Abstract

Objectives: Metabolic syndrome causes complications like cardiovascular disease and type 2 diabetes mellitus (T2DM). As metabolic syndrome develops, altered levels of cytokines and microRNAs (miRNA) are measurable in the circulation. We aimed to construct a panel detecting abnormal levels of cytokines and miRNAs in patients at risk for metabolic syndrome. **Methods:** Participants included 54 patients from a Family Medicine Clinic at Marshall University School of Medicine, in groups of: Control, Obese, and Metabolic Syndrome (MetS). **Results:** Serum levels of leptin, adiponectin, leptin: adiponectin ratio, IL-6, six miRNAs (320a, 197-3p, 23-3p, 221-3p, 27a-3p, and 130a-3p), were measured. Among the three groups, leptin, and leptin: adiponectin ratio, and IL-6 levels were highest in MetS, and levels in Obese were greater than Control ($p > 0.05$). Adiponectin levels were lower in Obese compared to Control, but lowest in MetS ($p < 0.05$). MiRNAs levels were lowest in MetS, and levels in Obese were lower than Control ($p > 0.05$). **Conclusion:** Our results support the clinical application of biomarkers in diagnosing early stage MetS, which will enable attenuation of disease progression before onset of irreversible complications. Since West Virginians are high-risk for developing MetS, our biomarker panel could reduce the disease burden on our population.

Key words: metabolic syndrome, microRNA, serum biomarkers, West Virginia.

Introduction

Adults in West Virginia have the highest prevalence of T2DM and hypertension in the US and are the second most obese state in the country [1]. As these conditions are associated with MetS, we conjecture that among adults, West Virginia has a high prevalence of this disease. MetS manifests as an aggregate of disorders including hypertension, central obesity, hyperglycemia, dyslipidemia, and insulin resistance. The nature of MetS is multi-factorial; delineating mechanisms of the pathogenesis is a

complex and unfinished task [2]. As a chronic disorder, MetS progresses discretely until potentially devastating complications arise [3-6]. Medical expenses of patients with MetS are higher than those without MetS with a 20% increase in cost for every additional component of MetS [7, 8]. Due to the indolent nature of MetS, the financial burden and the healthcare disparities, populations like those in West Virginia suffer a significant disease burden. Along with comprehensive community based programs for

disease management, prevention, and early intervention are vital components for combatting this disease [9]. Since this profoundly impacts our population, it is vital to determine a method that reduces MetS and associated complications [2].

From a literature review, we extrapolated biomarkers suitable for inclusion in a panel for MetS detection [2]. Leptin is found at increased levels in patients with MetS and specifically with abdominal obesity, and insulin resistance [10] [11-13]. Increased adiponectin levels improve insulin sensitivity, vasodilation, and lipid oxidation, while protecting against atherogenesis [14-16]. Levels are low in people at risk for developing T2DM, hypertension, and obesity [17, 18]. The leptin to adiponectin (LAR) ratio overcomes the limit that exists in the values of adiponectin and leptin during the fasting versus postprandial state [19]. MetS induces an inflammatory state, increasing levels of the pro-inflammatory cytokines, such as IL-6. IL-6 levels correlate with elements of MetS, MetS alone, and the severity of MetS [20-22].

MiRNAs are small single-stranded RNA molecules that alter gene expression by preventing translation; this happens after transcription coding messenger RNA is modified or silenced by miRNA [23, 24]. MiRNAs are transported into the circulation and function in various pathways such as metabolism [23, 25, 26]. A dysregulated metabolic process is caused by abnormally functioning miRNAs and is implicated in the development of CVD, MetS, and T2DM [23]. The use of miRNAs for clinical testing of disease is applicable since numerous studies conclude that a statistically significant variance exists between the control groups and people with metabolic disease. As reported in the literature, we selected miRNAs that correlated with components of MetS for the panel in our study. MiRNAs: 320a, 197-3p, 23-3p, 221-3p, 27a-3p, and 130a-3p exhibit altered levels correlating with pathophysiological components of MetS [24, 25, 27-32]. Levels of miR-320a, miR-27a-3p, miR-130a-3p, miR-23-a and miR-221 vary in the circulation of patients with MetS [25, 30, 33]. Studies revealed that levels of miR-130a-3p, miR-221, miR-197, and miR-23-a, corresponded to states of obesity [25, 30, 33]. Circulating levels of miR-23-a, miR-197, miR-27a-3p, and miR-130a-3p vary in the circulation of patients with hypertension [25, 30, 33]. Previous studies demonstrated the existence of a relationship between varied blood glucose levels and miR-320a miR-197 [25, 30, 33]. In patients with known insulin resistance miR-130a-3p and miR-320a tend to exhibit variation in circulating levels [24, 25, 30]. MiRNAs appear to be useful for pre-clinical diagnosis, since they are more sensitive and specific for early

diagnosis, risk assessment and monitoring disease progression [24]. MiRNAs exhibit remarkable stability under harsh conditions such as: pH, temperature, storage, and multiple freeze-thaw cycles [24, 31].

A panel of biomarkers used to diagnose MetS in the early stage, allows for prevention of debilitating conditions that accompany MetS [34]. In this study we measured serum biomarkers and miRNA associated with MetS. We studied a group of adult females in West Virginia with normal BMI, obesity and a diagnosis of MetS. Our objectives for this study included: detecting circulating levels of biomarkers associated with MetS in patients at risk for developing this disease and developing a biomarker panel providing early detection, risk assessment and monitoring of MetS. A biomarker panel for MetS, with the potential for prevention and early intervention, could greatly impact populations at high risk for the disease, such as the people of West Virginia [2].

Material and Methods

Patients

A total of 54 adult females, visiting the Family Medicine Clinic at Marshall University School of Medicine, were enrolled in this study and each signed an informed consent. The patients were grouped into categories based on BMI and MetS diagnosis: 1. Control group with a BMI <30; 2. Obese group with a BMI \geq 30 and no clinical diagnosis of MetS, and 3. MetS, patients carrying a clinical diagnosis of MetS. Patients with malignancy, trauma or age under 18 or over 45, were excluded from this study. Trained personnel followed a standard protocol to measure the height, weight, waist circumference (midway from the lowest rib to the iliac crest to the nearest 0.1 cm), and blood pressure of each patient. BMI was calculated for the individual by dividing weight (kg) by the square of height (m). The Ethics Committee of the Cabell Huntington Hospital, West Virginia approved this study.

Blood Samples

Study patients had venous blood drawn from an antecubital vein in EDTA tubes after fasting for at least 8 hours. The blood obtained was intended to acquire levels of inflammatory cytokines, miRNA, blood glucose levels, and lipid panels. Blood samples were processed by spinning blood at 3000 rpm for 10 minutes at 4°C. Serum for cytokine and miRNA analysis was frozen at -80°C prior to analysis. The laboratory, at Cabell-Huntington Hospital, analyzed blood for glucose levels and lipid panels; these values were obtained from the patient chart.

Biomarker Quantification

Enzyme-linked immunosorbent assays (ELISA) were used to determine levels of leptin (EMD Millipore Corporation, Billerica, MA), HMW adiponectin (Abcam plc, Cambridge, UK), IL-6 (R&D Systems, Inc., Minneapolis, MN). All protocols provided by the manufacturer were followed for each ELISA kit.

Extraction of miRNA

We performed RNA extraction using the miRNeasy SerumPlasma Kit (Qiagen, Hilden, Germany) according to the manufacturer's instructions. 1 ml of QIAzol reagent was added to 200 µl of serum sample. The samples were vortexed in a tube, followed by the addition of 200 µl of chloroform. After mixing vigorously, the samples were then centrifuged at 12,000 g for 15 min at 4°C. The upper aqueous phase was transferred to a new collection tube, and 900 µl of absolute ethanol was added. The samples were then applied directly to columns and washed. Total RNA was eluted in 14 µl of nuclease-free H₂O. The quality and quantity of RNA were evaluated by 260:280 ratio using NanoDrop analyzer (Thermo Scientific). For RT reaction, we used the miRCURY LNA Universal RT microRNA PCR Kit (Exiqon, Vedbaek, Denmark). Each RT reaction used 50 ng of total RNA. Total RNA was combined with 4 µl of 5x reaction buffer, 9 µl of nuclease-free water, 2 µl of enzyme mix and 0.5 µl of synthetic spike-in to a final volume of 20 µl. The RT-PCR was set as follows incubated at 42°C for 1 h, heat-inactivated at 95°C for 5 min and immediately cooled to 4°C. The expression levels of miRNA in serum samples were studied with a SYBR-based quantitative PCR using a miRNA specific primer and ExiLent SYBR Green Master mix (Exiqon). To normalize the miRNA expression the internal control, the synthetic spike-in, was used. The expression levels of miRNA were then assessed by real-time quantitative PCR (qRT-PCR) according to the manufacturer's instructions. A 4 µl aliquot of 40x diluted cDNA template was combined with 5 µl of SYBR green master mix and 1 µl of PCR primer mix to a final volume of 10 µl. Two technical replicates per sample were used for qRT-PCR amplification run on a 7500 Fast Real-Time PCR Systems (Applied

Biosystems). The sequence of miRNAs are listed below.

Table A: Sequence of miRNAs.

| miRNA | sequence |
|-----------------|------------------------|
| hsa-miR-320a | AAAAGCUGGGUUGAGAGGGCGA |
| hsa-miR-197-3p | UUCACCACCUUCUCCACCCAGC |
| hsa-miR-23-3p | AUCACAUUGCCAGGGAUUUC |
| hsa-miR-221-3p | AGCUACAUGUCUGCUGGGUUUC |
| hsa-miR-27a-3p | UUCACAGUGGCUAAGUUCGCG |
| hsa-miR-130a-3p | CAGUGCAAUGUUAAAAGGCAU |

Statistical Analysis

Data analysis was performed using GraphPad Prism 4.0. Within each of the three patient categories, Bartlett's test was applied for each biomarker to guarantee equal variance. For each biomarker, differences of statistical significance were identified in the average serum levels using ANOVA. Specification of the patient groups that showed statistically significant variances for the biomarker measured was achieved using the Turkey post-hoc test.

Results

In the clinic, 54 patients were recruited into the study and placed in one of three groups: individuals with a normal BMI and no MetS (n=24), obese individuals with no clinical diagnosis of MetS (n=17) and obese individuals with a clinical diagnosis of MetS (n=16). All participants were adults and female. There was no difference between the groups in the mean age ratio. Adult females with MetS showed significant differences in clinical markers compared to those without MetS. Additionally, obese adult females and adult females with MetS showed significant differences in the cytokines and miRNA associated with MetS compared to the Control patients.

Clinical markers of MetS

As shown in table 1, Systolic blood pressure was significantly elevated in Obese and MetS patients compared to Control (p<0.01). Fasting blood glucose and triglycerides were significantly elevated in patients with MetS only (p<0.01). HDL was decreased in the MetS group (p<0.01). These are the variables included in the IDF definition of MetS and are used to make the clinical diagnosis of MetS [5].

Table I. Patient Demographic and Clinical Profile.

| Groups | Number of Patients | Age (yrs.) | BMI (kg/m ²) | FBS (mg/dL) | SBP (mmHg) | DBP(mmHg) | TG (mg/dL) | HDL (mg/dL) |
|---------|--------------------|--------------|--------------------------|------------------|----------------|---------------|------------------|----------------|
| Control | 24 | 33.29 (±1.4) | 23.30 (±0.7) | 88.05 (±1.5) | 111.73 (±2.4) | 69.86 (±2.1) | 94 (±7.2) | 62.84 (±2.9) |
| Obese | 17 | 38.5 (±2.3) | 43.57 (±2.95) | 87.83 (±2.2) | 130.58 (±4.2)* | 77.76 (±3.1) | 81.5 (±7.2) | 66.67 (±2.9) |
| MetS | 16 | 38.5 (±2.2) | 48.5 (±3.73) | 111.62 (±7.2)* # | 136.3 (±4.9)* | 85.75 (±1.5)* | 141.86 (±9.4)* # | 43.4 (±1.8)* # |

Values represent means ± SEM. *p<0.01 vs. Control, # p<0.01 vs. Obese. Body mass index (BMI), Fasting blood sugar (FBS), Systolic blood pressure (SBP), Diastolic blood pressure (DBP), Triglyceride (TG), High density lipoprotein (HDL) in Control, Obese and MetS patients.

Serum cytokine biomarkers

Adipokines, leptin and adiponectin, are bioactive substances released by adipocytes that control appetite, promote effective glucose use, and enhance insulin sensitivity. As adipocytes accumulate in obesity, these cytokines become dysregulated initiating MetS [2]. Compared to the Control group, leptin was significantly elevated in the Obese group and even more so in the MetS group ($p < 0.05$), figure 1 (A). Adiponectin was significantly decreased in the Obese group and more so in the MetS group compared to the Control ($p < 0.05$) figure 1 (B). Obese patients showed significantly higher LAR to Control and LAR in the MetS group was the highest of the three groups ($p < 0.05$) figure 1 (C). The dysregulated adipokines of MetS induce an inflammatory response and release of pro-inflammatory cytokines such as IL-6 into the circulation [2]. Our results show that IL-6 was significantly highest in the MetS group and the Obese group had higher levels of IL-6 compared to Control ($p < 0.05$) figure 1 (D).

Circulating miRNA biomarkers

Altered function and variable circulating levels of miRNAs, regulators of genetic expression, correlate with MetS and its components [25]. All six miRNAs analyzed in the circulation of these patients followed

a similar statistically significant pattern. The following miRNAs: 320a, 197-3p, 23-3p, 221-3p, 27a-3p, and 130a-3p exhibit dysregulated activity in the setting of MetS resulting in variable levels [24, 25, 27-32]. Each miRNA studied showed greatest decrease in the circulation of the MetS group but was also decreased in the obese group compared to the Control ($p < 0.05$); results depicted in figure 2 and 3 (A-C respectively).

Comparing clinical markers and serum biomarkers

Mean clinical values, mean values of serum cytokine biomarkers and serum miRNAs were compared in table 2. Among the Obese group, mean values of systolic blood pressure, leptin, LAR, IL-6 were significantly elevated compared to Control ($p < 0.01$). Levels of adiponectin and miRNAs: 320a, 197-3p, 23-3p, 27a-3p, 130a-3p, were significantly decreased in the Obese group when compared to Control ($p < 0.01$). Among the MetS group, mean values of fasting blood sugar, systolic and diastolic blood pressure, triglycerides, leptin, LAR, IL-6 were significantly elevated compared to Control ($p < 0.01$). Levels of HDL, adiponectin, and miRNAs: 320a, 197-3p, 23-3p, 221-3p, 27a-3p, 130a-3p, were significantly decreased in the MetS group when compared to Control ($p < 0.01$). Among the MetS

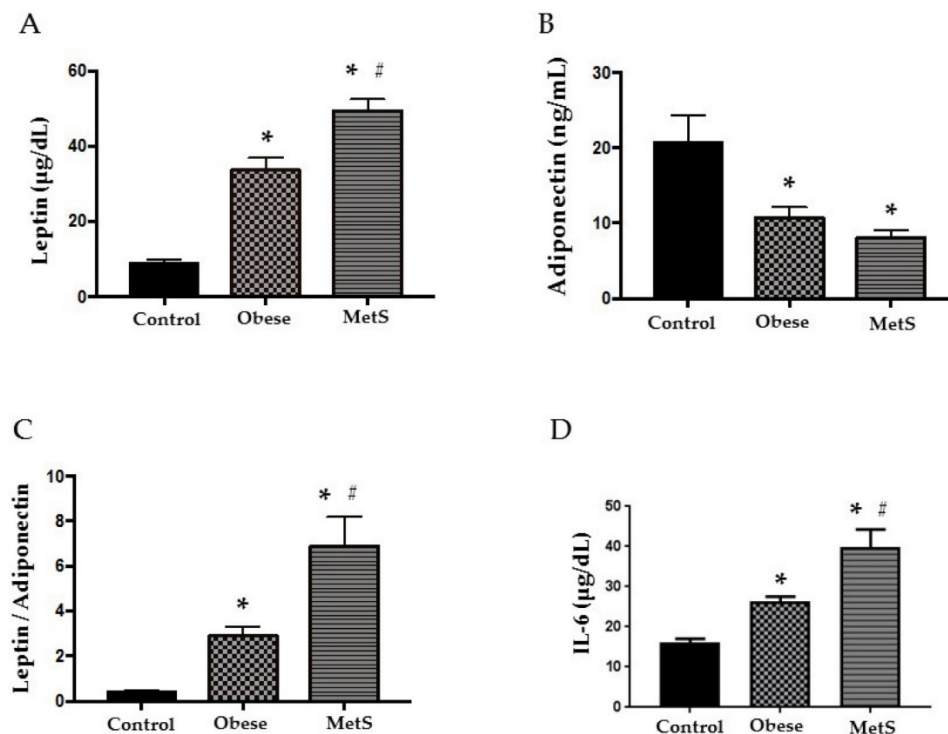

Figure 1. Cytokines. Assay of serum concentrations of (A) Leptin, (B) Adiponectin, (C) Leptin: Adiponectin Ratio, (D) IL-6 in Control (n=24), Obese (n=17), and MetS (n=16), patient groups. Values represent means \pm SEM. * $p < 0.01$ vs. Control; # $p < 0.01$ vs. Obese.

group, mean values of fasting blood sugar, triglycerides, leptin, LAR, IL-6 were significantly elevated compared to Obese ($p < 0.01$). Levels of HDL and miRNAs: 320a, 197-3p, 23-3p, 27a-3p, 130a-3p, were significantly decreased in the MetS group when compared to Obese ($p < 0.01$). The correlation between the mean values of serum cytokine biomarkers and serum miRNA from all three groups were depicted in scatterplots in figures 4-6. Adiponectin, leptin, and IL-6 values were compared to each miRNA individually in figures 4 (A-F), 5 (A-F), and 6 (A-F) respectively.

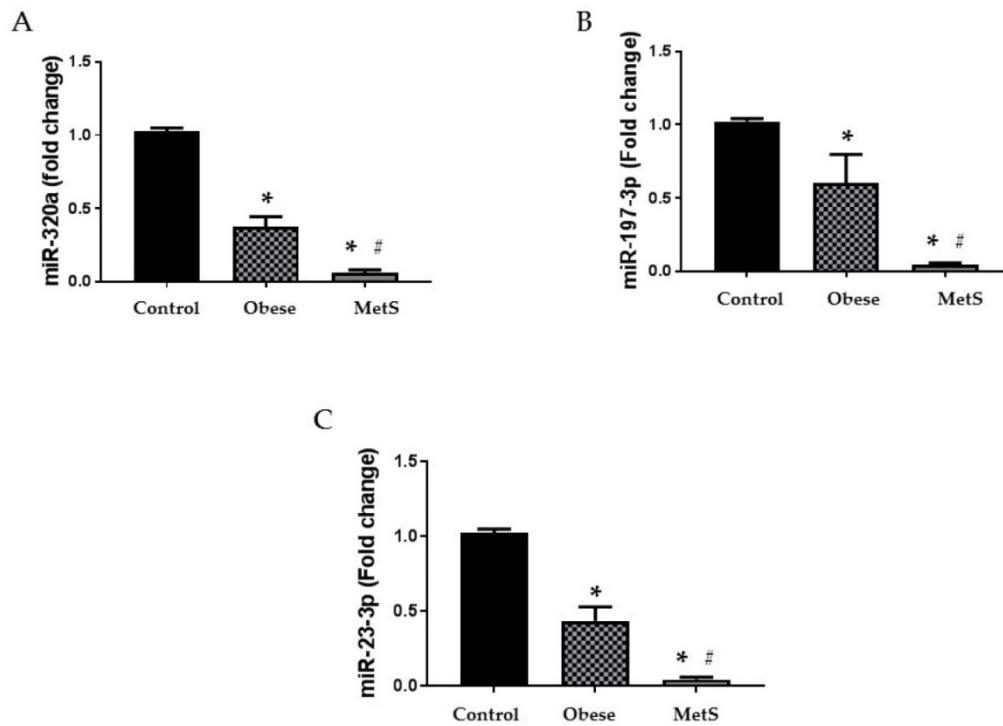

Figure 2. Circulating miRNAs. Assay of serum concentrations of circulating (A) miR-320a, (B) miR-197-3p, and (C) miR-23-3p in Control (n=24), Obese (n=17), and MetS (n=16), patient groups. Values represent means \pm SEM. *p<0.01 vs. Control; # p<0.01 vs. Obese.

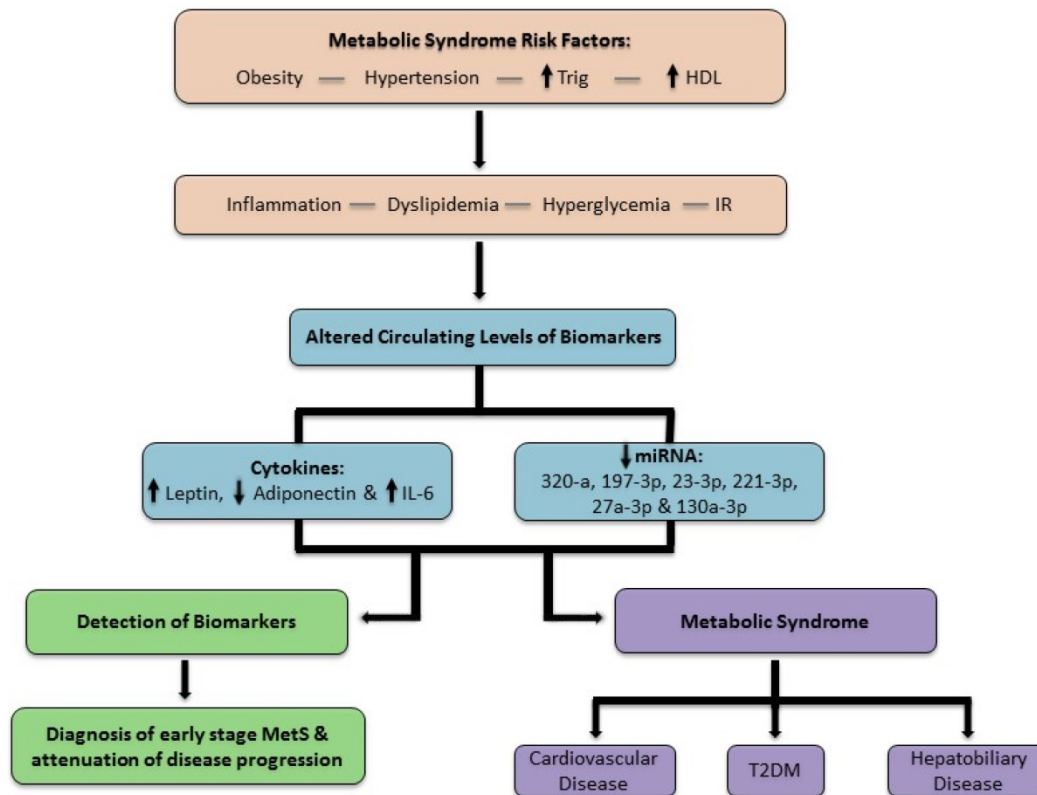

Figure 7. In this scheme, the progression of MetS is represented. Once the patient is at risk for MetS, pathophysiological changes alter biomarker levels. If a biomarker profile permits the diagnosis of MetS in the early stage, then disease progression is impeded prior to the onset of irreversible sequel.

Discussion

The results of our study indicate that a panel of biomarkers has a significant role in the detection of early stage MetS, before irreversible complications develop. Our results demonstrate statistically significant circulating levels of cytokines and miRNA associated with MetS displayed in a profile unique to each group of our population. This shows that pathologic changes occurring at the cellular level are translated through our data prior to perceptible clinical markers. This approach improves the recognition and diagnosis of MetS and is summarized in the schematic diagram, figure 7. Furthermore, a pattern of disease progression is evident in the biomarker profile. These trends are unique to the population of adult West Virginian females with obesity and MetS in our study. Our study indicated altered levels of cytokines (leptin, adiponectin and IL-6) and decreased levels of miRNAs (320-a, 197-3p, 23-3p, 221-3p, 27a-3p and 130a3p) appear in the circulation of patients indicating early stage MetS.

MetS is a multifactorial disease, and delineating pathogenic mechanisms is complex; however, insulin resistance and central obesity are instrumental in disease development. Current strategies of diagnosing MetS rely on lipid, insulin and glucose

levels, blood pressure and BMI or waist measurements [5]. Criteria that meet diagnosis of MetS indicate pathologic conditions of these levels and measurements. Once these indicators coincide with the diagnosis of MetS, complications develop with an increased risk of permanent disability and mortality, emphasizing the need to diagnose MetS in the early stage.

Dysregulation of leptin and adiponectin contribute to the progression of MetS. Deleterious effects of high levels of leptin, as in MetS, include: angiogenesis, hypertension, atherosclerosis and myocardial remodeling [14, 35, 36]. Leptin levels were highest in the MetS group and elevated in the Obese group compared to Control in our results. Elevated levels of circulating leptin indicate the metabolic changes are progressing to MetS. Protective properties of adiponectin fade at lower levels and are negatively correlated with glucose, insulin, and triglyceride levels, as well as adipose tissue accumulation and elevated blood pressure [12, 35, 37]. Consistent with previous studies, our data identified decreased levels of adiponectin in the MetS and Obese groups, indicating that disease progression of MetS occurs before recognition of current clinical measures.

The inflammatory state of MetS causes the release of the cytokine IL-6. In obesity, reactive

oxygen species are formed from high levels of lipid oxidation, which precipitates systemic stress and the release of inflammatory cytokines [38]. In this dysregulated environment, IL-6 activates receptors to induce insulin resistance. IL-6 damages vascular endothelium to initiate atherosclerotic plaque formation [39-41]. Circulating levels of IL-6 correlate with the severity of MetS [20-22]. In our data, IL-6 was increased in the Obese and even more so in the MetS group establishing congruity between elevation of this biomarker and formation of an early diagnosis of MetS.

From the literature we chose miRNAs: 320a, 197-3p, 23-3p, 221-3p, 27a-3p, and 130a-3p to investigate in our population [24, 25, 27-32]. This group was selected, based on previous studies, since they all detect MetS in the early stage. All six miRNAs were significantly decreased in the circulation of the Obese group and even more so in the MetS group. This pattern indicates the value of including these miRNAs in a biomarker panel for MetS in our population.

Levels of circulating miRNA are not uniformly expressed between studies, which may reflect intergroup variance. Expression of miR-320a is dysregulated within insulin-resistant adipocytes [25, 30, 33]. A study of patients with T2DM in the United Kingdom found levels of circulating miR-320a decreased in of patients with T2DM [32]. Conversely, a study from Singapore detected a positive correlation between circulating miR-320a and fasting blood glucose levels, up regulation of miR-320a levels in patients with MetS and T2DM was also observed [25]. In a group of Asian Indians, miR-197 negatively correlated with the level of glycemic impairment and also decreased in T2DM and among a different Asian population, miR-197 was down regulated in MetS [29, 32]. However, other studies reveal that circulating miR-197 levels are increased in MetS, decreased in hypertension and positively correlated with elevated BMI [25, 30, 33]. MiR-23-a is associated with several metabolic pathways such as: glucose homeostasis, insulin secretion, lipid and carbohydrate metabolism [31]. In a study of adult Chinese females, the levels were distinct in patients with pre-diabetes versus T2DM [31]. Circulating amounts of miR-23a vary, but are positively correlated with BMI, increased in MetS, decreased in T2DM and hypertension [25]. MiR-221 displays decreased expression in obesity [24, 33]. However, among a group of Chinese women, circulating levels of miR-221-3p were higher in non-obese with MetS [27]. Physical activity and bariatric surgery increased the expression of miR-221-3p; known to be down regulated in the circulation and adipocytes of obese individuals [30,

42]. MiR-27a-3p is a regulator in adipogenic pathways and studies report that levels are increased MetS and in T2DM, but decreased in hypertension [25, 27, 33]. Circulating miR-130a-3p exhibited variability as decreased levels in obesity, T2DM and cardiovascular disease, while levels were increased in MetS, hypertension and insulin resistance; diets low in glycemic index, decreases the expression of circulating miR-130a-3p [24, 25, 30].

MiRNAs are targets for therapeutic strategies since they are key regulators in various pathways of disease. Monitoring miRNA in the circulation could provide: evaluation of disease progression, risk, susceptibility, treatment while offering a confirmation of a preclinical diagnosis [24]. One study examined intergroup differences of circulating miRNAs associated with T2DM. Levels of MiR-144 were significantly high in a Swedish population with T2DM but not in Iraqis; ethnic variation could explain this difference [28]. Levels of miRNA signal variation between the sexes may account for the sex differences found in the cardiovascular sequela of MetS [27]. Whether this difference results from diversity of genetics, environment, diet or lifestyle remains to be determined. The use of miRNAs in clinical testing of disease is applicable as numerous studies find that they exhibit a statistically significant variance between healthy and metabolic diseased individuals. MiRNAs appear to be a useful addition to a panel of biomarkers for pre-clinical diagnosis, risk assessment, and monitoring progression of MetS [24].

Biomarkers, like cytokines and miRNA, allow clinicians to diagnose, manage and stratify a patient's risk for disease states as depicted in figure 7 (schematic). Clinical application of a panel for MetS could prompt early detection and intervention before development of systemic complications. Since biomarkers have roles in various pathways, a panel of several biomarkers increases the specificity and sensitivity of disease detection. The panel could profoundly impact populations affected by this disease, such as the people of West Virginia.

Conclusion

MetS places a major disease burden on the population of West Virginia. Although further research is necessary to determine the predictive value of the considered serum biomarkers and miRNAs in regards to MetS, our results demonstrate that the biomarkers and miRNAs studied all showed a significant correlation to the disease states of MetS and obesity in a population of West Virginia females. Our formulated biomarker and miRNA panel has significant potential for detection of MetS and attenuation of disease progression prior to onset of

irreversible complications. In turn, this could reduce the disease burden of MetS on our West Virginia population.

Abbreviations

T2DM: Type 2 Diabetes Mellitus
 miRNA/miR-: Micro-Ribonucleic Acid
 MetS: Metabolic Syndrome
 AHA: American Heart Association
 CVD: Cardiovascular Disease
 HMW: High Molecular Weight
 HDL: High Density Lipoprotein
 LAR: Leptin to Adiponectin Ratio
 BMI: Basal Metabolic Rate
 IDF: International Diabetes Federation
 EDTA: Ethylenediaminetetraacetic acid
 H: Hour
 µL: Micro Liter
 °C: Degrees Celsius
 ELISA: Enzyme-linked Immunosorbent Assay
 RNA: Ribonucleic Acid
 RT: Real Time
 cDNA: Complementary Deoxyribonucleic Acid
 PCR: Polymerase Chain Reaction
 ANOVA: Analysis of Variance
 H₂O: Dihydrogen Monoxide
 IL-6: Interleukin 6
 CDC: Center for Disease Control
