 for pptn. The ppt. was aged and washed. Thus, aq. H₂SO₄ was added to a soln. of 2500 ml Na silicate (28% SiO₂, 8.7% Na₂O), 3250 ml H₂O, and 1750 ml 30% NH₄OH. Gelation began at pH 10.95 and H₂SO₄ was slowly added to form a slurry at pH 10.4, which was filtered. The residue was washed with H₂SO₄, suspended again, and the mixt. passed through a jet pulverizer at 232^o and 10.5 atm gage. The formed product was dried at 200^o to give SiO₂ of surface area 449 m²/g, H₂O pore vol. 2.4 cm³/g, particle size 50-75 nm, and bulk d. 0.06. A mineral oil thickened with 2, 3, and 4% of this SiO₂ had a viscosity of 2250, 4500, and >10,000 cP, resp.

- 3 AUTH Adam, J.; Stulikova, M.
DATE 1974
TITL Selective extraction and determination of uranium using

URANIUM EXTRACTION FROM SEAWATER

(CONT.)

- diphenyl acetic acid.
- CITA Collect. Czech. Chem. Commun. 39(9): 2576-2580 (1974).
 COUN Czech
 ABST A benzene solution of diphenyl acetic acid is suitable for the extraction of uranyl ions from alkaline aqueous solutions. Addition of nitrilotriacetic acid to the aqueous phase renders the extraction selective for uranium in the presence of iron(III), nickel(II), lead(II), zinc(II), cobalt(II), cadmium(II), manganese(II), copper(II), chromium(IV), and molybdenum(VI) by selective masking of these ions. Gold(III) and platinum(IV) were found to interfere slightly. Transfer of the uranium into the organic phase is virtually quantitative after two extractions. Polarographic and spectrophotometric determinations were studied; in the latter case, dibenzoylmethane is added to the organic extraction phase as a colorimetric reagent. The polarographic determination is preferably performed after re-extraction of the uranium into aqueous solution (0.5M-KCl-0.5M-HCl). The former method provides a wider useful concentration range (10^{-5} to 5.10^{-3} M-U(VI) in the extract) than the latter (10^{-5} to 2.10^{-4} M-U(VI) in the extract); however, the latter has greater accuracy ($\pm 3\%$) than the former ($\pm 5\%$) as well as being more simple.

- 4 AUTH Adams,W.H.; Buchholz,J.R.; Christenson,C.W.; Johnson,G.L.; Fowler,E.B.
 DATE 1975
 TITL Studies of plutonium, americium, and uranium in environmental matrices.
 CITA Report by Los Alamos Scientific Lab, LA 5661: 26p (1975).
 COUN USA
 ABST A nitric acid-hydrofluoric acid treatment for dissolution of plutonium oxides in soils has been developed; its adaptation to other biological matrices is discussed. Plutonium recoveries of 94 to 99% from 1-g samples of spiked and heated soils are reported. Adaptation of the acid solution to subsequent anion exchange separation of plutonium, followed by coupling to known electroplating techniques, is described. The uptake of plutonium, americium, and uranium from spiked soils by alfalfa, beans, radishes, lettuce, tomatoes, and barley is reported. The "apparent" solubility of Pu(238)O₂ in tap water was measured, and the deposition of plutonium in fish, algae, and snails in aquaria containing Pu(238)O₂ microspheres is reported.

DATE 1975
TITL Extraction and photometric determination of uranium (VI) with N-p-tolylbenzohydroxamic acid (p-TBHA).
CITA Anal. Lett. 8(4): 257-267 (1975).
COUN India
ABST A rapid method for the simultaneous solvent extraction and spectrophotometric determination of hexavalent uranium with N-p-tolylbenzohydroxamic acid is described. The intense red complex with uranium can be extracted by chloroform at pH approx. 4.3. The red colored complex obeys Beer's law at 515 nm. A satisfactory separation from many commonly occurring metal ions is easily accomplished. Effects of acidity, reagent concentration and diverse ions on the visible absorption spectrum of the extracted complex have also been investigated.
KEY extraction, uranium, analysis, chemistry
- 6 AUTH Agrawal, Y.K.
DATE 1975
TITL Solvent extraction of uranium (VI) by N-m-tolyl-o-methoxybenzohydroxamic acid.
CITA Sep. Sci. 10(2): 167-173 (1975).
COUN India
ABST A simple and rapid spectrophotometric determination of uranium (VI) is described. The uranium (VI) N-m-tolyl-o-methoxybenzohydroxamic acid complex is extracted with chloroform at pH 5.3 to 5.5 from aqueous solution. Maximum absorption of orange-red extract occurs at 510 nm. The colored complex obeys Beer's law over the range 0.3 to 20 ppm of uranium. The effect of acidity, reagent concentration, and diverse ions on the visible absorption of extracted complex has been studied.
KEY extraction, uranium, chemistry, water, concentration
- 7 AUTH Ahrland, S.
DATE 1949
TITL On the complex chemistry of the uranyl ion. I. The hydrolysis of the six-valent uranium in aqueous solutions.
CITA Acta Chemica Scand. 3: 374-400 (1949).
COUN Sweden
ABST It has been shown by extinctionometric measurements that the uranyl ion UO_2^{2+} is the only existing complex of six-valent uranium in aqueous solution from $p[H^+] = 0.1$ (the lowest investigated) up to $p[H^+] = 2$. Over that $p[H^+]$ further hydrolysis complexes are gradually formed. So UO_2^{2+} may be regarded as a complex forming central group, and formulas for its complex formation have been developed in a manner analogous to other metal ions. The extinction curve of UO_2^{2+} has been determined; from

URANIUM EXTRACTION FROM SEAWATER

(CONT.)

this curve, the data of the literature have been found to be erroneous. Further investigation has been done for the hydrolysis of UO_2^{2+} .

- 8 AUTH Ahrlund,S.; Hietanen,S.; Sillen,L.G.
 DATE 1954
 TITL Studies on the hydrolysis of metal ions. X. The hydrolysis of the uranyl ion, UO_2^{2+} .
 CITA Acta Chemica Scand. 8: 1907-1916 (1954).
 COUN Sweden
 ABST All complexes from the hydrolysis of UO_2^{2+} which formed in appreciable amounts can be written in the form: $UO_2^- ((OH)_2UO_2)_n^{2+}$, or, which is equivalent, $UO_2(OUO_2)_n^{2+}$. A direct analysis of the Y(X) curve ($Y=1/2 Z$) showed that several complexes with different n are formed. In view of X-ray evidence on the structure of compounds that may be precipitated from uranyl solutions, it seems reasonable that the complexes are sheet-like, probably with double OH bridges. The most correct formula would thus be $UO_2((OH)_2UO_2)_n^{2+}$.

DATE 1958
TITL Synthetic inorganic ion-exchange materials-II. Hydrrous zirconium oxide and other oxides.
CITA J. Inorg. Nucl. Chem. 6: 236-245 (1958).
COUN UK
ABST The oxides ZrO_2 , ThO_2 , and TiO_2 behave as anion exchangers in acid and neutral solution and cation exchangers in alkaline solution, the pH at which their behavior changes depending upon the oxide itself and possibly also upon the nature of the exchanging ion. The oxides have been prepared in granular form and their reversible reactions with ions in solution have been studied; they are monofunctional exchangers, with appreciable rates of exchange, and display the expected affinity towards ions in solution. Owing to their weakly basic nature, exchanged ions are readily removed

URANIUM EXTRACTION FROM SEAWATER

16

(CONT.)

by treatment of water. When ZrO_2 is treated with phosphoric acid it is converted into zirconium phosphate having properties qualitatively similar to the material described in Part I; the reaction cannot be solely one of anion exchange, but must involve breakdown of the oxide and introduction of further acid phosphate groups by neutralization. WO_3 is a cation exchanger in acid solution, but dissolves in alkaline solution.

KEY ion exchange, titanium, chemistry

 DATE 1976
 TITL Solvent extraction of uranium for dilute solutions using a gas-bubble mixed extraction column.
 CITA Metall. Trans. B. 156(7B): 253-258 (1976).
 COUN USA
 ABST A modified solvent extraction process for recovering uranium from very dilute solutions, such as mine waters or copper dump liquors, has been developed and tested on a laboratory scale. The system utilizes a column in which the aqueous feed flows downward through a liquid organic extractant. A countercurrent flow of gas is used to achieve mixing and enhance mass transfer. Acid sulfate solutions at pH 1.5 containing either 0.010 or 0.015 g/l U_3O_8 comprised the feed. The extractant used was Alamine 336 dissolved in fuel oil. Critical parameters of the system, such as length to diameter ratio of the organic phase, volume ratio of aqueous to organic in the column, and flow rates of aqueous feed and gas are examined.

ABST Exploitation of the resources of the sea and sea-bed was the theme of a conference organized by the United Kingdom Atomic Energy Authority on behalf of the Ministry of Technology. Among the subjects covered were the technology of gaining food from the sea; movement and control of the sea-bed; sea rigs and platforms; information handling for oceanography and for meteorology over the oceans. Abstracts of the conference papers are published here. The full proceedings will be made available through H.M.S.O.

TITL Uranium-from-sea plant begins operation in Japan.
CITA Nuclear News (January): 66 (1976).
ABST Reports from Japan indicate that the Ministry of International Trade and Industry recently began operation of an experimental plant to recover uranium from seawater. Located on Shikoku island, the first-of-a-kind plant circulates 40 tons of water per day over an adsorber made of activated carbon and titanous acid. The seawater is circulated several hundred times while being stirred by an electric rotor. Uranyl carbonate extracted from the seawater is trapped by the adsorber and treated chemically. Reports

(CONT.)

indicate the experimental plant is expected to extract only about 10 grams of uranium a year. Earlier estimates of similar processes concluded that uranium produced from seawater would have to cost several hundred dollars per kilogram. The Japanese plant is designed to obtain basic technical information for a larger facility planned by the Resources and Energy Agency.

 TITL Titanium: mineral commodity profiles.
 CITA Bureau of Mines, U.S. Dept. of Interior, MCP-18: 19p (1978).
 COUN USA
 AREA North America, South America, Europe, Africa, Asia, Oceana
 ABST Production of titanium dioxide pigment in the U.S. in 1977 amounted to about 680,000 tons, valued at about \$580 million. Calculated production of titanium sponge metal was around 14,000 tons, worth about \$77 million. These two major uses account for over 96% of domestic consumption of titanium. Other uses of titanium-bearing raw materials are for manufacturing welding rod-coatings, titanium carbides, ceramics, chemicals, and various other products. Total U.S. primary demand for titanium in 1977 was about 30% of world primary demand. The mineral sources of titanium products are rutile and ilmenite. Rutile is far less common than ilmenite. World production is predominantly from deposits on Australia's east coast. U.S. demand for rutile, however, has risen from 12,000 tons in 1950 to 180,000 tons in 1977; demand in the rest of the world, while not increasing as sharply, is nevertheless rising. Present technology requires ilmenite for making titanium pigment by the sulfate-process, either directly or through a high-titania slag as an intermediate form. Rutile is more versatile; its foremost use is to make pigment via the chloride process. In 1977 demand for titanium metal was divided between military hardware (mostly aircraft), commercial aircraft, and industrial uses. The amount of titanium consumed in industrial uses, such as for reaction vessels, condensers, heat exchangers, and other chemical processing equipment, and in steel and other alloys, is generally increasing.

TITL Complexing of uranium in sea water.
CITA I. Geochemical Evidence for Stabilization in the Oceans.
II. UO_2^+ Hydrolysis. (University of Miami, Institute of Marine Science, Technical Report, 64-5, October): 23p (1964).
COUN USA
ABST I. The relatively high uranium concentration of sea water is discussed in terms of a supply-removal steady state. The comparison of average abundances of uranium and other elements indicates that complexation by sea water constituents makes uranium (VI) difficult to remove from solution. II. Hydrolytic quotients of uranium (VI) complexes $(UO_2)_q(OH)_m^{2q-m}$ are critically reviewed; for computation in sea water medium the following values are recommended: $K_{0-1} = 6 \pm 4 \times 10^{-9}$, $K_{0-2/2} = 1.0 \pm 0.2 \times 10^{-11}$, $K_{0-4/3} = 2.3 \pm 0.2 \times 10^{-15}$, $K_{0-5/3} = 1.8 \pm 0.2 \times 10^{-18}$. The concept of reduced instability quotients, $B = K - pB_{mq}/m$, is introduced as a measure of hydroxyl bonding strength. B decreases (logarithmic scale) from 11.02 in the 2-2 complex, to 10.50, 10.43, 10.05, in the 4-3, 5-3, 6-3 complexes, respectively. Further substitution reduces it to 9.68 in the 7-3 compound, and to 8.64 in $[(OH)_8(UO_2)_3]^-$. Computation of complex concentrations in sea water indicates that only UO_2OH^+ adds significantly to the species distribution. Hydrolysis reduces the average charge of uranium species, but condensation does not proceed in the presence of complexing anions: the net effect is stabilization of uranium in sea water.

DATE 1975
TITL Uranium in the Black Sea.
CITA Geol. Zh. 6: 16-26 (1975). (Russian).
COUN USSR
AREA Black Sea
ABST Water samples for uranium analysis have been collected over the entire Black Sea, from the surface to the sea floor. As distinct from the previously known facts, it has been established that the uranium content in different parts of the sea appears to vary both in extent and with depth. The behavior of uranium is governed by redox conditions of the environment. A decrease in pH value of water to 7.5 and a change of Eh value from +0.4 to -0.2 V lead to reduction of $U^{6+} \rightarrow U^{4+}$ and ensure higher sorption properties of the solid phases. The reducing reaction is proved possible through the calculated data. It is shown that the rate of uranium isolation is increasing with depth and its content is going down. Using optical properties of water, a hydrogeochemical behaviour of organic matter and uranium in water depths is explained. Role of organic matter and mineral components in the uranium deposition is described. Sorption of U ions on twelve components, which constitute a base of suspensions and floor sediments, has been also studied.

TITL Uranium extraction from seawater.
CITA INIS-mf-3844: 149p (1976).
COUN W Germany
ABST After an introduction to the physics and chemistry of the sea and an estimation of the chances for the absorption of uranium from rivers, the material-specific characteristics of the adsorber technology are described in detail. Then, the methods used for gaining uranium from seawater are described with special regard to the tidal and the so-called serial (sequency) method. Whether all methods described can be realised is an economic problem since very high quantities of water are necessary because of the low contents of uranium. A positive energy balance (gained energy/lost energy) is not definitely ensured yet for the production methods used. The development measures to be taken to obtain a positive energy balance are briefly described, and the research programme of the UEBG is mentioned.

DATE 1978
TITL Uranium extraction from seawater.
CITA Contribution to WG 1B of INFCE by the Delegation of the Federal Republic of Germany: 10p (1978).
COUN W Germany
ABST In view of the order of magnitude of the total uranium requirement to be expected the Federal Republic of Germany has made great efforts in the field of uranium prospection. The following study delineates a new process (UEB process) for the extraction of uranium from seawater which in our view is particularly promising. This process does no longer work with immobile adsorber granules packed in a solid bed through which seawater flows, but rather with mobile particles in a fluidized bed. There the adsorber granules are almost kept suspended by the deflected sea current, at the same time migrating from the feeding to the discharge station at right angles to the current. Thus allowance is made for the fact that mobile adsorber particles are more likely to come into contact with uranium molecules than fixed ones. The special advantage offered by this working principle is that it permits the conception of adsorber units which, installed at greater depths, take the entire process energy required for adsorption from the sea current.

 TITL Structure and ion exchange properties of titanium hydroxide. 2. Physicochemical study of the structure of titanium hydroxide samples produced by alkaline hydrolysis in the titanium(4) chloride-hydrochloric acid-water system.
 CITA Ionnyi Obmen Ionometriya 1: 21-33 (1976). (Russian).
 COUN USSR
 ABST X-ray diffraction data indicate that the structure of Ti hydroxide depends strongly on the condition for prep. the samples in the $TiCl_4-HCl-H_2O$ system during alk. hydrolysis. From solns. of $TiCl_4$, Ti hydroxide samples can have a rutile or anatase structure depending on hydrolysis conditions. Increasing the temp. of calcination of the air-dried samples led to an increase in the crystallinity. The samples were characterized by DTA and IR spectra.

TITL Ion-exchange properties of crystalline modifications of silica.
CITA Adsorbtsiya Adsorbenty 4: 49-53 (1976). (Russian).
COUN USSR
ABST The cation-exchange properties were studied of cryst. polysilicic acids from Li silicate, Li and K polysilicates, and mixed Li K Na polysilicates. The sorption of Li^+ , K^+ , Na^+ , and Cs^+ was studied at pH 2-10 by potentiometric and radiometric methods. The cation-exchange sorption on all cryst. polysilicic acids in acidic solns. increased with increase in the crystallog. radius in the series $Li^+ < Na^+ < K^+ < Rb^+ < Cs^+$ and $Ca^{2+} < Sr^{2+} < Ba^{2+}$. In alk. solns., this series of sorptive selectivity had the inverse sequence. This character of adsorption of cations resulted from $d_{\pi}-p_{\pi}$ -conjugation in siloxane and $SiO-M^+$ bonds. The cation-exchange capacity (esp. in acidic medium) was compared with that of silica gel, quartz, cristobalite, and tridymite. Adsorption of Na^+ on quartz was anomalously high. Adsorption of Na^+ on polysilicate in their Na form was also higher than that of other alkali cations. There was a memory effect in cation exchange with preferential sorption of those alkali cations (Na^+ and K^+) in the presence of which the hydrothermal crystn. of SiO_2 took place.

TITL Uranium determinations in deep-sea sediments and natural

(CONT.)

- waters using fission tracks.
- CITA Geochim. Cosmochim. Acta 34: 641-648 (1970).
 COUN USA
 ABST Uranium determinations by induced fission track analysis were done rapidly utilizing a discharge counter instead of visual counting. Sediments, rocks, freeze-dried river salts (with Na₂CO₃ carrier) and one freeze-dried sea salt were analyzed by this technique. Comparisons with samples whose uranium concentrations were determined independently indicate that the method is accurate. The uranium concentration in deep-sea sediments varies widely with oceanic depth and depth in the core ranging from 0.5-40 ppm U on a calcium carbonate-free basis. Seventeen river water samples range between <0.01 and 1.2 μ U/l with an average value of 0.27 μ U/l.

 TITL Uranium from sea-water. Possibilities of recovery, exploiting slow coastal currents.
 CITA Uranium ore processing. Proceedings of an advisory group meeting organized by the IAEA and held in Washington, D.C., 24-26 November 1975.
 ISBN-92-0-041176-2. IAEA, Vienna: 213-229 (1976).
 COUN Italy
 AREA Mediterranean Sea
 ABST The authors analyze the interest in uranium recovery from sea-water within the framework of uranium world supply problems. The most reliable methods proposed for recovery are summarized and discussed, both from the chemical and the plant project points of view. Tides as a source of energy for water movement cannot be used in the Mediterranean and therefore only currents can be taken into account. The acceptable cost of an exchanger, in relation to the uranium price, is considered and related to known exchangers. The characteristics of exchanging elements are examined and the influence of the speed of sea currents discussed. The extractable uranium is a function of the exchange rate and of the speed of the flow inside the exchanging system; therefore it is quite clear that the current speed is not a prerequisite and that coastal currents around Italy are suitable. Exchanging elements built with sheets parallel to the flow, exchanging pans containing granular or fibrous exchangers have been considered. The main characteristics of a 1000 t/a plant are discussed considering possibilities. The most acceptable seems to be the continuous extraction system. The parameters needed to calculate the dimensions of

(CONT.)

such a plant are given and the relation between the length and speed of the moving chain discussed. A rough economic evaluation of the plant cost - starting from known technologies - and of the final cost of the uranium oxide produced is made.

 TITL Ionic association in aqueous solutions of uranyl sulphate and uranyl nitrate.
 CITA J. Chem. Society, Suppl. No 2 : 286-294 (1949)
 ABST Spectrophotometric methods have been used to study ionic association in aqueous solutions of uranyl nitrate and uranyl sulphate. The stoichiometric association constants for the equilibria $UO_2^{++} + HSO_4^- \rightleftharpoons UO_2SO_4 + H^+$ and $UO_2^{++} + NO_3^- \rightleftharpoons UO_2NO_3^+$ were found to be 5.0 ± 0.34 and 0.21 ± 0.01 , respectively. These values were obtained for solutions 2.00 M. in hydrogen ion. Results for concentrations of nitrate greater than 3 M. could not be interpreted unequivocally. In this region, either small amounts of $UO_2(NO_3)_2$ are formed, or, more probably, the value of the association constant changes slightly with the ionic environment.

 TITL Extraction of uranium from seawater, phase I.
 CITA Project Report, Nov. 11, 1976, Dept. of Nuclear Engineering, O.S.U.: (1976).
 COUN USA
 ABST Tasks for this project included developing an analytical method for measuring uranium at very low concentrations, evaluating resins and adsorbents for their ability to selectively remove uranium from sea water, and evaluating processes for eluting the uranium from promising resins or adsorbents. The delayed fission neutron (DFN) counting method was the best analytical method of four tested, the other three being gamma ray spectrometry, x-ray spectrometry, and x-ray fluorescence. A thorough explanation of DFN's equipment, calibration and performance is given. Resins and adsorbents tested include chitosan, crushed crabshell, Duolite ES-I3I, blotter grade and laft grade cellulose, activated charcoal, polyacrylamide, silica gel and peat moss. Additional data are being collected on silica and peat moss, which had the highest loading capacities. Solutions of sodium carbonate, ammonium carbonate and ammonium hydroxide were the best eluting agents, as all were successful, but ammonium hydroxide may be the most promising as it is easily recoverable.

 DATE 1977
 TITL Extraction of uranium from seawater, phase I.
 CITA Project Report, July 22, 1977, Dept. of Nuclear Engineering, O.S.U.: (1977).
 COUN USA
 ABST Present refinements and possible future improvements of

(CONT.)

the delayed fission neutron (DFN) technique for measuring uranium content in seawater are discussed. Titanium hydroxide and silica gel were found to be the best agents for adsorbing the uranium from the seawater. $Ti(OH)_4$ had a higher loading capacity, but the silica gel was far more consistent. Acetic acid was found to be about ten times better than ammonium hydroxide as an elution solution for silica gel. A cost comparison between the $Ti(OH)_4$ adsorption and that of silica gel showed that costs were approximately the same in either case. Future plans include further analysis of silica gel as an adsorber, and testing of a more crystalline silica gel based on ionic radius information.

DATE 1978
TITL Extraction of uranium from seawater, phase I.
CITA Progress Report, July 7, 1978, Dept. of Nuclear Engineering, O.S.U.: (1978).
COUN USA
ABST In continuing the work described in two previous reports, the adsorption qualities of silica gel were further examined. The silica gel adsorbed 21.5 $\mu\text{g/g}$ in two days under the conditions of a low specific gravity sodium silicate solution (sp. gr. = 1.15), a three-day synerisis period and being freeze-dried as opposed to oven-dried. The previously reported high had been 5 $\mu\text{g/g}$ in 15 days. Also, experiments were done with topo-adsorbent silica gel with a pore size of 12\AA , to see if the larger pore size would increase the gel's loading capacity. No improvement was indicated, however. Present sensitivity of the delayed fission neutron (DFN) uranium counting system at 1 MW is 2000 counts per μg natural uranium. With a background of 32 counts, this represents a minimum level detection of 8.5 ppb. A study of potential sources of error showed no major problems. Future plans include the optimization of silica gel and the search for other resins and adsorbents, the construction of a new reactor made for long-term exposure of adsorbent to seawater, and a comparison of the He neutron detector with the BF_3 neutron detector. Also, the DFN technique is being tested for measurement of U-235, U-238, and Th-232.

TITL Ion exchange applications in desalination and hydrometallurgy.
CITA AMDEL (Aust. Miner. Develop. Lab) Bull. (12): 23-44 (1971).
COUN Australia
ABST Recently developed ion-exchange processes and techniques which are economically attractive for desalination and hydrometallurgy are discussed. The Desal, Sul-bi-Sul, and Sirotherm processes utilize low-cost chems. or low-grade heat to regenerate the adsorbing resin in the desalination of brackish waters. An increase in resin utilization, chem. efficiency, and product recovery results from using moving- or fixed-bed columns with countercurrent operation enabling higher salinity waters, up to 3000 ppm total dissolved solids, to be treated economically. Ion exchange as pretreatment to other desalination processes assists in scale prevention and heat recovery in distn. plants. Moving-bed techniques applied both to packed- and fluid-bed systems operate effectively for the recovery of U, Cu, and Zn from leach liquors and slurries. Low-grade liquors in high suspended solids can be treated for metal recovery without the high capital investment required for fixed-bed operation. Effluents can be treated for the purposes of recovering metal ions, controlling pollution, or enabling water to be reused.

TITL Postdepositional mobility of some transition elements, phosphorus, uranium and thorium in deep sea sediments.
CITA Geochim. Cosmochim. Acta 35: 189-201 (1971).
COUN USA

(CONT.)

ABST Deep sea hemipelagic sediments from the east Pacific show an oxidized upper zone of variable thickness and a reduced zone below. The geochemistry of a core from this region was studied in detail. The Eh of the upper zone is close to +100 mV, while in the lower zone it reaches about -400 mV. Reducing conditions in the lower section of the core are related to the oxidation of organic matter in the sediment, as indicated by the gradual decrease with depth of the concentration of nitrogen in the upper part of the core. Various elements, such as Mn, Ni, Co, P and La, are enriched in the upper oxidized zone, while Cr, V, U and S are enriched in the lower reduced zone. Postdepositional mobility of the elements in question, mainly by diffusion in the interstitial solutions, can explain their distribution in the core. Redox reactions can account directly for the mobilization of Mn, Ni, Co, Cr, V and U, indirectly for that of P and La. Fe and Cu do not migrate significantly, since they are immobilized as sulfides in the reduced zone. Th appears not to be affected by diagenetical mobility.

 TITL Ion-exchange and surface properties of titania gels from titanium(IV) sulfate solutions.
 CITA J. Colloid Interface Sci. 44(3): 430-442 (1973).
 COUN USA
 ABST Titania gels were prepd. by hydrolysis of Ti(IV) sulfate solns. with NaOH. The granular, air-dried gels had BET type I N adsorption isotherms and cation-exchange capacities $<3-6$ mequiv/g TiO_2 . Surface and ion-exchange properties were dependent on the final hydrolysis pH between 3 and 12. The max. effective surface area (420 m^2/g), pore vol. (0.19 ml/g), and pore radius, and the min. adsorbed Na^+ or SO_4^{2-} were obsd. for titania gels prepd. near pH 6, the isoelec. point for titania. Gels prepd. at pH <4 or >10 had pore entries too small to admit N and effective surface areas were <2 m^2/g . Ion-exchange desorption of Na^+ from the pores of a low surface area gel prepd. at pH 10 allowed entry of N into the fine pore structure and increased the effective surface area from <2 to 178 m^2/g . The Na^+/H^+ exchange rate (H^+ desorption- Na^+ adsorption) in concd. solns. was controlled by the rate of diffusion of Na^+ and H^+ within the gel granule, and apparent diffusion coeffs. $\sim 1.4 \times 10^{-8}$ - 5.3×10^{-8} cm^2/sec were measured. Gels prepd. at pH 6 had lower ion-exchange capacities, but faster Na^+/H^+ exchange rates than gels prepd. at pH 10.

- DATE 1976
- TITL Special sessions on breeding. I. Panel on uranium availability.
- CITA Nuclear Energy Maturity. Oxford: (1976).
- COUN UK
- ABST The main conclusions of the panel were the following: (1) Although there are immense quantities of uranium in the earth's crust (approx. 2×10^9 T) and in seawater (approx. 4×10^9 T), this does not have any influence on the present problems of nuclear strategy. (2) The real question is whether the extremely large quantities of natural uranium required by the end of the century and later can be discovered and extracted at the adequate time, rate, and competitiveness. (3) The general feeling is that there are, at less than \$30/lb (1973 price) 2 MT reasonably assured, and 8 MT hypothetical, still to be found, for deposits corresponding to a price of more than \$30/lb. Because of the lower grade, there are severe environmental problems to be expected which will limit the extraction. Extraction of uranium from seawater is by far still too academic and potentially too expensive to be taken into account in the present strategy studies. (4) The current rate of discovery is about 30 to 40,000 T/annum. Great confidence in the future of nuclear energy will be required to attract the

(CONT.)

necessary investment to reach rates of 200,000 T/annum or more by the end of the century.

CITA Battelle-Pacific Northwest Laboratories. Prepared for National Science Foundation. (December) PB-238 658: (1974).
COUN USA
ABST Presently, uranium extraction cannot be operated economically. Little research is being done at this time, and most firms that had been conducting studies have placed them on inactive status. For any of the processes, the pumping costs alone are many times the price now being obtained for uranium. Studies of tidal power have indicated a very high initial capital investment, which places some question as to the feasibility of this concept. With present technology and current economics, seawater uranium can only be viewed as a potential future source. Economic studies show that 4.8 million cubic feet of water must be moved to produce 1 lb of uranium at 100% efficiency, and for 1 year's production, estimated pumping costs alone would be \$33/lb of uranium produced. A survey is given of the six basic extraction methods studied so far: adsorption, absorption, ion exchange, solvent extraction, coprecipitation, and complexing.

TITL Adsorption properties of phosphoantimonic acid supported on silica gel.
CITA Radiochem. Radioanal. Lett. 9(4): 285-293 (1972).
COUN Czech
ABST At 22° in aq. 1-10M HNO₃, the order of increasing cation retention on phosphoantimonic(V) acid ion exchanger supported on silica gel was Sr ≈ Na < K < Rb < Eu < Cs, for ion exchangers with P₂O₅/Sb₂O₅ mole ratios α ≈ 0.5 and 1.0, resp., and which were prepd. by mixing SbCl₃ with aq. 85% H₃PO₄ and then oxidizing the Sb(III) to Sb(V) by addn. of concd. HNO₃. The order was Li < K ≈ Eu < Rb ≤ Cs < Sr < Na for an ion exchanger with α ≈ 0.2 that was prepd. by reaction of Sb₂O₅ and 7M H₃PO₄ at room temp. For a given ion exchanger and cation, the cation retention decreased with increasing HNO₃ concn. Adsorbed Na and K were eluted from the ion exchangers with M NH₄NO₃ or M HNO₃ + M NH₄NO₃. At 22°, the soly. of the ion exchangers in 1 or 10M HNO₃ increased with increasing α; for a given α, the soly. was greater in 1 than in 10M HNO₃.

TITL Uptake of inorganic acids on hydrogels of tetravalent hydroxides and its application for the preparation of some inorganic sorbents.
CITA J. Radioanal. Chem. 30(1): 155-172 (1976).
COUN Czech
ABST A study was made of inorg. acid uptake on hydrogels of Ti, Zr, and Sn hydroxides prepd. by the sol-gel method

(CONT.)

in the form of regular spherical particles. The aim of the work was the detn. of the basic conditions for the prepn. of inorg. ion exchangers by conversion of the hydroxide gel. The exchange of hydroxide groups of the gel phase for the resp. anions plays the decisive role in the uptake on Zr hydroxide. With similar Ti and Sn compds., the main process affecting the uptake is the formation of adsorption compds. and the free diffusion of the electrolyte into the gel phase. Uses of the sol-gel method for the prepn. of inorg. sorbents are discussed.

 TITL Developement of the surface of a titanium dioxide gel.
 CITA An. Quim. 67(6): 561-576 (1971). (Spanish).
 COUN Spain
 ABST TiO₂ pigments have mostly V-shaped micropores not very deep, and some pores in the form of a bottle neck which can be detected through hysteresis phenomena appearing in the isotherms at the highest partial pressures of adsorbed N. The surface evolution of a TiO₂ gel has been studied as a function of its sintering temp. by using a micro-BET set-up at 78°K and 2 TiO₂ samples, viz. anatase and rutile, both prepd. by hydrolysis of Ti₂(SO₄)₃ and ignition of the ppt. at 700°C and a 2nd portion at 800°C. Before measuring N adsorption isotherms, the samples were degassed in vacuum for 3 hr, either at 18 or 250°C. In the rutile sample, vacuum treatment at 250°C drives off some of the molecularly adsorbed H₂O, leaving ~50-65%; heating to 350°C leaves 25-33%. H₂O is only loosely bound to anatase, and

(CONT.)

heating to 250°C in vacuo leaves a practically anhyd. surface. For calogn. the Kelvin pore distribution, it could be assumed that all pores were <50 Å in size. In anatase and in rutile samples, degassing at 250°C led to a higher adsorption capacity than degassing at 18°C in relation to the presence of H₂O mols. on the oxide surface. Degassing rutile at 350°C did not produce a further increase of the adsorption capacity for N. The anal. of N adsorption isotherms at 78°K suggests that seed anatase particles formed through sintering at 700°C fuse together at higher temps. into larger rutile nuclei whereby the surface is decreased in area without changes taking place in the distribution of the pore sizes of the sample. Pores smaller than 15 Å could be detected in the rutile sample.

 TITL A study of the theory of stepwise equilibrium of inorganic ion exchange in seawater.
 CITA Sci. Sin. 17(4): 17p (1974).
 COUN China
 ABST This article deals with the three achievements acquired in the study of the theory of stepwise equilibrium of inorganic ion exchange in seawater, viz.: (1) It suggests that the theory of stepwise equilibrium of inorganic ion exchange in seawater is also applicable to ordinary aqueous solution system and introduces the average ion exchange number \bar{n} , which can be measured experimentally. Three ways are suggested for calculating the formation constants of ion exchange products, by means of general mathematical treatments, using the basic formula of \bar{n} . (2) A quantitative discussion of the relationship between the theory of stepwise equilibrium of ion exchange and the theory of adsorption is given. Experimental data obtained by using uranium-hydrous titanium oxide system etc. well confirm this relationship. (3) The theory of stepwise equilibrium of inorganic ion exchange has been used to explain the most important experimental fact in the exchange of inorganic ion - the relationship between ion exchange ratio and pH. Two ways have been suggested for calculating K, the equilibrium constant of ion exchange equilibrium. Experimental data of several separate systems have been utilized in making calculations, with the result that theory and practice comparatively agree.

TITL Extracting uranium from sea water.
CITA K'o Hsueh Shin Yen (7): 251-253 (1975). (Chinese).
COUN China
ABST Three methods are suggested for further research in extracting uranium from seawater: precipitation adsorption, ion exchange resin, and bubble separation. Titanium hydroxide is suggested as an adsorbent in precipitation adsorption. The ion exchange resin involves a chelate reaction in which there is an exchange of the uranyl ion with the resin. Acid phosphate ester is suggested as an active agent to produce bubbles for bubble separation. Research on how marine organisms, such as a kind of brown seaweed, concentrate uranium from seawater could be a promising approach. Future developments may also include constructing tidal basins with adsorption beds to extract uranium from seawater.

TITL Extraction of uranium from sea water. Part II. Extraction by organic and inorganic absorbers.
CITA Atomic Energy Research Establishment Report AERE-R-5024: (1965).
COUN UK
ABST The organic absorbers that have the highest loading values in seawater are copolymers of formaldehyde and resorcinol arsonic acid (H_2RA_p) with loadings of 1000 to 1100 μg U/g. With inorganic absorbers optimum loadings were attained by certain compounds of lead, basic zinc carbonate (BZC), and hydrated titanium oxide (HTO), which absorbed 200 to 900, 540, and 280 μg U, respectively, per g lead, zinc, and titanium in absorber. The solubility of HTO in seawater is $<0.1 \mu g$ Ti/ml and is not sufficiently high to render uneconomic its use as an absorber of uranium from seawater. The resorcinol arsonic acid resins (H_2RA_p) lose approximately 2.3% of their initial arsenic per week in contact with seawater while the losses due to solubility of lead absorbers and BZC in the same medium are not less than 0.5 μg lead or zinc per ml. These losses are considered too high for the economic use of H_2RA_p resins, lead compounds, and BZC as absorbers of uranium from seawater. Uranium(VI) and resorcinol arsonic acid monomer (H_2RA_m) form the 1:1 complex UO_2RA_m , and an analogous complex (UO_2RA_p) is formed between uranium(VI) and the functional group RA_p of the resin H_2RA_p . Carbonate and bicarbonate ions are liberated into solution during the absorption of uranium(VI) from solutions of sodium uranyl tricarbonate $Na_4UO_2(CO_3)_3$, by BZC and HTO.

TITL Electrolysis of brine with a mercury electrode.
CITA Span. 452,238 (Cl. C25B), Appl. 08 Oct. 1976: 13p (1977).
COUN Spain
ABST Brine is electrolyzed using a Hg cathode sepd. from the anode by a cation exchanging membrane having a pore diam. preventing the passage of Hg. The pore diam. of the membrane is $< 0.15 \Delta P$ (mm), where ΔP is the pressure difference between the Hg and the catholyte in N/cm². The method has the quality advantages of Hg cells, but

(CONT.)

avoids their risk of contamination. The membrane prevents short circuits between the electrodes, but permits a short distance between them, and it prevents particles from falling on the cathodic Hg film in horizontal cells. Thus, an electrolytic cell with vertical cathode, comprising a Nafion membrane having a surface area of 2.3 cm^2 ($r = 0.8 \text{ cm}$), using a cathodic pressure of 10 kg/cm^2 Hg anodic pressure of 1 atm, a brine concn. of 250 g/L , an anode of RuO/Ti with an active surface of 0.45 cm^2 , and an electrolyte temp. of 55° , produced Cl with an anodic c.d. of 20, 80, 160, 400, 600, and 1000 mA/cm^2 at a cell voltage of 2.73, 3.11, 3.25, 3.62, 3.90, and 4.5 V, resp.

 TITL Ion exchange on a silica gel surface.
 CITA God. Nauchnoizsled. Inst. Neftoprerab. Neftokhim. 5: 167-170 (1966). (Bulgarian).
 COUN Bulgaria
 ABST The mechanism of silica gel sorption was studied on samples with a surface of $430\text{-}120 \text{ m}^2/\text{g}$. A moisture content of 2.6% corresponds to $7 \text{ } \mu\text{moles OH/m}^2$. The replacement of H^+ by Cu^{2+} depends on pH. Only 60% of the OH-groups can react with the metal ions. The ir spectra of silica gel in the H^+ and Cu^{2+} state show differences at $3300\text{-}500 \text{ cm}^{-1}$. A well expressed peak at 3400 cm^{-1} appears for the Cu^{2+} state. The ion-exchange capacity is 1.8 meq/g . It does not depend on the concn. of the metal ion in the range $0.1\text{-}1.0\text{M}$ at $20\text{-}50^\circ$ but changes considerably with pH. The H^+ ions in the silica gel can be replaced by the $[\text{Cu}(\text{NH}_3)_4]^{2+}$ ions. The ir spectrum of silica gel in the $[\text{Cu}(\text{NH}_3)_4]^{2+}$ state has the same absorption max. for NH_3 as $[\text{Cu}(\text{NH}_3)_4]\text{SO}_4$. The amt. of NH_3 in the dried sample was detd. by heating at 450° . Cu^{2+} is absorbed as $[\text{Cu}(\text{NH}_3)_4]^{2+}$. During heating, the ion irreversibly converts to the metallic state. The kinetic curves of the sorption of metal ions were recorded under dynamic conditions. The mechanism of the sorption is ion exchange.

 COUN Japan
 AREA Japan, British Columbia (Canada), Australia
 ABST This report summarizes reconnaissance studies of the geochemical prospecting of U by natural water in the

(CONT.)

areas of Japan and overseas countries. The Power Reactor and Nuclear Fuel Development Corporation of Japan has been doing this prospecting since 1958. Each U content of water taken from eight geological terrains, hot springs, mineral springs, and rivers of the main island of Japan, central part of British Columbia, Canada and four geological terrains of Australia has been determined. The U contents of 14,764 water samples taken from main island of Japan are ranged from 0.00 to 68.5 part per billion (ppb) uranium, 68 water samples from British Columbia are ranged from 0.01 to 24.0 ppb and 246 water samples from Australia are ranged from 0.00 to 95.0 ppb. The content of U in natural water is so variable depending on chemical and physical factors of water that many determinations of the uranium content are necessary to set up the correct background and to evaluate the terrain.

TITL Correlation of the sorption of metal ions by silica gel with the solubility of the resulting sorption compounds. VI. Interaction of silica gel with copper(II) ions.
CITA Zh. Prikl. Khim. (Leningrad) 45(1): 33-37 (1972). (Russian).
COUN USSR
ABST Silica gel sorbs Cu(II) ions from an ammonia soln. KSK-2.0 and KSM-4.5, as well as A_1-A_6 silica gels were tested in dynamic and static conditions. Sorption takes place in 2 stages: ion-exchange and mol. adsorption. In the 1st stage, the const. regulating the process is the sorption product, defined as the product of the activity of Cu(II) and that of the sum of surface polysilicic acids and the dissolved polysilicic acids. In the mol. adsorption stage, it is the soly. product of the corresponding Cu(II) silicate. In the dynamic tests, a 0.024M soln. of $[Cu(NH_3)_4]^{2+}$ in 0.35N ammonia soln. was passed through a small 5 mm internal diam. column 100 mm high contg. 220 mg of KSM-4.5 silica gel at 0.2 ml/min. Total surface active silicic acid content was 0.49 mmole. Copper was practically completely adsorbed from the 1st portions of soln. Later it continued to be slowly adsorbed. In the 1st (ion exchange) stage the sorption product was almost const. and equal to $(1.3-2.3) \times 10^{-19}$. During the mol. adsorption stage, the soly. product of Cu silicate was $(1.3-7.8) \times 10^{-18}$. During static tests 4×10^{-2} to 8×10^{-2} mmole/ml of solid silicic acid were used, corresponding to 1 to 2 g of KSK-2.0 silica gel. This was contacted with 25 ml of a 0.1M soln. of $[Cu(NH_3)_4]^{2+}$. Contact time was 5 days in one case, 3 years in another. In the 1st case the Cu silicate soly. product was $(0.81-0.90) \times 10^{-18}$ and in the 2nd, $(0.12-0.15) \times 10^{-18}$.

TITL The concentration of radium, thorium, and uranium by tropical marine algae.

CITA Limnol. Oceanogr. 15: 945-955 (1970).

COUN USA

AREA Puerto Rico

ABST Twenty species of marine algae were collected between 1961 and 1968 from coastal waters of Puerto Rico and analyzed chemically for total organic material, protein nitrogen, and calcium, and radiochemically for the naturally occurring alpha particle emitters ²²⁶Ra, ²³²Th, and ²³⁸U. Study of these data suggests that the concentration of radium, thorium, and uranium by tropical marine algae is controlled by two mechanisms: 1) ion-exchange or coprecipitation of the ion with the calcium carbonate matrix, and 2) complex formation with either the protein nitrogen or some other component of the organic fraction. Radium (and possibly thorium) apparently is concentrated by both mechanisms, the dominant one depending on the phylum. For the Rhodophyta and the highly calcified Chlorophyta it is the former and for the Phaeophyta the latter. Uranium is concentrated by the first mechanism.

TITL Assessment of uranium and thorium resources in the United States and the effect of policy alternatives.

CITA NTIS, PB-238 658: 223p (1974).

COUN USA

AREA United States

ABST Objectives of this study were to analyze the known United States uranium/thorium resources and to determine the effect of various policy options on the availability of these resources. It was concluded from this study that, in general, uranium and thorium resources in the U.S. are extensive, but new or improved technology and higher prices are required before they will become economically viable. Five specific conclusions reached during this study were: (1) Reasonably assured uranium reserves recoverable at a 1974 forward cost of \$15/lb U_3O_8 should be adequate at least through 1985. (2) Uranium resources from conventional sandstone deposits recoverable at a 1974 forward cost of \$30/lb U_3O_8 should be adequate to the year 2000. (3) Thorium resources should be adequate to supply all conceivable needs through the year 2000. (4) Capital and manpower resources may be inadequate in the near future. (5) Production capacity may be inadequate in the short term.

DATE 1974
TITL The extraction of uranium from seawater.
CITA Central Electricity Generating Board, Long Term Study Symp., CERL 1974.
COUN UK
ABST Since the known world reserves of uranium will be gone by the turn of the century, there is some incentive to re-examine the possibility of obtaining the required uranium from the sea. The concentration of U in seawater is 3 ppb, and this low concentration, and therefore the enormous volumes of water necessary, precludes the extraction methods of chemical pretreatment or control or colloid flotation. Only filtration and possibly temperature increase by low grade heat are possibilities. Estimates of various seawater handling schemes and their projected annual uranium output include using desalinization plants (1 tonne U) all CEGB fossil stations (50 tonnes), all Magnox stations (23 tonnes), the Menai Straits (1x10³ tonnes), the Severn Barrage (1.6x10³ tonnes), world tidal power locations (2.5x10⁴ tonnes) and a pumped system (possibly unlimited). The "break-even point" for the pump system (no net energy gain) was calculated to be a head loss of 80 meters of water, but experimentally shown to be only 25 meters. Requirements for sites include constant current, high temperature and low solid content. Many sites were considered, the potentially best being the West Indies and Japan. Cost of uranium produced was at least \$70 per lb. and possibly much greater. The possible future development of absorbent beds, absorbents and eluents was discussed.

COUN UK
AREA UK Coastline, The Bahamas, Japan
ABST Recent predictions of the world demand for uranium fuel for thermal reactors show that known deposits are not sufficient to support demand past the end of the century. For some time consideration has been given to the recovery of uranium from seawater. The volume of seawater required daily to produce sufficient uranium to support even a moderately sized thermal reactor programme is shown to be outside the potential of the UK. Considered on a world wide scale the number of potential tidal power sites which could be adapted for use for uranium recovery is inadequate to support anticipated world demand. The possibility of employing a pumped scheme is discussed in terms of the siting of such a plant and energy balance considerations. An indication is given of areas where the technology of uranium extraction from seawater is considered to require further development.

TITL The abundance and distribution of uranium in some oceanic, continental ultramafic inclusions and host basalts.
CITA Chem. Geol. 16: 221-231 (1975).
COUN UK
ABST The abundance and distribution of uranium in various continental and oceanic ultramafic inclusions and host basalts are reported. Uranium was determined by neutron activation (fission products, fission tracks and delayed-neutron methods) and alpha-particle autoradiography; data is also reported for the uranium content of various USGS standard rock powders. The concentration of uranium in both oceanic and continental samples is similar, levels are controlled by mineral compositions, and their relative abundance in different rock types. Highest levels are found in feldspathic and lowest in olivine rich inclusions. Uranium is enriched in mylonitised samples and along some inter-crystal

(CONT.)

boundaries. With the exception of some apatites, highest levels of uranium are in clinopyroxenes (chrome) and lowest in olivines; no enrichment of uranium in orthopyroxenes was observed. Attention is drawn to the problem of obtaining representative samples from the sea floor which have not been altered by saline solutions and the identification of uranium and daughter products present along inter-crystal boundaries. Differences in observed heat flow between continental and oceanic areas may reflect inadequate sampling of representative rock types present below the sea floor and lack of information for the true abundance and distribution of uranium in such rocks.

COUN USA
AREA Menai Straits
ABST A cost commentary review is presented on a method proposed by U.K. investigators for recovery of uranium from sea water by sorption on hydrous titania. The review follows the original proposal in considering primarily water-sorber contact achieved by tidal flow, in a hypothetical plant at Menai Straits, Wales. Cost analyses of civil works, chemical plant, sorber inventory and makeup, chemical consumption, and other charges were based on available information supplemented with estimates, analogies, and some guesses. (In all

(CONT.)

uncertainties, the more optimistic value was selected.) Together with computer analysis of tides and flow resistances for the hypothetical site, these led to a minimum cost of about \$300/lb U at a production rate of about 500 tons U/yr. In general, the results indicate that the cost of uranium from sea water is not likely to be at a lower level than hundreds of dollars per pound, and might be at a much higher level.

TITL Evaluation of organic and inorganic adsorbents for the removal of uranium and plutonium from process streams.
CITA Mound Lab., Miamisburg Report MLM-2424 (OP): 17p (1977).
COUN USA
ABST Mound Laboratory is evaluating macroporous, ion exchange resins for the removal of plutonium, uranium, and various colloids from process waste treatment effluents. A number of organic ion exchange resins were evaluated for removal of $^{238}\text{Pu(IV)}$, $^{238}\text{Pu(VI)}$, and $^{233}\text{U(VI)}$ from water using batch isotherm tests. The capacity and equilibrium distribution coefficients were compared with each other and with bone char, an inorganic adsorbent consisting of hydroxyapatite (HAP). The various types of adsorbents showed that the extent of removal and the equilibrium coefficients (K_d) were functions of pH. For removal of polymeric plutonium, $^{238}\text{Pu(IV)}$, the best results were achieved using the inorganic adsorbent, bone char (hydroxyapatite), at pH 7. However, macroporous, weak base, anion exchange resins also showed reasonable K_d values at pH 7. Therefore, the best removal of polymeric plutonium can be achieved using chemisorption or weak base anionic exchange, indicating strongly ionized anions. Excellent results for removal of $^{238}\text{Pu(VI)}$ were achieved using macroporous, strong base, anion exchange resins and macroporous, strong acid, cation exchange resins. For removal of ionic $^{233}\text{U(VI)}$, the strongly acidic cation exchangers gave the better results; the K_d values were

(CONT.)

on the order of 10^2 better than bone char. Again, performance was strongly dependent upon pH. Adsorbent resins which remove constituents by physical adsorption did not perform well for uranium removal.

TITL Uranium, thorium, and radium, in ocean water and deep-sea sediments.
CITA Earth and Planet. Sci. Lett. 6: 112-116 (1969).
COUN W Germany
ABST From the data of 25 deep-sea cores it is possible to show that the U/Th ratio of sediments is nearly constant at a low CaCO_3 -content. This result and reflections about some other points have led to the assumption that U and Th are being transported into the sediment through the intermediary of minerals. During the transport U (preferably U-234), Ra, and some Th are leached by ocean water. This model provides for a possibility to interpret the activity ratio $\text{U-234}/\text{U-238} < 1$ in deep-sea sediments with low carbonate content as well as the activity ratio $\text{Th-228}/\text{Th-232}$ approx. 15 in ocean water. Likewise a part of the Ra-226 excess (compared with the I₀ in solution) may be caused by that leaching.

 TITL Recovery of uranium from wet-process phosphoric acid by solvent extraction.

(CONT.)

- CITA Trans. Soc. Min. Eng. AIME 262(3): 240-248 (1977).
COUN USA
ABST The rapid expansion of the phosphate fertilizer industry in conjunction with the projected shortage and spiraling price increase of uranium has greatly renewed interest in wet-process phosphoric acid as a significant source of uranium. Two attractive solvent extraction processes for recovering uranium from the acid have recently been developed and tested through bench-scale at Oak Ridge National Laboratory. One of the processes has been successfully tested on a pilot-plant scale at phosphate plants; the second process, which offers several potential advantages, still needs additional testing. The merits of each process are discussed.

 TITL The behavior of dissolved aluminum in estuarine and coastal waters.
 CITA Estuarine Coastal Mar. Sci. 5(6): 755-759 (1977).
 COUN UK
 AREA River Conway (North Wales), North Sea
 ABST The av. concn. of dissolved Al in surface waters of the North Sea with salinities >34‰ was 1.5 $\mu g/L$. The distribution was apparently a function of the Al amts. and distribution in the freshwater inputs. Values decreased away from coastal regions and suggest an oceanic value for dissolved Al of 1.0 $\mu g/L$. Freshwaters from the Rivers Great Ouse and Yare in East Anglia are basic (pH ~8.0) and contain 2-5 $\mu g Al/L$. Samples of freshwater (pH 6.5-7.9) collected from the drainage basin of the River Conway (North Wales) contain 4-98 $\mu g Al/L$. Approx. 30% of the dissolved Al entering the Conway Estuary in fresh water is removed during mixing with seawater in the estuary. Removal occurs during the early stages of mixing, being essentially complete by the time the water has reached a salinity of 8‰. The most probable explanation for the effect is one involving trapping of Al adsorbed on the surface of very fine clay particles entering with the fresh water as the particles are irreversibly coagulated on mixing with saline water in the estuary.

TITL Hydrous titanium oxide ion exchanger. I. Method of synthesis and some properties.
CITA J. Nucl. Sci. Technol. 13(2): 85-91 (1976).
COUN Japan
ABST Synthesis of hydrous titanium oxide ion exchanger was tried from three systems: (a) $\text{TiCl}_4\text{-NaOH-H}_2\text{O}$, (b) ATS (ammonium titanyl sulphate monohydrate)- $\text{NaOH-H}_2\text{O}$ and (c) $\text{TiCl}_4\text{-NH}_4\text{OH-H}_2\text{O}$. The first method gave the best results under the conditions covered in the present work. It was found that repeated washing and aging of the hydrous titanium oxide precipitate were indispensable in order to obtain reproducible results, and that this operation further obviated the need of precisely adjusting the conditions for mixing the reagents. Both the yield of exchanger and the ion exchange capacity of the resulting product increase with concentration of the reagents. A cation exchange capacity of about 3 meq. Na^+/g could be obtained, which is considerably higher than any corresponding value reported in literature. The value decreased with increasing drying temperature. Irrespective of the conditions of synthesis, the chemical composition was $\text{TiO}_2 \cdot (2.0\text{-}2.2) \text{H}_2\text{O}$, and the impurities contained in the product were found to be less than 0.1 w%. The exchanger produced is in granular form suitable for use in column operation. It is fairly stable in alkaline solution, and also in mineral acid solutions of <0.1N concentration.

TITL Studies of the hydrous titanium oxide ion exchanger. IV. The effect of radiation and heat treatment.
CITA Bull. Chem. Soc. Jpn. 51(3): 794-799 (1978).
COUN Japan
ABST The effects of ^{60}Co gamma-irradn. and of heat treatment in air were studied on the properties of the hydrous Ti oxide ion exchanger. The ion-exchange capacity of the Na form did not change at all, while that of the H form decreased a little, by the exposure of 5.2×10^8 R. The color of the exchanger, initially white, turned yellow upon irradn. This exchanger was stable against heat treatment up to $\sim 80^\circ$; thereafter the exchange capacity gradually decreased with the temp. until 324° , where it was abruptly reduced to $\sim 1/4$ of the initial value. The titrn. curves showed that the most acidic exchange site was weaker than less acidic sites against heat treatment. The structural formula of this hydrous Ti oxide ion exchanger is suggested on the basis of the ion-exchange capacity, thermal decompn. curves, x-ray diffraction, and IR spectra.

an international conference held by the IAEA in Salzburg, 2-13 May 1977. ISBN-92-0-050177-X. IAEA, Vienna: 431-441 (1977).

COUN Japan

ABST Nuclear power generation is considered to be very important in Japan, but known domestic uranium resources are very rare; therefore, extraction of uranium from sea-water has become of interest. Some experimental work on extraction of uranium from sea-water has been carried out since 1962 at the Japan Tobacco and Salt Public Corporation. Some results have also been obtained by Kyoto University, the Shikoku Government Industrial Research Institute, Tokyo University and others. To investigate the technical and economical feasibility of extracting uranium and other resources from sea-water, a research programme was started in 1975, sponsored by the Ministry of International Trade and Industry with a budget of about \$440000. In this programme, the conceptional designs of two types of model plants, the "column type" and the "tidal type" were drawn up. Several problems await solution, but these do not appear technically impossible to solve. Adsorption tests were carried out with more than eleven types of adsorbents, including titanium hydroxide which, it was found, when prepared from titanyl sulphate and urea, had the largest adsorption capacity for uranium. Elution experiments were performed with ammonium carbonate and the efficiency at 60°C was three times higher than at 20°C. A few long-term column operations were conducted mainly with the adsorbent, granulated titanium hydroxide, for 15-60 days. The maximum yield of uranium throughout these operations was over 20%, its maximum concentration in the eluate was 7 ppm.

TITL Coprecipitation of uranium with titanium hydroxide from seawater.
CITA Sov. Radiochem. 17(4): 463-467 (1975).
COUN USSR
ABST The process of coprecipitation of uranium with titanium hydroxide from seawater was investigated as a function of certain variable factors. It was shown that coprecipitation is of an adsorption nature, and its mechanism is determined by the concentrations of H^+ and CO_3^- ions in the seawater. It is suggested that when hydroxide is introduced into seawater, the equilibrium between the carbonate and hydrolyzed forms of uranium is disturbed. The extraction of uranium at pH = 8 reaches 70%. At pH = 5 a state of saturation is not reached even at a uranium content in the sorbent four times as great as the mass of the sorbent itself. The maximum capacity of the sorbent at pH = 8 is 0.073 mg U/mg Ti.

TITL Studies on the extraction of uranium from sea water.

CITA J. Brit. Nucl. Energy Soc. 7(2): 178-183 (1968).

COUN UK

ABST The oceans can be regarded as a vast reserve of a liquid low grade ore of well defined composition containing uranium at 3.34 $\mu\text{g}/\text{l}$. Studies were made on extracting U from sea water by absorption on hydrous TiO_2 . The absorber has been developed to a point where, although deficient in some respects, it shows a high capacity for absorbing U. Uranium can be eluted from the absorber by $(\text{NH}_4)_2\text{CO}_3$ solution, but a small proportion appears to be held firmly. For a large scale extraction plant, a system of two tidal lagoons, similar to that employed for tidal power schemes, was considered for providing the head of water necessary to pass sea water through the absorber.

TITL Extracting uranium from sea water.

CITA Indian East. Eng. 112: 337-339 (1970).

COUN UK

AREA Portland Harbor

ABST Methods for the extraction of uranium from sea water have been examined. Trials have been carried out at Portland harbor with seawater flowing through packed beds of granules of hydrous titanium oxide, which absorb uranium from seawater by ion exchange. The uranium can be leached from the absorber bed by treatment with ammonium carbonate solution and isolated. Several

(CONT.)

arrangements for presenting the absorber to the sea have received attention. Use of tidal energy to provide a larger head of water is contemplated. Capital costs, engineering difficulties and proper site selection are still some of the unsolved problems. It is hoped that these problems will be overcome and by the turn of the century the extraction of uranium from seawater will prove to be an economic and feasible project.

DATE 1977

TITL Recovery of uranium from sea water.

CITA Chem. Ind. (London) (14): 579-582 (1977).

COUN UK

ABST Recent estimates indicate that there will be a very large shortfall in known uranium reserves by the end of the century compared with world demand. It has been shown that the concentration of uranium in the ocean is reasonably constant at about three ppb representing a total uranium content of about 4×10^9 t. As such it offers a virtually limitless source of supply and it could be argued that as the grades of ore being exploited on land decrease, the prospects for sea water uranium become enhanced. These paper attempts to place these prospects in perspective. Some of the findings are of general applicability to the winning of other trace elements from the sea.

DATE 1967

TITL Extraction of uranium and other inorganic materials from sea water.

CITA Atomic Energy Research Establishment Report AERE-R-5500 (Vol.2): 387-398 (1967).

COUN UK

ABST The commercial success of plants for the extraction of magnesium hydroxide and bromine from sea water suggests that others of the more plentiful constituents could be separated if prices were favorable. It seems unlikely however, that this will happen so long as present prices prevail. The same is true of elements present at low concentration although special considerations apply in the case of uranium. Progress has been made towards a process based on absorption on hydrous titanium oxide with the aim of establishing a reserve of medium cost uranium. If a plant using this process became operative

(CONT.)

it might be possible to extract certain other useful trace elements at the same time.

TITL Spectroscopic studies on the binding of uranium by brown coal.
CITA Appl. Spectr. 32(5): 486-488 (1978).
COUN W Germany
ABST Brown coal removes U from sea water where it is present mainly as $[\text{UO}_2(\text{CO}_3)_3]^{4-}$. The adsorption and binding of U is studied by infrared spectroscopy. The spectra of the coal-uranium adducts still exhibit the asymmetric stretching vibration of the uranyl ion, but no CO_3^{2-} frequencies, suggesting that U is retained as UO_2^{2+} . The coal humic acids are shown to be responsible for the decomposition of the carbonate complex. The subsequent uptake of U is not a pure cation exchange process since the shift of the asymmetric uranyl stretching frequency from 950 cm^{-1} (hydrated UO_2^{2+}) to 890 cm^{-1} points to complexation of UO_2^{2+} by carboxylate groups which act as bidentate ligands.

TITL Uranium isotopes in sea-floor phosphorites.
CITA Geochim. Cosmochim. Acta 34: 3-24 (1970).
COUN USA
ABST Analyses of uranium concentration and $\text{U}^{234}/\text{U}^{238}$ activity ratios were performed on 40 samples of marine phosphorites, almost all of them dredged from the present sea floor. In each sample, the concentration and isotopic composition of total uranium and U(VI) were analyzed. Uranium concentrations in the analyzed nodules vary between 6 and 524 ppm, tetravalent uranium constituting 38-84 per cent of the total. Whereas the

(CONT.)

mean activity ratio for total uranium is 0.97, the ratio in the U(IV) uranium is 0.71 and the calculated activity ratio for U(IV) uranium is 1.57. The interpretation of these results has two consequences: (a) All the analyzed nodules are old (probably older than 8×10^5 yr), and are at the present being eroded rather than deposited; hence, the deposition of phosphorite in the present day ocean is rather doubtful; (b) The difference in isotopic ratios between the two oxidation states of uranium generally confirms previously proposed mechanisms of uranium isotope fractionation. Differential oxidation of U^{234} is largely responsible for the measured U^{234}/U^{238} disequilibrium ratios. A model for evolution of uranium isotope activity ratios in different oxidation states is presented.

COUN USA
ABST Sols of Al_2O_3 , Cr_2O_3 , Fe_2O_3 , TiO_2 , or Ti_2O_3 and SiO_2 sols coated with 0.1-1.0 monolayer of one of the metallic oxides were made by dissolving the corresponding chloride salt in H_2O or in a SiO_2 sol suspension and exchanging the chloride for bicarbonate with an anion exchange resin. For example, 441 g of a 30 wt.% SiO_2 sol, Nalcoag 1034 A, was added to a soln. of 28 g $Al_2(OH)_5Cl$ in 45 g H_2O . Then 50 g of an anion exchange resin, Nalcite SAR in bicarbonate form, was slurried in the suspension to absorb the chloride ions. The coated sol filtered from the exchange resin had pH 4.95, 1/2 monolayer coating of Al_2O_3 , and an Al_2O_3/SiO_2 ratio of 0.045. Elec. cond. of the sols, which are salt free, is given.

TITL Ion exchange properties of hydrous oxides.
CITA Proc. UN Intern. Conf. Peaceful Uses At. Energy, 2nd (Geneva) 28: 3-16 (1958).
COUN USA
ABST The large class of amorphous insoluble hydrous oxides has interesting ion exchange properties. These

(CONT.)

materials have high capacities and suitable exchange rates and may therefore be used in packed columns in typical chromatographic (ion exchange) manner. Hydrous oxides may exhibit either cation exchange or anion exchange properties, or both. The type of adsorption depends on the element on which the oxide is based, on the acidity of the medium and, to some extent, on the ion adsorbed. Though some of the most acidic oxides are soluble (e.g., P_2O_5) or easily dispersible (e.g., MoO_3 , WO_3) their intrinsic cation exchange properties may be utilized by incorporating them in excess into an insoluble matrix, i.e., by preparing certain insoluble acidic salts. Some of the materials with cation exchange properties may be used even with extremely small columns for the separation of the alkali metals from each other or of the alkaline earths. The specificity of these compounds for cesium in acidic solutions permits the almost unique isolation of this element from practically all others. Those oxides with anion exchange properties also have unusual selectivities compared with the organic ion exchangers. Oxides based on Bi(III) have high selectivities for the heavier halides and others, such as the oxides of Zr(IV), Nb(V), and Ta(V) for remarkable selectivities for fluorides.

 COUN USA
 AREA Pacific Ocean, Atlantic Ocean, Arctic Ocean, Antarctic Ocean

(CONT.)

- ABST Uranium concentrations and $^{234}\text{U}/^{238}\text{U}$ activity ratios have been determined in 63 seawater samples (nine vertical profiles) from the Atlantic, and Pacific, and Arctic, and the Antarctic oceans, using the alpha-spectrometric method for their determinations. Correlation between uranium and salinity is well manifested by the data from the Arctic and the Antarctic oceans, but such a relation cannot be clearly defined with the $\pm(1 \text{ to } 2)\%$ precision of uranium measurements for the Atlantic and Pacific data. At the 95% confidence level: (1) the uranium/salinity ratio is $(9.34 \pm 0.56) \times 10^{-8}$ g/g for the seawater analyzed with salinity ranging from 30.3 to 36.2 per thousand; the uranium concentration of seawater of 35 per thousand salinity is $3.35 \pm 0.2 \mu\text{g l}^{-1}$; (2) the $^{234}\text{U}/^{238}\text{U}$ activity ratio is 1.14 ± 0.03 . Uranium isotopes in interstitial waters of the Pacific surface sediments analyzed do not show large concentration differences across the sediment-water interface as suggested by previous measurements. Current estimations of the average world river uranium concentration ($0.3 \text{ to } 0.6 \mu\text{g l}^{-1}$) and $^{234}\text{U}/^{238}\text{U}$ ratio (1.2 to 1.3) and of the diffusional ^{234}U influx from sediments ($0.3 \text{ dpm cm}^{-2} 10^{-3} \text{ yr}^{-1}$) are essentially consistent with a model which depicts a steady state distribution of uranium in the ocean. However, the $0.3 \text{ to } 0.6 \mu\text{g l}^{-1}$ value for river uranium may be an upper limit estimate.

 CITA Geochim. Cosmochim. Acta 40(7): 849-852 (1976).
 COUN Denmark
 AREA Pacific Islands
 ABST Growth zones and individual sublayers from one manganese nodule and three manganese crusts from an area south of

(CONT.)

Hawaii were analyzed for U and Th by the delayed-neutron counting technique. The concentrations of uranium and thorium in the manganese nodule are highest in the outermost zone on top of the nodule, being the surface last exposed to sea water. In this zone U varies from 6.3 to a maximum of 8.3 ppm in different sublayers, decreasing to 5.0 ppm in the inner zones and 3.4 ppm in the outer zone last exposed to the sediment.

Ferromanganese material scraped from the zone last exposed to the sediment which has low concentrations of Fe, relative to the zone last exposed to sea water, has also low U contents (2.7 ppm). Th concentrations are higher in the outermost zone on top of the nodule (40 to a max. of 130 ppm) than in the zone last exposed to the sediment (about 20 ppm Th). Manganese crusts contain up to 9 ppm U in the outermost zones last exposed to the sea water. They also have higher concentrations of Th (up to 64 ppm) relative to the inner zones of the crust growing on altered andesitic rock, which contains about 8 ppm U and about 26 ppm Th as an average.

TITL Method for the extraction of trace elements from sea water.
CITA Geochim. Cosmochim. Acta 28(7): 1111-1117 (1964).
COUN India
ABST A simple technique is described that permits an in situ extraction of many elements present in trace quantities in sea water. The basis of the technique is adsorption of the elements on ferric hydroxide. A matrix of finely dispersed ferric hydroxide gel, using fibrous jute or spongin as the framework, is constructed through which water could flow freely; this matrix is towed through sea water permitting an in situ extraction of elements from large quantities of water. Four elements present in concentrations ranging from ca 10^{-4} to 10^{-9} g/l of sea water were extracted from the equivalent of a few hundred tons of coastal waters. In the beryllium and silicon extracts the radioactivities due to cosmic ray produced isotopes ^7Be and ^{32}Si were measured. The extraction technique described should prove valuable for studying the distribution and isotopic composition of several trace elements present in sea water as well as in lakes or rivers.

TITL Forms of uranium and Fe existence in natural water and leaching solutions.
CITA Geol. Geofiz. (2): 162-165 (1977). (Russian).
COUN USSR
ABST The measurement of pH, Eh and temperature in a number of pumped out and non-acidified wells in deposits and sampling of the solution from these wells for analysis and comparative evaluation of pH and Eh under laboratory conditions have been carried out in order to calculate experimentally the forms of U and Fe presentation in the leaching solution. For the sulphate solution with the minimum oxidizing potential $E_0 = 0.404$, ionic strength 0.05-2.75 and temperature 25°C , the ratio $(\text{UO}_2^{2+})/(\text{U}^{4+})$ is estimated to be 2.5×10^{18} and the ratio $(\text{UO}_2\text{SO}_4)/(\text{UO}_2^{2+})$ approximately 80, and hence in leaching solutions the concentration of U(4) in the form of sulphate complexes is higher than in the form of uranyl ions by 80 times. In the natural water with Eh = 0.247B, pH = 7.58 and E = 404 the ratio $(\text{UO}_2^{2+})/(\text{U}^{4+}) = 10^{25}$ and hence uranium is in the oxidized condition. When pH of the natural water equals 7 and the concentration of bicarbonate ions approximately 10^{-3} M the constant of the formation of carbonate complexes of uranyl is equal to 10^{22} which is higher than the constant of sulphate complexes by 18

(CONT.)

points, and consequently it is the most probable that U is present in such waters in the form of carbonate complexes. Forms of the Fe present have been calculated in the same way.

CITA Russ. J. Phys. Chem. 51(6): 856-859 (1977).
COUN USSR
ABST Acid-base equilibrium has been investigated on polymeric chelate compounds with groups of aminoethylphosphonium acids, AEP-3, their monoesters, AEP-2 and diesters, AEP-1. Values of the acid-base equilibrium constants of the chelate compounds have been calculated, and schemes of consecutive protonation of the ion exchangers investigated are suggested. Sorption characteristics for the series of U, Fe, Co, Ca, Th metals have been investigated. Values of the distribution coefficients and capacity from acid-base media of various concentration are given. Assumptions are made, which explain an increase in the selectivity and affinity in the series of the chelate compounds investigated. In the AEP-3 > AEP series-2 > AEP-1 weakening of the affinity to U, Fe, Th is observed.

 TITL How much of the rocks and the oceans for power?
 Exploiting the uranium-thorium fission cycle.
 CITA Atomic Energy of Canada Ltd. Report AECL-1916: 33p
 (1964).
 COUN Canada
 ABST When rich uranium ores become scarce, the price will rise from \$13/kg U, but with improved techniques of extraction and the choice of an economical fuel cycle, abundant uranium for many centuries appears to be available in the rocks and the oceans. Even from reactors already developed to the stage of engineering design it is possible to choose a fuel cycle to which uranium at \$250/kg U would contribute no more than 2 mill/kwh. Without suggesting when such a high cost might be reached, its implications are examined. The optimum fuel cycle would balance the financing charges on the fuel inventory and the costs of fuel make-up supply and reprocessing. By using uranium and thorium in combination it was calculated that at least 50,000 Mwd can be derived per ton of uranium. At a net conversion efficiency of 30% and an overall rating of 6 thermal kw/kg, the natural uranium inventory would cost at the suggested high price $\$250/(6 \times 0.3) = \$139/\text{ekw}$ and for 7000 hr/yr at 7% annual charges would contribute 1.4 mill/ekwh. At 50 Mwd/kg U the make-up supply contributes $250/(50 \times 24 \times 0.3) = 0.7$ mill/ekwh. Probably higher efficiency and possibly higher specific power ratings would be used to lower such costs. The value of uranium is related to its content of the fissile ^{235}U , and even though most power may be derived from thorium, it was concluded that its value will not rise comparably with that of uranium. The total cost of nuclear power also includes contributions from the cost of equipment and plant operation as well as from costs of fabricating and processing materials. Any other technique or fuel cycle is considered unable to supplant the thermal fission reactors merely by showing a lower demand for fissile material, but if plant and operating

(CONT.)

costs are not excessive, may enter the competition or become a valuable supplement. Three such techniques recognized are: fast neutron breeders, neutron production by the excitation of heavy nuclei to high energies, and controlled thermonuclear fusion.

CITA Atom (London) (238): 214-219 (1976).
COUN UK
AREA Straits of Dover, Irish Sea
ABST This paper is based on the conclusions of a working party set up by the United Kingdom Atomic Energy Authority some years ago to assess the problems involved in the extraction of U from sea water. Headings include the following: the sea as a source of U - an examination of possible schemes; energy balance analysis for extraction of U from sea water; environmental aspects; possible extractive plant sites; and sites of process development. Amongst conclusions reached are (i) there are a number of uncertainties associated with the process and extensive further research would be necessary to appreciably reduce the level of these uncertainties; (ii) the most promising extraction system is that based on pumped sea water flow; (iii) it seems unlikely that there are sites around the UK where U extraction from sea water could appreciably help UK requirements; (iv) a large scale U extraction plant could involve a major biological management effort both within the process and the environment, although the biological problems could probably be overcome; (v) in view of the uncertainties associated with such a project, it is at present unrealistic to attempt to give even approximate cost estimates; (vi) it would be unwise to expect U from sea water to contribute significant amount to world U demands for thermal reactors on an acceptable time scale.

(CONT.)

Washington, D.C., 24-26 November 1975. ISBN
92-0-041176-2. IAEA, Vienna: 205-212 (1975).

COUN UK

ABST The possibility of extraction of uranium from sea-water on a sufficiently large scale to contribute significantly to national UK requirements is placed in perspective. It seems unlikely that there are sites around the UK coast where this could be achieved, and insufficient work has been done to be confident that sites exist anywhere to enable uranium extraction to be carried out on a large scale. Process techniques have been developed on a small scale, but extensive further research work would be necessary to reduce appreciably the present uncertainties. It would be unwise to expect uranium from sea-water to contribute significant amounts to the world's uranium demand for thermal reactors on an acceptable timescale.

TITL Adsorption of uranyl species on pyrophyllite, quartz, and acid-treated South African uranium ores. A preliminary investigation.

CITA National Inst. for Metallurgy Report NIM-1205: 21p (1971).

COUN S Africa

ABST The adsorption of ionic species of uranium by pyrophyllite and quartz was investigated. A more detailed study of the adsorption and desorption of uranyl species (from sulfate solution) by ore from the Rossing deposit was also undertaken. Owing to poor reproducibility, the interpretation of the results was difficult. However, it was found that complete desorption of the uranium occur after adsorption from solutions containing 8.5 ppm of uranium. Adsorption of uranyl species by Buffelsfontein ore was also investigated. It was concluded that the amounts of uranium that might be lost due to adsorption in the extraction process were probably very small, amounting to less than 0.6% of the head value of the uranium.

 TITL Sandia solidification process: a broad range aqueous waste solidification method.
 CITA Report SAND-75-5907: 15p (1976).
 COUN USA
 ABST Ion-exchange material of the hydrous oxide type were developed for solidifying aq. radioactive wastes. These materials have the general formula: $M[M'_2 Q_y H_z]_n$, where M is an exchangeable cation of charge n and M' may be Ti, Nb, Zr, or Ta. Affinities for polyvalent cations were very high and ion-exchange capacities large (e.g. 4.0-4.5 mequiv./g for $NaTi_2 O_5 H$ [60704-88-3], depending on moisture content). The effectiveness of the exchangers for solidifying high-level waste resulting from reprocessing light-water reactor fuel was demonstrated in small-scale tests. Used in conjunction with anion exchange resin, these materials reduced test soln. radioactivity from ~ 0.2 Ci/ml to as low as ~ 2 nCi/ml. The residual radioactivity was almost exclusively due to ^{106}Ru and total α activity was only a few pCi/ml. Alternative methods of consolidating the solidified waste were evaluated with nonradioactive simulants. Best results were obtained by pressure-sintering which yielded essentially fully dense ceramics, e.g. titanate/titania ceramics with bulk d. as < 4.7 g/cm³, waste oxide content as high as 1.2 g/cm³, and leach resistance comparable to good borosilicate glass. A baseline process for solidifying high-level waste was defined and approx. economic anal. indicated costs were not prohibitive. Also, operating conditions could be modified to allow recovery of radiocesium (and perhaps other isotopes) during solidification of the remaining constituents of high-level waste. These materials might be used for treating tank-stored neutralized wastes.

TITL Carboxylic acids as metal extractants.
CITA Talanta 21(7): 685-703 (1974).
COUN Scotland
ABST One of the problems in the extraction of trace elements is that matrix elements must usually be masked, involving the addition of large amounts of extra reagent and thus increasing the risk of contamination. If the matrix element is to be removed, an extraction system of high capacity is needed to avoid dilution effects. In this respect, long chain or substituted carboxylic acids show great promise. A literature review on their use as metal extractants is presented. The metals extracted include U, Th, Zr, Nb, rare earth metals, In, Te, V, Cd, Y, Sc, Ce, Sr, Be, Ru, Cs.

TITL Treatment of uranium-containing solutions on a mobile layer of ion exchange resins.
CITA Ind. Chim. Belge 32(1): 526-529 (1967). (French).
COUN Belgium
ABST Trials were run on a pilot installation comprising an extrn. and an elution column operating simultaneously. Mine water, 30 m.³/hr., with an av. content of 100 mg. U/l. were treated. The eluate is chlorosulfate at 10 g./l. The resin was moved intermittently from the bottom towards the top of the bed. Full-scale industrial columns have been designed from the data obtained on the two in pilot plant columns. The presence of clay in the water necessitated periodic countercurrent washing of the columns (bottom to top). No problems as to wear of valves by the resin were experienced at flow rates under 70 l./hr.; this flow rate could be increased if countercurrent flow in the valves was avoided.

 TITL A new method of spectrophotometric determination of uranium in sea water and uranium content with $^{234}U/^{238}U$ ratio in the Pacific water.
 CITA Rec. Oceanogr. Works Jpn. 11(2): (1972).
 COUN Japan
 AREA North Pacific (Japan), Japan Sea
 ABST A new method of determination of uranium in sea water is devised. The uranium is adsorbed on a chelating resin (Dowex A-1 or Chelex-100) under the presence of CyDTA at pH 3, and then eluted with 5 M HCl. For the spectrophotometric determination of uranium, Arsenazo-III is used at pH 1. Uranium forms 1:1 complex with Arsenazo-III which has a maximum absorption at 650 m μ . The average recovery of uranium in sea water is $99.7 \pm 0.5\%$. By using the above method and alpha-ray spectrometry, the content of uranium of 3.31×10^{-6} g/l and the activity ratio $^{234}U/^{238}U$ of 1.13 were obtained on the average in sea water in the western North Pacific off Japan and the Japan Sea.

TITL Uranium concentrations in marine sediments.

CITA Geochim. Cosmochim. Acta 37: 35-51 (1973).

COUN USA

AREA Pettaquamscutt River (Rhode Island), Gulf of Mexico, Pacific

ABST Uranium concentrations in a large number of marine samples of different types with world-wide spatial distribution have been determined using the rapid, precise and nondestructive technique of counting the delayed neutrons emitted during U^{235} fission induced with thermal neutrons. Several interesting relationships were apparent. (1) A direct proportionality was observed between percentage of organic carbon and uranium in sediments deposited in an anoxic environment in the Pettaquamscutt River in Rhode Island with concentrations ranging from 7 per cent organic carbon and 7 ppm uranium to 14 per cent organic carbon and 30 ppm uranium. A similar relationship was found in cores of sediments deposited on the Sigsbee Knolls in the Gulf of Mexico. (2) For manganese nodules a direct relationship can be seen between uranium and calcium concentrations and both decrease with depth of deposition. For nodules from 4500 m in the Pacific, concentrations are 3 ppm uranium and 0.3 per cent calcium compared with 14 ppm uranium and 1.5 per cent calcium at 1000 ppm. (3) Relatively high uranium concentrations were observed in carbonates deposited in the deepest parts of the Gulf of Mexico, with the $>88\mu$ carbonate fraction in Sigsbee Knoll cores having as much as 1.20 ppm. A model to explain the observed variations must include uranium enrichment in near shore environments via an anoxic pathway, followed by redeposition in a deep ocean environment with dilution either by low-uranium-bearing foraminiferal or siliceous oozes or, along the continental margins, dilution with high-uranium-bearing carbonate sands.

chelating ion-exchange resins.

CITA Iowa State Univ. (Ames), University Microfilms, 3 341
000: (1976).

COUN USA

ABST Arsonic acid resins are synthesized on XAD-1, -2, and -4. The physical properties are compared as a function of the surface area and pore diameter. The selectivity order of the resin is Th(IV) > U(VI) > Re(III) = Cu(II) = Pb(II) = Al(III), Fe(III) = Zn(II) = Ni(II), Co(II) = Cd(II) = Mn(II) = Mg(II). AA-4 which contains 0.75 mmole arsenic/benzene ring is used to concentrate trace heavy metals. The effects of pH and complexing agents and a comparison of batch and column techniques on recovery are studied. Separations of U(VI) and Th(IV) from other metal ions are developed. XAD-4 was used as a starting material for the synthesis of an N-hexylthioglycolate resin. Batch capacity studies show the resin to form 1:1, 2:1, and 3:1 R:M complexes with Ag(I), Hg(II), and Au(III). Bi(III), Ag(I), Hg(II), and Au(III) can be separated from each other and other metal ions by selectivity complexation from 0.1 M perchloric acid and sequential elution with 0.5, 2.0, and 6.0 M hydrochloric acid and pH 3.0-thiourea. A new spectrophotometric method for gold is reported. A propylenediamine tetraacetic acid resin synthesis is described. Stability constants of the resin are determined for four metal ions and compared to the monomer and EDTA. The resin has a stability order of Zr(IV) > Th(IV) = U(VI) = Bi(III) = V(V) = Fe(III) = Cr(III) = Pb(II) = Cu(II) = Ni(II) = Co(II) = Zn(II) = Cd(II) = Mn(II) = Mg(II) in hydrochloric acid. Uranium(VI), thorium(IV), and zirconium(IV) can be separated from each other and other metal ions by selective complexation from 0.01 M HCl and sequential elution with 0.1 M and 1.0 M HCl and 1.0 M H₂SO₄. The determination of uranium in low grade ores and thorium in monazite sand is demonstrated.

(CONT.)

- TITL Some aspects of fixation of uranium from natural waters.
 CITA Kozan Chishitsu 15: 287-298 (1965). (Japanese).
 COUN Japan
 ABST Uranium in natural waters can be fixed either by precipitation of uranium minerals or by adsorption on some adsorbents such as clay minerals and carbonaceous materials. The precipitation is controlled by factors contributing to the conditions of a system from which a uranium mineral is precipitated, such as temperature, pressure, pH, Eh, and concentration of the elements constituting it. Each factor was examined thermochemically. Decrease in Eh is most effective for the formation of primary uranium minerals, while pH and concentration of such anions as those of phosphorus, vanadium, and arsenic play the most important role in the precipitation of secondary uranium minerals. Adsorption and desorption experiments of hexavalent uranium on montmorillonite, kaolin, and limonite reveal that they have more or less an order of 10,000 ml/g of enrichment factor (Kd) at about pH 6. The adsorbed uranium was found to alter to a uranium mineral most favorable to the surrounding condition when aged experimentally. It suggests that the adsorbents perform a kind of catalytic action for the formation of uranium minerals from very dilute solution such as surface waters.

 ABST The absorption spectra of aq. solns. of $UO_2[Et_2NCS_2]_2$ which were prepd. by mixing calc. amts. of aq. solns. of $UO_2(NO_3)_2$ and Na diethyldithiocarbamate (I), are shown; absorbance peaks are observed at $\lambda = 533, 665, \text{ and } 726 \text{ m}\mu$. The absorbance at $665 \text{ m}\mu$, measured at different $UO_2^{2+} \cdot [Et_2NCS_2]^-$ ratios in the soln., had a max. value when the above ratio was 1:2; this max. becomes even sharper when the measurements are carried out in a soln. contg. 34 g. KCl/l. The absorbance of solns. contg. the uranyl complex of I obeys the Beer-Lambert law. Although the exptl. data indicate that $UO_2[Et_2NCS_2]_2$ is the predominant complex formed in aq. solns., the existence of other complexes or double salts is not excluded. Under dynamic conditions, the adsorption of I on activated C increases from 100 to 240 g. I/g. C when the I concn. in the starting aq. soln. is increased from 0.01 to 0.3-0.5M. The adsorption of I on activated C

(CONT.)

increases in the presence of KCl in the aq. soln.; the increase is $\sim 16\%$, and changes in the KCl concn., in the range 34-306 g./l., have no effect on the adsorption of U. The adsorption of U (as $\text{UO}_2[\text{Et}_2\text{NCS}_2]_2$) on activated C increases from 50 to 320 mg./g. when the starting U concn. in the soln. is increased from 71 to 250 g./l.; when measuring the adsorption of U, the $\text{UO}_2^{2+}:\text{[Et}_2\text{NCS}_2]^-$ ratio in the starting soln. was 1:3 instead of 1:2, in order to eliminate the presence of uncomplexed uranyl ions in the soln. The max. adsorption of U is obtained from solns. at pH 5.75-6.00, and the adsorption decreases when the pH is reduced below those values (e.g., from a soln. at pH = 3, the max. adsorption of U is only 12 mg./g.); the $\text{UO}_2[\text{Et}_2\text{NCS}_2]_2$ complex is most stable at pH 5.5-6.5, and is completely dissociated at pH ≤ 1.5 . The uranium may be desorbed quantitatively from the activated C by leaching with a soln. of 10 g. H_2SO_4 /l.; the activated C may be reused for the adsorption of more U, but its capacity is reduced to only 70% of the initial value.

TITL Uranium resources - are they adequate?
CITA Nuc. Technol. 30(3): 224-231 (1976).
COUN USA
ABST Uranium resources continue to be an important concern in assessing energy options and strategies. The question

(CONT.)

of the uranium supply for the development of nuclear power has also become one of the major focal points in the controversy over the breeder reactor program and nuclear fission energy in general. World reserves at a cutoff cost of production up to \$15/lb of U_3O_8 are approx. 1.1 million MTU, and the estimate of undiscovered potential resources approx. 1.7 million MT. Exploration throughout the world has not yet identified significant numbers of new types of uranium deposits that might begin to fill the apparent gap between long-term demand and supply; that is, large intermediate-grade deposits containing 100 to 700 ppm uranium. In 1973 the U.S. Atomic Energy Commission initiated an accelerated and expanded resource evaluation program to ascertain the total U.S. uranium resource base, including the potential of areas largely ignored in past exploration. Preliminary investigations to date have indicated additional potential resources in the possible and speculative categories of approx. 850,000 MT at a production cutoff cost of up to \$30/lb. It is unlikely however, that the annual production of approx. 100,000 MT projected by the year 2000 could be achieved from the presently estimated resource base of 2.7 million MT - reserves plus potential - 80 percent of which remains to be found. Thus, information to date continues to support the need for the early introduction of the breeder reactor.

TITL Extraction of uranium from seawater. I. Coprecipitation of uranium in seawater with metal hydroxides.
CITA Nippon Genshiryoku Gakkaishi 10(12): 672-678 (1968).
COUN Japan
ABST With the view to studying the possibility of separating uranium from seawater by coprecipitation, the carrier properties of ferric, aluminum, and titanium hydroxides were examined, with the following results: (1) The values of pH at which uranium started to coprecipitate with the carriers were 8 to 9 for aluminum and ferric hydroxides, and 4.5 for ferric hydroxide, 5.0 for aluminum hydroxide, and 2.8 for titanium hydroxide. (2) Optimum pH values for decarbonated seawater to obtain maximum recovery of uranium were 4.5 to 9 for titanium hydroxide with natural seawater; the values were appreciably lower for ferric and aluminum hydroxides; but unchanged for titanium hydroxide. (3) In the case of ferric and aluminum hydroxides, the coprecipitation ratios of uranium were much smaller in natural than in decarbonated seawater. With titanium hydroxide, however, uranium coprecipitated with equal ease in natural seawater and decarbonated seawater. (4) Uranium was effectively separated from the carriers by carbonate salt extraction but not by acid extraction.

TITL Recovery of uranium from sea water.
CITA Genshiryoku Kogyo 16(12), 19-22 (1970). (Japanese).
COUN Japan
ABST The status of investigation of uranium recovery from seawater is reviewed. Recent values of uranium content in seawater are from 0.0030 to 0.0035 ppm, and the total amount of uranium in the world's seawater is estimated as 4,500 million tons. English investigators recently obtained 550 µg of uranium per 1g of titanium, using titanitic acid adsorbent. Inoue and Kokibama reported 1550 µg of adsorbed uranium per 1g of titanium, using titanitic acid by a thermal dissociation process. This method is explained together with the method that uses titanitic acid prepared from a neutralization process. Factors that have great effects on the adsorption of uranium in seawater, such as temperatures and amount of contacting seawater, are discussed.

TITL Collection of uranium in sea-water. VI. Adsorption of uranium in sea-water with titanitic acid.

(CONT.)

CITA Nippon Genshiryoku Gakkaishi 13(3): 121-127 (1971).
(Japanese).

COUN Japan

ABST The adsorbing capacity for uranium shown by titanitic acid prepared in homogeneous and acidic solution was found larger than titanitic acid prepared in nonhomogeneous and neutral solution. The uranium adsorbed on titanitic acid increased with rising temperature of seawater. The adsorption reached equilibrium within 2 days. The concentration of uranium in the titanitic acid was found experimentally to have a maximum value of $U/Ti=1,500\mu g/g$.

The concentration of uranium adsorbed on the titanitic acid at a given temperature was determined by the amount of seawater and the concentration of uranium in seawater on the same titanitic acid. An empirical formula was obtained for this relationship; the adsorption was applied to Freundlich's isotherm, and the distribution coefficients were found nearly constant within the range of seawater volume covered by the present experiment. The adsorption capacity was estimated from the term of multiplication of the distribution coefficient and the concentration of uranium in seawater. The maximum value evaluated was $U/Ti=4,200\mu g/g$, with the titanitic acid prepared by hydrolysis. The uranium adsorbed on the titanitic acid increased with rising temperature of the seawater, the empirical relationship being $c=k \exp(\alpha t^2)$, (c : concn. of U., t : temp., k and α : const.).

TITL Collection of uranium in sea-water. VII. Desorption of uranium adsorbed on titanitic acid.

CITA Nippon Genshiryoku Gakkaishi 13(5): 253-259 (1971).
(Japanese).

COUN Japan

ABST A basic study was carried out on the desorption of uranium adsorbed on titanitic acid, using alternatively, a mixed solution of $(NH_4)_2CO_3$ and NH_4OH , a mixed solution of Na_2CO_3 and $NaHCO_3$, dilute H_2SO_4 , or dilute HCl . The titanitic acid used was prepared by homogeneous precipitation, in which urea was added to $Ti(SO_4)_2$ solution and then the solution was heated to produce titanitic acid precipitate. Uranium was adsorbed by dipping the titanitic acid in natural seawater. In the case of uranium desorption with carbonate solution, there was little dissolution of the titanitic acid and of impurities in the solution after desorption, but the drawback of this agent is its expensiveness and it is further liable to be gradually consumed upon repeated

(CONT.)

use. Desorption with acid, which it was believed to have the disadvantage of dissolving titanitic acid in much greater quantity, proved on experiment not to be any worse than with carbonate. The cost of acid, moreover, is lower, and there is little deterioration of the adsorption ability of titanitic acid because of the small amount of impurities remaining in it. It was concluded that desorption with acid could be used in practice with good chances of rivaling the carbonate method. For the desorption, it is recommended to heat above 90°C the titanitic acid carrying the uranium in HCl (0.5N) or in a mixed solution of Na₂CO₃/NaHCO₃ (8/2 to 0/10) containing over 6% CO₃.

 TITL Fundamental study on the recovery of uranium in seawater.
 CITA Nippon Kaisui Gakkai-Shi 24(5): 197-212 (1971). (Japanese).
 COUN Japan
 ABST Through the course of a fundamental study on the collection of uranium in seawater, an extensive improvement was made in the separating and determining methods of uranium. Various studies were made on the collecting methods of uranium in seawater, the adsorption method with titanitic acid being the most effective. Chemical species of uranium in seawater were researched by the stability constants of such components as Na⁺, K⁺, Ca²⁺, Mg²⁺, Cl⁻, SO₄²⁻, F⁻, PO₃³⁻, HPO₃²⁻, CO₃²⁻, OH⁻, and UO₂²⁺. As consequence, most of the dissolved uranium species were found to be UO₂(CO₃)₃⁴⁻. The adsorption mechanism of uranyl carbonate complex ion on titanitic acid was presumed an anion exchange reaction. The adsorption of uranium was governed by the kind of titanitic acid, the temperature of seawater, the contacted volume of seawater, and the concentration of uranium in seawater.

 TITL Approach to industrialization on collection of uranium in sea-water.
 CITA Genshiryoku Kogyo 20(12): 51-56 (1974). (Japanese).
 COUN Japan
 ABST Research for collecting uranium in seawater was started in Japan in 1967, but it has been interrupted since

(CONT.)

about 1971 except Shikoku Industrial Laboratory, MITI. Knowledges and experiences obtained so far are introduced, as the research project is going to start again. The methods used for collecting uranium in seawater are briefly reviewed. Methods and apparatuses for adsorption are referred to. The method of flowing seawater through columns charged with particle form adsorbent is suitable for test plants, but cannot be used over 2 cm/sec flow speed. Filter type, fluidized bed type, and cyclone type show good recovery rate, but pumps are required. In pool type, formed adsorbent (particles, films, and nets) is packed in the channels of pools. This method can be used for the dam method utilizing tide. The dam method is estimated at \$62 per lb in Japan. Adsorber type idea was contemplated to solve the fault in changing to fresh seawater in tide-utilizing method. Problems in the tide-utilizing dam system may be siting conditions where fresh seawater can be introduced, sufficient tide difference, relatively high temperature, large ground area required, for example 1.57 km² of bed area only, the quality and form of adsorbent, unbalance in material account, and the deterioration of adsorbent by repetition of use, the obstruction of adsorption and flow by diatom and green weed, and the effect of the titanate acid because of contaminant adsorption. Desorption step must be studied further.

COUN Japan
AREA Seto Inland Sea
ABST The problems of a future plant having the capacity of

(CONT.)

extracting 1,000 tons of uranium per year from sea in Japan are studied. The investigations into the extraction of uranium from sea water in F.R. Germany, United Kingdom, France, United States of America and other foreign countries are described. The operation of a test plant having the capacity of ten kg uranium per year will be started by a project team in Japan. The team consists of four sub teams to study separately the total system, the absorption and desorption, the enrichment and separation, and the location and environment. About 40,000 tons of sea water per day are required for the test plant at the recovery rate of 27.7% during 300 operation days. The concentration of uranium in sea water of the Seto inland sea is assumed as 3.0 microgram per litre. The adsorption power was compared among titanitic acid adsorbent, the composite adsorbent of activated carbon and titanitic acid, and galena adsorbent. As a result of testing, the titanitic acid indicated the adsorption capacity of 750 U-microgram/g; the composite showed 1,200 U-microgram/g; and the galena gave 550 U-microgram/g. For the desorption process, 1 M carbonate solution or 0.05 N dilute hydrochloric acid solution is used. For the processes of enrichment, separation and purification, the system of ion exchange membrane electrodialysis and flash evaporator may be the most effective. The aim for future is the production cost of uranium of 150 dollars/lb.

COUN Japan
AREA Odawara Coast
ABST A study was made to improve the separation method and fluorophotometric method for the determination of U in seawater without using the isotope dilution method. Uranium in the sample of seawater was adsorbed into titanate acid and extracted with mixture of sodium carbonate and sodium hydrogen carbonate at 100°C. The extracted solution was passed through an anion exchange resin of carbonate type, and the U adsorbed into the resin was eluted with HCl solution. The recovery of U by this method represented 90%, which was higher than the conventional methods but was still incomplete. Therefore, the condition of adsorption must be kept stable to obtain the recovery with small variation, and the determined value was corrected with the recovery. A given amount of this pretreated solution was pipetted into a Pt dish, dried, and melted at 665°C with carbonate - sodium fluoride flux, and the fluorescence strength of the dish was measured. The error caused by the variation of melting condition could be decreased by using a furnace with a fan and correction by simultaneous operation with the U standard solution. The unevenness of the fluorescence strength in the dish could be decreased by using the temporary standard and rotating the fused dish during the measurement, and the measuring error was below 2%. Uranium content in seawater collected along the coast of Odawara showed 3.34 µg/l by this method.

CITA Nippon Kaisui Gakkai-Shi 24(130): 149-153 (1971). (Japanese).
COUN Japan

(CONT.)

ABST General properties of titanitic acid used as adsorbent of U in sea water were investigated by x-ray diffraction, iv spectroscopy, electron microscopy, thermal anal., electrophoresis, and soly. in mineral acids. Four types of titanitic acid were prepd. from $Ti(SO_4)_2$ by the following procedures: neutralization at room temp. or at the b.p., and homogeneous pptn. with NH_4OAc or urea. The products of neutralization procedures and pptn. by using NH_4OAc were bulky, fibrous, and amorphous, contg. a large quantity of adsorbed water. The product of pptn. by using urea was powder-like cubic crystals. Regardless of the types, soly. of titanitic acid in HCl and H_2SO_4 depended on the concn. of the acids and temp. Although the product of neutralization at room temp. was sol. in the acids at room temp., the soly. decreased gradually as time proceeds. Surface charge of the titanitic acid in sea water was neg. The product of neutralization at room temp. was $TiO_2 \cdot 3/2H_2O$ and that at the b.p. was $TiO_2 \cdot 5/3H_2O$; the product of both homogeneous pptn. techniques was $TiO_2 \cdot H_2O$.

 CITA Nippon Genshiryoku Gakkaishi 13(10): 560-565 (1971). (Japanese).
 COUN Japan
 ABST The chemical state of uranium in seawater was sought from stability constants. It was estimated that uranium in seawater existed as U(VI) and that the distribution of the chemical species in standard seawater was: $UO_2(CO_3)_3^{4-}$ 97.9%, $UO_2(OH)_3^-$ 1.73%, and $UO_2(CO_3)_2^{2-}$ 0.4%. The cation-exchange ability of titanitic acid was demonstrated

(CONT.)

from the fact that the pH value of NaCl solution shifted toward the acidic side by the addition of titanitic acid. But, despite this cation-exchange ability, it is thought that the form in which titanitic acid adsorbed uranium is probably $UO_2(CO_3)_3^{4-}$, because it was found to adsorb HCO_3^- in quantities proportional to uranium. From the results of the present and previous studies, it is presumed that uranium is adsorbed by the coordinate bond.

TITL Extraction of uranium from seawater. II. Adsorbents for extraction of uranium from seawater.

CITA Nippon Genshiryoku Gakkaishi 11(2): 82-87 (1969). (Japanese).

COUN Japan

ABST About fifty insoluble compounds of titanium, aluminum, magnesium, calcium, silicon, zinc, chromium, lead, and tin were examined in a search for suitable adsorbents of uranium in seawater. The only materials that exhibited an effective uptake were titanium hydroxide, lead sulfide, and chromium hydroxide, the uptake capacities of which were 196, 134, 68 $\mu\text{g/g}$, respectively. While their uptake capacity was small, manganese dioxide, zinc hydroxide, and lead hydroxide also adsorbed uranium in the pH range of seawater. Ferric hydroxide, ferrous sulfide, ferric phosphate, tin sulfide, titanium hydroxide, and manganese oxide were found to be good adsorbents in acidified seawater, though acidification of seawater would not be practical in industrial scale operations. Tannic acid salts of magnesium, calcium, and titanium adsorbed uranium in seawater, but had the drawback of relatively large solubility.

CITA Sci. Rep. Kanazawa Univ. 22(1): 106-116 (1977).
COUN Japan
AREA Malay Peninsula, Ryukyu Islands
ABST Some hermatypic corals, molluscs, and their inhabiting sea water were collected from the tropical (Malay Peninsula) and subtropical (Ryukyu Islands) localities, and the $m_{\text{UO}_2^{2+}}/m_{\text{Ca}^{2+}}$ of them were determined in order to evaluate the apparent distribution coefficient of uranyl between biogenic carbonate and seawater, which can be an aid to understand the factors controlling uranium concentration in skeletal calcium carbonates. The result suggests that the compositional factor such as mineral phases and organic matrices and the physiological factor such as chemistry of the body fluid and extrapallial fluid become of major causes to control uranium concentration in skeletal carbonates. Moreover, a little difference in distribution coefficient of uranyl in coralline aragonite between Malay Peninsula and Ryukyu Islands may be attributed to the difference in water temperature. The difference in uranium concentration between two shell layers of an individual specimen of Tridacnid may be interpreted as the result of a subtle control over physiological process during shell formation, rather than compositional and environmental causes.

CITA Coprecipitation and Adsorption of Radioactive Elements, Akademiia Nauk USSR. Trans. from Russian by Israel Program for Sci. Trans., Ltd.: 183-187 (1967).
COUN USSR
ABST From determinations of the molar ratio of the amount of chlorine displaced from the anion-exchange resin to the amount of uranium sorbed on it, and the molar ratios F^-

(CONT.)

: UO_2^{2+} in the resin and filtrate, it was established that uranium is sorbed from stoichiometrically neutral uranyl fluoride solutions in the form of monovalent complex anions, $UO_2F_3^-$. At a certain stage of the sorption process, when the uranium concentration in the resin phase is high, the sorbed ions become complex as a result of hydrolysis and subsequent complex formation. The low degree of dissociation of UO_2F_2 in aqueous solutions and the breakthrough of uranium into the filtrate in the form of the most stable complex ions UO_2F^+ confirm the validity of the sorption mechanism derived from an analysis of the effluent curves. The neutral uranyl fluoride molecules attach themselves to the fluoride ions in the resin to form complex anions.

TITL The sorption of uranium (VI) from HCl-HF solutions on anion exchange resins.
CITA Coprecipitation and Adsorption of Radioactive Elements, Akademiia Nauk, USSR. Trans. from Russian by Israel Program in Sci. Trans., Ltd.: 203-209 (1967).
COUN USSR
ABST The sorption of uranium (VI) from HCl-HF solutions on the AV-17, AV-16G, EDE-10P, and AN-2f anion-exchange resins was studied under dynamic conditions. It was found that the addition of hydrofluoric acid to uranyl solutions in HCl causes a sharp increase in the sorbability of uranium, which is due to the appearance of $UO_2F_3^-$ complex monovalent ions in the solutions. These anions are readily sorbed on the anion-exchange resins. It was found that uranium is not eluted from the anion-exchange resins by dilute HCl containing HF. Nitric acid and acidified ammonium nitrate solutions, however, readily eluted the sorbed uranium. The anion-exchange resins studied can be arranged in the following order according to their regeneration capacity: AV-17>AV-16P>EDE-10P>AN-2f.

 COUN India
 ABST To assess structural changes in the double layer, systems of TiO_2 sols., with surface-active agents were studied by measuring the changes in pH and cond. Zeta potentials were also measured by microelectrophoretic

(CONT.)

techniques. Two max. occur in the pH and cond. curves (vs. log concn. of surface-active agent). The first max. was ascribed to ion exchange by adsorption from the Stern layer; the added ions are due to exchange release of OH^- , which are responsible for the increase in cond. Heats of ion exchange calcd. for different surface-active agents are ~ 1 kcal/g-ion. Zeta potentials are practically const. in this region. The 2nd max. was assigned to further release of OH^- ions from the Stern layer due to the adsorption of surface-active agents with long chains. The concns. at which the 2nd max. occur are nearly equiv. to those at which $\zeta = 0$. Heats of adsorption calcd. from electrophoretic data are 6-8 kcal/mole for different surface-active agents. A mechanism of interaction of the long-chain ions with the sol. are suggested.

DATE 1973

TITL Method of extracting uranium from sea-water.

CITA U.S. Patent 3,721,533. Priority date 6 Jun 1969: 4p (1973).

COUN W Germany

ABST A method is presented for extracting uranium in the form of tricarbonato complexes of UO_2^{++} from seawater or other liquids rich in metal ions. The seawater is acidified to a pH of approximately 5 (e.g. with hydrochloric acid or HNO_3), and then is treated with ultramarine blue in an ion-exchange relationship until equilibrium is reached in the distribution of uranium between the ultramarine blue and the seawater. Elution of the uranium is carried out with an alkali carbonate solution.

DATE 1976

TITL Method of obtaining uranium from uranium compounds dissolved in sea water.

CITA German (F.R) patent 1928864/C/. Int. Cl. C01G 43/02: 3p (1976). (German).

COUN W Germany

ABST The patent deals with an ion exchange separation process for uranium compounds dissolved in sea water. The uranium is generally present here as tri-carbonato complex. Synthetic ultramarine blue is used for the exchange of the uranyl ions, which, compared to other ion exchange materials, has the advantage of favourable exchange kinetics and is also cheaper. The loading takes place at pH 5 with a ratio exchanger to seawater of 1:100. Alkali carbonate solution is used for the elution.

TITL Co-extraction and separate recovery of uranium and thorium from acid solutions.
CITA U.S. Patent 3,835,213. Filed date 1 Oct 1971: 6p (1974).
COUN Canada
ABST A process is described for separating uranium and thorium from an aqueous acid solution containing them together with rare earth elements. The process comprises contacting the solution with a water-immiscible organic solution of a high molecular weight primary or secondary amine whereby the uranium and thorium values are co-extracted and separating the resulting uranium and thorium loaded amine solution from the aqueous solution. The uranium and thorium are then easily separated from the loaded amine solution either by selective stripping or co-stripping and selective extraction.

ABST The GEOSECS project is a multi-institutional investigation of the geochemistry and mixing dynamics of the oceans. The objective of this study is to utilize the oceans' chemical and radionuclide constituents to

(CONT.)

characterize the biogeochemical and physicochemical processes occurring in the oceans. Results are reported from the characterization of a large group of trace elements in the oceans, and the measurement and utilization of cosmic-ray and fallout radionuclides as tracers of aerosol deposition and ocean mixing processes. The radionuclide studies have now been completed and the program has been directed towards measurement of the distributions of trace metals of geochemical and environmental interest in the oceans utilizing the valuable inventory of well documented GEOSECS samples. The analyses of sea water from open ocean GEOSECS tracks are being supplemented by trace metal measurements of seawater samples collected on cruises extending from the coastlines of the U.S. to open ocean areas. These data will help define the natural and anthropogenic processes which create concentration gradients between the coastal and open ocean waters. The air-to-sea transfer of airborne trace metals to the coastal marine environment, the chemical species after dissolution, and subsequent chemical reactions which will affect bioavailability were also studied. The validity of ^7Be as a tracer for air-sea transfer of trace metals is being investigated presently. The distribution chemical/physical forms of plutonium in the Pacific Northwest coastal waters and sediments is also being studied to predict the future consequences of plutonium inputs to the coastal ecosystem.

ABST In southern Texas, loosely consolidated uranium bearing sand stone occurs at depths of 300 to 700 feet. Development of a successful in-place leaching technique could mean low capital and operating costs, minimum land-surface disruption and avoidance of disposal or storage of mill tailings. The clue to in-place leaching of the Texas uranium deposits without excessive reagent use and without plugging the ore formation appears in the use of extremely dilute alkaline leach solution with a low uranium-loading and a high circulation rate. For meeting the uranium requirements of nuclear power generation, 125 tons of U_3O_8 is roughly equivalent to the annual requirement of a 500-mega watt reactor.

COUN USA
AREA Gulf of Mexico
ABST The economic importance, the dissimilarity in chemical behavior of its two oxidation states and the unique usefulness of its radioactive daughter products make uranium and its geochemistry extremely interesting to earth scientists. The Gulf of Mexico (GOM) has the attractive feature of being a semi-closed system that offers the possibility of a complete monitoring of all inputs and removal processes for trace elements such as uranium. Experimental values obtained in this study of the geochemical cycle of uranium in the GOM are presented. High uranium concentrations in midwest U.S.A. rivers relative to other rivers of the world can be explained by solubilization of the uranium in phosphate fertilizers applied to the land surface. Estimated pre-fertilizer uranium input to the GOM is nearly balanced by uranium co-deposition with carbonates on the Yucatan shelf.

(CONT.)

- COUN USA
ABST Approximately 10^{15} $\mu\text{g}/\text{yr}$ of dissolved uranium are being removed from the ocean by each of the generally accepted significant sinks for uranium-carbonate deposits and deep anoxic basin sediments. However, these sinks account for only 10% of the estimated present-day input of uranium. Possible explanations for this discrepancy are: contemporary input values are too high owing to a significant contribution from man's effects, such as uranium input via phosphate fertilizers or world-wide cultivation leading to premature leaching of uranium from soils; or there are other important uranium sinks such as the abundant siliceous oozes or continental shelf anoxic sediments.

CITA Russ. J. Inorg. Chem. 21(3): 409-412 (1976).
COUN USSR
ABST Sorption of uranium has been studied on strongly basic anion-exchange resin from nitric acid solutions with concentration in metal 10-150 g/l in presence of sodium, calcium, and aluminium nitrates. Sorption of uranium from solutions has been performed by the static method with the aid of contacting the initial solution with air-dry resin for 4 hours, resin to solution ratio being 1:12.5. It has been established that sorption of uranium increases with a rise in concentration of salting out agents in the following order: $\text{Al}(\text{NO}_3)_3 > \text{Ca}(\text{NO}_3)_2 > \text{NaNO}_3$. It has been shown spectrophotometrically that in solutions of nitrates and HNO_3 with a concentration < 6 mol/l, uranyl-ion is present, mainly, as neutral complex ions when its concentration is 100 g/l. The formation of anion complex uranyl-ions is observed when concentration of HNO_3 exceeds 6 mol/l.

TITL Highly dispersive ion exchangers in the analytical chemistry of uranium, particularly regarding separation methods.
CITA INIS-mf-3441: 92p (1975). (German).
COUN W Germany
ABST The reaction of water-insoluble polyvinyl pyrrolidone with uranium VI was investigated and a determination method for uranium was worked out in which the polyvinyl pyrrolidone was used as specific exchanger. Good separations of uranium from numerous transition metal ions were achieved here. The application of this exchanger for a fast and simple elution and determination method was of particular importance. A possible sorption mechanism was suggested based on the capacity curve of uranium with polyvinyl pyrrolidone and nitrogen chloride content at maximum load. The sorption occurs by coordination of the carbonyl oxygen of single pyrrolidone rings with the protons of the complex acids and uranium. This assumption is supported by IR investigations. The sorbability of other inorganic acids was also investigated and possible structures were formulated for the sorption mechanism. In addition to this, ion exchangers were prepared based on cellulose by converting cellulose powder with aziridine and tris-1-aziridinyl-phosphine oxide. A polyethylene imine cellulose of high capacity was obtained in the conversion of cellulose powder with aziridine. This exchanger absorbs cobalt III very strongly. The exchanger loaded with cobalt III was used to separate the uranium as cyanato complex. The exchanger obtained in converting chlorated cellulose with tris-1-aziridinyl-phosphine oxide also absorbs uranium VI very strongly. Thus a separation method of high specificity and selectivity was developed.

- ABST Porous substrates impregnated with P-contg. ion exchanger were prepd. by steeping the substrate with a sol. precursor and then converting it to the insol. exchanger by chem. treatment. Suitable substrates may consist of SiO_2 , Al_2O_3 , or Al and/or Mg silicate spheres or cylinders, 1-10 mm in size, with porosity >40%, such as 72% with av. pores of 125 Å. Useful ion exchangers are quadrivalent Ti, Sn, and Zr salts of phosphoric or phosphonic acid, and acid phosphate esters, or mixts. thereof. These are prepd., resp., by steeping the substrate in a soln. of a peroxytitanyl salt of phosphoric and/or phosphonic acid or salt thereof, and treating with a reducing agent such as HCHO, steeping with an acid soln. of SnCl_4 and the above P acids or salts and neutralizing with an alk. soln., and steeping with a soln. of Zr complex with tartaric, citric, oxalic or hydrofluoric acid and hypophosphites and/or phosphonates and treating with an oxidizing agent such as H_2O_2 and a mineral acid. The examples describe the prepn. of 12 ion exchangers and the partial removal of As, Sb, and Bi from a soln. from the electrolytic deposition of Cu. After use, the ion exchangers may be regenerated by treatment with aq. acid or alk. solns., including sequential treatments with some selective removal of the metal ions.

DATE 1977
TITL Extraction and separation of uranium, thorium and cerium from different mixed media with HDEHP.
CITA J. Radioanal. Chem. 36(2): 389-397 (1977).
COUN W Germany
ABST Systematic studies were carried out on the extraction of U(VI), Th(IV) and Ce(III) with HDEHP from pure hydrochloric and sulfuric acid solutions as well as from their binary mixtures. The influence of water-miscible alcohols and acetone on the extraction of these elements was also investigated. Results were discussed and procedures for the separation of the concerned elements have been recommended. The removal of fission products (rare earths , etc.) from uranium is one of the most important separation problems in reactor chemistry. Ce(III) can be eliminated from U(VI) at 4.5M HCl or H_2SO_4 solutions as well as at 2.5M HCl in presence of 50% ethanol which is more plausible. For the stripping of U(VI) from the organic phase, successive with 11M HCl can be used. U-Th separation can be achieved by successive extraction at 11M HCl or 4.5M HCl in presence of 50% ethanol. Higher separation factors for these

(CONT.)

elements could be obtained when working in HCl-H₂SO₄ solutions. Thorium can easily be separated from Ce(III) at 4.5M HCl or at 5M H₂SO₄. The addition of isopropyl alcohol is recommended for the separation of Th-Ce(III). Quantitative separation for Th-Ce(III) can be achieved from HCl-H₂SO₄ media. A suggested extraction mechanism is presented in the light of the obtained results.

TITL Separation and concentration of uranium by ion flotation method.
CITA Fusen 55: 1-6 (1975). (Japanese).
COUN Japan
ABST The concentration of uranium from seawater has been investigated from the viewpoint of adsorption method and coprecipitation method. In this study a procedure is described for the separation of uranium present as a stable uranyl cation or a tricarbonatouranyl anion by ion flotation which utilizes dicarboxylate and quaternary ammonium chloride as a collector, respectively. When dicarboxylate was used, uranium floated in the pH region 3 to 7 with a maximum recovery of 93% at pH 5. When quaternary ammonium chloride was used, uranium floated at pH values above about 4 and the maximum recovery was 95% at pH 8. The former has the highest concentration ratio because the floated uranium forms a scum, while the latter has the lower concentration ratio because uranium floats with foam.

TITL Extraction of uranium(VI) from sea water using titanium hydroxide-polyacrylamide gel by batch method.
CITA Nippon Genshiryoku Gakkai-Shi 18(12): 796-799 (1976). (Japanese).
COUN Japan
ABST Studies have been made on the extraction of U(VI) from sea water by the adsorption on the gel particles containing titanium hydroxide. The adsorbents were prepared with acrylamide, N,N'-methylenebisacrylamide

(CONT.)

and titanium hydroxide. Uranium(VI) was able to be desorbed from the adsorbent with 1 M sodium carbonate or 1 M ammonium carbonate solution. The following various factors affecting the extraction of U(VI) were studied; the amount of adsorbent, the effect of temperature on the adsorption, the stirring time, the recycle usage of the adsorbent, etc. It was found that the adsorption of U(VI) tended to rise with the increase of shaking time, though it was not affected by temperature. When 25 g of adsorbent was added to 40 l of natural sea water, 84 μg of U(VI) was able to be extracted by slow stirring for 24 hr. It seems that the proposed method having the better selectivity of adsorption and separation is superior to the method using ion exchange resin.

TITL Basic study on uranium extraction from sea water. II. Extraction of uranium(VI) by polyacrylamide gel containing various metal hydroxides.
CITA J. Nucl. Sci. Technol. 14(11): 811-815 (1977).
COUN Japan
ABST U was recovered from seawater by adsorption on gel particles contg. various metal hydroxides, including $\text{Ti}(\text{OH})_4$ and $\text{Zn}(\text{OH})_2$, dispersed in polyacrylamide gel particles. The hydroxide adsorbent thus prepd. in gel form was packed in a column for processing the seawater. The U collected in the column was eluted with a 0.10M Na_2CO_3 soln. Of Fe, Pb, Mn, Ti, and Zn hydroxides, only $\text{Ti}(\text{OH})_4$ functioned usefully as an adsorbent for the U. The degree of polyacrylamide crosslinking had no relation to adsorption performance, which, on the other hand, was significantly influenced by changes in $\text{Ti}(\text{OH})_4$ in the gel. The amt. of U adsorbed reached a max. at 2 mg Ti/mL gel. Also, the adsorption improved with decreasing concn. of U contained in the original seawater, down to 10^{-6}M .

TITL Change in the structure and adsorption properties of titanium dioxide during hydrothermal treatment.
CITA Russ. J. Phys. Chem. 47(2): 278 (1973).
COUN USSR
ABST Addnl. data considered in abstracting and indexing are available from a source cited in the original document. An amorphous sample of TiO_2 was hydrothermally treated in an autoclave at $50-350^\circ$ for 3 hrs. Both the phase compn. and the dimensions of the particles changed. Up to 50° , reduction of particle size prevailed, and this caused an increase in the sp. surface. On further temp. increase the sample was converted to anatase and particle size increased, causing surface area redn. These processes brought about changes in the pore dimensions while the sp. pore vol. remained nearly unchanged. The sorption of Cu^{2+} and Ca^{2+} changed with treatment temp. in the same manner as the surface area, which suggests that cation exchange on such sorbents involves OH-groups, since the no. of OH-groups is proportional to the surface area.

 TITL Mechanism of the sorption of protactinium by silica gel.
 CITA Radiokhimiya 14(2): 220-227 (1972). (Russian).
 COUN USSR
 ABST The sorption mechanism of ²³³Pa by silica gel in 0.01-8M HClO₄ and HNO₃ (C_{acid}) was studied. Results were compared with sorption by anion- and cation-exchangers AV-17 and KU-2. The amt. of Pa adsorbed (α) in C_{acid} < 2M increased with pH. The existence of nonionic Pa at [H⁺] < 0.2M was confirmed by the fact that α on AV-17 decreased at [H⁺] > 0.2M. The distribution coeff. on silica gel decreases as on KU-2. At [H⁺] < 1M, silica gel adsorbs PaO(OH)²⁺ preferentially by the ion-exchange mechanism of replacing H⁺ from the soln. and coupling with O atoms of the silanol group. At [H⁺] > 1M, the cation form of Pa together with neutral complexes adsorbed by the gel, exhibit intradiffusion characteristics and α depends on the pore dimensions of the gel. The rate at which equil. is established depends on [H⁺] attaining a min. at 0.5-1.5M.

(CONT.)

acid catalysis. Comparison of the cation exchange capacities in relation to pH of the oxidized carbons OU and BAU₀ with that of the carboxyl ion-exchange resin KB-4P-2 showed that with increasing pH the exchange on the carbon began at pH = 1-2 vs. pH ~ 3 (the point at which dissoen. of COOH groups begins) for KB-4P-2. This indicated that groups more highly acidic than the ordinary COOH groups were present on the surface of the oxidized C. A study of the catalytic effects of the sulfonic resin KU-2, KB-4P-2, and OU in the inversion of sucrose, hydrolysis and formation of EtOAc, -and the pinacolin rearrangement showed that OU was more active than KU-2 in the reactions in question except that of the pinacolin rearrangement, while KB-4P-2 was practically inactive in all of them. The increased protogenic activity of acidic groups on the surface of oxidized C can be explained by a high concn. of electrons that form a neg. charge attracting free H⁺ from H₂O or formation of H-bonds between COOH groups and phenol H groups. Forms of silica which do not contain delocalized electrons also show a high acidity in cation exchange reactions and impart an acidic reaction to salt solns. by replacing metal cations with H⁺. An increase in the acidic range of adsorption with increasing radii of cations in the order Mg²⁺ < Ca²⁺ < Sr²⁺ < Ba²⁺ showed that the SiO₂ centers responsible for cation exchange were strongly acidic. However, the adsorption capacity of silica gel was very low because of the small no. of SiO⁻H⁺ centers. The order of adsorption of cations on the Ca, Na, or similar forms of silica gel was inverted to Be²⁺ < Mg²⁺ < Ca²⁺ < Sr²⁺ < Ba²⁺ because of the contribution of the covalent component of cations to the electrostatic interaction with the SiO₂ surface. On the surface, those cations must be most strongly adsorbed which compete most effectively with the Si atom for the electronic d. of O, i.e., the least basic cations. In alk. solns. a similar inversion took place for the adsorption on SiO₂ of alkali metal cations, so that the adsorption order Li⁺ > Na⁺ > K⁺ > Rb⁺ applied.

TITL Preparation and properties of the aluminium-activated carbon composite adsorbent for extraction of uranium from sea water.
CITA Nippon Kaisui Gakkai-Shi 30(1): 43-49 (1976). (Japanese).
COUN Japan
ABST The effects of the hydrolysis pH and temperature of aluminium chloride in the presence of activated carbon on the properties of the products were studied to clear the preparation conditions of the composite adsorbent (C-Al-OH) for the extraction of uranium from sea water. Aluminium contents of the adsorbent increased when the hydrolysis pH and the temperature became higher. The adsorptive capacity for uranium was closely related to the physical and chemical properties of the adsorbent: the capacity increased in proportion to the mean pore size and the quantity of acid group, which was determined as alkaline consumption, whereas the capacity was inversely proportional to the specific surface area of the adsorbent. Most of the adsorbent was amorphous in X-ray diffraction pattern. Several adsorbents, which showed crystallinity in X-ray diffraction pattern, showed their low adsorptive capacity for uranium. The Freundlich's relationship was observed between the concentration and the capacity of uranium. Uranium uptake from natural sea water by the adsorbent was found to be 160-280 $\mu\text{g/g}$ adsorbent after 30 days stirring.

TITL Radiochemical separation of fission products from large volumes of sea water. Strontium, cesium, cerium, and promethium.
CITA Anal. Chem. 31: 44-49 (1959).
COUN USA
ABST Chemical methods were used to isolate 28-year strontium-90, 30-year cesium-137, 280-day cerium-144, and 2.4-year promethium-147 from as much as 200 liters of sea water. Strontium separation involves precipitation of mixed strontium-calcium carbonates directly and in the presence of (ethylenedinitrilo)tetraacetate ion, precipitation of strontium nitrate, scavenging with ferric hydroxide-barium chromate, and conversion to strontium carbonate. Strontium-90 activity is measured by separating and counting the daughter yttrium-90 activity. Cesium is coprecipitated with dipotassium sodium cobaltinitrite, separated as cesium silicotungstate, converted to the perchlorate, and freed of trace potassium and rubidium by ion exchange. Rare earths are removed by initial coprecipitation on ferric hydroxide. Uranium, protactinium, and thorium are removed by ion exchange; radium and lead are scavenged with barium sulfate. The cerium fraction is obtained in pure form by separation as cerium(IV); promethium, by cation exchange.

TITL Coupled cationic and anionic method of separating uranium.
CITA US Patent 3,966,872. Int. Cl.B01D11/00: 2p (1976).
COUN USA
ABST Uranium is separated from contaminating metal ions in an aqueous feed liquor containing the uranyl ion. The liquor is extracted with a first, non-interfering water-immiscible, organic solvent containing a reagent which reacts with the uranyl ion to form a complex soluble in the organic solvent. The organic solvent is scrubbed with water if necessary, then stripped with a stripping liquor of an aqueous sulfuric acid liquor having a pH of about 0.5 to about 6 containing a reducing ion or an aqueous carbonate solution having a pH of about 9. If the sulfuric acid liquor is used, the stripped uranous ion is oxidized and the sulfuric acid liquor is diluted to prevent the precipitation of a uranium complex. The stripping liquor is extracted with an amine liquor comprising a second, noninterfering, water-immiscible, organic solvent and a tertiary or quaternary amine. The amine liquor is stripped with an ammonium carbonate solution to precipitate a uranium complex. The uranium complex is filtered off and may be calcined to produce U_3O_8 or UO_2 .

TITL Method of separation of uranium from metal ions of the groups II and III.
CITA German (F.R.) patent document 2440054/A/. Int. Cl. C01G 43-00: 15p (1975). (German).
COUN USA

(CONT.)

ABST In the known methods of separating uranium by means of solvent extraction (di-2-ethyl-hexyl phosphoric acid and tri-n-octyl phosphine oxide in kerosine) as complex compound from impurities (metal ions of the groups II and III), especially iron, and then precipitation with ammonium carbonate as ammonium uranyl tricarbonate, about 2 to 4% of iron (relative to uranium) cannot be separated. The new process alters the working conditions by washing the solvent with water before the precipitation with ammonium carbonate and/or bicarbonate ions with the addition of sulphide ions (H_2S and/or ammonium sulphide) where the impurity metal ions are precipitated as sulphide and can be filtered off. The ammonium uranyl tricarbonate after this separation is calcined to U_3O_8 or UO_2 . The iron impurity is between 0.005 and 0.03% (relative to uranium). The method is described in detail and pH values, mole concentration, flow rates, etc. are given for each step.

TITL Method of separation of uranium from contaminating ions in an aqueous feed liquid containing uranyl ions.

CITA German (F.R.) patent document 2451596/A/. Int. Cl. C01G 43-00: 23p (1975). (German).

COUN USA

ABST A coupled cationic/anionic method for the separation of uranium from contaminated aqueous solutions which contain uranyl ions is proposed. The fluid is extracted using an organic solvent containing a reagent which, together with the uranyl ions, forms a soluble aggregate in that solvent. As an example, 0.1 - 1 Mol/l Di-2-ethyl-hexyl-phosphorus acid in kerosene is mentioned. The organic solvent is then treated with a sealing liquid (volume ratio 20 - 35). For separation, an aqueous carbonate solution or a sulfuric acid solution can be used; the most favorable pH-values and concentrations for both cases are mentioned. The U^{+4} -ion at the sulfuric acid separation is subsequently oxidized to the uranyl ion with air. In each case, an extraction with an amine follows; after that, the amine is separated using an ammonium-carbonate solution and the uranium aggregate is precipitated, for example as ammonium uranyl tricarbonate, and then further processed to uranium oxide. The solvents and fluids used are led back in closed circuit; a flow diagram is given.

DATE 1971
TITL Separation of uranium in seawater.
CITA Mizu Shori Gijutsu 12(4): 3-8 (1971). (Japanese).
COUN Japan
ABST Uranium is present in seawater as $[UO_2(CO_3)_3]^{4-}$. Methods of separation are coprecipitation, adsorption, ion flotation, solvent extraction, and biological. In the coprecipitation method, uranium is precipitated with $Fe(OH)_3$, $Al(OH)_3$, and $Ti(OH)_4$. However, the precipitation rate of the hydroxides is generally low. In the adsorption method, titanates, resorcinol, and arsonic acid resin are useful as adsorbents. Basic zinc carbonate, lead sulfide, and active carbon also show good adsorptivity. Estimated cost of uranium collected by this method is about 30 to 35 million yen per ton. In the flotation method, surface-active agents are added to seawater and air is blown in to form bubbles. Phosphoric acid esters show excellent bubbling effect in seawater. For the solvent extraction method, kerosene and dibutyl phosphate are possible solvents. Few studies have been made on concentration of uranium in seawater by microorganisms.

DATE 1970
TITL Properties of metal ions caught on silica gel surface by ion exchange.
CITA Nippon Kagaku Zasshi 91(6): 529-533 (1970). (Japanese).
COUN Japan
ABST The phys. chem. properties of metallic ions caught on the surface of silica gel by ion exchange were studied by the electronic spectra, x-ray diffraction, and the magnetic anal. The metals were Mn, Co, Ni, Cu, and Zn. When the surface concn. of these metals was < 1.2 wt.%, the measurements of magnetic susceptibilities showed that these metal ions are divalent and in high spin states. The uv spectra showed that Mn(II) and Ni(II) ions were in an octahedral ligand field, Cu(II) ion in a square planar, and Zn(II) and Co(II) in a tetrahedral. When the surface concn. was $> 70\%$ exchange level (80 wt.%), some of Ni(II) ions aggregated to form metallic particles on the surface. Co(II) ions were stable up to 90% exchange level.

TITL Adsorption of uranium by ion-exchange resins in presence of chlorate and perchlorate.
CITA Rev. Roum. Chim. 14(5): 599-604 (1969). (French).
COUN Romania
ABST Amberlite IRA-400, having been treated (under dynamic conditions) successively with 4% HCl, H_2O , 2% NaOH, H_2O , 4% HCl, and H_2O , was satd. with U by 4 repeated contacts for 30 min. each (under static conditions) between 3 cc. resin and 230 cc. $Na_4[O_2U(CO_3)_3]$ contg. 0-1.5 g. $KClO_3$ or $KClO_4/l$. Increase of the $KClO_3$ concn. increased the amt. of U remaining unadsorbed in the effluent, the resin adsorbing progressively less U. The amt. of U adsorbed decreased as well for each $KClO_3$ concn. with increase in the no. of contacts or with increase in the amt. of ClO_3^- and $[UO_2(CO_3)_3]^{4-}$ passed by the resin.

(CONT.)

The U adsorption in the last stages of contact decreased as a function of the initial KClO_3 concn. in the soln. Despite the redn. of the amt. of U adsorbed in each satn. stage, the adsorption capacity of the resin increased after each contact with the soln. contg. KClO_2 .

Under the conditions considered, even in the course of the last contact, the U desorption did not exceed its adsorption by the resin. The values established for the adsorption capacity decreased, however, with increase of the ClO_3^- concn. in soln. from 93.2 mg. U/resin at 0 g. $\text{KClO}_3/1.$ to 55.1 at 1.5. The ClO_4^- decreased the adsorption of U by the resin much more strongly. Even at concns. as low as 0.25-0.5 g. $\text{KClO}_4/1.$, the concn. of U in the effluent exceeded its concn. in the influent at the last stages of satn., signifying that ClO_4^- elutes the U adsorbed before. The intensity of the desorption depended on the ClO_4^- concn. in the soln. Both ClO_3^- and ClO_4^- had a new effect on the U adsorption on the resin, but while ClO_3^- only decreased it, ClO_4^- eluted the U adsorbed before. This was explained on the basis of several reaction equil. and affinities of ions for the resin. Although ClO_4^- suggests itself as an efficient eluent of U from resins employed in extn. of U from leach liquo, its possible oxidizing effect on the org. part of the resin argues against it; hence, ClO_3^- and ClO_4^- should be avoided in uranifous solns. subjected to ion-exchange treatment.

 TITL Uranium from seawater: an energy cost study.
 CITA Programmes Analysis Unit, Chilton (UK); Tidal or Pumped

(CONT.)

Schemes R14/74: (1974).

COUN UK

AREA Menai Straits

ABST A meeting was held in Economics and Programmes Branch, UKAEC, on 10th May 1974 to review the current position on the technology of extraction of uranium from seawater. The possibilities of both tidal and pumped schemes were discussed, and though it was agreed that the latter had advantages in flexibility of location, some concern was expressed at the large quantities of pumping energy required. It was decided therefore that the PAU should be invited to carry out an initial energy costing exercise on the pumped scheme, taking account not only the direct energy requirements, but also the indirect inputs needed to produce the capital equipment, operating materials, etc. The total energy input could then be compared with the energy released from the extracted uranium, which is used as fuel in a thermal reactor. The present report begins with a discussion of the technique of energy accounting, and the merits and limitations of the two principal approaches are compared. These are respectively, Process Analysis and Input-Output Analysis, otherwise referred to as the "Energy Cost of Materials" and "Energy Cost of Money", respectively. A "Best Estimate" is compiled which calls on both the tidal and pumped schemes, and this indicates that on an energy cost basis the pumped scheme is three times as expensive as the tidal scheme. In conclusion a point is made that while an energy costing exercise can be very instructive, care is needed in defining the system boundary. Equally important is the use of the true opportunity cost of energy consumed in the system under review. This is particularly important when examining schemes making use of new sources of power like tidal forces.

TITL Spectroscopic study of copper(II) ions supported on silica gel by the cation exchange method.
CITA J. Catal. 40(2): 197-202 (1975).
COUN Japan
ABST The ESR and the elec. spectra of cupric ions introduced on silica gel by cation exchange between surface hydroxyl groups of silica gel and tetrammine cupric ions were investigated. The cupric ions in the initial state had the distorted octahedral configuration of which coordinated ammonia mols. were less than four. The evacuation treatment at temps. over 200° led to desorption of ammonia and to change in configuration of Cu ion to tetrahedral. For samples treated below 400° , the subsequent exposure to ammonia restored the original coordinate environment. Two different ESR parameters were obsd. with the water adsorption, and one was assigned to the distorted octahedral and the other to the tetrahedral configuration. The former disappeared by evacuation at room temp. The elec. spectrum also suggested the existence of the tetrahedral cupric ions. The ESR parameters of cupric ions depended on the adsorption temp. of pyridine. At lower temp., the configuration of cupric ions was similar to that of the ammoniated cupric ions. When the adsorption temp. was

(CONT.)

raised to 200-300°, the marked decrease of the hyperfine splitting of cupric ion was obsd. indicating the distortion of the configuration of cupric ion from octahedral towards tetrahedral.

TITL Design requirements for uranium ion exchange from acidic solutions in a fluidized system.
CITA U.S., Bur. Mines, Rep. Invest., RI 8282: 29p (1978).
COUN USA
ABST Integrated multiple-compartment absorption and elution columns were used in which the soln. flows were continuous, except for short periods when resin increments were withdrawn. Soln. retention time is a major limiting variable in the absorption process, while resin residence time is the detg. factor in the elution process. As the soln. flow-rate increases, more of the column is used to obtain the same amt. of U extn. from the soln. There is a compromise between the effects of soln. residence time per stage and the no. of stages in the column. Obtaining higher grades of eluate and/or lower exiting resin values requires a taller column to provide longer resin residence time. The min. eluant flow rate of 2-2.7 gal/mm/ft², which allows the max. resin residence times, is optimum to obtain good elution of the resin and reasonable eluate grades. The min. aq.-to-resin ratio for good elution is $\approx 4:1$.

 TITL Study of the physicochemical properties of silica gel
 modified by titanium dioxide.
 CITA Kinet. Katal. 17(5): 1357 (1976). (Russian).
 COUN USSR
 ABST Modification with hydrated TiO_2 was done in a vacuum
 adsorption app. by treating silica gel with $TiCl_4$ vapors
 followed by hydrolysis. The modified samples were
 studied by adsorption, x-ray, and ion exchange methods.
 The sp. surface and pore vol. were decreased, but the
 effective size of the pore opening remained const. The
 decrease in the sp. surface was due to increase in the
 size of primary particles and the decrease of the
 surface near the contacts for particles as the
 modifier's granules grew over it. Thermal treatment of
 the modified silica gel shifted the phase conversions
 for the TiO_2 towards higher temps. The ion exchange
 capacity increased with an increase in the TiO_2 concn.,
 for sorption of Cu ions from acid solns.

(CONT.)

- TITL Sorption properties of hydrated titanium dioxide and its dehydration products.
- CITA Izv. Akad. Nauk SSSR, Neorg. Mater. 12(8): 1415-1418 (1976). (Russian).
- COUN USSR
- ABST The cation exchange properties of $TiO_2 \cdot xH_2O$ are detd. by the presence of OH groups with $pK_1 = 5.0 \pm 1.0$, $pK_2 = 7.9 \pm 1.7$, and $pK_3 = 10.6 \pm 0.4$ at total ion exchange capacity 0.48 mequiv./mmole TiO_2 (6 mequiv./g). The exchange capacity decreases in the order $Li^+ > Na^+ > K^+ > Rb^+ > Cs^+$ and is related to the channel structure in the exchanger. Heating $TiO_2 \cdot xH_2O$ in the H-form increases condensation of OH groups resulting in loss of ion exchange properties. The Li-form has higher thermal stability; after heating to 480-520°, Li^+ selectivity is acquired.

- TITL Determination of nanogram uranium content in solutions by the fission track method.
- CITA Radiochim. Acta 19(1): 37-40 (1973).
- COUN W Germany
- ABST A fission track method was adapted for the determination of uranium in nanogram quantities in solutions, without any preliminary chemical treatment of the solution. Polycarbonate foil was used as a fission track detector. Experimental conditions were worked out to accommodate the method for as small volumes of uranium solutions as 1 ml. The uranium solution was either directly contacted with the detector foil, or after being fixed on Bio-Gel matrix. A proper arrangement of the foils for the sparking process leads to very small spark holes, considerably improving the detection. The fraction of the tracks that may be rendered visible due to etching and sparking was found to be of a constant

(CONT.)

value for given irradiation conditions and matrix. The intensity of gamma radiation existing in the irradiation position of the reactor influences significantly the value of this fraction.

TITL Anion-exchange behavior of some elements on a weakly basic anion exchanger in hydrobromic acid medium.
CITA J. Chromatogr. 102: 277-285 (1974). (French).
COUN Poland
ABST The adsorbability of several elements was studied in the system: weakly basic anion exchange resin Amberlite IRA-68 (Br^-)- $\text{HBr} + \text{Br}_2$. Distribution coefficients of more than 30 elements were determined by batch equilibration in HBr concentration range 0.01 to 12M. In most instances the distribution coefficients increase

(CONT.)

with increase in acid concentration. Some elements, such as Cu, Co, Fe, Mn, In, Ga, and U, are adsorbed only at acid concentrations greater than 4 M. Pt, Hg, Ag, and, to a somewhat smaller extent, Au, Tl and Re, show high distribution coefficients in dilute HBr solution. In general, the adsorbabilities of elements on Amberlite IRA-68 in the bromide system are lower than the adsorbabilities in analogous system with strongly basic Dowex 1 resin. The observed differences in distribution coefficients are high enough for some interesting separations to be obtained. The possibility of column separations of several mixtures, such as Eu-U, Zn-Cd-Hg and Cu-Ag-Au, was demonstrated. The influence of temperature on the separation of the latter mixture was studied, and the most important chromatographic parameters (distribution coefficients, separation factors, resolutions, and plate heights) were calculated.

TITL Ocean raw materials.

CITA Kirk-Othmer Encyclopedia of Chemical Technology, Second Edition, 14: 150-157 (1967).

COUN USA

ABST The oceans of the world cover nearly three-quarters of the surface of the earth to an average depth of over 12,000 ft. The presence of this vast quantity of water gives our planet a special position in the solar system. No other is believed to have substantial quantities of liquid water. The economic uses of the ocean are even now, quite impressive. It has been estimated that the annual value of oceanic activities (not including transportation, conventional recreation, most naval operations) is more than \$7.6 billion and that the growth rate of ocean-connected market is close to 15% each year. In addition to being a source of raw materials, the oceans serve as a major heat sink, as an artery of commerce, as a source of fresh water, and as a repository for the waste products of mankind. The present annual value of the production of raw materials and products from the ocean is given, excluding fish or marine mammal products. These materials are produced from seawater, beach sands, the surface and beneath the surface of the continental shelf. The water of the oceans is quite probably the most complex solution that will ever be encountered. More than 77 elements have been found dissolved in seawater. The technical chemistry of seawater, despite the complexity of the solution is determined by the nine major components and

(CONT.)

it is from these nine that industrial products are now recovered. Cations include sodium, magnesium, calcium, potassium, and strontium. Anions include chloride, sulfate, bicarbonate, and bromide. All other constituents of seawater total less than 1% of the weight of the dissolved materials.

CITA German (FRG) Patent 2,326,224/A/: (1974). (German).
COUN W Germany
ABST The method uses low molecular complexing agents to obtain heavy metals, e.g. also uranium, from sea, sweet-water or waste water using 8-hydroxyquinoline. Cells from organisms, e.g. erythrocytes, are added as complexing agents in bubble form to a solution whose osmolarity is lower than the cell content. After balancing the osmolarity of the cell content and the solution, these osmotic active substances such as calcium, potassium, and sodium ions are added and the osmolarity is further increased until the original osmolarity of the cells is reached again. The separation of the bubbles follows which are then put into an aqueous solution. Due to the permeability of the bubble skin, the heavy metal ions, e.g. nickel, can diffuse from the solution into the bubbles and be converted there by the complexing agents into hard-to-dissociate insoluble complexes. The cells are separated by flotation, sedimentation, filtration, or centrifuging.

- 521 AUTH Zimmermann,U.
DATE 1975
TITL Method to separate ionized substances with special chemical or physical characteristics from an aqueous solution.
CITA German (FRG) Patent 2,326,224/B/: (1975). (German).
COUN W Germany
ABST Ionized substances may be separated from aqueous solutions containing at least 0.5 mm Mg and/or Ca or K ions with the aid of complexing agents which form compounds hard to dissociate or dissolve with the substances to be separated. The present method uses bubbles of living cells (e.g. bacterial cells) containing complexing agents, whose osmolarity is different from that of the aqueous solution. Mass transfer takes place through the cell membrane. Separation is carried out by well-known processes (flotation, sedimentation, filtration etc.). The varying osmolarity of the successive process steps is achieved by adding osmotically active substances. It is one of the main advantages of the process that the

(CONT.)

acidity of seawater need not be changed in the case of substances dissolved in seawater. Also, raw materials can be regained from waste water in an economical way. For different ionized substances to be extracted and separated from each other, suitable complexing agents may be used one after the other or in separate chambers. The process also works with low-molecular complexing agents (e.g. uranium extraction from seawater using 8-hydroxyquinoline). When using bacterial cells, the process is carried out at temperatures between 15°C and 40°C, pH 8, with addition of the potassium salt of ethylene diamine-tetracetic acid and lysozyme. The example given in the paper describes a solution for the extraction of nickel.

KEY marine organisms, uranium, seawater, extraction, trace metals, chemistry, filtration, temperature, water

155 Matrix consisting of cultivable mutants of unicellular green algae and method of uranium production using this matrix.
158 Matrix of algae and method of making same and method of obtaining uranium from seawater by said matrix.
156 Matrix of algae, method of fabrication of the matrix, and method of uranium extraction from seawater by means of this matrix.

Wald, M.

- 494 Determination of nanogram uranium content in solutions by the fission track method.
157 Extraction of uranium from sea water by cultured algae.

(CONT.)

- 155 Matrix consisting of cultivable mutants of unicellular green algae and method of uranium production using this matrix.
- 158 Matrix of algae and method of making same and method of obtaining uranium from seawater by said matrix.
- Wald, N.
- 156 Matrix of algae, method of fabrication of the matrix, and method of uranium extraction from seawater by means of this matrix.
- Walford, F.J. (Analyst).
- 470 Uranium from seawater: an energy cost study.
- Wallace, R.A.P.
- 495 Removing concentrated solutions of ionizable compounds from aqueous solutions.
- Wang, L.C.
- 496 A novel method for the preparation of uranium metal, oxide and carbide via electrolytic amalgamation.
- Wastler, T.A.
- 497 Estuarine and coastal pollution in the United States.
- Weaver, J.N.
- 498 Rapid, instrumental neutron activation analysis for the determination of uranium in environmental matrices.
- Webster, R.K.
- 503 A comparison of three methods of determining the concentration of uranium in sea water.
- Weigand, N.
- 499 New types of cation exchangers based on silica gel. I. Preparation and properties.
- Weimer, W.C.
- 377 Geochemical ocean sections study (GEOSECS). Chemistry of ocean solutions.
- Weissbuch, H.
- 500 Spectrophotometric method for the simultaneous determination of uranium and thorium in natural water.
- Weng, P.S.
- 266 Use of dinonylnaphthalenesulfonic acid for the determination of environmental uranium in air, sea, and soil.
- Wenrich-Verbeek, K.J.
- 76 Chemical analysis and statistical data for water samples collected in Colorado, New Mexico, and Arizona as part of a study of surface-water and stream-sediment sampling

(CONT.)

techniques used in uranium exploration.

Wesolowski, K.

501 Heavy metal concentrates from dilute waste solutions.

Wiegand, G.

494 Determination of nanogram uranium content in solutions by the fission track method.

Wilkerson, C.L.

377 Geochemical ocean sections study (GEOSECS). Chemistry of ocean solutions.

Wilson, A.

502 River discharges to the sea from the shores of the conterminous United States.

Wilson, J.D.

503 A comparison of three methods of determining the concentration of uranium in sea water.

289 The determination of uranium in sea water by pulse polarography.

Winyall, M.E.

2 Silica of high pore volume.

Wodkiewicz, L.

504 Anion-exchange behavior of some elements on a weakly basic anion exchanger in hydrobromic acid medium.

Woodroof, J.G.

505 Ocean raw materials.

Wooten, M.J.

506 Uranium recovery from seawater. Final report.

Wu, S.C.

103 Adsorption of uranium from dilute aqueous solution on inorganic adsorbents.

Yamabe, M.

507 Heavy metal adsorbent.

508 Uranium adsorption from seawater.

484 Uranium from sea water.

510 Uranium from sea water.

509 Uranium from seawater.

Yamabe, T.

511 Separation of trace elements, particularly uranium, from sea water.

512 Separation of uranium from sea water by precipitation method.

(CONT.)

- 453 Separation of uranium from sea water by using hydroxylapatite.
- 454 Separation of uranium in seawater.
- Yamanouchi, A.
513 Uranium collection from seawater by adsorption.
- Yamashita, H
514 Collection of uranium from sea water with hydrous oxide adsorbents. I. Ion exchange properties and uranium adsorption of hydrous titanium(IV) oxide.
- Yamazaki, Y.
515 Porous adsorbent for uranium compound adsorption.
- Yamazaki, Y.
183 Uranium adsorbents.
- Yatsevskaya, M.I.
130 Sorption of uranium from aqueous solutions by mineral sorbents and carbon modified by titanium dioxide.
- Yokoyama, R.
516 Heavy metal removal from sea water or brine.
- Yonemochi, J.
292 Composite-base ion-exchanger.
- Yoshida, S.
466 Acidity and the catalytic activity of metal ion-exchanged silica gel.
467 Coordination states of some metal ions on silica gel surface.
465 Properties of metal ions caught on silica gel surface by ion exchange.
- Young, C.T.
505 Ocean raw materials.
- Young, J.A.
377 Geochemical ocean sections study (GEOSECS). Chemistry of ocean solutions.
- Yusa, H.
211 Adsorption of ions on titanium oxide at temperatures up to 280°C.
- Zaitseva, T.D.
83 Separation of zirconium and hafnium by adsorption on silica gel from hydrochloric acid solutions.
- Zaki, A.B.

(CONT.)

- 517 Particle diffusion of an anionic uranium-(+6) sulfate complex in Wofatit SBW ion-exchange resin.

Zavezenov, V.K.

- 352 Ion exchange properties of titanium dioxide hydrate ($\text{TiO}_2 \cdot x\text{H}_2\text{O}$), zirconium dioxide ($\text{ZrO}_2 \cdot x\text{H}_2\text{O}$), and cation exchangers prepared from them.

Zeitlin, H.

- 261 Improved separation and determination of uranium in sea water.
- 38 Preconcentration of various trace elements in sea water by solvent extraction and the ring oven.
- 212 Separation of trace-metal ions from seawater by adsorptive colloid flotation.
- 213 Separation of uranium from seawater by adsorbing colloid flotation.

Zelenin, V.I.

- 363 Sorption of uranium(6) from solutions of various electrolytes on granulated iron hydroxide.

Zhitkov, A.S.

- 221 Nature of the distribution of uranium in ultrabasites of Indian Ocean rift zones.

Zhorov, V.A.

- 519 Coprecipitation of trace amounts of copper and zinc from sea water on titanium hydroxide.
- 195 Coprecipitation of uranium with titanium hydroxide from seawater.
- 47 Sorption of molybdenum(VI) and uranium(VI) ions by titanium(IV) hydroxide from sea water.
- 42 Uranium in the Black Sea.
- 518 Use of adsorption colloidal flotation for separating trace elements from sea water.
- 48 Use of ampholytes for removing trace elements from sea water by a froth flotation method.

Zil'berman, M.V.

- 355 Synthesis of the cation exchangers ISM-1A and IST-1A with increased exchange capacity.

Zimen, K.E.

- 61 Activation-analytical determination of uranium traces in marine systems with separation of neptunium-239 by countercurrent ion migration.

Zimmermann, U.

- 521 Method to separate ionized substances with special chemical or physical characteristics from an aqueous solution.
- 520 Procedure for separating ionized substances distinguished by

(CONT.)

chemical and physical properties, out of an aqueous solution.

Zubakova, L.B.

422 Grafting of poly(2-methyl-5-vinylpyridine) on the surface of some inorganic supports.

233 Production of mineral-organic sorbents by chemical grafting of 2-methyl-5-vinylpyridine to silica gel.

Zudov, V.G.

88 Purification of neutral waste waters from production of titanium dioxide using ion exchange.

3.2 COUNTRY OF AUTHOR INDEX

The following listing is a compilation of the bibliography according to the country of the author. For each country, entries are listed by the citation number and name of authors, as found in Chapter 2.
