## PREFACE

This report documents one of a series of scoping calculations performed as part of the dose code recovery activities for the Hanford Environmental Dose Reconstruction Project. These scoping calculations form a mutually-dependent set that build upon each other, and each is best read in the context of the others. The complete list of scoping reports is given below.

<u>Title</u>	<u>Calculation Number</u>
Scoping Calculation for Components of the Cow-Milk Dose Pathway for Evaluating the Dose Contribution from Iodine-131	001
Determination of the Contribution of Livestock Water Ingestion to Dose from the Cow-Milk Pathway	002
Determination of Radionuclides and Pathways Contributing to Dose in 1945	003
Determination of Radionuclides and Pathways Contributing to Cumulative Dose	004
Determination of Dose Distributions and Parameter Sensitivity	005
Determination of the Feasibility of Reducing the Spatial Domain of the HEDR Dose Code	006
Determination of the Spatial Resolution Required for the HEDR Dose Code	007
Determination of the Temporal Resolution Required for the HEDR Dose Code	008

Additional scoping calculations are in progress or planned, and each will be documented in similar project reports.

## **1.0 INTRODUCTION**

A series of scoping calculations has been undertaken to evaluate the absolute and relative contributions of different radionuclides and exposure pathways to doses that may have been received by individuals living in the vicinity of the Hanford Site. These scoping calculations may include some radionuclides and pathways that were included in the Phase I air-pathway dose evaluations, as well as other potential exposure pathways being evaluated for possible inclusion in future Hanford Environmental Dose Reconstruction Project (HEDR) modeling efforts.

This scoping calculation (Calculation 003) examined the contributions of numerous radionuclides to dose via environmental exposures and accumulation in foods. This study builds on the work initiated in the first scoping study of iodine in cow's milk (Calculation 001). Addressed in this calculation were the contributions to organ and effective dose of infants and adults from 1) air submersion and groundshine external dose, 2) inhalation, 3) ingestion of soil by humans, 4) ingestion of leafy vegetables, 5) ingestion of other vegetables and fruits, 6) ingestion of meat, 7) ingestion of eggs, and 8) ingestion of cows' milk from Feeding Regime 1 as described in Calculation 001.

Recommendations determined from scoping calculations are provided to the HEDR Technical Steering Panel (TSP) with the intent of providing a definitive technical basis to assist in deciding whether specific radionuclides and exposure pathways should or should not be included in the main computer code used for the HEDR dose estimation process for individuals.

## 2.0 TECHNICAL METHODS

Effective doses and critical-organ doses were calculated for a highly exposed infant and adult in a highly exposed area and time period. Parameters in the calculations were selected to be approximate average, median, or best-estimate values, rather than conservative, upper-bound values. Individuals were assumed to have a rural lifestyle, with milk supplied by a backyard cow supported on Feeding Regime 1 (HEDR staff 1991, page 2.17).

Calculations used are based on methods presented in Napier et al. (1988 volume 1, pages 4.66 - 4.76) and Napier (1991, pages A.2 - A.6). Doses are calculated on a monthly basis using steady-state assumptions but changing the time-dependent parameter values monthly.

The location of exposure selected was the region of Franklin County included as part of Census District 4 (Figure 1). This area lies directly east of the Hanford site, and was shown in the Phase I air-pathway report (HEDR staff 1991, Appendix C) to be one of the most highly affected regions. The time period selected was the year 1945, which accounted for about 80% of the releases during 1944 through 1947 (Heeb 1992, page 4.36).

Surface deposition and integrated air-concentration data used were not Phase I values; rather they were recalculated (J. V. Ramsdell Jr., personal communication, October 1992) using the RATCHET atmospheric dispersion code (Ramsdell and Burk 1992) based upon the latest Hanford iodine-131 source term information reported by Heeb (Heeb 1992, page 4.36). Because of time constraints, monthly surface deposition and integrated air concentrations from only a single realization were used in these scoping calculations (J. V. Ramsdell Jr., personal communication, October 1992). Recent results from Ramsdell indicate that the particular realization used is well within a factor of two for all months of the maximums of the 100 realizations ultimately planned to be used for this particular location, and, therefore, this realization is considered to be a conservative, but reasonable, representation of this location (J.V. Ramsdell, personal communication, November 1992).

The Ramsdell data were presented by their location on an atmospheric dispersion grid map; as discussed by Shipley and Napier (1992, page 2) and

shown in Ikenberry et al. (1992, page 1.4). The node selected lies with the area encompassed by Franklin County Census District 4, and appeared to be the highest node value in the general area for this realization.

The surface deposition and integrated air-concentration values for iodine-131 for the 12 months of 1945 for node location 18,25 (x,y) used in the scoping calculations are shown in Table 1. Also shown are Heeb's (1992) estimates of monthly radioiodine release for these months. These data were used to estimate monthly integrated atmospheric dispersion parameters for this node. The dispersion parameters relate time-integrated air concentration to a unit release.

## 2.1 CALCULATION OF EXTERNAL DOSES

Two types of external dose were calculated and summed. These included both dose from submersion in contaminated air and dose from irradiation from material deposited on the ground. A semi-infinite plume approximation was used for the air submersion, and an infinite flat plane approximation was used for the deposited material (DOE 1988b). Continuous exposure was assumed (8760

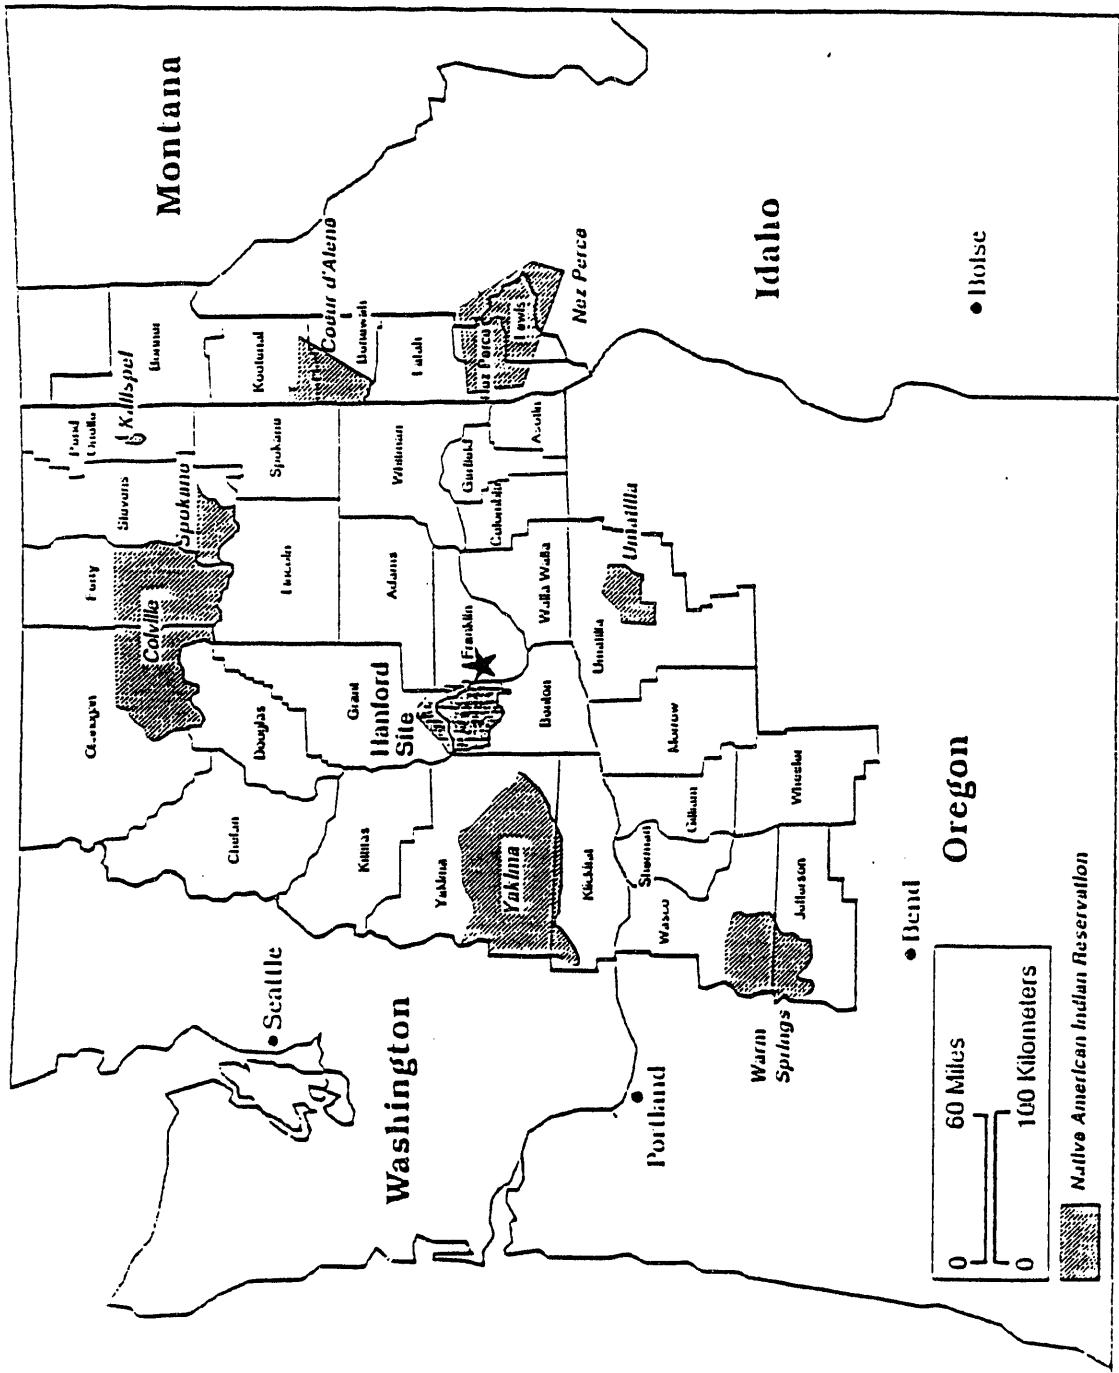

FIGURE 1. Approximate Location (\*) Within the HEDR Study Area Selected for Scoping Calculations

HEZ00131

hours per year), with no modifications for shielding. The time-integrated air concentrations were used for submersion, and the month-end deposition values were assumed to represent uniform contamination levels throughout the month for the deposited material. The basic equation is

$$Dose\ External_i = X_i DF_{as} + S_{end\ i} DF_{ex}$$

where  $X_i$  = the time-integrated air concentration for month i, Ci-sec/mo-m<sup>3</sup>  
 $DF_{as}$  = the air-submersion dose factor, rem/sec per Ci/m<sup>3</sup>  
 $S_{end\ i}$  = the surface deposition of radionuclide on the ground at the end of month i  
 $DF_{ex}$  = the groundshine dose factor, rem/mo per Ci/m<sup>2</sup>.

The month-end depositions for radionuclides other than I-131 were approximated assuming that the air concentrations represented by the time-integrated concentration  $X_i$  were uniform throughout the month, accounting for radioactive decay, and compounding from month to month. This was calculated as

$$S_{end\ i} = S_{end\ i-1} e^{(-\lambda_r 30)} + X_i V_d \frac{(1 - e^{-\lambda_r 30})}{30 \lambda_r}$$

where  $\lambda_r$  = the radiological decay constant, d<sup>-1</sup>  
 $V_d$  = the deposition velocity, m/s, taken to be 0.01 for iodines, 0.001 for other particulates, and 0 for noble gases.

## 2.2 INHALATION

Dose from inhalation during month i was calculated as

$$Dose\ Inhalation_i = X_i BR DF_{inh}$$

where  $BR$  = the breathing rate,  $\text{m}^3/\text{s}$  (separate values used for infant and adult)

$DF_{inh}$  = the inhalation dose factor, rem/Ci inhaled.

Inhalation dose factors for adults were taken from DOE (1988a), and those for infants from ICRP (1989).

### 2.3 HUMAN SOIL INGESTION

People routinely ingest small amounts of soil, in association with food or from minor hand to mouth contact. The dose potentially resulting from ingestion of radionuclides in surface soil via this pathway was estimated as

$$Dose_{Soil_i} = (S_{end_i} / \rho) C_{soil} 30 DF_{ing}$$

where  $C_{soil}$  = the consumption rate of soil, kg/day, assumed to be 0.001 for infants and 0.0001 for adults

$\rho$  = the surface soil areal density, assumed to be  $13 \text{ kg/m}^2$  (mixing to a depth of 1 cm)

30 = conversion factor, days/month

$DF_{ing}$  = the ingestion dose factor, rem/Ci ingested.

Inhalation dose factors for adults were taken from DOE (1988a), and those for infants from ICRP (1989).

### 2.4 CONSUMPTION OF VEGETABLES AND FRUITS

The dose from consumption of fresh leafy vegetables was modeled as

$$Dose_{Veg_i} = (D_{end_i} r TF WC + S_{end_i} CR / \rho) IR 30 DF_{ing}$$

where  $D_{end_i}$  = the month-end deposition, not accounting for prior months' accumulations, similar to  $S_{end}$  but without the term accounting for prior months

$r$  = the foliar interception fraction divided by the biomass,  $\text{m}^2/\text{kg}$ , calculated as

$$r = (1 - e^{(-Y \alpha f_s)}) / (Y f_s)$$

where  $Y$  = the maximum dry biomass of a plant,  $\text{kg}/\text{m}^2$  dry

$\alpha$  = empirical interception parameter,  $\text{m}^2/\text{kg}$  - A value of 2.9 was used for all plant types.

$f_s$  = available fraction of maximum wet biomass, unitless, varies by month and plant type, see Calculation 001

$WC$  = the weathering correction to account for the difference between simple radiological decay on the soil surface and weathering plus decay on the leaves, calculated as

$$WC = (1 - e^{-(\lambda_x + \lambda_w) 30}) \lambda_x / [(1 - e^{-\lambda_x 30}) (\lambda_x + \lambda_w)]$$

(this term is needed use of the total month-end deposition value alone neglects weathering removal processes from vegetation)

where  $\lambda_w$  = the weathering rate constant,  $\text{d}^{-1}$ , taken to be 0.693/14

$TF$  = the translocation factor, unitless, to account for translocation from foliar surfaces to the interior of the edible portion of the plant, taken to be 1.0 for leafy vegetables and 0.05 for others

$CR$  = the soil-to-plant concentration ratio, unitless, to account for root uptake

$IR_v$  = the ingestion rate of the vegetable or fruit type,  $\text{kg}/\text{d}$ .

Ingestion of produce after the end of the harvest season requires that the dose rate at the time of harvest be calculated first using the above equation; that dose rate is then decayed to the current month and integrated over the current month, as

$$\text{Dose Veg}_{\text{postharvest}} = \text{Dose Veg}_h e^{-\lambda_x t_p} \frac{(1 - e^{-\lambda_x 30})}{30 \lambda_x}$$

where the first exponential term represents the decay to the start of the current month, time  $t_p$ , and the second term represents the integral of the intake over the current month.

## 2.5 INGESTION OF MEAT

Dose resulting from ingestion of meat was estimated on the basis of range-fed beef. Cows were assumed to be slaughtered as required to maintain a supply of meat. All meat was assumed to be consumed "fresh"; only a 15-day period from slaughter to consumption was used. This series of assumptions should be conservative: it is unlikely that people who raised their own beef cattle in rural locations would have such a minimal holdup time before consumption on a regular basis. The calculation assumed that the cattle were on pasture grass 100% of the year. The doses were estimated as

$$Dose_{meat_i} = (D_{endi} WC_r + S_{endi} \frac{CR}{\rho}) IR_{cattle} TF_{beef} IR_{meat} 30 DF_{ing} e^{-\lambda_r 15}$$

where  $IR_{cattle}$  = the ingestion rate of pasture grass by beef cattle, kg/day dry

$TF_{beef}$  = the feed-to-meat transfer coefficient, day/kg.

Ingestion rates for meat for adults and infants were taken from Nelson and Yang (1948).

## 2.6 INGESTION OF EGGS

Calculation of dose from ingestion of eggs produced by free-ranging hens was performed in a manner analogous to that for beef. The chickens were assumed to eat a portion of their diet as grass, and also to consume a significant amount of soil. The hens were assumed to range freely all year long, and to provide fresh eggs with essentially no holdup. Doses were calculated as

$$Dose_{eggs_i} = ((D_{end_i} WC_i + S_{end_i} \frac{CR}{\rho}) IR_{hen} + S_{end_i} IR_{cs}) TF_{egg} IR_{egg} 30 DF_{ir}$$

where  $IR_{hen}$  = the chicken's ingestion rate of grasses, kg/day  
 $IR_{cs}$  = the chicken's ingestion rate of soil, kg/day  
 $TF_{egg}$  = the feed-to-egg transfer coefficient, day/kg

## 2.7 MILK INGESTION

For conservatism, the milk was assumed to be provided by a backyard cow grazing under Feeding Regime 1. All equations and parameters were copied from the spreadsheet prepared for Calculation 001 (Ikenberry and Napier 1992). The soil components were updated to use the running month-end quantity,  $S_{end_i}$ , rather than just the monthly average deposition,  $D_{end_i}$ .

## 2.8 RADIOMUCLIDE INVENTORY ESTIMATES

For all radionuclides other than iodine-131, estimates had to be made of the quantity processed through the Hanford separations plants in 1945. Heeb (1992) provides total monthly throughput and monthly mass-weighted cooling times. These are recapitulated in Table 2. A calculation was performed using the ORIGEN2 computer code to provide representative contents of one ton of fuel discharged from a Hanford production reactor operating at conditions typical of 1945 (C. Heeb and U. Jenquin, personal communication, October 1992). The quantities of radioactivity of 14 radionuclides identified as being the highest contributors to dose in Phase I (Napier 1991), or else of identified public interest, are given in Table 3. The contents are provided at three separate cooling times after discharge; it is evident that radioactive decay prior to release is important. The monthly amounts processed through the separations facilities were estimated for each month using logarithmic interpolation of the values in this table for the month-average cooling time.

## 2.9 RADIOACTIVE DECAY AND DAUGHTER INGROWTH

Several of the radionuclides listed in Table 3 are members of decay chains, and have either precursors or successors in these chains. Fortunately for this scoping study, the behavior and impact of these radionuclides could be described with simple one-member exponential decay with a few assumptions. In the radionuclide chains Ru-106/Rh-106, Ru-103/Rh-103, Ce-144/Pr-144,

Cs-137/Ba-137m, and Zr-95/Nb-95, the parent is sufficiently long lived, and the daughters sufficiently short lived, that the chains could be considered to be in secular equilibrium at all times in the environment. The effective decay energies were summed, and the ingestion and inhalation dose factors adjusted to account for these chains. The chain Te-132/I-132 was considered in estimating the amount of I-132 remaining in the fuel and thus releasable, but the release fractions (described below) were sufficiently disparate that the I-132 could be considered in isolation in the environment.

## 2.10 RADIONUCLIDE RELEASE FRACTIONS

The key to determining the relative importance of the radionuclides in the fuel is the fraction of the separation plant throughput that is emitted to the atmosphere. Assessments commonly assume that the release fraction for noble gasses (Xe and Kr) is 1.0. Heeb demonstrated that the release fraction for iodine (I-131, I-132, and I-129) is 0.9. In Phase I scoping, a relatively large value was also given to ruthenium isotopes (Ru-103 and Ru-106). This was done to compensate for the initial impression that relatively large amounts of ruthenium were emitted in episodic events. Historical documents now available to HEDR now indicate that problems perceived in terms of "hot particles" were, in fact, manifestations of a much more general release of "mists" from the dissolver vessels. Greager and MacReady (January 1948, page 2) state that "the amount of radioactivity associated with the rust particles is only a small portion of the total activity carried by the airstream. The bulk of this entrained activity is presumed to be in the form of liquid droplets which constitute a 'mist' given off from the processing tanks during normal operations." Parker (March 1948, page 28) continues, "It is concluded that the main picture of fission product deposition" (other than iodine-131, Ed.) "approaches a continuous distribution rather than a particulate one. To summarize the inferences from old data, the emission of active droplets has been known from the start of operations." Furthermore, Healy (August 1948, page 7) shows that radiochemical analysis of non-iodine fission products on sage from the 200-West Area shows a radionuclide spectrum very much like that presented in Table 3, and specifically reporting on both ruthenium isotopes. Analysis of data in these reports, as well as later reports describing the

efficiencies of filters applied afterwards, leads to an upper bound release fraction for the first few years of operation for all other radionuclides of  $1 \times 10^{-5}$  (i.e., 1 part in 100,000 escaping from the dissolvers).

The particulate release fraction may also be estimated from early vegetation monitoring data. Parker (March 1948) describes vegetation contamination after one year of operations as being mostly iodine-131 with 0.05% other fission products. Healy (August 1948) also provides such information for 1945, 1946, and 1947. The activity ratios of deposited particulate radionuclides to deposited iodine-131 support release fractions of less than  $1 \times 10^{-5}$  for all non-volatile radionuclides.

Calculated amounts released, derived monthly integrated air concentrations at the Franklin County location of interest, and resulting month-end depositions are provided in Tables 4, 5, and 6, respectively.

### **3.0 RESULTS/DISCUSSION**

The results of calculations for each of the pathway components for each of the radionuclides for the year 1945 in Census District 4 of Franklin County are presented in Tables 7 and 8 for infants and adults, respectively. Each table presents both effective dose equivalent (whole-body dose) and critical-organ dose (the dose to the organ receiving the highest dose). Doses are presented for each of the eight pathways described above.

Although not the maximum doses that could be calculated, the doses in Tables 7 and 8 are for individuals in a highly-impacted location, living a lifestyle that would tend to maximize doses. It is the opinion of the author that it is unlikely that median or mean doses calculated with more detailed models would exceed those presented here, for any radionuclide. A separate scoping study is underway to evaluate the position of this deterministic result in the overall range of possible dose results.

The results presented here support those drawn by Napier (1991) that I-131 and the milk-ingestion pathway are the most important to the HEDR study. Tables 9 and 10 present the percentage contribution to the total dose of each radionuclide and pathway combination. Iodine-131 alone provides over 99.9% of the dose to both the infant and the adult. Iodine-131 by the milk pathway provides nearly 90% of the dose (for Feeding Regime 1). Even if the milk pathway is totally excluded, Iodine-131 provides over 99% of the dose via the other pathways.

Pathways of exposure other than milk can be seen to be relatively important for the other radionuclides. External dose dominates for the noble gasses. Inhalation is controlling for Pu-239, Zr-95, and Ru-106. Ingestion of meat is important for Sr-90. However, in the context of the total dose from Hanford operations, since no radionuclides are emitted in isolation, the controlling radionuclide/pathway combination is I-131/milk. This is illustrated in Figure 2. The dominance of this single radionuclide is so notable that it calls into question the need for detailed analyses of the others.

**FIGURE 2. Pathway Contributions**

The results of this scoping study parallel those of Phase I (Napier 1991). With the revision of the release fraction for ruthenium isotopes, the ruthenium isotopes fall to the general level of the other fission products. The major difference between the two studies is that this one deals with absolute magnitudes, rather than relative ratios. This type of comparison was not possible until the declassification of the radionuclide production information (Gydesen 1992a; 1992b) and the recent development of the source term model (Heeb 1992).

The dose decision levels provided by the Technical Steering Panel (Shleien 1992) require a two-part analysis of doses—an annual dose and a cumulative dose over the period of Hanford operations. This scoping study addresses the annual doses for 1945 only, although they are by far the largest. A separate scoping study is underway to extend the results of this study over the period of interest through 1972.

#### **4.0 RECOMMENDATIONS**

Scoping calculations were performed for that portion of Franklin County considered to be the most exposed area in the HEDR study region. Based on the results of this scoping study, and the companion study on cumulative dose, the following recommendations are made regarding exposure pathways, calculational methods, and included radionuclides for the calculation of individual doses for the HEDR project:

##### **EXPOSURE PATHWAYS**

Although external dose, inhalation dose, and dose from ingestion of soil by humans all contribute less than one percent of the total dose, each individually has the potential to contribute a sizable fraction of the TSP's dose decision level. Each of these pathways also shares the characteristic of being simple to calculate from information that will be available. For each of these reasons, and because their inclusion would enhance the validity of the estimated doses, it is recommended that they be retained in the model. The remaining pathways evaluated each have the potential to contribute some multiples of the TSP dose decision level, even if only for a very limited geographical area or for a limited target population. Thus, they should also be retained.

##### **CALCULATIONAL METHODS**

A term noted in the development of this spreadsheet scoping study for which there are currently only very limited data available is the holdup time from slaughter to consumption of meat. The distribution of holdups (all consumed relatively fresh, or long holdups in freezers or lockers) will have a significant impact on the magnitude of this value. Additional information is required from the Demography and Food Habits Task to help better define this value. A study of the secondary literature will be requested of Task 06.

## INCLUDED RADIONUCLIDES

The results indicate very plainly that the radionuclide of greatest interest is iodine-131. The doses, either to adults or children, from any pathway, are four to seven orders-of-magnitude smaller for any other radionuclide than they are from iodine-131. This calls into question the need to investigate these other radionuclides in great detail. A driving force for retaining the capability for estimating doses from other nuclides was the possibility that they could contribute significantly to the dose. It is apparent from this analysis that this will not be the case.

It is recommended to the TSP that the detailed analysis be limited to the doses from iodine-131 from the air pathways. If the TSP wishes to continue to evaluate doses from other radionuclides, such analyses should be performed in a greatly circumscribed fashion. Options include additional spreadsheets such as the one used for this analysis, deterministic calculations with the larger dose code (i.e., using the same code but with only one realization of source, dispersion, uptake, and dose), or scaling from the more completely calculated iodine doses. Any of these options would greatly reduce the computational complexity required of the main dose code, and also reduce the effort required to obtain adequate data to support the main dose code.

## 5.0 QUALITY ASSURANCE

Quality assurance was undertaken in accordance with PNL-MA-70, Volume 1, Procedures for Quality Assurance Program, under PNL administrative procedure PAP-70-301, "Hand Calculations, General." Complete documentation of the calculation was prepared by the senior author, who independently prepared the calculational spreadsheets and performed the spreadsheet calculations. A thorough independent review was conducted by the developer of the milk dose spreadsheet. Spreadsheet documentation is on file and available for review.

## **APPENDIX C**

### **SUMMARY OF PARAMETERS USED**

APPENDIX C.1

DESCRIPTION OF VARIABLES AND VALUES USED

Parameter Symbol	Description of Parameter and Value Used in Scoping Calculation	Reference
$D_{\text{end } i}$ $D_{\text{end } h}$	Surface deposition of iodine-131 on the ground at the end of month $i$ and harvest month $h$ ( $\text{Ci}/\text{m}^2$ ); varies by month; value used: see Table 3.	Ramsdell Jr., J. V., personal communication, October 1992, and calculation
$\gamma$	Maximum dry biomass of a plant, $\text{kg}/\text{m}^2$ dry; value used: 0.3 for pasture and silage; 0.2 for alfalfa; combines the $\gamma$ and $f_d$ parameters presented in Shindle et al.	Shindle et al. 1992, pages 2.4 and 2.5
$\alpha$	Empirical interception parameter, $\text{m}^2/\text{kg}$ ; value used: 2.9 for pasture, silage, and alfalfa	Shindle et al. 1992, page 2.6
$f_s$	Fraction of maximum biomass available, unitless; varies monthly for pasture, silage, and alfalfa; value used: see Ikemberry and Napier 1992.	Shindle et al. 1992, page 2.5
$IR_{\text{infant}}$	Milk ingestion rate for an infant, $\text{L}/\text{d}$ ; value used: 1.0	Callaway Jr., J. M. 1992, page 19
$IR_{\text{adult}}$	Milk ingestion rate for an adult, $\text{L}/\text{d}$ ; value used: 0.5	Callaway Jr., J. M. 1992, page 19
$IR_{\text{cow}}$	Ingestion rate by cows of various feed types, $\text{kg}/\text{d}$ ; varies monthly by feed type value used: see Ikemberry and Napier 1992.	Beck et al. 1992, page 54
$\lambda_w$	Weathering removal rate constant, $\text{days}^{-1}$ ; value used: 0.0495 (weathering halftime = 14 days)	Snyder et al. 1992, page $\lambda_{\text{weather}}$

DESCRIPTION OF VARIABLES AND VALUES USED (cont'd.)

Parameter Symbol	Description of Parameter and Value Used in Scoping Calculation	Reference
$f_{hay}$	Fraction of total hay consumption from a given hay cutting; value used: 1.0 June, July; 0.5 August; 0.33 September to December	Beck et al. 1992, page 61
$FS_{cow}$	Soil ingestion rate of dairy cows, kg/d; varies by season (month) and feeding regime type; values used: see Ikenberry and Napier 1992.	Snyder et al. 1992, page $FS_{cow}$ Darwin 1992, all
$\rho_{cs }$	Density of soil layer consumed by cows, kg/m <sup>2</sup> ; value used: 13 (assumed 1-cm depth)	derived from data in: Snyder et al. 1992 page $\rho_{us }$ Ikenberry et al. 1992, page 2.15
$SA_{bale}$	Exposed surface area of stored feed, m <sup>2</sup> ; value used: 0.62 for an individual hay bale	empirically determined
$Mass_{bale}$	Mass of stored feed, kg; value used: 30 for an individual hay bale	empirically determined
$IHR_{cow}$	Cow inhalation rate, m <sup>3</sup> /s; value used: 0.0017 (100 l/min) $59-(90)-104$ L/min $[85-(130)-150]$ m <sup>3</sup> /d]	Black and Barth 1976, page 15, Zack 1985, page 739
$ADJ_z$	Adjustment factor to account for differences in transfer to milk between inhalation and ingestion (unitless); value used: 0.48	Zack 1985, page 741
BR	Breathing rate, m <sup>3</sup> /s; values used: Infants              0.0000188 Adults              0.000255	Snyder et al. 1992

DESCRIPTION OF VARIABLES AND VALUES USED (cont'd.)

Parameter Symbol	Description of Parameter and Value Used in Scoping Calculation	Reference
$V_d$	Deposition Velocity, m/s: values used: Noble gases 0.0 Iodines 0.01 Particulates 0.001	Napier et al. 1988, page 5.719 Volume 3
$IR_v$	Ingestion rate of fruits and vegetables, kg/d (dry): Infant leafy vegetables 0.0023 Infant other vegetables and fruit 0.0345 Adult leafy vegetables 0.006 Adult other vegetables and fruit 0.067	Marsh et al. 1992. Appendix B
$IR_{meat}$	Human ingestion rate of meat, kg/d: Infant 0.045 Adult 0.2	Nelson and Yang 1987
$IR_{hen}$	Rate of ingestion of pasture grasses by laying hens, kg/d (dry); value used: 0.05	Snyder et al. 1992.
$IR_{cs}$	Rate of ingestion of surface soil by laying hens, kg/d; value used: .001	Snyder et al. 1992.
$IR_{egg}$	Human ingestion rate of eggs, kg/d: Infants 0.005 Adult 0.035	Nelson and Yang 1987
$X_1$	the time-integrated air concentration in month i ( $\text{Ci} \cdot \text{s}/\text{m}^3$ ); varies monthly; value used: see Table 3.	Ramsdell Jr., J. V., personal communication, October 1992 and calculation
