ACKNOLEDGEMENTS

I would like to thank Ph.D. Peter Stevens, for all his time, patience, and suggestions. I would also like to thank Ph.D. Peter M. Jørgensen and Ph.D. John M. MacDougal, for their support, encouragement, suggestions and for the invaluable comments that helped me get a better understanding of this group.

I am grateful to the Project “Untangling the passionflower vines: phylogeny, species diversification, and character evolution in *Passiflora* subg. *Decaloba* (Passifloraceae)” for providing financial support for my graduate studies and for my fieldwork. I also thank the Missouri Botanical Garden for their support to graduate students. I am also grateful to my professors for their guidance throughout my graduate studies. Peter Stevens, Amy Zanne, Bette Loiselle, and Mick Richardson.

I would also like to thank Kristen Porter-Utley, and Shawn E. Krosnick, for their assistance. I thank Ph.D. Jim Solomon, curator at the Missouri Botanical Garden, for his help with the loans and facilitating the collections at MO, and to the curators of the others herbaria, F, G, GH, K, MICH, NY, P, PH, and US among many others for providing material on loan. I also want to thank people from the Missouri Botanical Garden: Carmen Ulloa, Mary MacNamara, Andrea Voyer, and Ana Spencer for their invaluable help.

I want to express my special thanks to Alba Arbelaez, Juan Carlos Penagos, Carolina Romero, Dilys Vela, Rosa Ortiz-Gentry, John Pruski, Vania Torrez, Saul Hoyos and David Kenfack and other people who were incredibly academically and socially helpful during the last two years.

Finally, I would like to thank my parents to whom I dedicate this work.

ABSTRACT

Passiflora subgenus *Decaloba* section *Xerogona* is a group of herbaceous vines found in subtropical and tropical regions of America. The 15 species, including two subspecies, recognized here are primarily distributed in Central America, with a few also found in South America. The species of the section are recognized by their very unusual dehiscent capsular fruit, absence of bracts and laminar nectaries and their transversely grooved seeds. The section contains two problematic species complexes; *P. capsularis* and *P. rubra*. The morphological variation among and within these two complex species are examined in this study using Principal Component Analysis (PCA) based on correlation matrices of morphological characters. The variation of these two complexes was studied throughout their distributional range. Within the *P. capsularis* complex only one species has been recognized. However, two species were recognized within the *P. rubra* complex based mainly on floral characters: *P. cisnana* and *P. rubra*. A key, detailed descriptions, distribution maps, and photographs are included in the revision. The distribution and ecology of the 15 species recognized are also discussed.

Key words: *Passiflora*, section *Xerogona*, Principal Component Analysis

INTRODUCTION

Passiflora is a large genus of more than 557 species of vines and lianas, it is primarily distributed in the New World tropical, subtropical, and occasionally temperate areas, but there are also about 25 species in India, Southeast Asia, Oceania, and Australia. It is most diverse in the tropical regions of America where it is found in a variety of habitats from deserts and floodplains to Andean slopes up to the lower limits of the *puna* and *páramo*, in forest margins up to 3800 m in the high Andes, but the populations there are generally small (Holm-Nielsen et al., 1988).

Vegetatively, *Passiflora* displays a wide range of leaf shapes and great variation in the types of extrafloral nectaries present on leaves, bracts, and petioles. *Passiflora* has a complex floral structure and is characterized by several unique floral features. The most distinctive characteristic is the corona of showy filaments, which plays a very important role in the pollination of most of the species. The innermost series of the corona, the operculum, is often basally connate and frequently membranous. The limen is a disk shaped organ at the base of the androgynophore, which comes into contact with the operculum and together they regulate access to the nectar ring; at the floor of the floral tube. The limen is absent in some species. The androgynophore is elongate, and the ovary is located at the point where the stamens diverge from the androgynophore. Variation in these floral and vegetative features forms the basis of a complex taxonomic subdivision of *Passiflora* into subgenera, sections and series (Killip, 1938; Muschner et al., 2003; Feuillet and MacDougal, 2004).

Passiflora comprises five subgenera, *Astrophea*, *Decaloba*, *Deidamiooides*, *Tetrapathea*, and *Passiflora* (Feuillet and MacDougal, 2003). Subgenus *Astrophea* includes approximately 57 South American woody lianas, and a few trees and shrubs, some with cauliflorous inflorescences. The flowers are white to pink or purple, or red to orange and usually have thick yellow coronal filaments and an obvious floral tube formed by the fused calyx and corolla. The flowers are mostly bee or hummingbird pollinated (Krosnick, 2006). Subgenus *Deidamiooides* is relatively small with only 13 species; it is distinguished by having a whitish to yellow corona with two or four rows of filaments and whitish or greenish white flowers with a broad floral tube. The flowers may be

pollinated by bees (Krosnick, 2006). Subgenus *Passiflora* is the largest subgenus with 251 species of vines or lianas with large colorful flowers often with complicated corona or sometimes with a long floral tube with very reduced corona; the floral bracts are usually conspicuous. There are various floral morphologies within subgenus *Passiflora*. Pendulous red or pink colored flowers are pollinated by hummingbirds, upright red flowers with coronal filaments arranged to form a narrow tube are also pollinated by hummingbirds, and dish-shaped white flowers are pollinated by bats, however, most species are pollinated by bees (Ulmer and MacDougal, 2004). Subgenus *Tetrapathea*, which has been recently included within genus *Passiflora* based on phylogenetic analyses (Krosnick and Freudenstein, 2005), contains only 3 species, restricted to New Zealand; it is characterized by having flowers with four to five stamens and two or three carpels, and is completely dioecious (De Wilde, 1971, Krosnick & Freudenstein, 2005). Finally, the second largest subgenus, *Decaloba*, with more than 233 species, includes herbaceous climbers and lianas with great morphological, biogeographical, and ecological diversity. The most remarkable morphological variation is in leaf shape: the leaf blades may look like swallowtails, shields, sausages, duck feet, boomerangs, kitten heads, coins, and half moons, and there is also variation in variegation and the arrangement of extrafloral nectaries on the petioles or laminas. Flowers range from green small and less than 1 cm diam., whitish and ca. 2.3 cm diam., to red with a long androgynophore ca 2.9 cm. The majority of species are pollinated by bees and wasps, but there are some species adapted to hummingbird pollination (Ulmer and MacDougal, 2004) and at least one species is known to be pollinated by bats: *P. penduliflora* (Kay, 2001).

Feuillet and MacDougal (2003) proposed that subgenus *Decaloba* be divided into eight supersections, *Pterosperma*, *Hahniopathanthus*, *Disemma*, *Multiflora*, *Auriculata*, *Cieca*, *Bryonioides*, and *Decaloba*, seven of which grow in the New World and one, *Disemma*, in the Old World. Supersection *Decaloba* is the largest group in the subgenus with about 120 species. The leaves are mostly 2-lobed by the reduction of the central lobe of a 3-lobed lamina. The laminar nectaries appear as ocellae between the main veins, but there are no petiolar nectary glands. Two sections are recognized within supersection *Decaloba*: section *Decaloba* consisting of approximately 106 species, and section *Xerogona*, which includes about 15 species that are characterized by a very unusual

dehiscent capsular fruit. The fruits of all other passifloras are berries (Ulmer and MacDougal, 2004). Killip (1938) placed *Xerogona* as a section within subgenus *Plectostemma* (supersection *Decaloba* of Feuillet and MacDougal, 2003) in a classification based primarily on floral morphology.

My study focuses on species of section *Xerogona*. They are distributed primarily in Central America, with a few also found in South America. The most important morphological features distinguishing section *Xerogona* are the absence of bracts and laminar nectaries, dehiscent fusiform fruit, and the transversely grooved seeds (Killip, 1938; Ulmer and MacDougal, 2004).

Within *Xerogona* the Central American species are relatively well defined, while, the most difficult portions of section *Xerogona* are two species complexes in South America and in the Caribbean Islands. These are traditionally named *Passiflora capsularis* L. and *Passiflora rubra* L., and within each there is much morphological variation; furthermore, it is often difficult to distinguish between the two complexes. The three most important features that have been used to differentiate between the two complexes are the indumentum of the ovary, the shape of the fruit (Killip, 1938; Holm-Nielsen et al., 1988), and the color of the corona (Killip, 1938; Ulmer and MacDougal, 2004).

Objectives

The main goal of this study is to update our knowledge of the species of *Xerogona*. The particular objectives of this study are:

- To elucidate the number of taxa within section *Xerogona*.
- To evaluate which are the most useful characters to identify these taxa.
- To provide a key to differentiate the species recognized.
- To describe all species within section *Xerogona* in a monographic format.

MATERIALS AND METHODS

Morphological Data Set

This study is based primarily on the examination of the external morphology of over 1400 dried collections from more than 70 herbaria, supplemented with observations from plants preserved in FAA, photographs, and living plants in the field. Specimens of the *P. rubra* complex were collected during field work in Peru and Bolivia.

All of the herbarium specimens representing section *Xerogona* were carefully observed, and those spanning the morphological variation and geographical range of each species were chosen for measurement. Characters were measured from corresponding positions on mature, reproductive plants in order to minimize variation due to developmental differences. Given that this study is developed under the Project “Untangling the passionflower vines: phylogeny, species diversification, and character evolution in *Passiflora* subg. *Decaloba* (Passifloraceae)”, the characters used were selected from the morphological character dataset used by the entire project. A total of 66 morphological characters were measured or observed on the selected plant specimens. All measurements were taken from herbarium material using a caliper and dissecting microscope (Nikon SMZ-1). Because the species of *Passiflora* exhibit much morphological variation even in a single plant I recorded the maximum and minimum measurements of each character for each specimen.

Characters chosen for measurements were based in part on those that have been previously used to differentiate species within genus *Passiflora* and within section *Xerogona*. Particular emphasis was placed on leaf shape, flower structure including, corona morphology, and details of operculum, limen, androgynophore, floral nectary, fruit shape, and seeds. All the characters measured are listed in Table 1. All the measurements were made in mm except for the qualitative characters.

Foliar characters measured are shown in Fig.1:

- length and width of the blade
- number of lobes (unlobed leaves occur in *Passiflora cobanensis*, 2-lobed in *P. rovirosae* and *P. goniosperma*, and 3-lobed leaves are rarely present in *P. capsularis* and *P. citrina*).

- length and width of the deepest lobe
- the angle between the lateral veins (the angle between lateral lobes has been used to differentiate species within *Passiflora* (Escobar, 1980; MacDougal 1994, Porter-Utley 2003; Milward-de-Acevedo 2004)
- length of lateral and central veins

Floral characters were observed on herbarium specimens rehydrated by placing flowers in warm water. The flowers of species of section *Xerogona* range from about 1.5 cm in diam., in *P. tenella* and *P. pusilla*, to about 4 cm in diam. in *P. costaricensis* and *P. rovirosae*. The floral characters that I measured are shown on Fig. 2 and 3. These characters include

- length and width of the sepals and petals
- length of corona filaments
- height of the operculum
- length and width of anthers
- style length

(* characters used in PCA Analyses).

Principal Component Analysis (PCA)

Within *Xerogona* the Central American species are relatively well defined and easy to distinguish. They present no taxonomic or morphological problem (see taxonomic treatment). However, *Passiflora capsularis*, *P. rubra*, and *P. cervii* are difficult to distinguish and morphologically very variable. So in order to find distinguishing characters and reach a better understanding of their morphological variation PCAs were carried out on the *P. capsularis* and *P. rubra* complexes and including the closely related *P. cervii*.

Principal Components Analysis (PCA) is a useful statistical method to evaluate morphological variation. It has been used to circumscribe taxa of plants such as Bromeliaceae (Gardner, 1983), Passifloraceae (Porter-Utley, 2003; Ocampo, 2007), Fabaceae (Castro et al., 2005), Arecaceae (Henderson, 2004; Henderson 2006), and Calceolariaceae (Puppo, 2008), among others. The data used in the PCA analyses were the mean values of measurements from each specimen.

A total of 66 morphological characters were recorded. However, only 24 quantitative and one qualitative characters were used (Table 1). The qualitative characters were not included in the analyses because they are not really appropriate for the method used (Sneath and Sokal, 1963, 1973; Quinn and Keough, 2002; Jolliffe, 2002; Gotelli and Ellison, 2004).

Only 131 collections provided complete data for the analyses of *P. capsularis*, *P. cervii*, and *P. rubra* (Appendix 1); *P. cervii* is represented by only a few collections, perhaps reflecting its restricted distribution in the southern region of Brazil. The material included, when possible, specimens from the entire distributional range and specimens that reflect the variation within species as gauged by eye. Data was stored in TROPICOS® and from there a matrix was built using the variables listed in Table 1.

Data analyses were carried out using the computer program SPSS 17.0 for Windows. The one sample Kolmogorov-Smirnov test was performed to test the normality of the data. Outliers were checked with box plots.

Only those axes corresponding to components with eigenvalues greater than 1.0 were extracted and the individuals were projected on the first three PCA components. Specimens that lacked much data were deleted from the analyses.

More than 15 sets of analyses were made; but only the most relevant are included here. These were separated into two sets (Table 2). The first included all the data of *P. capsularis* and *P. rubra* complexes, and *P. cervii*. The second included the specimens of the *P. rubra* complex and *P. cervii*. The specimens used for the various analyses are listed in Appendix 1. *Passiflora capsularis* and *P. rubra* were recognized by Killip (1938), while *P. cervii* is a new species published by Milward de Acevedo (2008).

Table 2. List of the different PCAs carried out including the number of specimens and characters available for analysis.

Analyses	No. specimens	No. characters
1	i. All species, all characters	15
	ii. All species, only vegetative characters	113
	iii. All species, only floral characters	43
	iv. All species, vegetative and floral	42
	v. All species, vegetative and fruit	58
2	i. <i>P. rubra</i> complex/ <i>P. cervii</i> , all characters	12
	ii. <i>P. rubra</i> complex/ <i>P. cervii</i> , only vegetative	72
	iii. <i>P. rubra</i> complex/ <i>P. cervii</i> , only floral	38
	iv. <i>P. rubra</i> complex/ <i>P. cervii</i> , vegetative and floral	37
		22

Since there is little overlap between flowering and fruiting periods only approximately 12% of the specimens (15 out 131) could be scored for all characters. Analyses of foliar characters (113 specimens), floral characters (39 specimens), floral + foliar characters (42 specimens), and foliar + fruit characters (58 specimens) were carried out separately. The second group of analyses focused on the *P. rubra* complex and *P. cervii*. Only 12 specimens were scored for all characters, 72 for foliar characters, 38 for floral characters, and 37 for foliar + floral characters. The results from the PCAs are represented as bivariate scatter plots. The ellipses drawn indicate the groupings of the specimens.

RESULTS

Analysis 1 – All species

i. All characters

This first analysis included specimens that represent all the different morphologies within the species complexes and included specimens from all parts of their distributional range. The PCA including all specimens with all characters suggest that there are two main groups (Fig. 4). These main groups separate clearly the two species recognized by Killip (1938) *Passiflora capsularis* and *P. rubra*. Within the *P. rubra* complex two subgroups were distinguished, one from South America and the other from the Caribbean Islands. *P. cervii* is placed close to the South American group of *P. rubra*.

The first three components explained approximately only 28, 18, and 12% respectively of the variance (Table 3). Characters that influence the variance of the first component were blade lateral vein length (BLVL), blade length outline (BLO), and blade width (BW). Sepal width (SW), fruit length (FL), and petal length (PL) explained most of the variation in the second component, while petal length (PL), petal width (PW), and blade lateral vein angle (BLVA) loaded heavily on the third component (Table 4).

Several scatter plots were made using different combinations of the components on the axes (not shown). Since they all were similar, only one is shown here: the bivariate scatter plot of component 1 vs. component 2 (Fig. 4).

Figure 4. Bivariate scatter plot of the first two components of the analysis of all species – all characters.

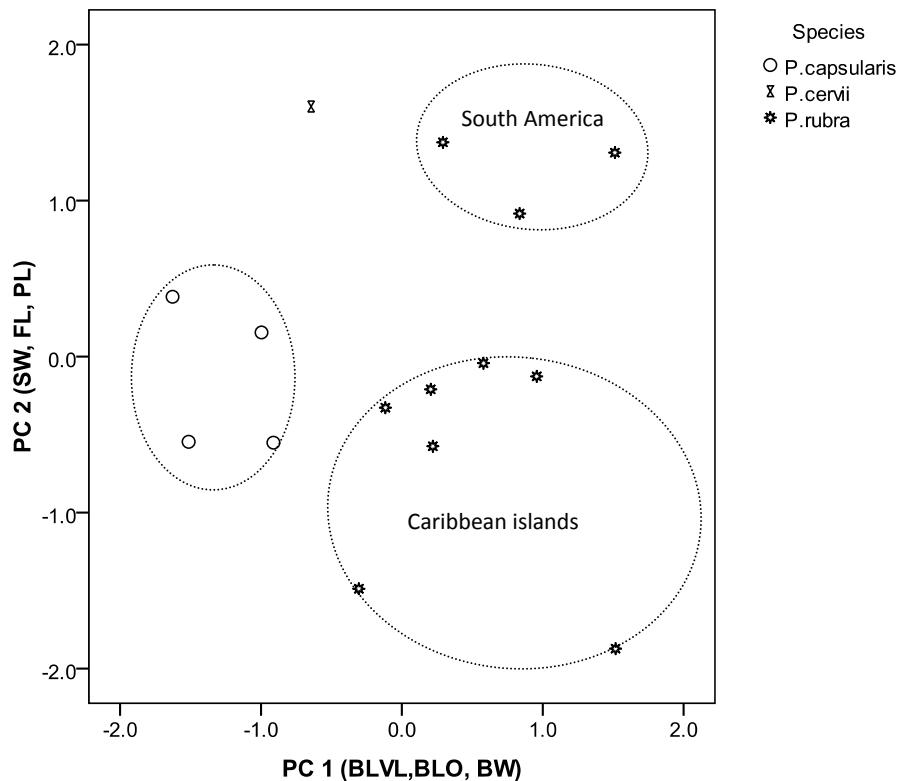

Table 3. Principal Components loadings from the analysis of all species - all characters

Ovary indumentum	-.834	.153	.149

ii. Only vegetative characters

To see whether vegetative characters alone can differentiate between *P. capsularis*, *P. rubra*, and *P. cervii* I analyzed only foliar characters. The two first components explained approximately 48 and 18% respectively of the total variance (Table 5). As in the analysis 1, the characters that explain the first component were blade lateral vein length (BLVL), blade length outline (BLO), and blade width (BW). For the second component, the characters that explains most of the variation were blade lateral veins angle (BLVA), and blade lateral lobe length and width (BLLbL, BLLbW) (Table 6).

In the scatter plot, *P. capsularis* and *P. rubra* are not clearly separated, the species overlapping considerably. In the morphological space in the center of the overlap area

where the ellipse is drawing are specimens of *P. capsularis* from Central America and *P. rubra* from the Caribbean islands and *P. cervii* from Brazil. (This shows the vegetative similarities between the three). The specimens of both species in this area of the graph have 2-lobed leaves, while outside of the ellipse the specimens of both species are from South America and have 3-lobed leaves. *P. cervii* appeared towards the periphery of the overlapping space (Fig. 5). Clearly, leaf morphology is extremely variable, even within one individual, and cannot be used by itself to distinguish the species.

Figure 5. Bivariate scatter plot of the first two components of the analysis of all species – vegetative characters only.

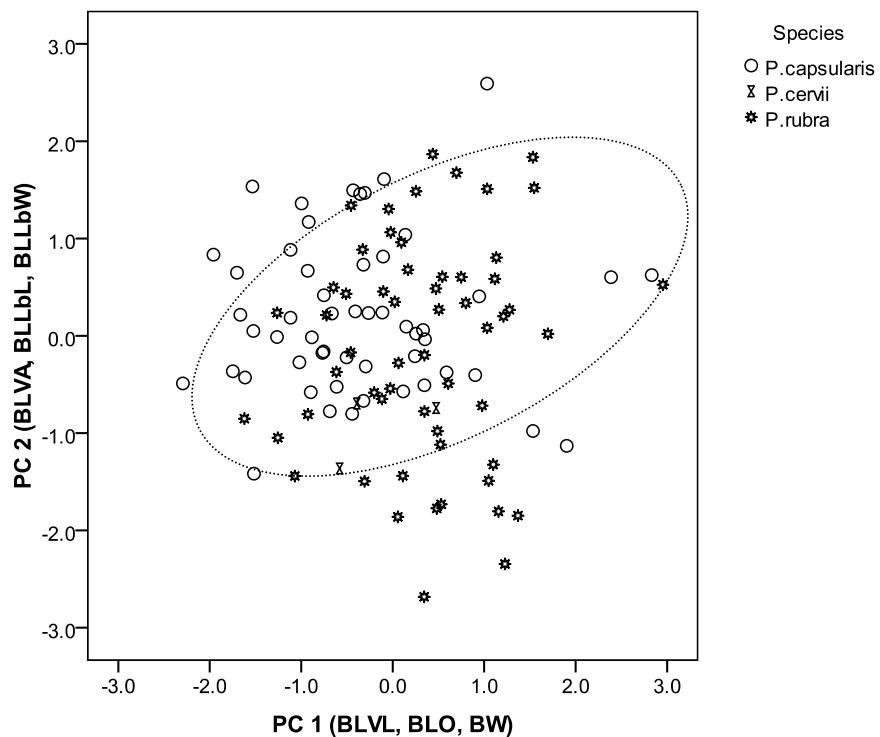

Table 5. Principal Component loadings from the analysis of all species – vegetative characters only.

Component	Initial Eigenvalues		
	Total	% of Variance	Cumulative %

Petiole length	.644	.142	-.401
Stipule width	.572	-.165	.587
Stipule length	.495	-.257	.561
Blade lateral lobe length	.345	.567	-.433
Blade lateral veins angle	.106	.825	.442

iii. Only floral characters

In this PCA I included the 35 specimens with floral characters. The two first components explained approximately 24 and 20% of the variance respectively (Table 7). Characters that loaded heavily on the first component were sepal width (SW), corona outer row number (CORL), and sepal length (SL). For the second component, the characters responsible for the variation were petal width (PW), petal length (PL), and anther width (AW) (Table 8).

The scatter plot of the variation in floral characters (Fig. 6) shows two coherent but only weakly distinct groups, *P. capsularis*, and *P. rubra*, with almost no overlap. *Passiflora cervii* is placed within the morphological space occupied by *P. rubra*.

Style length	.263	-.526	.555

iv. Vegetative and floral characters

The PCA of vegetative and floral characters together showed the same general pattern as the previous analysis. The first, second, and third components explained 27, 13, and 11% of the total variance respectively (Table 9). As in the analyses i and ii, the characters that loaded heavily on the first component were blade lateral vein length (BLVL), blade width (BW), and blade lateral lobe width (BLLbW). The second component was represented by a combination of vegetative and floral characters, while the third component was mainly explained by floral characters such as style length (StyL), operculum height (OH), and ovary indumentum (OvI) (Table 10).

The scatter plot of the variation in vegetative + floral characters (Fig. 7) displayed two groups. As with the analysis of floral characters alone, there was very little overlap between the *P. capsularis* and *P. rubra* complexes. Finally, as in some previous analyses, *P. cervii* appeared within the *P. rubra* complex.

Ovary indumentum	-.463	-.182	.398
Style length	.030	.219	.530

v. Vegetative and fruit/seed characters

The PCA of vegetative, fruit, and seed characters showed similar patterns to those in the previous analyses. The first, second, and third components explained 37, 16 and 15% respectively of the total variance (Table 11). As in the previous analyses, the characters that loaded heavily on the first component were leaf characters such as blade lateral vein length (BLVL), blade length outline (BLO), and blade width (BW). The second component was also represented by leaf characters, while the third component was explained mainly by a combination of leaf and fruit characters such as stipule width (StW), seed length (SeL), and seed width (SeW) (Table 12).

A scatter plot of the variation in vegetative plus fruit and seed characters (Fig. 8) displayed an overlapping area between *P. capsularis* and the *P. rubra*.complex. Similar to the analysis of vegetative characters *P. cervii* was placed in the overlapping area.

Figure 8. Bivariate scatter plot of the components of the analysis of all species – vegetative and fruit characters.

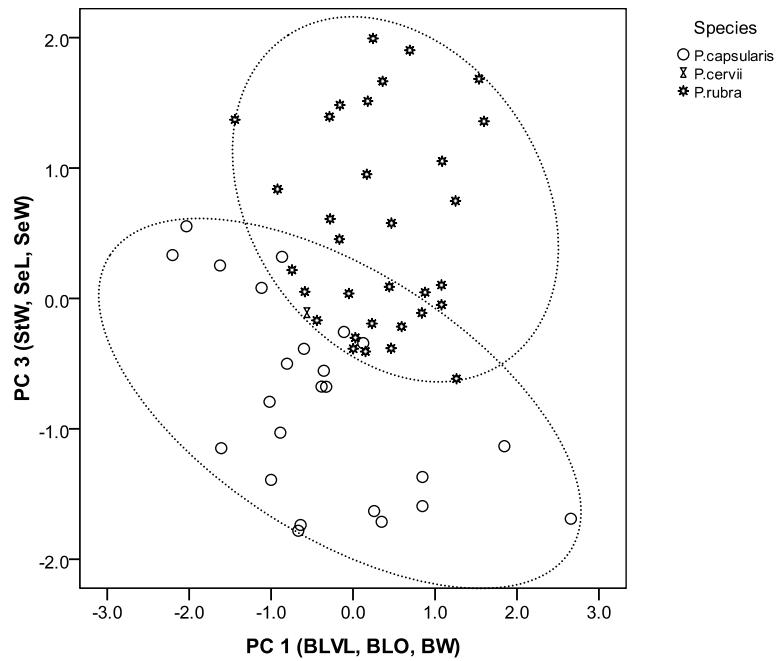

Table 11. Principal Component loadings from the analysis of all species – vegetative and fruit character).

Analysis 2: *Passiflora rubra* complex – *P. cervii*

The *P. rubra* complex is a group of species that have been variously circumscribed by previous authors (Velloso, 1827; Lindley, 1830; Roemer, 1846; Harms 1894). Because *P. cervii* came out several times with *P. rubra* in the preceding analyses, it was also included in these analyses.

i. All characters

A PCA results in the recognition of two coherent not sharply separated groups within *P. rubra*, and the single specimen of *P. cervii* appears separately from these two groups (see Fig. 9). All Caribbean specimens represent one group and the other consists of only the South American specimens. The first three components accounted for 22, 20, and 18% respectively of the total variance (see Table 13). The characters that explained most of the variations for the first component were blade width (BW), blade lateral lobe width (BLLbW), and blade lateral lobe length (BLLbL). The second component was explained by leaf characters such as blade length outline (BLO), blade central vein length (BCVL),

and blade lateral vein length (BLVL)(see Table 14). *Passiflora cervii* is separate because it has very broad 3 lobed leaves. The South American specimens have 2 or 3 lobed leaves and the Caribbean specimens have 2 lobed leaves. These two groups are adjacent (Fig. 9) probably because they share the character of having 2 lobed leaves.

Figure 9. Bivariate scatter plot of the components of the analysis of the analysis of *P. rubra* and *P. cervii* – all characters.

Seed length	.569	.052	.683
Seed width	.463	.053	.519

ii. Only vegetative characters

In the PCA that use exclusively vegetative characters there is substantial overlap between Caribbean and South American specimens of *P. rubra*; *P. cervii* again appeared along with South American specimens of *P. rubra* (Fig. 10). The first component accounted for 41% of the variance while the second and third components accounted for 24% and 10% respectively of the variance (Table 15). Characters that load on the first component were blade width (BW), blade lateral vein length (BLVL), and blade lateral lobe width (BLLbW). The second component was explained by blade central vein length

(BCVL), blade length outline (BLO), and blade lateral vein length (BLVL) (see Table 16).

Figure 10. Bivariate scatter plot of the 1st and 2nd components of the first analysis of vegetative characters only of *P. rubra* and *P. cervii*.

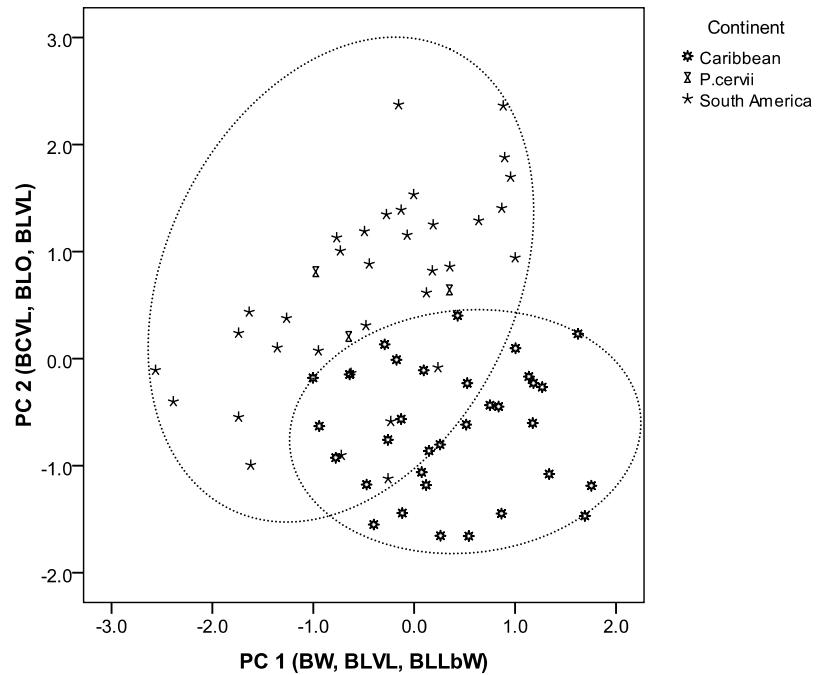

Table 15. Principal Component's loadings from the analysis of *P. rubra* and *P. cervii* – vegetative characters only.

Component	Initial Eigenvalues		
	Total	% of Variance	Cumulative %
1	4.538	41.252	41.252
2	2.652	24.110	65.362
3	1.078	9.799	75.160

Blade length outline	.762	.606	-.129
Blade basal lobe length	.738	.155	.287
Blade width	.908	-.290	-.015

iii. Only floral characters

The PCA that use exclusively floral characters explained approximately 32 and 15% of the variance respectively in the first two components (Table 17). Characters that loaded heavily on the first component were corona outer row length (CORL), sepal width (SW), and anther width (AW). For the second component, the characters responsible for the variation were ovary indumentum (Ovi), style length (StyL) and petal width (PW) (Table 18).

The scatter plot of the variation in floral characters shows no grouping within *P. rubra*, however, *P. cervii* is quite separate. It is characterized by having puberulous ovary while South American and Caribbean specimens of *P. rubra* have hirsute ovaries (Fig. 11).

Figure 11. Bivariate scatter plot of the 1st and 2nd components of analysis of *P. rubra* and *P. cervii* (arrow) – Only floral characters.

Androgynophore length	0.336	-0.583	-0.322
Ovary indumentum	0.279	0.483	0.560

iv. Vegetative and floral characters

The PCA of vegetative + floral characters largely showed the same pattern as the previous analysis. The first, second, and third components explained 27, 16, and 13% respectively of the total variance (Table 17). The characters explaining most of the variation in the first component were blade width (BW), blade lateral vein length (BLVL), blade lateral lobe width (BLLbW). The second component was explained by sepal width (SW), petal width (PW), and sepal length (SL). While blade lateral vein angle (BLVA), anther width (AW), and androgynophore length (AGL) explained most of the variation in the third component (Table 18). Given that there is no clear differentiation in sepal and petal lengths, the second component was not used in the scatter plot. Specimens again cluster in two overlapping groups, but now *P. cervii* is again within the group of South American specimens (see Fig. 11).

DISCUSSION

1. Principal Component Analyses of the species complexes

The PCA analyses of the quantitative morphological characters for *P. capsularis* and *P. rubra* complexes support the delimitations in the earlier taxonomic treatment of Killip (1938) and Holm-Nielsen et al. (1988). However, it was not until an analysis of the floral characters alone was undertaken that *P. capsularis* and *P. rubra* became phenetically separable. Floral characters such as indumentum of the ovary (Killip, 1938; Holm-Nielsen et al., 1988) and the color of the corona (Killip, 1938; Ulmer and MacDougal, 2004) had been used before as the most important features to differentiate between the two complexes; the analysis of floral characters here provides more characters to differentiate the two. Characters such as sepal and outer corona filament morphologies loaded heavily on the variance of the first component in the analyses 1.i, and 1.iii (see Table 4, 8; and Figs. 4, 6). Petal length and width, anther width, style length, operculum height, and ovary indumentum explained most of the variation of the second component in the analyses 1.iii, and 1.iv (see Table 8, 10; and Figs. 6, 7). However, these taxa can also be distinguished mainly by the shape of the fruit (Killip, 1938; Holm-Nielsen et al., 1988) not included in the analyses, which in *P. capsularis* is fusiform or broadly fusiform, slightly to sharply hexagonal, and glabrous, while in *P. rubra* it is obovoid, rounded or abruptly acute at apex, sub-6-angled, and hirsute. The size of seeds and the sculptural designs of the sclerotesta present good taxonomic characteristics in species of *Passiflora* (Killip, 1938; Tillet, 1988; MacDougal, 1994; Deginani, 2001; Ulmer and MacDougal, 2004; Pérez-Cortez, 2007; Estrada and Rodriguez, 2009), and *P. capsularis* and *P. rubra* are no exceptions. The seeds of both are almost of the same size and are transversely sulcate, but there are differences in shape. The seeds of *P. capsularis* have a large projection at the apex which is oriented to one side and the base is acute, while *P. rubra* lacks the projection.

In addition, *P. capsularis* and *P. rubra* have slight differences in leaf shape and flower morphology. *P. capsularis* has very broadly obovate to depressed obovate leaves that almost always have two lobes. *P. rubra* has also very broadly obovate (South American specimens) to depressed obovate leaves (Caribbean specimens) that have two

or three lobes. However, these quantitative data overlap in morphological space (Fig. 5), and the two species are very similar morphologically. Differences in the sizes of the various parts of the plant may reflect the environmental conditions of the areas where the plants of these very widespread species grow (Raunkier, 1934). Therefore, qualitative characters may be more informative about the differentiation between species. PCAs analyses were based on quantitative data only, and there are clearly no discrete breaks among and between the two complexes. Killip (1938) and Holm-Nielsen et al. (1988) noted that the fruit characters were very useful in distinguishing *P. capsularis* from *P. rubra*. However, fruit characters such as fruit length and width, which might be useful, were it not (Fig. 8) for the fact that there are relatively few specimens with ripe fruits.

However, inclusion of qualitative characters such as presence, density and type of hairs in the abaxial or adaxial blade surface, number of lamina lobes, number of corona rows, and presence, density and type of hairs on the ovary strongly supported the recognition of differences between *P. capsularis* and *P. rubra*. Thus, although *P. capsularis* and *P. rubra* are poorly separated in the majority of PCA analyses, I decided to keep them as separate species because of differences in the ovary indumentum, color of the corona filaments, differences in size of floral characters (Fig. 6), and differences in fruit and seed morphologies (Table 21).

Recently, a new species of section *Xerogona* from Brazil, *P. cervii*, was described by Milward de Acevedo (2008). This species resembles *P. capsularis* and *P. rubra* but can be differentiated from these by leaf shape, filamentous corona, and oblate-spheroid pollen grains (Table 21). *Passiflora cervii* was recognized to be sympatric with *P. capsularis* and allopatric with *P. rubra* (Milward de Acevedo, 2008). Indeed, there are some specimens of *P. capsularis* from the south and southeast of Brazil that share the same geographic area with *P. cervii*. On the other hand, the geographical distribution of *P. rubra* in Brazil is restricted to a very small area located in the Northeastern part of the country, where *P. cervii* is not found. I have seen only three specimens of *P. cervii*, one from Minas Gerais: Vicos, which is the type locality (*Mexia* 5402), one from Paraná (Rio Branco do Sul; *Oliveira* 691) and the other from Rio Grande do Sul (Montenegro; (*Sehnem* 2430). These specimens represent almost the complete known geographical range of *P. cervii*.

P. cervii in the all character analysis 1.i (Fig. 4), appears isolated from both complexes (*P. capsularis*, and *P. rubra*). However, in analysis 1.ii (Fig. 5), using only vegetative characters the specimens of *P. cervii* appear in the morphological space where both complexes overlap, all three species having similar leaf morphology. The same pattern occurs when vegetative plus fruit characters are analyzed 1.v (Fig. 8). The fruit of *P. cervii* can be ovoid as in *P. rubra* or it can be fusiform as in *P. capsularis*, and glabrous as in *P. capsularis*, so fruit characters do not distinguish these species. Similarly, when vegetative and floral characters or only floral characters are used the specimens of *P. cervii* appear within the morphological space occupied by *P. rubra* (Fig. 6 and Fig. 7). *Passiflora cervii* is characterized by having densely villous hairs on both surfaces of the 3-lobed leaf blade, a single series of corona filaments, and ovary with puberulous indumentum, while *P. rubra* has very densely hirsute hairs on both surfaces of the 2 or 3-lobed leaf blade, 1 or 2 series of corona filaments, and ovary with densely and long hirsute indumentum. Nevertheless, *P. cervii*, *P. capsularis*, and *P. rubra* are morphologically similar when only quantitative data are considered.

In analysis 2, where *P. rubra* from South America and the Caribbean and *P. cervii* are compared, and when all characters are used two adjacent groups can be distinguished within the *P. rubra* complex and *P. cervii* appears to be separated from both. A group of *P. rubra* of specimens from the Caribbean islands and another group of South American specimens (Figs 4, 9) are weakly separated in morphological space. The two are mainly distinguished by leaf characters such as blade width (BW), blade lateral lobe length width (BLLbW), blade lateral lobe length (BLLbL), blade length outline (BLO), blade central vein length (BCVL), and blade lateral vein length (BLVL) (see Fig. 9). When only vegetative characters (leaves) are used, the two groups overlap somewhat in morphological space (see Fig. 10) with *P. cervii* in the space occupied by South American morphological space of *P. rubra*. The group of South American specimens has almost always very broadly obovate leaves with 2 or 3 lobes, with the exception of few specimens from the Southwest of Colombia (Silverstone-Sopkin 2573, 6184) and in the Northwest of Peru (Ule 6546) that have depressed obovate leaves with 2 lobes. Caribbean specimens have broadly obovate to depressed obovate leaves that always have 2 lobes; *P. cervii* shares morphological space with *P. rubra* because of the 3-lobed leaves they have in common. The characters that explain most of the variation are blade width (BW), blade

lateral vein length (BLVL), blade lateral lobe width (BLLbW), blade central vein length (BCVL), and blade length outline (BLO. When only floral characters are included there are no groupings within the *P. rubra* complex because variation in these quantitative characters is limited.

When vegetative and floral characters are both included the pattern does not change from when only vegetative characters are used; there are still two overlapping groups (see Fig. 11). Here the characters that account for most of the total variance are leaf characters in the first component of the variation and leaf and floral characters in the second and third component. The pattern of variation becomes clear when qualitative floral characters are taken into account. Characters such as sepal and petal apices and color of the outer corona along with corona row number that were not included in the analysis can help to differentiate South American specimens from the Caribbean specimens (see Table 21).

There are some differences in the qualitative variation of sepals and petals. South American specimens are characterized by having sepals with an acute apex, petals about half as long as the sepals and petals with a slightly praemorse to obtuse or retuse apex; while the Caribbean group is characterized by having sepals with an acuminate apex, petals only slightly shorter than sepals and with an acute apex. There are differences in the number of rows of corona filaments and their length. The South American specimens have almost always two rows of corona filaments (except in Lasser 1552, Venezuela and Knapp 2838, Guyana) and the length of the outer row of filaments is intermediate between that of the sepals and petals. The Caribbean specimens have a corona with only one or two rows of filaments, and the outer row is almost always shorter than both the sepals and petals. The corona filaments also differs in these two groups: they are purplish or red at the base, and cream to white higher up in South America, while they are purple or pink dotted their entire length in Caribbean specimens. The ovary shape is also different between these two groups, being ellipsoid in the South American group and ovoid to round in the Caribbean group (see Table 21). *Passiflora cervii* is quite separate from both groups. The most important qualitative character separating *P. cervii* from the *P. rubra* complex is the ovary indumentum which is merely puberulous in *P. cervii* while it is densely hirsute in the *P. rubra* complex (see Table 21).

2. Section *Xerogona*

Reduction has taken place in section *Xerogona* and several organs have been lost (bracts, petiolar, and laminar glands) reducing the number of characters available to distinguish species elsewhere in the genus.

The section *Xerogona* is characterized by capsular fruit which dehiscence in an unusual way. In capsular fruits the pericarp usually dehisces along regular lines and splits into as many valves as there are carpels to expose the seeds. In section *Xerogona*, the capsule splits into as many angles as there are in the capsule and expose the seed along every other capsule valve. Although I have observed this unusual fruit dehiscence in photographs of *P. capsularis* (Plate 1C), *P. escobariana* (Plate 8C), and on living plants of *P. cissana* in the field (Plate 2C), it needs further observations in the other species of the section.

The seeds in section *Xerogona* are transversely sulcate with the ridges between the grooves often smooth and shiny. However, there are some variations in the seed sclerotesta morphology. The seeds of *P. goniosperma* are strongly compressed laterally with narrow ridges; the grooves are reduced to a row of teeth along this narrow ridge (Plate 9D). Seeds also may have slightly rugulose ridges as in *Passiflora sanguinolenta* (Plate 14 C) or have strongly rugulose ridges as in *P. tenella* (Plate 15 C).

Within section *Xerogona* the morphologically most different species, *P. tenella*, is a small and poorly known herb from dry coastal Ecuador and Peru. *Passiflora tenella* rarely reaches 0.9 m tall and is apparently annual. Its fruit does not appear to be a capsule and the seeds have strongly rugulose ridges unlike other members of *Xerogona*, but the shape of the leaves and the absence of floral bracts and laminar nectaries suggest affiliation with this section and a preliminary DNA analysis place the species as sister to the rest of the section (Porter-Utley com. pers.).

Within section *Xerogona* there are some species that may look morphologically similar but these species differ in some morphological features and also in their geographical distribution.

Passiflora citrina is similar to *P. sanguinolenta* having flowers with floral tubes almost the same shape and size, but they differ in color, the flowers of *P. citrina* being light to bright yellow while the flowers of *P. sanguinolenta* are red to reddish violet.

They also differ in geographical distribution. *Passiflora citrina* is found in Mexico, Nicaragua, and Costa Rica, while *P. sanguinolenta* is endemic to Ecuador.

Passiflora cobanensis, *P. conzattiana*, and *P. goniosperma* all have flowers with short outer corona filaments that are purplish at the base and yellow at the apex. However, *P. cobanensis* can be differentiated from the other two by having unlobed leaves. *Passiflora conzattiana* differs from *P. goniosperma* by having seeds with transverse grooves and smooth ridges while *P. goniosperma* has strongly compressed seeds with grooves reduced to a row of teeth.

Passiflora rovirosae is often confused by its similarity to *P. costaricensis*. However, *P. rovirosae* differs from *P. costaricensis* in its short indumentum and 5-angulate not 3-angulate stems.

Passiflora cobanensis was previously circumscribed by Killip in 1938 as two different species *P. cobanensis* and *P. brevipes*. MacDougal in 2004 recognized only a single species, *P. cobanensis*. Within *P. cobanensis* two variants can be recognized as subspecies *P. cobanensis* ssp. *cobanensis* and *P. cobanensis* ssp. *brevipes*. These two subspecies have been recognized based on differences in stem, leaf, corona filaments, and ovary characters. The former is characterized by having 4 to 5-angulate stems, thinner leaves that are slightly reticulate and sparsely pubescent beneath, linear-clavate outer corona filaments, and glabrous to puberulous ovary. The later is characterized by 3-angulate stems, thicker leaves conspicuously reticulate beneath with nerves and veins elevated and densely pubescent, filiform outer corona filaments, and a tomentose ovary.

CONCLUSION

Passiflora subgenus *Decaloba* (DC.) Rchb. section *Xerogona* consists of 15 species and 2 subspecies of small to medium sized climbing vines that have unusual dehiscent capsular fruits, absence of bracts and laminar nectaries, and smooth grooved seeds. The species are primarily distributed in Central America with 9 species while 3 species are found in South America. Two taxa are found in both Central America and South America, *P. capsularis* and *P. costaricensis*. *Passiflora cisnana* is widespread in South America and *P. rubra* widespread in the Caribbean islands.

Passiflora cobanensis was separated into two subspecies, *P. cobanensis* ssp. *cobanensis* growing in mesic to wet uplands in Chiapas; and *P. cobanensis* ssp. *brevipes* in hotter lowland and seasonally drier areas. The separation of this species in two subspecies is based on differences on stem, leaf, corona filaments and ovary characters.

The morphological pattern of variation shown by all specimens assigned to the *P. capsularis* and *P. rubra* species complexes showed that those complexes are actually made up of four separate groups (Fig. 4 and Fig. 6). The *P. capsularis* complex forms a single group, while the *P. rubra* complex can be separated into two groups (Fig. 4 and Fig. 9), *P. cervii* can also be distinguished from these complexes. These other two taxa can be distinguished mainly by qualitative features as shown in Table 21, as well as by geography; one is from the Caribbean islands and the other is from South America. The type and original description of *P. rubra* was based on material from the Caribbean Islands consequently the Caribbean group will keep the species name of *P. rubra* L, and the South America group will take the name *P. cisnana* Harms as that is the oldest available name.

Table 21. Summary of distinctive qualitative characters separating species in the *P. capsularis*/*P. rubra* complexes

Character	<i>P. capsularis</i>	<i>P. cervii</i>	<i>P. cIsnana</i>	<i>P. rubra</i>
Leaf shape	broadly obovate to depressed obovate	very broadly obovate	very broadly obovate	broadly obovate to depressed obovate
Leaf lobe number	almost always 2-lobed	3-lobed	2 or 3-lobed.	2-lobed
Leaf indumentum (abaxial)	densely hirsute	densely villous	densely hirtellous	densely hirsute
Leaf indumentum (adaxial)	sparsely hirsute	sparsely villous	densely hirsute	sparsely hirsute
Peduncles	solitary	solitary	solitary, very rarely in pairs	solitary or in pairs
Sepal apex	acute	acuminate	acute	acuminate
Petal length	about half as long as the sepals	shorter than sepals	about half as long as the sepals	shorter than sepals
Petal apex	slightly praemorse or retuse	acute	slightly praemorse to obtuse or retuse	acute
Corona rows number	1 rarely 2 (Colombia, Brazil, Argentina, and Haiti)	1	2 , except in Venezuela (Lasser 1552) and Guyana (Knapp 2838).	1 or 2
Corona filament shape	filiform	ligulate	filiform	filiform
Corona filament length (in contrast to sepals and petals)	almost always shorter than sepals and petals	shorter than sepals and petals	shorter than sepals and petals or in between	between sepals and petals or as long as the petals
Color of the corona	pure white very rarely with pink base.	unknown	purplish, pink or red at base, cream to white above	purple or pink dots the entire length
Ovary shape	narrowly ovoid to fusiform-ellipsoid	ellipsoidal to ovoid	ellipsoidal	ovoid to round
Ovary indumentum	glabrous to minutely puberulous	hispid to puberulous	densely hirsute	densely hirsute
Pollen grains	prolate-spheroid, 12-colporate	oblance-spheroid, 12 colporate	prolate-spheroid, 12-colporate	prolate-spheroid, 12-colporate
Fruit shape	fusiform or broadly fusiform, slightly to sharply hexagonal, glabrous.	ovoid or fusiform, glabrous	ellipsoidal to ovoid or abruptly acute at apex, 6-angled, hirsute	rounded to ovoid 6-ribbed, pubescent
Seed shape	with a large projection in the apex oriented to one side of the seed.	ellipsoidal, 5 or 6-sulcate	lacks the projection	with a small projection in the apex oriented to one side of the seed

Taxonomic Treatment

The species concept used for this study is the general lineage concept of De Quieroz (1998) “...., a species lineage is composed of a series of ancestral and descendant species”, “Species are more inclusive population level lineages...” therefore, a species is a segment of an evolutionary lineage at the population level. The species criterion I used is that of phenetic similarity. So species are “...the smallest populations permanently separated from each other by distinct discontinuity in the series of biotypes...” (Davis & Heywood, 1973), and those discontinuities may reflect geographical, ecological and/or reproductive isolation.

The taxonomic revision of section *Xerogona* is based on morphological observations. It includes a description of the section, an identification key, the descriptions of the taxa themselves, notes on their distribution, ecology and phenology, and distribution maps of each species. The descriptions of the taxa are based on mature reproductive herbarium specimens and photographs. The descriptive terms used follow those in Hickey & King (2000) and Stearn (2004) and colors in the description refer to those of fresh material and photographs. Since maximums and minimums of each character (in parenthesis) were measured quantitative data are expressed as follows: the first number is the smallest measurement then the average of the minimum followed by the average of the maximum and then largest measurement (e.g. Stipules (2.8--)4.4--5.0(--8.1) × (0.3--)0.6--0.7(--0.8) mm). All measurements are expressed in mm except for leaf length and width which is expressed in cm. Width measurements, were taken at the widest point of the structure involved. Exceptions of the descriptions are cited in parenthesis.

Every effort was made to use foliar characters in the key, since leaves are almost always diagnostic if careful measurements are taken (MacDougal, 1994), and few collectors make detailed descriptions of the flowers (Jørgensen et al. 1984). Distribution maps were produced in ArcView GIS Version 9.5. The latitudes and longitudes concerning 15 species were gathered from TROPICOS ® and georeferenced when coordinates were not directly available in order to construct the distributional maps.

Passiflora* subgenus *Decaloba (DC.) Rchb. **section *Xerogona*** (Raf.) Killip. Publ. Field Mus. Nat. Hist., Bot. Ser. 19: 26 1938. *Xerogona* Raf. Fl. Tellur. 4: 103 1836. [1938].
TYPE: *Xerogona biloba* Raf., nom. illeg. (based on *Passiflora capsularis* L.)

Small to medium sized climbing perennial vines (herbaceous annual vine). Stems slightly striate to 3--5-angular. Stipules linear to linear-triangular; petioles eglandular; lamina with entire margin, abaxially puberulous to pubescent, adaxially puberulous to hirsute (glabrous); 2--3-lobed (unlobed), the lateral lobes acuminate to rounded, base cordate to round, laminar nectaries absent. Peduncles articulate with the distal part (the 'floral stipe'). Bracts absent (a single linear bract less than 4 mm long at the apex of the peduncles). Flowers with a shallow dish shaped floral cup (floral tube); sepals linear or narrowly triangular, not corniculate, white, pale greenish yellow, or red, often conspicuously 3-veined; petals linear to narrowly elliptic, white, pale greenish to greenish yellow, yellow, or red, sometimes tinged with pink or purple at the base; corona filaments in 1 or 2 series; the outer white, greenish with yellow apex, reddish purple with yellow apex, or white with pink or purple at the base; inner filaments capillary or absent; operculum membranous-plicate; nectar ring annular; limen annular, close to androgynophore. Carpels 3; ovary ellipsoid, ovoid, obovoid or fusiform, minutely puberulous to densely pubescent; stigma capitate. Fruit fusiform, ellipsoid, or obovoid, 6-angular to 6-keeled, reddish, purplish red, red and white, (greenish), dehiscent; arils white; seeds transversely sulcate, the ridges smooth (rugulose, with two longitudinal row of teeth per face or reduced to a row of teeth along the ridge), black. Chromosome number: n = 6. Germination type is epigeal.

Key to the Species of *Passiflora* Section *Xerogona*

1a. Lamina unlobed, narrowly obovate to very broadly obovate.

5. *P. cobanensis*

1b. Lamina 2-lobed or 3-lobed (the central lobe, if present, reduced).

2a. Plant smaller than 0.9 m; lamina 1--5 × 2--8 cm, depressed obovate.

Corona filaments in 2 series.

3a. Lamina densely pubescent, lateral lobes apex obtuse to round.

Corona inner filaments white. Ovary tomentose. Seeds with two longitudinal rows of 5--6 teeth per face. Mexico, Nicaragua, and Costa Rica.

10. *P. pusilla*

3b. Laminas sparsely pubescent, lateral lobes apex acute. Corona inner filaments violet tinged. Ovary glabrous. Seeds with 4--5 transverse sulci which are strongly rugulose. Ecuador and Peru.

14. *P. tenella*

2b. Plant 1--7 m or more; lamina 2--16 × 2--13 cm, narrowly to very broadly obovate or depressed obovate. Corona filaments in 1 or 2 series.

4a. Floral tube present. Androgynophore 15--29 mm long.

5a. Stems 5-angular. Lamina broadly obovate. Floral tube light to bright yellow, corona filaments in 1 rarely 2 series. Honduras, Guatemala, and El Salvador.

4. *P. citrina*

5b. Stems 3-angular. Lamina depressed obovate. Floral tube red or reddish violet, corona filaments consistently in 2 series. Ecuador and Peru.

15. *P. sanguinolenta*

4b. Floral tube absent. Androgynophore 2--10 mm long.

6a. Androgynophore 2--4 mm long. Outer corona filaments purplish at the base and yellow at the apex, 2--10 mm long.

- 7a. Lamina 2(--3)-lobed, depressed obovoid. Seeds not compressed laterally with smooth grooves.

6. *P. conzattiana*

- 7b. Lamina 2-lobed, very broadly obovate. Seeds compressed laterally with a narrow longitudinal ridge and grooves reduced to a row of teeth along ridge.

9. *P. goniosperma*

- 6b. Androgynophore 4--10 mm long. Outer corona filaments white, white with pink or purple base or white with yellow tips, 5--20 mm long.

- 8a. Stems 5-angular. Corona filaments in 2 series.

- 9a. Petioles 11--14 mm long. Laminas 2(--3)-lobed, the angle between the lateral lobes veins 41--50°. Peduncles 18--42 mm long usually solitary. Floral stipe 2--5 mm long (to 5--9 mm in fruit). Stigma 0.5--1.6 mm diam. Plant pubescent throughout.

11. *P. quinquangularis*

- 9b. Petioles 21--26 mm long. Laminas 2-lobed, the angle between the lateral lobes veins 27--33°. Peduncles 5--25 mm long usually in pairs. Floral stipe 5--11 mm long (to 5--19 mm in fruit). Stigma 1.1--2.8 mm diam. Plant puberulous throughout.

12. *P. rovirosae*

- 8b. Stems 3- or 3(--5)-angular. Corona filaments in 1 or 2 series.

- 10a. Vine 4--12 m long. Laminas 7--16 cm long, the angle between the lateral lobes veins 28--59°. Fruit ellipsoid or fusiform.

11a. Stems sharply 3-angulate. Plant densely tomentose throughout with trichomes 0.5--2.0 mm long. Lamina 2-lobed. Floral stipe 2--7 mm long (to 4--11 mm in fruit). Operculum usually finely pubescent, yellowish green. Androgynophore 4--8 mm long.

7. *P. costaricensis*

11b. Stems 4--5-angulate. Plant puberulous throughout with trichomes 0.1--0.6 mm long. Lamina 2(--3)-lobed. Floral stipe 2--3 mm long (to ca. 4 mm in fruit). Operculum glabrous, light purple. Androgynophore 7--8 mm long.

8. *P. escobariana*

10b. Vine 2--4(--8) m long. Lamina 2--10 cm long, the angle between the lateral veins 32--108°. Fruit ovoid, obovoid, globose or broadly fusiform.

12a. Ovary glabrous to minutely puberulous.

13a. Floral stipe 2--5 mm long (to 2--15 mm in fruit). Sepals with acute apex. Petals about half as long as the sepals, with slightly praemorse or retuse apex. Lamina 2(--3)-lobed. Central America to South America

1. *P. capsularis*

13b. Floral stipe 3--4 mm long (to ca. 8 mm in fruit). Sepals with acuminate apex. Petals slightly shorter than the sepals, with acute apex. Lamina 3-lobed. Southeast of Brazil

2. *P. cervii*

12b. Ovary densely hirsute.

14a. Lamina 2--3-lobed. Floral stipe 1--7 mm long (1--8 mm in fruit). Sepals with acute apex. Petals about half as long as the sepals, with slightly praemorsus to obtuse or retuse apex. Corona filaments in 2 very rarely 1 series, outer filaments shorter than sepals and petals, purplish or red at the base, cream to white above. Ovary ellipsoid. South America.

4. *Passiflora cissana*

14b. Lamina 2-lobed. Floral stipe 1--4 mm long (1--3 mm in fruit). Sepals with acuminate apex. Petals slightly shorter than sepals with acute apex. Corona filaments in 1 or 2 series, outer filaments between sepals and petals in

length, with purple or pink dots along the entire length.

Ovary ovoid to globose.

Caribbean Islands

13. *P. rubra*

Vine 2--4(--8) m, sparsely pubescent to glabrescent; stems 3--5 angular, striate, pubescent when young while older parts glabrescent. Stipules (1.9--)3.7--4.5(--7.4) × (0.1--)0.3--0.4(--0.7) mm, linear to linear triangular, more or less falcate, very sparsely pubescent abaxially; petiole (7--)15--21(--53) mm long; lamina (2.4--)5.0--6.7(--10.8) ×

(2.5--)5.4--6.7(--11.8) cm, very broadly obovate to depressed obovate, base cordate, densely hirsute abaxially with trichomes 0.1--1.1 mm long, sparsely hirsute adaxially with trichomes 0.2--1.1 mm long; 2(--3)-lobed, the lateral lobes acuminate to acute (the central lobe reduced or rounded, cusp-like); the angle between the lateral veins (37--)56--66(--102)°. Peduncles (12--)27--34(--62) mm long, slender, solitary (in pairs); floral stipe 1.5--5 mm long; flowers (19--)31--35(--48) mm diam., greenish white or pale yellow-green; sepals (10.9--)14.7--16.3(--21.9) × (1.6--)2.7--3.4(--4.7) mm, narrowly triangular, sparsely hirsutulous pubescent, apex acute, pale green to white (base pink); petals (4.5--)8.4--9.8(--14.6) × (0.9--)1.7--2.0(--2.9) mm, linear to narrowly triangular; about half as long as the sepals, apex slightly praemorse, white; corona filaments in 1 (2) series, filaments of outer series 30--32, (6.3--)9.2--10.3(14.4) mm long, pure white (base pink); (filaments of the inner series (1.3--)2.7--2.9(--3.0) mm long; operculum (0.6--)1.3--1.5(--2.2) mm; limen erect; androgynophore 4.6--8.6 mm long, green; stamens with filaments (4.3--)4.6--5.3(--5.6) mm long; anthers (1.9--)3.0--3.2(--3.6) × (0.6--)1.1--1.3(--1.8) mm; ovary 3--5 × 2--3 mm, ovoid to fusiform-ellipsoid, glabrous to minutely puberulous; styles (1.6--)3.1--3.8(--5.1) × 0.2--0.3 mm; stigma (0.7--)0.9--1.2(--1.4) mm diam. Fruit (32--)45--50(--76) × (9--)14--15(--37) mm, fusiform to broadly fusiform with more abruptly tapering apex, slightly to sharply hexagonal, glabrous, reddish brown, dark purplish red or red (white or cream between the ridges); stipe 2.0--15.0 mm long; seeds (1.3--)2.7--3.0(--3.9) × (1.1--)1.6--1.8(--2.1) mm, transversely sulcate with 6--9 sulci, and with a large projection in the apex oriented to one side (Plate 1D).

Local Names: “*Calzoncillo*” (Salvador); “*maracuja branco miudo*” (Brazil).

Distribution and Ecology: From Mexico to Panama; Colombia, Venezuela, French Guiana, Ecuador, central Brazil to Paraguay, Bolivia, and the Greater Antilles (Cuba, Dominican Republic, Haiti and Jamaica) in moist, wet, rain and cloud forests from 50 to 2600 m altitude mainly in secondary forest edges, secondary open areas and roadsides.

Phenology: Flowers observed from May to December. Fruits documented from April to July and from December to January.

Selected specimens examined: ARGENTINA. **Corrientes:** Depto. San Ignacio, Salto Tabay, 15 Feb 1980, A. Schinini 19878 (CTES); **Misiones:** Santa Ana, 27°23'00"S 055°35'00"W, 06 Dec 1945, J. Decaloba smithii M. Roem. was considered by Killip (1938) to be a synonym of *P. capsularis* L. Indeed, Roemer (1846) described *D. smithii* as a replacement of the earlier name, *P. capsularis* sensu Smith, described by John Smith in 1819. Smith's description seems to fit *P. capsularis* except when he mentions – "There are two glands at the base of the leaf"; *P. capsularis* L. lacks glands on the leaf. Smith's description may apply to several other species such as *P. tuberosa* (MacDougal, comm. pers.). I have therefore eliminated *Decaloba smithii* of the synonymy of *P. capsularis*.

Passiflora capsularis and *P. rubra* have often been confused by early authors because it is difficult to distinguish the two in the absence of flowers and fruits. The first description by Plumier (1703) of *P. rubra* is actually an attempt to clarify the distinction between the two species.

Passiflora capsularis is characterized by having solitary flowers, sepals with acute apices, petals with slightly praemorse apices and about half as long as the sepals,

while *P. rubra* have solitary flowers or in pairs, sepals with acuminate apices, petals with acute apices and a bit short than the sepals. The corona filaments of *P. capsularis* are in 1 rarely 2 series, the outer filaments are almost always shorter than sepals and petals, pure white (but in a dried state this difference is not perceptible); in *P. rubra* having 2 series of corona filaments is more common, the outer series of filaments is between the sepals and petals in length, with purple or pink dots along their entire length. The ovary in *P. capsularis* is narrowly ovoid to fusiform-ellipsoid, glabrous to minutely puberulous, whereas in *P. rubra* it is ovoid to round, densely pubescent with white to brown trichomes; the fruits are fusiform, or slightly to sharply hexagonal, and glabrous in *P. capsularis*, while in *P. rubra* they are ovoid to rounded, and hirsute. The seeds of *P. capsularis* differ from those of *P. rubra* by having a longer projection 0.7--1.0mm in the apex oriented to one side. *Passiflora rubra* have a shorter projection, only 0.3--0.5 mm long.

Passiflora capsularis and *P. cisnana* are very similar when only vegetative characters are considered. However, these species can be distinguishing when floral characters are used. *Passiflora capsularis* is characterized by having the outer corona filaments pure white, while in *P. cisnana* the outer corona filaments are purplish, pink to red at the base and cream to white above. The ovary in *P. capsularis* is narrowly ovoid to fusiform-ellipsoid and glabrous to minutely puberulous, whereas in *P. cisnana* it is ellipsoid and densely hirsute. Fruit shape also differ: it is fusiform or broadly fusiform, sharply hexagonal, and glabrous in *P. capsularis*, and ellipsoid to obovoid to abruptly acute at apex and hirsute in *P. cisnana*. The seeds of *P. capsularis* differ from those of *P. cisnana* by having a large projection in the apex oriented to one side while *P. cisnana* seeds are acute at the apex and lack the distinct projection.

2. ***Passiflora cervii*** Milward de Azevedo, Brittonia 60(4): 310-312 (2008).

TYPE: Brazil. Minas Gerais: Viçosa, *unknown s.n.* (holotype, VIC not seen).

Vine moderately to densely villous throughout. Stem 3-angular, striate. Stipules (4.6--)4.9--5.6(--6.1) × (0.3--)0.4(--0.5) mm, narrowly triangular, very sparsely pubescent abaxially; petiole (9--)12--18(--23) mm long; lamina (5.0--)5.7--6.5(--7.4) × (4.9--)5.2--5.8(--6.1) cm, very broadly obovate, base cordate, densely villous abaxially with trichomes 0.4--0.5 mm long, densely villous adaxially with trichomes 0.3--0.5 mm long, 3-lobed, the lateral lobes acute to obtuse, the central lobe, reduced and obtuse; the angle between the lateral veins (45--)48--56(--58)°. Peduncles (23--)27--49(--67) mm long, slender, solitary; floral stipe 3.1--3.6 mm long; flowers (26--)27--29(--31) mm diam.; white; sepals (12.7--)15.6--17.3(--19.8) × (1.9--)2.6--3.4(--4.3) mm, narrowly triangular, apex acuminate, sparsely hirsute pubescent outside; petals (8.6--)10.2--11.0(--13.6) × (1.2--)2.1--2.3(--2.6) mm, linear to narrowly triangular, apex acute, shorter than sepals; corona filaments in 1 series, filaments of outer series 30--32, (8.3--)9.6--10.8(11.7) mm long, shorter than the sepals and petals; operculum (1.9--)2.0--2.3(--2.6) mm; limen cupulate; androgynophore 5.8--8.1 mm long; stamens with filaments 4.4--5.1(--5.5) mm; anthers 3.2--3.7(--3.9) × (1.2--)1.4--1.5 mm; ovary 3.1--4.5 × 1.7 mm, ellipsoidal to ovoid, minutely puberulous; styles (3.3--)3.5--4.1(--4.6) mm; stigma 1.0--1.1 mm diam. Fruit ca. 44 × 15 mm, ovoid to fusiform, color unknown; stipe ca. 8.1 mm long; seeds 1.8--2.5 × 1.2--1.5 mm, transversely sulcate with 5--6 sulci, rounded at the base.

Local Names: “*maracujazinho*” (Santa Catarina - Brazil).

Distribution and Ecology: Restricted to the south east of Brazil in the states of Minas Gerais, São Paulo, Paraná, Santa Catarina, and Rio Grande do Sul in both montane rain forest and coastal forest.

Phenology: Flowers observed in October to April. Fruits documented from February to June and from October to December.

Selected specimens examined: BRAZIL. Minas Gerais: Vicosá. Road to Barroso.

Fazenda de Aguada, 20°45'20"S 042°52'02"W, 11 Dec 1930, Y. Mexía 5402 (CAS, G,

GH, MO, NY, S, US); **Paraná**: Lavarinha (mun. Rio Branco do Sul) Paraná, 25°11'24"S 049°18'51"W, 25 Nov 1982, P. I. Oliveira 691 (HBG, NY, SP); **Rio Grande do Sul**: S. Salvador, Montenegro, R.G.S., 29°41'59"S 051°28'46"W, 04 Jan 1949, A. Sehnem 2430 (CAS).

Passiflora cervii is very closely related to *P. capsularis* and *P. rubra*. The most important character to distinguish the three is the ovary, which is glabrous or minutely puberulous in *P. capsularis*, puberulous to hispid in *P. cervii*, and densely white to brown hirsute in *P. rubra*. *Passiflora cervii* can be distinguished also by its very broadly obovate leaves, ligulate corona filaments, oblate-spheroid pollen grains, and by its distribution (Milward-de-Azevedo, 2004).

3. ***Passiflora cismana*** Harms, Bot. Jahrb. 18 (Beibl. 46): 5 (1894).

TYPE: Ecuador: Loja, near El Cisne, 1200--1500 m. *Lehmann* 4833 (holotype, B, destroyed; isotype, K; photo, F, MO, NY).

Passiflora lunata Vell. Fl. Flumin. Icon. 9: pl. 80. 1827. -- *Decaloba semilunaris* M. Roem., Fam. Nat. Syn. Monogr. 2:154 (1846), nom superfl. -- TYPE: the cited plate.

Vine 2--4 m long, densely and softly pubescent. Stems 3--4-angular. Stipules (2.2--)4.4--5.0(--7.8) × (0.3--)0.5--0.7(--1.0) mm, linear to linear triangular, more or less falcate, very sparsely pubescent abaxially, petiole (5--)14--20(--33) mm long; lamina (3.1--)5.5--6.6(--9.1) × (2.7--)5.4--6.5(--9.5) cm, very broadly obovate; base deeply cordate, densely hirtellous abaxially with trichomes 0.2--0.9 mm long, densely hirsute adaxially with trichomes 0.4--1.1 mm long, 2--3-lobed, the lateral lobes acuminate to acute, (the central lobe, obtuse or rounded); the angle between the lateral veins (32--)51--58(--76)°. Peduncles (4--)16--21(--46) mm long, slender, solitary very rare in pairs; floral stipe 1.0--6.5 mm long; flowers 43--45 mm diam., greenish white or pale yellow-green; sepals (10.3--)16.7--18.2(--24.4) × (2.2--)3.0--3.6(--5.8) mm, narrowly triangular, sparsely hirsutulous pubescent outside, apex acute, white (base pink); petals (5.1--)10.3--11.7(--15.3) × (1.2--)1.9--2.2(--4.4) mm, linear to narrowly triangular; about half as long as the sepals, apex slightly praemorse to obtuse or retuse, white; corona filaments in 2 (1) series, filaments of outer series 32--38, (5.4--)10.1--11.1(--15.8) mm long, filiform, purplish, pink or red at base, cream to white above, (filaments of the inner series (1.2--)1.8--2.0(--2.5) mm long); operculum (0.9--)1.3--1.5(--2.2) mm; limen erect; androgynophore 5.1--9.9 mm long, green; stamens with filaments (2.7--)3.8--4.2(--4.8) mm long; anthers (2.2--)3.3--3.6(--5.3) × (0.8--)1.2--1.3(--1.7) mm; ovary 2.1--4.0 × 1.1--3.0 mm, ellipsoid, densely brownish hirsute hairs; styles (1.9--)2.9--3.3(--4.6) × 0.2--0.3 mm; stigma (0.6--)0.9--1.1(--1.6) mm diam. Fruit (21--)36--44(--63) × (7--)14--19(--39) mm, ovoid, rounded or abruptly acute at apex, slightly hexagonal, hirsute, reddish brown, dark purplish red or red (white or cream between the ridges); stipe 1.4--7.5 mm long; seeds (1.9--)2.8--3.1(--3.7) × (1.3--)1.6--1.8(--2.0) mm, transversely sulcate with 6--7 sulci, apex without projection.

Local Names: “*mazomanchachi*” Cusco, Peru.

Distribution and Ecology: From Colombia, Venezuela, Guyana, Suriname, French Guiana, and northeastern Brazil to Bolivia, Peru and Ecuador, in surrounding lowland Amazonian rain forest, from 150 to 3000 m altitude.

Phenology: Flowers observed in January, February and from September to November. Fruits observed in January and from March to July and December.

Selected specimens examined: BOLIVIA. 1895, *M. Bang* 2836 (B, BM, CTES, F, G, GH, K, MICH, MIN, MO, NY, PH, S, US, W); **Chuquisaca:** Hernando Siles, Suroeste del poblado de Monteagudo, serranías bajas, colinados, bastante antropizados, 19°35'22"S 064°05'19"W, 19 Dec 2006, *J. Passiflora cisnana was originally described by Harms in 1895 as a species from Loja, Ecuador distributed from 1200 to 1500 m altitude. Later Killip in 1938 placed *P. cisnana* in synonymy, under *P. rubra* because it appeared to be simply a form of that species from Ecuador with denser indumentum and smaller leaves.

Sterile collections of *P. cisnana* and *P. rubra* are indeed difficult to distinguish. However, there are differences in sepals, petals, corona filaments, and ovary shape

between the two. *Passiflora cisnana* is characterized by having sepals with acute apices, petals about half as long as the sepals and with a slightly praemorse to obtuse or retuse apices; while *P. rubra* is characterized by having sepals with acuminate apices, petals shorter than sepals and with acute apices. The corona of *P. cisnana* usually has two series of filaments (but see *Lasser* 1552 and *Knapp* 2838), the length of the outer series is intermediate between that of the sepals and of the petals; while *P. rubra* has 1 or 2 series of corona filaments, the outer shorter than both sepals and petals. The color of the corona filaments also differs between the species: The filaments are purplish or red at the base, and cream to white above in *P. cisnana* or with purple or pink dots their entire length in *P. rubra*. The ovary shape is also different: ellipsoid in *P. cisnana* and ovoid to globose in *P. rubra*. *Passiflora cisnana* is widely distributed in South America while *P. rubra* is restricted to the Caribbean islands.

TYPE: Honduras. Comayagua: El Carrizal, 14 km NW of Siguatepec, 900 m, 27 Jun 1971, *Molina & Molina* 26057 (holotype, F; isotypes, EAP not seen, NY, US not seen)

Vine 2--4 m tall, pubescent throughout with 0.4--0.8 mm long, erect trichomes. Stem 5-angular, striate; internodes 5.9--8.1 cm long. Stipules (2.8--)4.4--5.5(--8.1) × (0.3--)0.6--0.7(--0.8) mm, linear to narrowly triangular, very sparsely pubescent abaxially, apex acuminate; petiole (4--)7--10(--19) mm long; lamina (2.5--)4.2--5.4(--8.6) × (1.4--)3.3--3.9(--5.8) cm, broadly obovate or obtriangular, base rounded or slightly cordate, sparsely pubescent abaxially with trichomes 0.6--0.8 mm long, densely pubescent adaxially, trichomes 0.7--0.8 mm long, 2(--3)-lobed, the lateral lobes acuminate to rounded (a small central lobe obtuse to mucronulate), the angle between the lateral veins (26--)43--48(--66)°. Peduncles, 1--2 mm long, solitary (pairs), (one bract near the apex); floral stipe 1.3--3.9 mm long; flowers light to bright yellow, floral tube (0.5--)0.8--0.9(--1.4) × (0.5--)0.6--0.8(--1.3) cm; sepals (11.5--)18.4--19.5(--27.4) × (1.8--)2.7--3.3(--5.1) mm, triangulate, sparsely pubescent outside, apex obtuse, light to bright yellow; petals (9.5--)15.5--16.7(--25.7) × (1.3--)2.0--2.7(--3.8) mm; narrowly triangular, apex acute; corona filaments in 1(2) series, pale yellow with yellow tips, filaments of outer series 15, (6.2--)10.7--11.9(--15.5) mm long, erect, filiform, filaments of inner series (2.2--)4.8--5.8(--8.6) mm long; operculum (1.0--)1.6--1.9(--2.8) mm long, slightly plicate; nectary concave; androgynophore (18.9--)20.6--22.2(--28.6) mm long; stamens with filaments (3.5--)4.9--5.4(--7.3) mm long, flattened; anthers (4.1--)5.0--5.2(--6.2) × (0.9--)1.2--1.5(--2.0) mm; ovary 3.5--3.8(--5.5) × 1.1--1.5(--3.2) mm, fusiform-ellipsoid, densely pubescent; styles (2.8--)3.7--4.3(--5.4) × 0.3(--0.4) mm long; stigma 0.6--0.8(--1.1) mm diam. Fruit (29--)34--38(--42) × (12)13--14(--19) mm, fusiform-ellipsoid or slightly ovoid, strongly 6-angular, reddish; stipe 3.8--4.9 mm long; seeds (2.7--)3.0--3.3(--3.6) × (1.6--)1.9--2.1(--2.4) mm, obovate, testa transversely grooved, with 6--7 sulcae, the ridges continuous, smooth.

Local Names: “*hoja de hechicería*” (Chiquimula – Guatemala).

Distribution and Ecology: central and western Honduras, adjacent eastern Guatemala, and recently collected in northern El Salvador; in moist *Pinus*--*Liquidambar* forest.

Phenology: Flowers observed in May to December. Fruits documented from April to July and from December to January.

Selected specimens examined: GUATEMALA. **Chiquimula:** Cut-over forest of La Cumbre on old road to Quezaltepeque, 14°37'37"N 089°23'11"W, 28 Sep 1971, A. Molina R. & A. R. Passiflora citrina is characterized by yellow flowers with a distinctive long floral tube. The long tube separates the species from other members of sect. *Xerogona* except *P. sanguinolenta* Masters. However, *P. sanguinolenta* differs from *P. citrina* by having triangular stems and red to purplish flowers that consistently have a second very small row of coronal filaments. Although, section *Xerogona* is characterized by absence of bracts, *P. citrina* occasionally has been observed with a single bract at the apex of the peduncle 1.6--4.0 × 0.2--0.3 mm (See Molina 6510).

5. ***Passiflora cobanensis*** Killip.

Vine 3--6 m long, puberulous to densely pubescent throughout. Stems 3--5 angular, and striate. Stipules (6.0--)7.7--8.6(10.4--) × (1.6--)2.5--3.0(--5.1) mm, linear-lanceolate or oblongate, more or less falcate, very sparsely pubescent abaxially; petiole (6--)8--11(--17) mm long; lamina (5.6--)7.9--10.0(--19.6) × (2.6--)3.7--4.5(--7.1) cm, narrowly obovate to very broadly obovate, rounded or slightly cordate at the base, densely hispid abaxially with trichomes 0.2--0.4 mm long, sparsely to densely hispid adaxially with trichomes 0.2--0.3 mm long, unlobed, strongly 3-nerved in proximal half, the angle between the lateral veins (18--)35--41(--64)°. Peduncles (5--)9--11(--18) mm long, usually in pairs; floral stipe 2.4--3.0 mm long; flowers (8--)16--20(--29) mm diam., pale green to light greenish-yellow; sepals (10.1--)11.8--13.0(--14.2) × (1.7--)2.4--2.7(--3.4) mm, narrowly triangular, sparsely hirsutulous pubescent outside, apex acute, greenish; petals (4.9--)6.5--6.8(--9.2) × (1.0--)1.5--1.8(--2.3) mm, linear to narrowly triangular; apex obtuse, greenish; corona filaments in 2 series (1), filaments of outer series 20--25, (3.0--)3.8--4.3(--6.0) mm long, purplish brown and yellowish at the apex, linear-clavate to filiform; filaments of the inner row (1.2--)1.4--1.6(--1.8) mm long; operculum (1.1--)1.5--1.8(--2.3) mm long; androgynophore (3.1--)3.9--4.1(--5.1) mm long, green; stamens with filaments (2.3--)2.9--3.2(--3.8) mm long; anthers (1.8--)2.2--2.4(--2.9) × (0.6--)0.9--1.1(--1.3) mm; ovary 1.3--3.5 × 0.7--1.6 mm, ovoid to slightly fusiform, puberulous to densely tomentose; styles (1.7--)2.1--2.5(--3.2) × 0.2--0.3 mm; stigma (0.4--)0.5--0.7(--1.2) mm diam. Fruit (26--)34--38(--49) × (12--)13--16(--24) mm, ovoid or ellipsoid, basally stipitate or attenuate, acutely 6-angled, reddish brown; stipe 5.1--6.6 mm long; seeds (1.9--)3.7--4.1(--5.0) × (1.6--)2.1--2.3(--2.7) mm, transversely sulcate with 6--7 sulci.

Passiflora cobanensis is unique within section *Xerogona* in having unlobed leaves. *Passiflora cobanensis* is found from Atlantic lowland humid forest to lower montane rainforest, especially on ridges and limestone outcrops of Chiapas, Mexico through central Guatemala to Belize from 120--1700 m altitude. There are two variants within *P. cobanensis*: one grows in mesic to wet uplands in Chiapas, Mexico, and the

other one grows in lowland warmer and seasonally drier areas. The recognition of these two variants as subspecies was suggested before by MacDougal (2003) in Flora Mesoamerica (still unpublished). In the present revision the two variants have been recognized as subspecies based on differences in stem, leaf, corona filaments, and ovary characters.

Key to the subspecies of *Passiflora cobanensis*

1a. Stem 4--5-angular; stipules oblong, subfalcate; lamina 2.6--5.2 cm across, thinner with rounded base, slightly reticulate beneath and sparsely pubescent; outer corona filaments linear-clavate; ovary glabrous or puberulous (rarely densely tomentose).

5A. *P. cobanensis* ssp. *cobanensis*.

1b. Stem 3 angular; stipules linear-lanceolate; lamina 3.0--7.1 mm across, thicker with cordate base, conspicuously reticulate beneath with nerves and veins elevated and densely pubescent; outer corona filaments filiform; ovary densely tomentose.

5B. *P. cobanensis* ssp. *brevipes*.

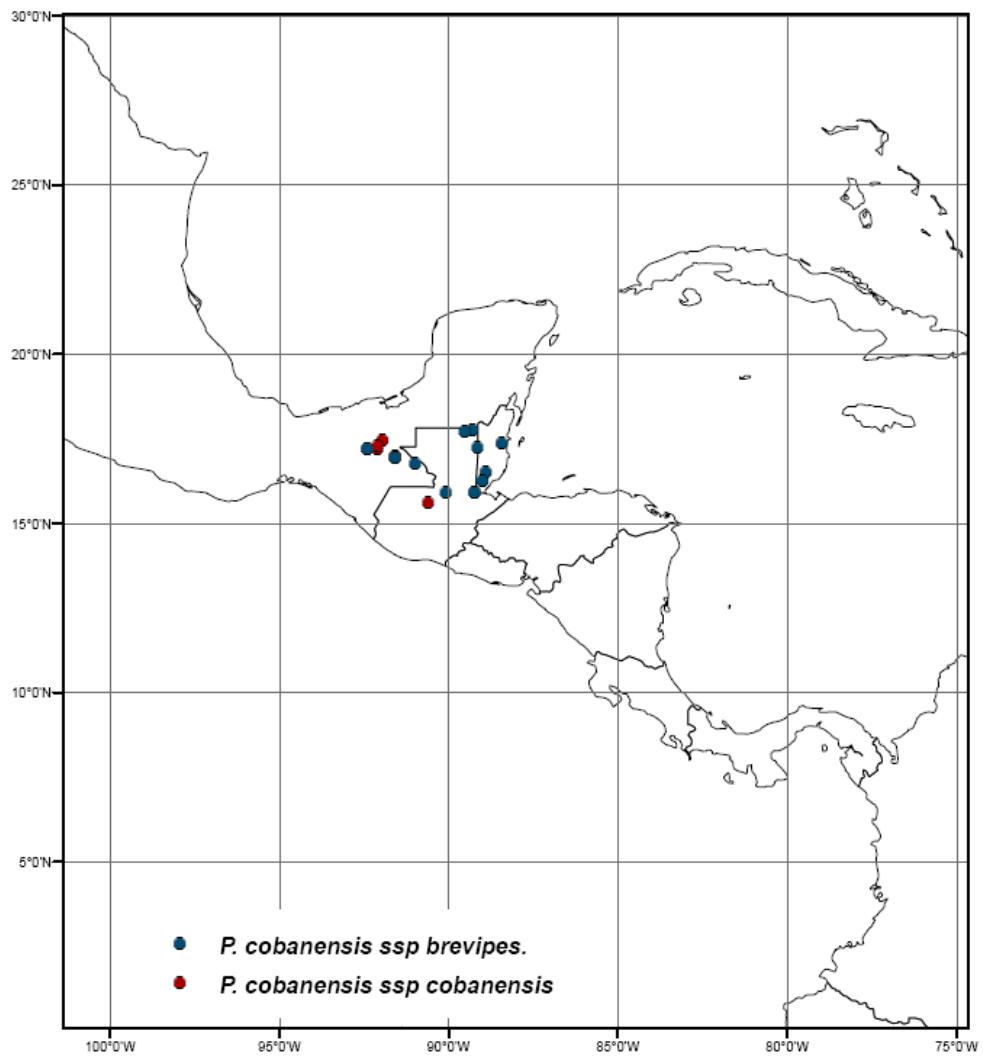

Figure 18. Distribution of *Passiflora cobanensis* Killip.

5A. *Passiflora cobanensis* subsp. *brevipes* (Killip) Boza Comb. nov.

BASIONYM: *Passiflora brevipes* Killip, Publ. Carnegie Inst. Wash. 461(13): 312--313, t. 2. (1936). -- TYPE: British Honduras: Jacinto Hills, alt. 120 m, W. A. Schipp 1304 (holotype, F; isotypes, BRH not seen, G, MICH, MO.).

Vine densely short hispid throughout. Stems 3-angular, striate. Stipules (6.8--)7.7--8.8(--10.4) × (2.0--)2.8--3.2(--5.1) mm, linear-lanceolate, very sparsely pubescent abaxially; petiole (6--)8--10(--15) mm long, lamina (5.6--)6.7--8.2(--11.4) × (3.0--)3.8--

4.6(--7.1) cm, broadly obovate, cordate at the base, densely pubescent abaxially, trichomes 0.2--0.4 mm long, glabrous to densely pubescent adaxially with trichomes ca. 0.3 mm long, unlobed, strongly 3-nerved in proximal half with conspicuous reticulation beneath (nerves and veins elevated), the angle between the lateral veins (32--)42--50(--64)°. Peduncles (6--)9--11(--18) mm long, in pairs; floral stipe 0.8--2.8 mm long; flowers (8--)17--23(--29) mm diam.; sepals (10.1--)11.3--12.7(--13.4) × (1.7--)2.1--2.4(--3.3) mm, sparsely hirsutulous pubescent outside; petals (4.9--)6.4--7.3(--9.2) × (1.0--)1.4--1.6(--2.0) mm, linear to narrowly triangular; corona filaments in 2 series, filaments of outer series 20--25, (3.0--)3.6--4.2(--6.0) mm long, filiform; filaments of the inner series (0.9--)1.1--1.3(--1.5) mm long; operculum (1.1--)1.5--1.7(--2.3) mm; androgynophore (3.1--)4.3--4.5(--5.1) mm long; stamens with filaments 2.9--3.5(--3.8) mm long; anthers (1.8--)2.1--2.3(--2.7) × (0.6--)0.9--1.1 mm; ovary 2.0--3.5 × 0.9--1.6 mm, ovoid to ellipsoid, puberulous; styles (1.8--)2.3--2.8(--3.2) mm long; stigma (0.4--)0.5--0.7(--1.2) mm diam. Fruit (23--)30--32(--38) × (12--)13--14(--15) mm, ovoid; stipe 1.1--5.1 mm long; seeds (3.6--)3.8--3.9(--4.2) × (1.9--)2.1--2.2 mm.

Distribution and Ecology: From Mexico to northern Guatemala and Belize in warm and seasonally dry areas from 150--1700 m altitude.

Phenology: Flowers observed from Feb to June. Fruits in March and from Jun to July.

Selected specimens examined: BELIZE. **Belize:** Gracie Rock, 1.5 mi. S of Mile 22 on Western Highway, 17°23'N 088°26'W, 04-05 Jun 1973, *T. B. Passiflora cobanensis Killip. J. Wash. Acad. Sci. 14: 111. 1924. TYPE:

Guatemala: Alta Verapaz: between Chama and Cobán, 950 m, 26 July 1920, *Johnson* 411 (holotypes, F not seen, US not seen).

Vine 3--6 m long, sparsely short hispid throughout. Stems 4--5 angular, striate. Stipules (6.0--)7.9--8.6(10.0--) × (2.2--)2.4--3.1(--4.2) mm, oblong, more or less falcate, very sparsely pubescent abaxially; petiole (6--)8--12(--17) mm long; lamina (7.0--)9.5--12.8(--19.6) × (2.6--)3.4--4.4(--5.2) cm, margin entire, narrowly obovate, rounded at the base, sparsely to densely hispid abaxially with trichomes 0.1--0.2 mm long, glabrous to sparsely hispid adaxially with trichomes ca. 0.1 mm long, unlobed, strongly 3-nerved in proximal half and slightly reticulate beneath, the angle between the lateral veins (18--)27--31(--36)°. Peduncles (5--)7--9(--12) mm long, usually in pairs; floral stipe 2.4--3.0 mm long; flowers (13--)19--20(--25) mm diam; sepals (12.2--)12.7--13.9(--14.2) × (2.9--)3.1--3.3(--3.4) mm, sparsely hirsutulous outside; petals (6.0--)6.2--7.1(--7.4) × (1.6--)1.8--2.1(--2.2) mm, linear to narrowly triangular; corona filaments in 2 series, filaments of outer series ca. 20, (4.0--)4.1--4.4(--4.5) mm long, filaments linear clavate; filaments of the inner series (1.1--)1.2--1.5 mm long; operculum (1.4--)1.5--1.8(--2.0) mm; androgynophore (3.0--)4.3--4.5 mm long; stamens with filaments (2.3--)2.9--3.2 mm long; anthers (2.2--)2.3--2.6(--2.9) × 0.9--1.1(--1.2) mm; ovary 1.3--1.6 × 0.7--1.0 mm, ovoid, glabrous to puberulous (rarely densely tomentose); styles (1.7--)1.8--1.9 mm long; stigma (0.4--)0.5--0.7 mm diam. Fruit 44--45(--49) × (12--)18--23(--24) mm, ovoid; stipe 3.6--6.6 mm long; seeds (3.8--)4.2--4.8(--5.0) × (2.2--)2.3--2.4(--2.7) mm.

Distribution and Ecology: From Mexico to northern Guatemala in lower montane rainforest, especially limestone outcrops or ridges in Chiapas, Mexico, from 300--1700 m altitude.

Phenology: Flowers observed in February. It fruits from February to April.

Selected specimens examined: GUATEMALA. Alta Verapaz: Chamá to Cobán, 15°36'08"N 090°36'40"W - 15°37'00"N 090°34'00"W, 26 Jul 1920, *H. Johnson* 411

Passiflora cobanensis subsp. *cobanensis* and *P. cobanensis* subsp. *brevipes* both are to be found in Peltalcingo Chiapas, Mexico and Alta Verapaz, Guatemala. The subspecies can be distinguished by stem shape which is 3-angular in *P. cobanensis* ssp. *brevipes* and 4--5-angular in *P. cobanensis* subsp. *cobanensis*. The stipules of *P. cobanensis* subsp. *cobanensis* are oblong, more or less falcate, while those of *P. cobanensis* subsp. *brevipes* are linear to lanceolate stipules. The leaves of *P. cobanensis* subsp. *cobanensis* are longer, narrower, thinner with a rounded base, acuminate apex, less indumentum, and are slightly reticulate beneath; in *P. cobanensis* subsp. *brevipes* the leaves are wider, thicker, with a cordate base, acute apex, dense indumentum and are conspicuously reticulate (veins are prominent) beneath. There are 2 (1) series of corona filaments in *P. cobanensis* subsp. *cobanensis*, members of the outer series filaments having a clavate apex; while in *P. cobanensis* subsp. *brevipes* the corona always has 2 series, the outer filaments being liguliform. The ovary in *P. cobanensis* subsp. *cobanensis* is ovoid and glabrous to puberulous; whereas in *P. cobanensis* subsp. *brevipes* it is narrowly ovoid and densely tomentose.

Plate 5. *Passiflora cobanensis* ssp. *cobanensis* (Killip) Boza (Veliz et al. 19960).

6. ***Passiflora conzattiana*** Killip. J. Wash. Acad. Sci. 17: 425(1927)

TYPE: Mexico: Veracruz: Mirador, June 1921, *Purpus* 8804 (holotype, US not seen; isotype, MO).

Vine 5--7 m long, sparsely pubescent to glabrescent. Stems 3-angular, slender, terete, turning reddish brown. Stipules (1.6--)3.6--4.4(--5.6) × (0.2--)0.4--0.5(--0.8) mm, linear to linear triangular, very sparsely pubescent abaxially; petiole (7--)13--17(--29) mm long; lamina (1.8--)3.2--4.0(--6.1) × (3.1--)4.3--5.3(--6.9) cm, depressed obovate, cordate at the base, densely hirsute abaxially with trichomes 0.3--1.0 mm long, sparsely hirsute adaxially with trichomes 0.6--1.2 mm long, 2(--3)-lobed, the lateral lobes acuminate to acute, (the central lobe reduced or cusp-like), 3-nerved (nerves often terminating in a short mucro); the angle between the lateral veins (44--)79--87(--122)°. Peduncles (8--)17--20(--44) mm long, slender, solitary (in pairs); floral stipe 0.8--3.3 mm long; flowers (16--)19--20(--27) mm diam., greenish white to yellowish green; sepals (4.6--)8.4--9.4(--14.1) × (1.6--)2.1--2.7(--3.9) mm, linear to narrowly elliptic, sparsely hirsutulous pubescent outside, yellowish green, apex acute, yellowish green; petals (3.2--)5.9--6.7(--9.4) × (1.0--)1.4--1.8(--2.5) mm, linear to narrowly elliptic; about half as long as the sepals, apex slightly praemorse to retuse, greenish white; corona filaments in 1(2) series, filaments of outer series 20, (2.2--)3.5--4.0(--6.2) mm long, densely spotted with deep purple in the lower two-thirds, yellow in the upper third; filaments of the inner series (0.7--)0.9--1.2(--1.3) mm long; operculum (0.7--)1.1--1.3(--1.9) mm, pale purple, limen erect; androgynophore 2.4--3.3(--4.0) mm long, green; stamens with filaments (1.8--)2.3--2.7(--3.4) mm long; anthers (1.6--)2.1--2.2(--2.6) × (0.5--)0.9--1.1(--1.4) mm; ovary (1.2--)1.7--2.0(--2.7) × (0.8--)1.0--1.3(--2.0) mm, ellipsoid to ovoid or fusiform, densely puberulous; styles (1.1--)1.8--2.1(--2.7) × (0.1--)0.2--0.7(--1.8) mm; stigma (0.5--)0.7--0.9(--1.2) mm diam. Fruit (27--)40--51(--63) × (8--)9--12(--15) mm, narrowly ellipsoid to fusiform, finely pubescent to glabrous, 6-keeled, dark purplish red; stipe 3.2--4.0 mm long; seeds (2.5--)2.7--3.0(--3.1) × (1.5--)1.9--2.4(--2.6) mm, transversely sulcate with 5--6 sulci, ridges smooth.

Local Names: “*Ehiil i okob thut*” (Huasec San Luis Potosí, Mexico).

Distribution and Ecology: East-central Mexico in wet montane cloud forest from 800 to 1980 m altitude mainly in woodlands of pine and oak forest.

Phenology: Flowers were observed in May to August. Fruits were observed from July to August.

The flowers of *P. conzattiana*, *P. cobanensis*, and *P. goniosperma* are very similar. It is possible to distinguish among these species by the shape of their leaves and by the number of coronal rows. *Passiflora goniosperma* has 2-lobed leaves, *P. conzattiana* has 2-lobed leaves and rarely 3-lobed leaves, while *P. cobanensis* has unlobed leaves. *Passiflora conzattiana* has only one series of corona filaments, as well as *P. goniosperma*, while *P. cobanensis* has 2 series of corona filaments.

Although species of section *Xerogona* characteristically lack floral bract *P. conzattiana* rarely has a single bract 1.7--2.5 × 0.2--0.4 mm (*Marquez* 140A and *Inzunza* 94).

7. ***Passiflora costaricensis*** Killip. J. Wash. Acad. Sci. 12: 257(1922)

TYPE: Costa Rica: Talamancas: Xirores [Shirores], *Tonduz* 9327 (holotype, US not seen; isotypes, BR, CR not seen, US not seen).

Vine 4--12 m long, sparsely to densely tomentose throughout. Stems sharply 3-angular, hirsute with light brown hairs. Stipules (3.1--)6.0--6.8(--13.5) × (0.6--)0.9--1.1(--1.8) mm, linear-falcate, entire, very sparsely pubescent abaxially; petiole (10--)21--28(--64) mm long; lamina (7.9--)10.6--12.4(--16.0) × (5.4--)7.7--8.9(--12.8) cm, broadly obovate, rounded to cordate at the base, densely tomentose abaxially with trichomes 0.5--1.5 mm long, densely pilose adaxially with trichomes 0.8--2.0 mm long, 2-lobed, the lateral lobes acuminate or acute, mucronate, 3-nerved, the angle between the lateral veins (28--)36--40(--59)°. Peduncles (6--)9--12(--16) mm long, slender, solitary (in pairs); floral stipe 1.9--7.4 mm long; flowers (41--)44--46(--52) mm diam., white, cream, or pale greenish white; sepals (13.5--)18.1--19.5(--21.2) × (2.4--)3.9--4.6(--6.0) mm, linear to triangular, sparsely hirsutulous pubescent outside, apex acute, pale green to white (flushed purple); petals (10.7--)12.6--13.1(--16.4) × (1.9--)3.3--3.8(--5.3) mm, linear to narrowly triangular; apex obtuse to rounded, white occasionally flushed purple; corona filaments in 1 or 2 series, those of outer series 30--36, (8.3--)11.0--12.0(--14.8) mm long, white with pink base; those of the inner series 1.4--1.6(--1.7) mm long; operculum (1.9--)2.2--2.5(--2.9) mm, closely plicate, usually finely pubescent, trichomes ca. 0.6 mm long; androgynophore 4.4--7.6 mm long, green; stamens with filaments (2.8--)4.3--5.0(--6.0) mm long; anthers (2.9--)3.9--4.2(--5.7) × (1.0--)1.4--1.7(--2.3) mm; ovary 3.1--7.1 × 0.7--3.0 mm, ellipsoid to fusiform, minutely puberulous; styles (3.5--)4.6--4.9(--6.3) × (0.2--)0.3--0.4(--0.5) mm; stigma (1.1--)1.3--1.5(--2.3) mm diam. Fruit (50--)69--93(--134) × (10--)14--18(--31) mm, ellipsoid or fusiform, glabrous, 6-keeled, dark red to purplish-red and often pink to white between the ridges (nearly all white); stipe 3.5--11.4 mm long; seeds (1.3--)3.3--3.4(--4.4) × (1.2--)1.8--1.9(--2.2) mm, narrowly ovate, transversely sulcate with 7--9 sulci, smooth ridges.

Distribution and Ecology: From eastern Mexico to the pacific coast of Colombia and Ecuador in lowland to premontane tropical wet forest, from 0 to 1800 m in the edges of primary forest and in secondary growth.

Phenology: Flowers and fruits observed during most of the year.

Selected specimens examined: BELIZE. **Toledo:** Southern Maya Mountains, Bladen Nature Reserve, West Snake Creek, 16°27'24"N 089°01'01"W, 28 May 1997, *D. L. Holland & B. Kid* 95 (BRH, MO). Dressler* 5380 (MO).

Passiflora costaricensis is closely related to *P. rubra* by its leaves and thick triangular stem. However, its 2-lobed leaves and relatively long and conspicuously tomentose indumentum distinguish it from *P. rubra* which has two lobed leaves that are broader than long, and have hirsute indumentum.

8. ***Passiflora escobariana*** J.M.MacDougal. Novon 2: 365(1992)

TYPE: Colombia: Antioquia: Mun. de Frontino: road between Nutibarra and La Blanquita, region of Murrí, ca. 24.5 km from Nutibarra, 06°40'N, 076°26'W. Bosque pluvial premontano. 1090 m, 8 Feb. 1991 [1989], *J. M. MacDougal, Restrepo, and Sylvia* 3823 (holotype, HUA not seen; isotypes, BM not seen, COL not seen, CR not seen, HUA not seen, MEDEL not seen, MO, TEX, US not seen).

Vine 5--10 m long, minutely puberulous throughout. Stems 3--5-angular, reddish. Stipules (3.6--)4.4--5.2(--6.6) × (0.3--)0.6--0.8(--1.0) mm, linear-triangular to falcate; petiole (16--)29--36(--61) mm long; lamina (7.0--)8.7--9.9(--11.1) × (7.3--)7.7--8.5(--10.1) cm, broadly obovate, base cordate, densely hirsute abaxially with trichomes 0.1--0.3 mm long, sparsely hirtellous adaxially with trichomes 0.1--0.6 mm long, 2(--3)-lobed, the lateral lobes acute to acuminate (the central lobe, obtuse); the angle between the lateral veins (35--)43--48(--58)°. Peduncles 14--18(--23) mm long, slender, solitary or usually in pairs, red; floral stipe 2.4--2.9 mm long; flowers 40--50 mm diam., cream to whitish (pale pink); sepals (23.0--)24.1--26.4(--28.0) × (2.1--)2.7--3.2(--4.3) mm, narrowly triangular, sparsely hirsutulous pubescent outside, apices acute, cream or whitish (base pale pink); petals (16.8--)19.1--20.0(--22.8) × 1.3--1.9 mm, linear to narrowly triangular, apices acute, whitish to pale pink; corona filaments in 1 or 2 series, filaments of outer series 20--26, (12.0--)12.4--14.4(--14.5) mm long, white in the lower half, pale yellow in the upper half; filaments of the inner series 2.0--2.3 mm long; operculum (1.3--)1.6--1.7(--1.9) mm, light purple; limen erect; androgynophore 7.0--7.6(--19.7) mm long, light greenish; stamens with filaments (4.9--)5.1--5.4(--6.4) mm long; anthers (3.6--)4.6--4.7(--5.7) × (1.0--)1.2--1.3(--1.4) mm; ovary 3.2--5.6 × 1.8--1.9 mm, ellipsoid to fusiform, densely puberulous; styles (4.0--)4.4--4.8(--5.3) × 0.2--0.4(--0.6) mm; stigma (1.1--)1.4--1.7 mm diam. Fruit 29--70 × 25--29 mm, fusiform, 6-keeled, red on ridges cream between; stipe ca. 4.3 mm long; seeds unknown.

Distribution and Ecology: Northern Colombia and Panama in lowland and premontane tropical wet forest, from 100 to 1000 m. at the edge of primary forest.

Phenology: Flowers and fruits observed in February.

Selected specimens examined: Cultivated: PANAMA. Darién: Parque Nacional Darién, Estación Pirre, a orillas del Río Perresénico entre la Estación Pirre y la cascada, 08°00'N 077°45'W, 10 Oct 1990, H. Herrera 720 (MO).

9. ***Passiflora goniosperma*** Killip. J. Wash. Acad. Sci. 17: 424(1927)

TYPE: Mexico: Oaxaca: Niña [Mina] de Dolores, Aug 1842, *Liebman* 4076 (holotype, C).

Vine 3--4 m long, hirsutulous throughout. Stems sub 3-angular. Stipules (2.4--)3.5--4.0(--6.0) × (0.3--)0.5--0.7(--1.2) mm, linear, subfalcate, sparsely pubescent abaxially; petiole (2--)7--12(--29) mm long; lamina (3.3--)3.8--5.2(--6.9) × (2.7--)3.3--4.7(--7.5) cm, very broadly obovate, rounded at the base, densely hirsute abaxially, trichomes ca. 0.3--0.9 mm long, densely hirsute adaxially, trichomes ca. 0.8--1.0 mm long; 2-lobed, the lateral lobes obtuse or slightly rounded, often mucronate at the end of the midnerve, the angle between the lateral veins (31--)46--52(--70)°. Peduncles (4--)14--17(--27) mm long, usually in pairs or occasionally solitary; floral stipe 1.0--3.1 mm long; flowers 16--17 mm diam., pale yellowish green; sepals (6.3--)8.5--9.2(--17.6) × (1.6--)2.0--2.3(--2.8) mm, triangular, sparsely hirsutulous pubescent outside, apex acute, pale yellowish green; petals (3.2--)4.4--6.2(--12.1) × (0.9--)1.3--1.6(--2.3) mm, narrowly elliptic, apices acute, white or white with pale pink nerves; corona filaments in 1 series, filaments 20, (1.7--)3.3--4.0(--10.4) mm long, purplish red at base, light greenish yellow or light yellow at the slightly swollen apex; operculum (0.7--)0.9--1.2(--1.9) mm, closely plicate, white or pale purple; androgynophore 2.7--4.4 mm long, green; stamens with filaments (1.6--)2.4--4.1(--4.3) mm long; anthers (1.9--)2.5--2.7(--4.2) × (0.6--)1.1--1.3(--1.8) mm; ovary 1.5--4.1 × 0.7--1.3 mm, ellipsoid or ovoid, white puberulous; styles (1.0--)2.1--2.3(--3.8) × (0.1--)0.2--0.4 mm; stigma (0.4--)0.5--0.7(--0.9) mm diam. Fruit (31--)36--42(--67) × (7--)8--9(--12) mm, narrowly ellipsoid or fusiform, slightly to sharply hexagonal, 6-keeled, light green or yellowish green at maturity or the ribs flushed with red; stipe 3.0--5.5 mm long; seeds (2.9--)3.0--3.5(--3.7) × (1.7--)1.9--2.1(--2.2) mm, obovoid and strongly compressed laterally with a narrow longitudinal ridge, and transverse grooves are reduced to a row of teeth along longitudinal ridge.

Distribution and Ecology: Southern Mexico in tropical deciduous forest from 30 to 1350 m altitude, mainly in secondary forest edges and roadsides.

Phenology: Flowers observed in April to August. Fruits observed in August and November.

Selected specimens examined: MEXICO. **Jalisco:** Mun. La Huerta, Rancho Cuixmala, Cumbres 01, last bajada on rd. between Cumbres 01 and Station 45, just before arriving at 45, 19°26'24"N 104°58'48"W, 10 Jul 1991, *E. J. Lott & Phillips* 3670 (MO); La Huerta, Rancho Cuixmala, Cumbres 01, hills and canyons behind Station, Km 45 of the Puerto Vallarta-Barra de Navidad Hwy., 19°26'N 104°59'W, 18 Aug 1991, *E. J. Lott et al.* 3785 (CAS, LL, MO, RSA, XAL); Rancho Cuixmala, Cumbres 01, Arroyo Cajonas, ca. 3 km inland from the Puerto Vallarta, Barra de Navidad Hwy., 19°22'48"N 104°58'48"W, 19 Aug 1991, *E. J. Lott et al.* 3799 (CAS, LL, MICH, MO, NY); Camino antiguo sur, camino a las cuencas 4 y 5, cerca de la brecha de la Cia. Tenorio L. & R. Torres C.* 226 (DUKE).

The seeds of *P. goniosperma* differ from the other species of section *Xerogona*. They are strongly compressed laterally with a narrow longitudinal ridge and the transverse grooves which normally extend from margin to margin in the species of section *Xerogona* are reduced to a row of teeth along this longitudinal ridge. The dehiscent narrowly ellipsoid or fusiform 6-keeled fruit and the absence of bracts and foliar nectaries show the relationship of *P. goniosperma* to section *Xerogona*.

10. ***Passiflora pusilla*** J. M. MacDougal. Ann. Missouri Bot. Gard. 75(1): 392 -- 395
(1988)

TYPE: Nicaragua: Chontales: Hacienda Corpus, W of Juigalpa, ca. 100 m, 14 Jun 1984,
Stevens 22968 (holotype, MO; isotype, HMNH not seen).

Herbaceous vine 12--55(--90) cm long, hirsutellous throughout. Stems triangular or subtriangular. Stipules (0.2--)2.0--2.7(--4.4) × (0.1--)0.3--0.5(--1.1) mm, linear to linear triangular, sparsely hirsutellous abaxially; petiole (15--)20--27(--47) mm long; lamina (1.2--)2.1--2.7(--4.6) × (2.1--)3.4--4.3(--6.6) cm, depressed obovate, cordate at the base, densely hirsutellous abaxially with trichomes 0.8--1.2 mm long, sparsely hirsutellous adaxially with trichomes 1.0--1.9 mm long, 3-lobed, the lateral lobes obtuse or rounded, the central lobe broadly obtuse; the angle between the lateral veins (79--)85--98(--106)°. Peduncles (7--)10--12(--25) mm long, solitary; floral stipe 0.8--2.5 mm long; flowers ca. 14.5 mm diam., pale yellowish green; sepals (4.8--)6.0--6.7(--8.4) × (0.8--)1.2--1.5(--2.2) mm, narrowly triangular, sparsely hirsutulous pubescent outside, apex acute, pale yellowish green; petals (3.2--)3.4--4.0(--4.4) × (1.0--)1.2--1.3(--1.9) mm, linear to narrowly elliptic, acute to round apex, pale yellowish green; corona filaments in 2 series, filaments of outer series 20, (2.1--)3.8--4.3(--5.8) mm long, yellowish green or greenish, yellow toward the apex; filaments of the inner series (1.0--)1.3--1.4(--1.7) mm long; operculum (0.5--)0.8--0.9(--1.1) mm; androgynophore 3.0--5.0 mm long; stamens with filaments (1.2--)1.5--1.7(--2.1) mm long; anthers (1.5--)1.8--2.0(--2.3) × (0.5--)0.7--0.8(--1.0) mm; ovary 1.4--2.3 × 0.5--1.0 mm, narrowly ellipsoid, densely puberulous or tomentose; styles (0.9--)1.8--2.1(--2.8) × 0.1--0.2 mm; stigma 0.3--0.5 mm diam. Fruit (6--)23--30(--45) × (3--)4--5(--8) mm, narrowly fusiform, 6-keeled, sparsely puberulous, green; stipe 1.9--3.0 mm long; seeds (2.7--)3.1--3.3(--3.4) × (1.5--)1.7--1.8(--1.9) mm, transversely sulcate with 5--6 sulci, with 2 longitudinal rows of 5--6 teeth down each margin edge.

Distribution and Ecology: Southern Mexico, Nicaragua and Costa Rica. It is found in low tropical moist and dry forest associated with the distinctive soil type called “sonsocuite” in Nahuatl and characteristic of poorly drained, seasonally inundated forest

(MacDougal, 1988) below 300 m altitude. *P. pusilla* grows mainly in open areas, roadsides, and pastures edges.

Phenology: Flowers observed from May to June and from August to December. Fruits from July to August and from November to December.

Selected specimens examined: COSTA RICA. **Guanacaste:** Santa Rosa National Park, 30 km W of Liberia, 10°49'48"N 085°34'48"W, 18 Aug 1984, *Janzen* 12412 (MO); En bosquecillo sobre monticulo rocoso, en terreno plano 5 km al NE de Bagaces, 10°33'36"N 085°16'12"W, 22 Jul 1964, A. *Jiménez* 2136 (CR, F, NY); Savannah, 10 km W of Liberia, west of Airport., 10°30'00"N 085°33'36"W, 25 Jun 1977, R. MEXICO. **Oaxaca:** Open grazed areas about 2 km N of the village Ixhuatán, 23 Jul 1959, R. *Merrill* 1983 (LL). NICARAGUA. **Chontales:** Hda. Corpus, W of Juigalpa, 12°07'N 085°28'W, 20 May 1984, W. D. *Stevens* 22898 (HNMN, MO).

Passiflora pusilla and *P. tenella* are similar vegetatively, but they have different geographic distributions. *Passiflora pusilla* is distributed in Mexico, Nicaragua and Costa Rica while *P. tenella* is endemic to the tropical deciduous forest of Ecuador and Peru (Holm-Nielsen et al., 1988). The two species share a much reduced size. *Passiflora pusilla* is characterized by having densely pubescent leaves with obtuse or rounded apices to the lateral lobes and a tomentose ovary, while *P. tenella* has less pubescent leaves with acute apices of the lateral lobes and a nearly glabrous ovary.

11. ***Passiflora quinquangularis*** S. Calderón ex J. M. MacDougal. Novon. 14(4): 454--456, f. 4 (2004)

TYPE: El Salvador: San Salvador: S of San Salvador, July 1922, *Calderón* 851 (holotype, US; isotypes, GH not seen, US not seen).

Vine 2--4 m long, pubescent throughout. Stems 5-angular, sometimes glabrescent with age. Stipules (2.2--)3.9--4.6(--8.4) × (0.3--)0.5--0.7(--1.0) mm, linear to narrowly triangular, falcate, very sparsely pubescent abaxially; petiole (6--)11--14(--24) mm long; lamina (4.3--)6.6--8.2(--12.6) × (3.4--)5.2--6.2(--10.4) cm, very broadly obovate, rounded to subcordate at the base, densely hirsute abaxially with trichomes 0.2--0.5 mm long, sparsely hirsute adaxially with trichomes 0.4--0.8 mm long, 2(--3)-lobed, the lateral lobes long, acuminate (the central lobe reduced and cusp-like); the angle between the lateral veins (30--)41--50(--68)°. Peduncles (18--)26--32(--42) mm long, slender, solitary, very rarely in pairs; floral stipe 2.2--4.8 mm long; flowers 43--45(--54) mm diam., greenish white to cream; sepals (12.2--)19.6--21.5(--29.2) × (2.1--)3.8--4.2(--6.4) mm, narrowly triangular, sparsely hirsutulous pubescent outside, apex acuminate, light yellow green and often flushed with red spots abaxially; petals (7.6--)9.8--11.8(--14.8) × (1.1--)1.9--2.4(--3.8) mm, linear to narrowly triangular; apex acuminate or obtuse, white or pale green yellow; corona filaments in 2 series, filaments of outer series 35--39, (5.9--)12.3--14.0(--19.5) mm long, pure white with purple or purplish red base; filaments of the inner series (2.0--)2.6--3.3(--4.2) mm long; operculum (0.9--)1.6--1.9(--2.4) mm, light purple and white apex; limen pale red-purple; androgynophore 5.8--8.7 mm long, green; stamens with filaments ca. 3.5 mm long; anthers (3.1--)3.6--3.8(--4.2) × (0.8--)1.2--1.4(--1.8) mm; ovary 3.1--7.7 × 1.2--3.0 mm, narrowly ellipsoid or ovoid, densely minute puberulous; styles (1.9--)3.2--4.0(--5.4) × 0.2--0.3(--0.4) mm; stigma (0.5--)0.7--1.1(--1.6) mm diam. Fruit 38--49 × 15--16 mm, ellipsoid to broadly fusiform, 6-keeled, slightly puberulous, yellowish green; stipe 5.2--8.5 mm long; seeds (3.1--)3.3--3.6(--3.9) × 1.6--1.7(--1.8) mm, transversely sulcate with 6--7(--8) sulci, smooth ridges.

Local Names: “*calzoncillo*, *bejuco calzoncillo*, *calzón de mujer blanco*, *bejuco calzón de hembra*, *ala murciélago*” (El Salvador).

Distribution and Ecology: Southern Mexico, Guatemala, El Salvador and Costa Rica in seasonally dry and deciduous forest from 580--1600 m altitude, mainly in thickets and brushy hillsides.

Phenology: Flowering and fruiting throughout the year.

Selected specimens examined: COSTA RICA. **Heredia:** Santo Domingo, Cuenca del Tárcoles, INBio parque, 09°58'20"N 084°05'40"W, 04 March 2002, A. Standley* 78118 (F); MEXICO. **Oaxaca:** Juchitan, 1 km al S de Guevea de Humboldt, $16^{\circ}47'24''\text{N}$ $095^{\circ}21'36''\text{W}$, 16 Mar 1983, *R. Torres et al.* 2521 (F, MEXU, MO, XAL).

The name of *P. quinquangularis* refers to the 5-angulate stems of this species. *Passiflora quinquangularis* can be confused with *P. rubra*, both having acute flower buds, although the buds of *P. quinquangularis* hang down on very slender peduncles, while those of *P. rubra* are more robust. Additionally, *P. rubra* does not occur in Mexico or Central America.

12. ***Passiflora rovirosae*** Killip. J. Wash. Acad. Sci. 12:259(1922)

TYPE: Mexico: Tabasco: Atasta, 15 Jun 1890, *J. N. Rovirosa* 813 (holotype, PH, US not seen).

Vine 4--15 m long, puberulous throughout. Stems 5-angular, striate. Stipules (3.7--5.0--5.8(--8.8) × (0.3--)0.5--0.6(--1.2) mm, linear-triangular, falcate, very sparsely pubescent abaxially; petiole (12--)21--26(--35) mm long; lamina (5.3--)8.6--9.8(--12.9) × (4.2--)6.0--6.7(--8.4) cm, narrowly obovate to obovate, deeply cordate at the base, densely tomentose abaxially with trichomes 0.2--0.4 mm long, glabrous to sparsely hirsute adaxially with trichomes 0.1--0.6 mm long, 2-lobed or truncate at apex, the lateral lobes acute; the angle between the lateral veins (15--)27--33(--48)°. Plants often cauliflorous, the inflorescences being borne on short shoots thus appearing racemose. Peduncles (5--)10--14(--25) mm long, in pairs (solitary); floral stipe 5.2--11.2 mm long; flowers (38--)48--54(--64) mm diam., cream, or pale yellow; sepals (15.5--)21.7--22.9(--30.4) × (3.5--)4.9--5.6(--7.1) mm, narrowly triangular or narrowly elliptic, apex obtuse, light greenish yellow; petals (11.7--)18.7--19.8(--24.4) × (2.8--)3.5--4.1(--5.1) mm, linear to narrowly triangular apex obtuse, cream; corona filaments in 2 series, filaments of outer series 24--30, (7.5--)12.8--13.9(--16.5) mm long, white or cream tinged with purplish red at the base; filaments of the inner series (2.1--)2.9--3.4(--5.8) mm long; operculum (2.0--)2.8--3.1(--4.5) mm, closely plicate; limen erect; androgynophore 6.1--10.2 mm long, green; stamens with filaments 4.6--4.9 mm long; anthers (3.5--)4.7--5.0(--6.2) × (1.0--)1.6--1.8(--2.5) mm; ovary 3.1--5.7 × 1.6--2.8 mm, narrowly ovoid, sharply 6-angled, densely puberulous; styles (3.8--)5.2--5.7(--7.0) × 0.3--0.5 mm; stigma (1.1--)1.6--1.9(--2.8) mm diam. Fruit (65--)72--79(--90) × (18--)24--25(--36) mm, ellipsoid to fusiform, 6-keeled, dark reddish or purplish red; stipe 5.4--18.9 mm long; seeds 3.6--3.8 × 2.0--2.3 mm, transversely sulcate with 7--9 sulci, slightly rugulose ridges.

Distribution and Ecology: Southeastern Mexico, northeastern Guatemala and Belize in tropical wet forests from sea level to 350 m. altitude, mainly on the edges of primary forest.

Phenology: Flowers observed in Feb, March and from June to December. Fruits from June to August and from October to December.

Selected specimens examined: BELIZE. **Corozal:** Cerros Maya Ruins, Lowry's Bight, coastal area, 18°20'58"N 088°21'51"W, 29 Mar 1981, *C. J. Crane* 176 (LL); Corozal, 18°23'N 088°23'W, *P. H. Passiflora rovirosae can be distinguished from *P. costaricensis* by its short indumentum and 5-angular stem, *P. costaricensis* has 3-angular stem and long indumentum. Very rarely *P. rovirosae* can have a bract-like structure ca. 0.5 mm long associated with the flower (see *Matuda* 3283).

13. ***Passiflora rubra*** L. Sp.Pl. 2:956(1753)

TYPE: Caribbean: Jamaica, Browne s. n. (lectotype, LINN).

Granadilla rubra (L.) Moech, Suppl. Meth. 15. 1802. – *Decaloba rubra* (L.) M. Roem., Fam. Nat. Monogr. 2:153. 1846.

Vine 2--3 m long, densely, softly pubescent, slightly woody. Stems 3--4-angular. Stipules (2.7--)4.2--4.9(--7.1) × (0.2--)0.4--0.6(--0.8) mm, linear to linear triangular, more or less falcate, very sparsely pubescent abaxially; petiole (9--)17--23(--40) mm long; lamina (4.0--)5.4--6.6(--9.5) × (4.7--)7.0--8.5(--12.4) cm, very broadly obovate to depressed obovate, deeply cordate at the base, densely hirsute abaxially with trichomes 0.2--0.7 mm long, sparsely hirsute adaxially with trichomes 0.2--0.8 mm long, 2-lobed, the lateral lobes acuminate to acute; the angle between the lateral veins (48--)66--75(--108)°. Peduncles (9--)21--25(--62) mm long, slender, solitary or in pairs; floral stipe 1.0--3.5 mm long; flowers (27--)35--38(--49) mm diam., greenish white or pale yellow-green; sepals (11.7--)14.8--15.9(--24.5) × (2.2--)3.2--3.8(--5.4) mm, narrowly triangular, sparsely hirsutulous pubescent outside, apex acuminate, pale green to white (base pink); petals (6.4--)8.9--9.8(--11.8) × (1.0--)1.8--2.1(--2.8) mm, linear to narrowly triangular, apices slightly praemorse, white; corona filaments in 1(2) series, filaments of outer series 24--32, (8.1--)9.9--10.8(--17.2) mm long, white with pink base; filaments of the inner series (0.4--)1.3--1.5(--2.3) mm long; operculum (1.0--)1.3--1.5(--2.3) mm; limen erect; androgynophore 5.5--8.0 mm long, green; stamens with filaments (2.7--)3.8--4.2(--4.8) mm long; anthers (2.8--)3.4--3.6(--4.5) × (1.0--)1.3--1.5(--2.0) mm; ovary 2.1--4.0 × 2.1--3.0 mm, ovoid to spherical, densely whitish hirsute; styles (1.7--)3.0--3.5(--4.3) × 0.3--0.4(--0.7) mm; stigma (0.7--)1.0--1.2(--1.6) mm diam. Fruit (11--)29--32(--48) × (10--)13--16(--32) mm, globose to ovoid, 6-ribbed, reddish brown, dark purplish red or red; stipe 0.8--2.9 mm long; seeds (2.7--)3.1--3.4(--3.8) × (1.4--)1.7--1.8(--2.2) mm, transversely sulcate with 6--7 sulci, smooth ridges, apex with a large projection oriented to one side.

Local Names: “*Pasionaria de cerca*” (Cuba); “*liane couleuvre*” (Haiti); “*bull hoof*.” “*Dutchman’s laudanum*” (Jamaica).

Distribution and Ecology: From the Bahamas, throughout Greater and Lesser Antilles to Trinidad and Tobago at 50 to 1300 m altitude.

Phenology: Flowers and fruits are observed throughout the year.

Selected specimens examined: CARIBBEAN. **Guadeloupe:** 11 Nov 1942, A. Questel 5012 (US); 10 May 1936, H. Stehlé 1851 (US); 25 Jul 1937, H. Stehlé 2704 (US);

14. ***Passiflora sanguinolenta*** Mast. & Linden. Gard. Chron. 1868: 1162(1868)

Type: locality unknown, probably Loja, Ecuador or Northern Peru, *Wallis s.n.* (holotype, K not seen).

Passiflora mastersiana Harms, Bot. Jahrb. Syst. 18(Beibl. 46): 8. 1894. – TYPE: Ecuador: Loja. Las Juntas et Pucala, 1800--2200 m, *Lehmann* 4836 (holotype, B (destr); isotypes, F, GH, K not seen, S).

Vine 2--3 m long, densely villous throughout. Stems 3-angular, striate. Stipules (1.3--)2.8--3.4(--5.9) × (0.2--)0.3--0.4(--0.8) mm, linear, setaceous; petiole (5--)12--17(--44) mm long; lamina (2.1--)3.7--4.7(--10.2) × (3.2--)4.4--5.7(--12.2) cm, depressed obovate, cordate at the base, densely hirsute pubescent abaxially with trichomes 0.2--0.8 mm long, sparsely hirsute adaxially with trichomes 0.2--0.8 mm long, 2(--3)-lobed, the lateral lobes obtuse to acuminate (the central lobe reduced and obtuse); the angle between the lateral veins (42--)56--64(--85)°. Peduncles (4--)18--21(--40) mm long, solitary; floral stipe 2.5--4.8 mm long; flowers are red or reddish violet; floral tube (9--)11--14(--16) × (4--)6--7(--11) mm reddish; sepals (19.4--)25.0--26.5(--29.0) × (3.2--)3.6--4.8(--5.8) mm, narrowly triangular, sparsely hirsutulous pubescent outside, apex acuminate, reddish; petals (15.0--)17.8--21.5(--24.1) × (1.5--)2.3--2.4(--3.3) mm, linear to narrowly triangular; apex obtuse, reddish; corona filaments in 2 series, filaments of outer series 28--30, (2.7--)5.7--6.6(--17.7) mm long, red with white apex; filaments of the inner series (0.9--)1.5--1.7(--2.7) mm long; operculum 1.4--1.9 mm; limen erect; androgynophore 14.7--29.1 mm long, green; stamens with filaments (3.1--)4.1--4.8(--7.2) mm long; anthers (3.5--)4.1--4.2(--4.7) × (1.3--)1.5--1.9 mm; ovary 2.3--7.3 × 1.0--3.2 mm, ellipsoid to ovoid, densely puberulous to villous; styles (2.6--)3.4--3.6(--4.0) × 0.2--0.3 mm; stigma (0.6--)0.8--1.0(--1.4) mm diam. Fruit (20--)32--35(--53) × (8--)12--13(--27) mm, ellipsoid or fusiform, slightly to sharply hexagonal, dark red; stipe 3.9--9.5 mm long; seeds (2.1--)2.5--2.9(--3.3) × (1.4--)1.7--1.9(--2.5) mm, transversely sulcate with 7--8 sulci, the ridges slightly rugulose.

Distribution and Ecology: Mountains of southern Ecuador from 800 to 2800 m altitude.

Phenology: Flowers observed in September to February. Fruits in January, February, and in September to November.

Selected specimens examined: ECUADOR. **El Oro** : Between Chaguarpamba and Balzas, 03°49'15"S 079°48'15"W, 15 Nov 1982, *G. Harling et al.* 20757 (AAU, GB); **Loja:** btw. 15. *Passiflora tenella* Killip. J. Wash. Acad. Sci. 20: 375(1930)

TYPE: Peru: Túmbez: SE of Hacienda La Choza, 100 -- 200 m, *Weberbauer 7704*

(holotype, F; isotypes, G, K not seen, MO photo, US not seen).

Vine 10--50 cm long, glabrous throughout. Stems subangular, striate. Stipules (1.1--)1.9--2.3(--3.5) × (0.1--)0.2--0.3(--0.5) mm, linear; petiole (9--)17--21(--30) mm long; lamina (1.3--)2.1--2.5(--3.2) × (3.2--)4.9--5.8(--7.6)cm, depressed obovate, cordate at the base, sparsely pilose abaxially with trichomes 0.5--1.0.mm long, sparsely pilose adaxially with trichomes 0.6--1.2 mm long, 3-lobed, the lateral lobes acute, the central lobe retuse or obtuse; the angle between the lateral veins (88--)111--119(--134)°. Peduncles (7--)15--18(--22) mm long, solitary (pairs); floral stipe 0.4--0.9mm long; flowers (14.7--)15.1--15.9(--16.8) mm diam., greenish white; sepals (5.7--)7.6--8.3(--10.8) × (0.7--)1.3--1.7(--2.4) mm, narrowly linear or narrowly elliptic, sparsely pilose pubescent outside, apex acute, greenish white; petals (2.1--)2.9--3.3(--4.0) × 0.8--1.0(--1.1) mm, linear to narrowly triangular, apex retuse, greenish white; coronal filaments in 2 series, filaments of outer row 20--26, (4.2--)6.1--7.1(--9.6) mm long, greenish white; filaments of the inner row 0.9--1.1(--1.2) mm long, violet tinged; operculum (0.4--)0.7--0.9(--1.2) mm, slightly plicate; androgynophore 2.8--4.8 mm long, green; stamens with filaments 2.0--2.3(--2.5) mm long; anthers (1.1--)1.6--1.8(--2.1) × (0.6--)0.7--0.9(--1.1) mm; ovary 1.4--1.9 × 0.8--1.3 mm, narrowly ellipsoid, glabrous (sparsely puberulous); styles (1.7--)2.5--3.0(--4.1) × 0.1--0.2 mm; stigma (0.2--)0.3--0.5 (--0.6) mm diam. Fruit (17--)23--26(--32) × (5--)6--7(--11) mm, ellipsoid to fusiform acuminate at apex, 6-ribbed; stipe 0.8--1.9 mm long; seeds (2.3--)2.7--2.9(--3.1) × 1.4--1.6(--1.8) mm, ovate, transversely sulcate with 4--5 sulci, the ridges strongly rugulose.

Distribution and Ecology: Dry coast of Peru and Ecuador in degraded primary dry forest from 0 to 450 m altitude mainly on forest edges and roadsides.

Phenology: Flowers and fruits observed in January to April, August and November.

Selected specimens examined: ECUADOR. **El Oro** : "Bosque Petrificado Puyango", slopes from Mirador #2 to rock pools, 03°52'30"S 080°05'01"W, 26 Feb 1997, *B. B. Passiflora tenella is a poorly known species from dry coastal Ecuador and Peru that is apparently a diminutive annual; the plant reaches only 90 cm tall. The fruit does not appear to be a capsule and the seeds have transversely rugulose ridges unlike those other members of section *Xerogona*, but the shape of the leaves and the absence of floral bracts and laminar nectaries suggest affiliation with this section, molecular studies of section *Xerogona* (Porter-Utley comm. pers.) place *P. tenella* as sister to the rest of the section.

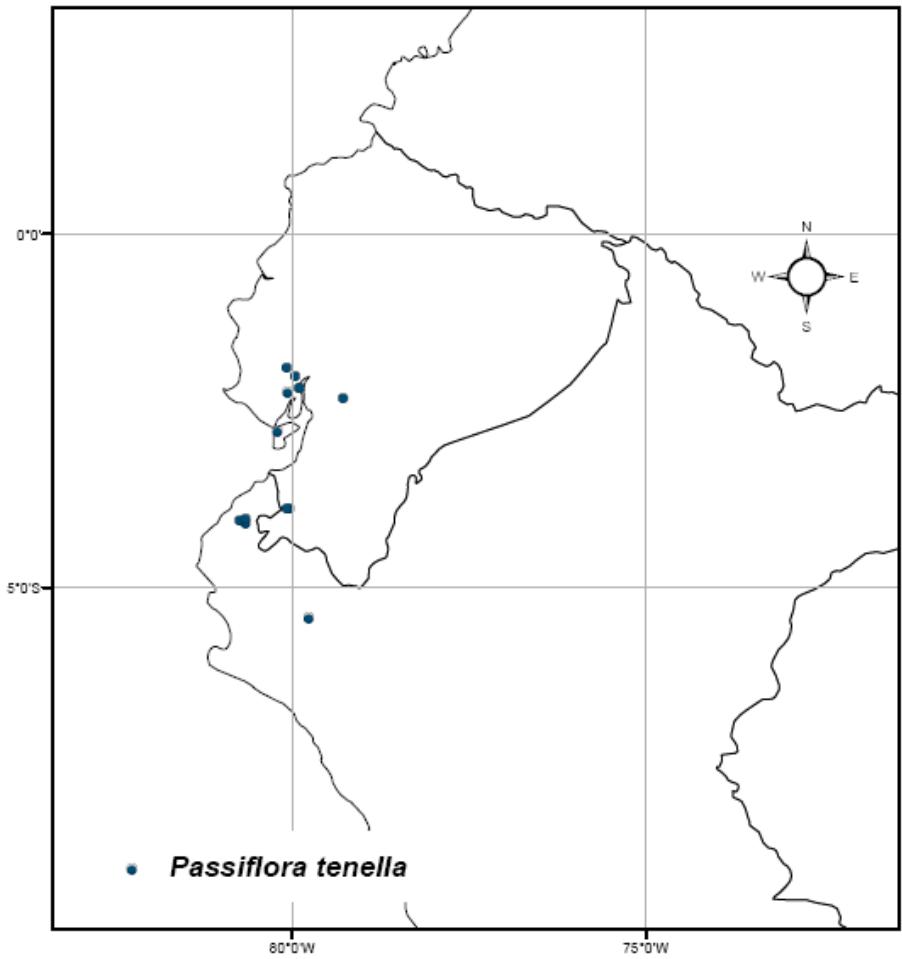

Figure 28. Distribution of *Passiflora tenella*.

Plate 15. *Passiflora tenella* Killip. A. Fruit (*Jørgensen 2455*). B. Flower (*Jørgensen 2455*). C. Seed (*Jørgensen 2455*).
