47 technical issues with equipment (Shorten & Robertson, 1996; Winters et al., 2003). The limited  
48 availability of equipment, laboratory time, and a faculty resource were concerns too (Winters et  
49 al., 2003). Students' perceived as a drawback the added time it took to learn how to use the  
50 equipment in addition to the time needed to learn a new nursing skill (Winters et al., 2003).

51         The first author drew teaching strategies from the successes and drawbacks reported in  
52 existing studies and added others to develop an approach to the HTT assessment video  
53 assignment plan. From the successes, students worked in self-selected triads, rotating roles of  
54 nurse, patient, and videographer (Shorten & Robertson, 1996; Winters et al., 2003). Once a  
55 student had videotaped his or her HTT, he or she could review, erase, reshoot, and ultimately  
56 submit the video to the faculty when they were satisfied with it (Shorten & Robertson, 1996).  
57 Each student received a rubric to self-grade his or her performance (Yoo et al., 2009). Once  
58 graded, each student met with the first author to review his or her video and get personalized  
59 feedback on his or her performance (Shorten & Robertson, 1996).

60         From the drawbacks, the students practiced with the cameras before officially using them,  
61 the skills lab availability was assured, and a faculty resource was available when videotaping  
62 (Winters et al., 2003). The faculty added preparatory materials for the students and an edict to  
63 individualize the HTT sequence so that it made sense to them. As part of the self-grading, the  
64 faculty instructed the students to write a reflection on their HTT performance to include what  
65 they did well, what areas needed growth, and a plan to improve on the areas identified as  
66 unsatisfactory (Milan, 2003).

67         This study's purpose was to explore third-semester baccalaureate nursing students'  
68 perception of the value of using student-produced video as an approach for learning HTT  
69 assessment, an essential clinical nursing skill taught in the classroom.

### Methods

90

#### Design

91

92

Collins, Brown, and Newman's (1987) Cognitive Apprenticeship Model guided the study. Its premise is that while classroom teaching is effective, the ideas and skills taught there are disconnected from where they will be used. The model proposes four elements - *content*, *method*, *sequencing*, and *sociology* – to create an effective learning environment, one that places students in the intended setting to learn to function there. First, the content element includes *tricks of the trade*, use of repetition to master skills, *control strategies*, alternate approaches to problem-solving, and *learning strategies*, the ability to know how to learn. Second, the method element defines teaching techniques that foster exploration and independence. Teaching techniques include *modeling* – skill demonstration, *coaching* – provide tips and feedback, and *scaffolding* – provide preparatory materials to students. The teacher encourages students to *articulate*, to express thoughts and problem-solving abilities, and *reflect*, to critique their work to improve thinking. To help foster learner independence, the teacher promotes *exploration*, setting goals for the student. Third, the sequencing element allows the student to acquire various skills that build complex skills on the basic skills learned first. The fourth element, sociology, refers to a learning environment that mirrors the character of the setting where the skills will be used.

This model was a good guide for this nursing education study because it aligns with the importance of creating an effective learning environment to connect classroom learning of HTT assessment with application to clinical practice.

The design was cross-sectional. A convenience sample of third-semester baccalaureate students enrolled in spring 2015 in an applied assessment and nursing fundamentals course at a

93 well-established university nursing school in the Western United States participated. The  
94 university's human subjects committee approved the study.

### 95 **HTT Assessment Video Assignment**

96 A month before the assignment was due, the students received written expectations for  
97 the videotaping process and a head-to-toe study guide. On videotaping day, they arrived at the  
98 skills lab, obtained a camera from the faculty, and proceeded to a cubicle with their self-selected  
99 triad to tape individual videos which could not be more than 15 minutes in length. Prompts of  
100 any kind, such as the study guide, were not permitted in the cubicle. When each student was  
101 satisfied with his or her videotaped HTT performance, he or she kept a copy of his or her video,  
102 submitted a copy of it to the faculty, and received a rubric for self-grading and reflection on his  
103 or her video performance. Each student brought his or her self-graded rubric and written  
104 reflection to a 30 minute, one-to-one review with the first author.

### 105 **Measure**

106 The researchers developed the study's 34-item survey in two phases, focus groups and  
107 survey development using an iterative, descriptive content analysis process. The survey used  
108 Likert-like item responses with 4 = strongly agree, 3 = agree, 2 = disagree, and 1 = strongly  
109 disagree. Because each student completed the HTT assessment video assignment, "not  
110 applicable" was not offered as a response item.

### 111 **Data Collection**

112 In the absence of the first author, the second author briefed the students during the last  
113 10 minutes of the class period. Each student received a one-page handout detailing the study's  
114 purpose, the planned use of results, and the voluntary and confidential nature of their  
115 participation. The handout also included an assurance that participation or non-participation  
116 would have no impact on their course grade and the contact information for the second author.

117 Interested students were asked to complete the 34-question survey without including any  
118 identifying information. They were encouraged to ask questions before filling out the survey and  
119 informed that submission of the completed survey constituted consent to participate.

## 120 **Results**

121 Out of the 80 students enrolled, 72 participated in the survey, a 90% response rate. For  
122 data analysis, the researchers used the Statistical Package for the Social Sciences (SPSS) version  
123 22.0 for Windows (2013, IBM Corp., Armonk, NY, USA). They performed an exploratory  
124 factor analysis on the newly developed measure. Table 1 (see Appendix A) displays the mean,  
125 standard deviation, and Cronbach's Alpha for each of the four subgroupings produced. Further,  
126 the researchers calculated the percent frequency and mean for the individual items in each of the  
127 four subgroupings (see Table 2, Appendix B).

### 128 **Exploratory Factor Analysis**

129 The researchers emphasize the exploratory nature of the factor analysis. There is  
130 disagreement among scholars about what constitutes a sample size adequate for factor analysis  
131 (Hair, Black, Babin, & Anderson, 2010; Nunnally & Bernstein, 1994; Tabachnick & Fidell,  
132 2007). The Kaiser-Meyer-Olkin Measure of Sampling Adequacy on this study's data was .673. A  
133 sample size is considered adequate when the value is .6 or more (Kaiser & Rice, 1974; Pallant,  
134 2010). Factors were identified based on loadings of above .5 (Nunnally & Bernstein, 1994) and  
135 interpretability. Of the 34 original items, a total of 23 items loaded on one of the four factors. All  
136 factors correlated positively with each other with correlations ranging from 0.21 to 0.49.  
137 Researchers use face validity to decide the degree to which the items in a scale relate to a  
138 construct (Hair et al., 2010). In this study, the researchers used face validity to make sense of the  
139 item loadings on each factor in terms of learning.

164 the HTT assessment, and a worthwhile learning experience overall. Their perceptions may be  
165 grounded in the process used to accomplish the student-produced video assignment; the support  
166 and feedback they received from their didactic course and clinical faculties; the minimal barriers  
167 to learning reported; and their sense of confidence and independence to perform the HTT  
168 assessment.

169         The results also suggest that the learning environment created was effective. The  
170 videotape HTT assignment was designed from teaching strategies from the work of previous  
171 researchers with new ones that the current researchers added (Milan, 2003; Shorten & Robertson,  
172 1996; Winters et al., 2003; Yoo et al., 2009). To create an effective learning environment where  
173 students could connect classroom learning with clinical application, the four elements from  
174 Collins et al.'s (1987) Cognitive Apprenticeship Model-content, method, sequencing, and  
175 sociology-framed the strategies.

176         Regarding teaching strategies framed in the element of content, the students reshot their  
177 videos to master the HTT through repetition, a trick of the trade. Given the parts to include in  
178 the HTT, the students successfully put it together in a sequence that made sense to them, a  
179 control strategy. Learning strategies were self-grading and feedback from faculty during a one-  
180 to-one meeting.

181         For the method element, the first author demonstrated the HTT in class (modeling) and  
182 provided preparatory materials, a HTT demonstration video and study guide and, confirmation  
183 that the skills lab and cameras were available for practice (scaffolding). The written faculty  
184 expectations for videotaping set goals (exploration). During the individual review with the first  
185 author, each student received tips for success (coaching). At the same time, they were asked to
