Abstract

In this study, I intend to show how text based unstructured data, such as word processor documents and e-mails, can be systematically parsed for instances of data classes. Data classes can be any data type that can be fully described using the defined syntax of regular expressions. Examples of data classes can include SHA1, or MD5 hash values, Internet Protocol (IP) addresses, or any other data type whose format is well defined. Furthermore, possible correlations between datasets may be identified by grouping instances of equal or similar values within a data class. This approach of utilizing regular expressions to define the search criteria negates the need to predetermine what keyword to search for.

Acknowledgements

I offer my sincerest gratitude to my supervisor, Mr. Sigurd Murphy, and the government lead for the section I currently support, Special Agent Kevin Rivera, who have supported me with their patience, allowing me the ability work on this project. I would also like to acknowledge Mr. Michael Burtowski, the General Dynamics Advanced Information Systems contract lead, who saw fit to approve the funding of my masters program entirely through the company's employee higher education program. The completion of this degree program would not have been possible without their belief in me, nor without their monetary support. I would like to thank my two children, Jacob and Peter, who have come to expect their father to come home and start working on his school work. They have both learned to adjust to the limited time they have available with their father, but the success to how they have matured, goes entirely to my wife, Sasha. Without her support, both in encouragement and by taking care of the kids, this project would not have been possible.

Chapter 1 – Introduction

A database system can provide an organization with the means to manage large amounts of data on customers, suppliers and other pertinent data. This is due to a relational database system's ability to handle a tremendous amount of data with relative ease. The structured query language (SQL) is also very efficient in extracting information based on patterns, providing both detail data and *big picture* information to those querying. This approach works well for data that has already been structured to conform to the underlying database schema, more problematic is when the raw data is unstructured with little possibility of transforming it into something more meaningful. According to a recent survey cited by McKendrick in Unstructured data: the elephant in the Big Data room "unstructured data is growing at a faster clip than relational data." (McKendrick, 2011) Worse still, this survey reveals that "– 91% say unstructured information already lives in their organizations, but many aren't sure what to do about it" (McKendrick, 2011).

Unstructured data can take on many forms, including audio/video, graphics, e-mails, text documents, and social media messages among others (McKendrick, 2011). Great strides have already been made on search techniques for text based unstructured data. Microsoft's Windows operating system now offer indexing of the contents of the information contained on a system's hard drives. Google's Search Appliance can also parse the contents of files located anywhere on a corporate intranet. These search capabilities however, have one significant drawback; they all require the user to know exactly what they want to search for.

There is no systematic approach to search through text based unstructured data to extract classes of data, and then group cases with similarities between extracted instances of a data class to establish possible links between the different datasets.

For certain types of organizations with large volumes of text based unstructured data; it would be valuable to provide a means to search through their volumes of unstructured data to find information whose format matches a class of data rather than a specific search term. In this context, a data class may be e-mail addresses, phone numbers, IP addresses, or zip codes or other data class types that can be fully described using an established set of rules. Furthermore, once instances of the data class have been extracted, matching values between datasets may reveal previously undiscovered connections between those datasets. A dataset, in context for this research study, are the collection of unstructured text based data all related to an individual case. Rather than providing, for example, an individual e-mail address to search for, the data class search extracts all occurrences of everything whose format looks like an e-mail address contained within the unstructured data. Cases where the same values of e-mail address are extracted may in fact be connected. Furthermore, cases that share multiple data items may have a higher likelihood of being connected to each other. Additionally, two, or more, cases with no common shared information between them, but rather show common traits with a third case may also be connected, creating a web of connections not realized solely from the original source data.

As an investigative tool, many organizations could take advantage of this type of search capability to *connect the dots* between different datasets. Examples with a need for just such a capability include law enforcement agencies, insurance companies and organizations with a counter intelligence/counter terrorism mandate.

Local police precincts regularly process a large volume of text based unstructured data. These agencies often take witness statements, incident reports, confessions, etc., that contain specifics to individual cases. Currently, to find possible connections to other suspects or cases, law enforcement officers often utilize a system called CopLink. CopLink allows officers to

perform text searches such as “for a suspect known only by his first name” (Chen, Zeng, Atabakhsh, Wyzga, Schroeder, 2003). By entering a name, the search returns other suspects with similar names. This approach requires the officer to know what he is looking for. By culling class data from their reports, what may seem like unrelated cases, may turn out to have several similarities.

Insurance companies also often process text based unstructured data as well, in the form of claim reports, claimant statements, witness statements, etc. To minimize the possibility of fraud, they regularly investigate the validity of a claimant’s statement. “Increasingly, the industry is seeking technological solutions, via two main approaches. The first, data mining, utilizes artificial intelligence and database techniques to discover patterns and inconsistencies in client records and claims histories” (Ormerod, Morley, Ball, Langley, Spencer, 2003). Common traits identified by data class searches with other claims may help identify evidence of possible fraud.

Counter intelligence/counter terrorism agencies of the federal government must process large amounts of text based unstructured data. Counter Intelligence (CI) agencies often provide “Forensic examinations that involve cyber crimes and fraud” (Laboratory Services) as well as “Forensic examinations on cases that involve security violations, espionage, classified information, and support for the war on terrorism” (Laboratory Services). CI agencies can utilize this search approach to identify links between cases that may seem unrelated otherwise.

Chapter 2 – Review of Literature and Research

Parsing unstructured text based data to identify possible connections between documents is not a new endeavor. The literature on searching unstructured text presents various algorithms and techniques to perform searches and then identify methods of grouping like documents together.

Search Techniques and Data Correlations

The ability to *connect the dots* between ideas contained in different documents has shown to be a very valuable concept. One such method to process unstructured text involves the use of Natural Language Processing (Fan, Wallace, Rich, Zhang, 2006) which has led to the creation of technologies that allow computers to process natural language (Fan, Wallace, Rich, Zhang, 2006). In Tapping the Power of Text Mining, the authors discuss the case where a University of Chicago professor, while researching articles on migraines, identified the keywords that appeared at a significant frequency (Fan, Wallace, Rich, Zhang, 2006). One such significant keyword he discovered was *spreading depression* (Fan, Wallace, Rich, Zhang, 2006). While following the same process of culling the significant keywords for documents that contained spreading depression, he found *magnesium deficiency* (Fan, Wallace, Rich, Zhang, 2006) as a keyword. The professor theorized that there may be a connection between migraines and magnesium deficiencies. "The hypothesis was made only by linking related documents from migraines to those covering spreading depression to those covering magnesium deficiency. The direct link between magnesium deficiency and migraine headaches was later proved valid through scientific experiments" (Fan, Wallace, Rich, Zhang, 2006). In this case, the searches by the professor were performed by hand but simulated the same concept-linkage technology text-mining products provide. (Fan, Wallace, Rich, Zhang, 2006) This case is significant, in that it demonstrates the

ability to tie concepts contained within unrelated documents to give insight into new intelligence not previously known without the correlation. Another method of linking documents is through *clustering* (Fan, Wallace, Rich, Zhang, 2006). Through clustering, similar documents are clustered on the fly by creating "a vector of topics for each document and measures the weights of how the document fits into each cluster" (Fan, Wallace, Rich, Zhang, 2006). Given a keyword, such as "Saturn," clustering engines may create topic vectors such as "planet, photo, car, and performance" (Fan, Wallace, Rich, Zhang, 2006), with users narrowing the choices for which types of documents to present to the user. International Business Machines' (IBM) Text Navigator application uses clustering methods to group document together according to their contents and annotates each document with the two most frequently used words in the group of document clustered together (Feldman, 2006). To further enhance clustering results, parsing documents for terms will also increase the accuracy of how each document is clustered. Term extraction will need to be processed by an actual human reader that creates tokens of parts of speech. Examples may include terms such as "[wall] and [street]" (Feldman, 2006,). This process increases the need for human interaction to process each document to extract terms; however it reduces the number of insignificant results (Feldman, 2006).

Another novel approach to processing unstructured data is discussed by the authors of Efficiently Linking Text Documents with Structured Information. Their approach attempts to link the contents of unstructured data with the instances of data already within a structured database. As an example, they cite an organization with a network of multiple stores but have an inflow of complaints into a centralized location. Complaints can come from various sources, such as web-form, email, fax and voice-mail that are "typically a free-flow narrative text about one or more sales transactions" (Chakaravarthy, Gupta, Roy, Mohania, 2006). The actual complaint may

not contain specific data to identify a particular transaction, but may reveal information such as the store name, partial list of items bought, or the purchase dates that can assist in creating a list of possible transactions that can be acted upon to address the complaint. To accomplish this task, documents are viewed as a "sequence of sentences where a sentence is a bag of terms" (Chakaravarthy, Gupta, Roy, Mohania, 2006). Some of the terms are potentially useful since they also come up in the database as well, such as a store location. A part-of-speech parser is used to identify the nouns in sentences contained within the complain, and filters out the rest with the assumption being made that the nouns are more likely to appear as values in the database (Chakaravarthy, Gupta, Roy, Mohania, 2006). To optimize the process of linking terms to a possible entity, the approach utilizes a context cache that can be viewed as a set of relationships of the form *(e, t)* meaning that the term *t* is contained in the context of the entity *e* (Chakaravarthy, Gupta, Roy, Mohania, 2006). The two operations that actually accesses the database are "*GetEntities(t)*" and "*GetTerms(e)*" (Chakaravarthy, Gupta, Roy, Mohania, 2006). GetEntities(t) is defined as "given a term t appearing in D, this operation queries the database and returns the set of all entities that contain the term t in their context." GetTerms(e) is defined as "given an entity e, this operation queries the database and returns the set of all terms from D that are contained in the context of e" (Chakaravarthy, Gupta, Roy, Mohania, 2006). As a final entry on combining structured data with unstructured, the authors of Text-to-Query: Dynamically Building Structured Analytics to Illustrate Textual Content propose a framework for presenting a query to a database by simply using natural language statements. They propose a scenario in which a travel agency, which manages reservations for multiple resorts around the world that would like to prepare specific graphs. By typing "Sales analysis by region" (Thollot, Brauer, Barczynski, Aufaure, 2010) several appropriate sales chart are generated and made available to be selected. If the user

further adds a specific resort as a detail, additional charts showing the amount of sales in the specific resort are added. To accomplish this, the framework relies on three components which are described as "metadata stored in a data warehouse, a state-of-the-art entity extraction framework and pre-defined analysis categories" (Thollot, Brauer, Barczynski, Aufaure, 2010). The data warehouse is designed to hold "multi-dimensional OLAP cubes that can be defined over a structured database" (Thollot, Brauer, Barczynski, Aufaure, 2010). The cubes are defined to hold numerical facts and can be aggregated against different dimensions. Furthermore, a user can drill down, or filter on some specific value to restrict the scope of analysis. The entity extraction is defined over "57 predefined entity types such as person, organization or geographic location" (Thollot, Brauer, Barczynski, Aufaure, 2010). Additionally, this list can be further supplemented with extra dictionaries, "capturing canonical and alternative names to recognize custom entities" (Thollot, Brauer, Barczynski, Aufaure, 2010). Categories are generated from the data warehouse and each category is associated with the terminology that related to it. To actually extract the data from the warehouse database, a "large dictionary that contains reference entities to be extracted in text documents" (Thollot, Brauer, Barczynski, Aufaure, 2010) are automatically generated.

Chapter 3 – Methodology

As stated purpose of this research project is to develop a method to systematically search case-related, text based unstructured data to extract instances of data classes, and then identify possible associations among those instances based on similarities within the extracted data classes. To accomplish this goal, a series of software tools and applications were designed and developed. To act as the data repository, a database system to house basic case related data in conjunction with the documents that pose as the unstructured text was developed. Additionally, the database system is also responsible for managing the case indicators, which are the instances of the data classes extracted from the documents. A database schema was modeled to manage these data items, and was instantiated on a MySQL database server; the database creation script is included in Appendix A. The database was then populated with basic case data and representations of documents posing as the unstructured text based data associated with specific cases. With the database instance in place, a Windows based case viewer application used to insert and manipulate the data held within the database was created. The case viewer tool would serve as an organization's main portal to manipulate and view case related data, including the documents. To perform the regular expression searches, an additional Windows based application was developed that would systematically parse each document contained within the database against a series of regular expressions designed to extract the case indicators. In conjunction with the application, the actual regular expressions were developed and tested to ensure they extracted the data as expected. Additionally, since it would be reasonable to expect an organization to desire the scanning of their documents to be automated as they are added and modified within the repository a Windows based service application was developed. The service application runs in the background on an application server computer with minimal user

interaction. This is ideal for large organizations with constant additions and updates to their document set. The method each of these tools utilizes is detailed in the following section, along with an explanation of how each tool contributes toward the satisfying of this research project.

Database Schema

The design of the database schema was made to handle several data areas pertinent to this research project. The primary data area housed within the database is the data related to each case along with the documents associated with a case. As stated above, presumable, an organization would already have this portion of their database already established. The secondary area of the database schema is dedicated to providing support to hold the regular expressions that define the data classes and the case indicators extracted from the documents.

This schema subdivides all cases by year; this was desirable for this research project to simplify the display of case data within the case viewer application that was developed. An organization may decide not to follow this model if their data does not lend itself to being subdivided by year. Additionally, no additional data of importance is being maintained at year table level; however, an organization may choose to keep year specific data if they so choose. The case_file table is responsible for capturing essential facts about a particular case. For this research project, the data maintained at the case_file level is also limited due to it not being relevant toward this project. An organization would presumably keep more specific case data within or as a child entity off of this table. The case_document table holds the actual instances of the unstructured text relevant for this research project. An organization may choose to merely hold the file system path to the actual document, however; considering how volatile a file system directory structure can be, it was decided that to satisfy the requirements for this research project, the actual documents would be housed within the database table itself within a binary large object

field. The document_type table provides the means for the organization to classify each document within a subtype. The document types can be expanded as needed by an organization to accommodate new types as they are needed.

Figure 1 – Data Model of Basic Case Data Subject Area

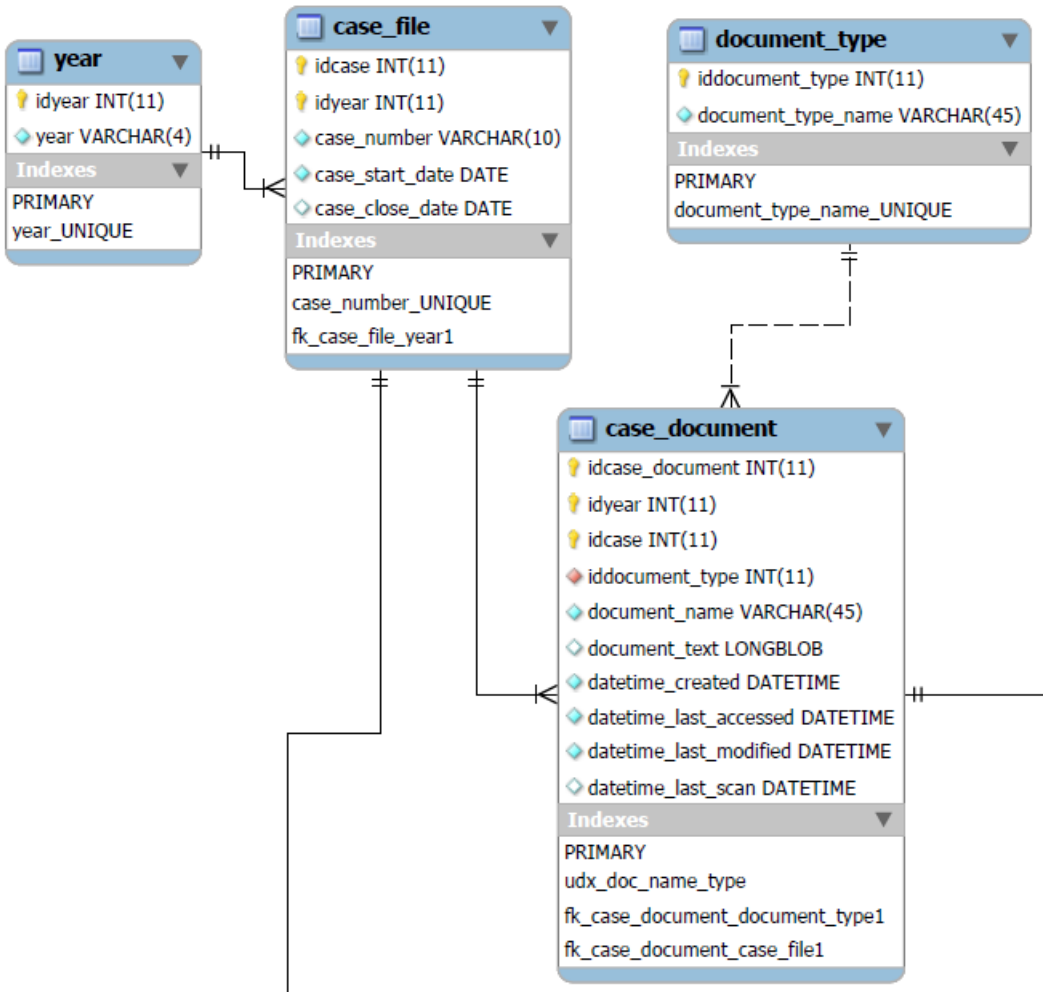

Figure 1. Main data areas associated with a typical organization maintaining case data with instances of the unstructured text based documents.

The secondary data area is responsible for maintaining the regular expressions and the case indicators extracted from the database.

The regex_pattern table is designed to hold the regular expressions, along with the expression options necessary to perform the searches. The post_process table is used to hold

structured query language statements that will be used, in essence, to filter invalid instances of the extracted indicators from the results of the regular expression parsing process. This process will be further detailed in the description of the search method. The searched_document and matched_text tables hold all the instances of case indicators extracted during the search process

Figure 2 – Data Model of Regular Expression/Case Indicator Subject Area

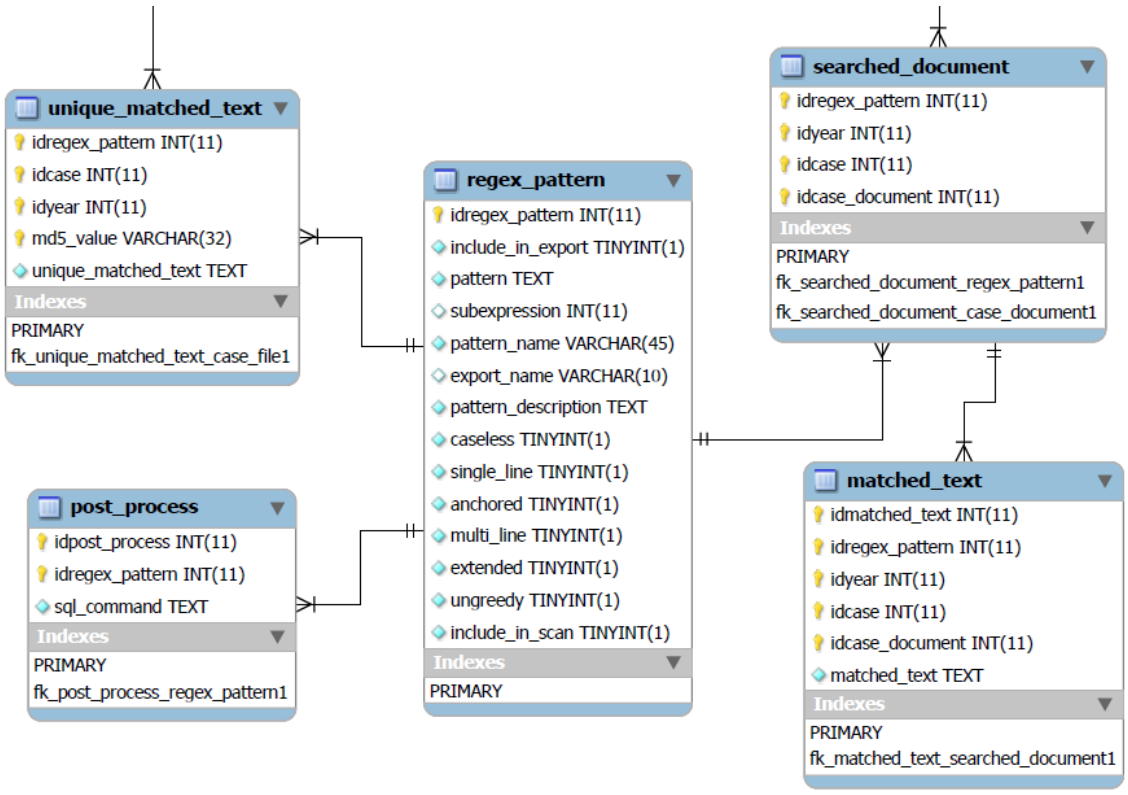

Figure 2. Main focus of this research project is captured by these tables. The regex_pattern fully describes a regular expression and the unique_matched_text table will ultimately hold the instances of case indicators (class data extracted from the case documentation).

and relate them to the document they were found in. An important aspect to realize is that a search may reproduce the same indicator for a given document and/or case. During the searching phase, reproduced indicators are maintained within the matched_text table but need to be condensed down to just one instance later. Optimally, these two tables, in a production environment, would be better suited as temporary tables only accessible to the current user,

however were included in the schema merely to highlight their function within the search process. As a centralized table, visible to all users could cause problems if more than one user were to conduct regular expression parsing at the same time. The unique_matched_text table is responsible for managing the condensed list of indicators and relates them to their associated case. An additional point to observe is that during the search phase, all indicators held within the matched_text table are associated to the document they were extracted from, while the condensed list of indicators held within the unique_matched_text table are associated directly to the case they are related to.

The following tables describe the database schema. Table one describes each database table, its overall purpose, and then describes the columns of each database table. Table two identifies the indexes created describing the business rules the index enforces within the schema.

Table 1

Database Schema, Table Description

Table Name (Note)	Table Purpose	Column Names	Column Purpose
year (For the purposes of this research project, no data is actually held within this table. Any such information an organization would care to hold within this table would not play a significant role for this project)	Allows the display of case data subdivided by year	idyear	Primary key column for table (auto increment field)
		year	Holds the year that cases will be related to

Table Name (Note)	Table Purpose	Column Names	Column Purpose
case_file (For the purposes of this research project, only basic case data are held. The actual data held in this table does not play a significant role for this project, however; in an organization, this information would be more detailed)	Holds basic data related to a case for an organization	idcase	Primary key column for table (auto increment field)
		idyear	Primary key column for table (foreign key from year table)
		case_number	unique number to identify a case
		case_start_date	date the case was started
		case_close_date	date the case was closed
document_type	Provides a list of possible categories that a document can be classified into.	iddocument_type	Primary key column for table (auto increment field)
		document_type_name	The category name that a document can be classified into
case_document	Holds the unstructured text (documents) that are associated with a particular case.	idcase_document	Primary key column for table (auto increment field)
		idyear	Primary key column for table (foreign key from case_file table)
		idcase	Primary key column for table (foreign key from case_file

Table Name (Note)	Table Purpose	Column Names	Column Purpose
			table)
		iddocument_type	Primary key column for table (foreign key from document_type table)
		document_name	The name of the document, the document type and document name must be unique for a particular case.
		document_text	The unstructured text of the document. The document text is not limited to solely text. It may also contain graphics or other embedded objects, however; only the text will be searched for instances of data classes.
		datetime_created	date time stamp of when the document was first inserted within the table.
		datetime_last_accessed	date time stamp of when the document was last accessed by a user. Accessing the document for the purposes of searching, is not registered.
		datetime_last_modified	date time stamp of when the document was last modified.
		datetime_last_scan	date time stamp of when the document was last scanned by the search process.
regex_pattern	Is the list of regular expressions that define a data class, and is used by the search process to extract the case indicators	idregex_pattern	Primary key column for table (auto increment field)
		include_in_export	Flag to indicate if the case indicators found to match a particular regular expression should be included in the XML export report.

Table Name (Note)	Table Purpose	Column Names	Column Purpose
		pattern	The regular expression that defines a data class.
		subexpression	For regular expressions that use a particular token to find a data class, it may not be desirable to actually return the token as part of the data found. Subexpressions allow the regular expression to be broken into subgroups (within parenthesizes). If subexpression has a value other than zero (0), then only the nth group is returned as the extracted data class.
		pattern_name	A short name used to identify the regular expression,
		export_name	The name used for a particular pattern within the XML export report.
		pattern_description	A full description of the regular expression.
		include_in_scan	Flag to indicate if the regular expression pattern should be used in the search.
		caseless	Regular expression flag option – performs the search where comparisons disregard character case.
		single_line	Regular expression flag option – Allows lines that span more than one line within the text to be treated as a single line.
		anchored	Regular expression flag option – Regulates if the next match starts right after the first character the previous match, or at the end of the previous match.
		multi_line	Regular expression flag option – Treats one string with multiple lines as multiple strings.

Table Name (Note)	Table Purpose	Column Names	Column Purpose
		extended	Regular expression flag option – Allows the regular expression pattern to contain extra white space, newlines, and perl-style comments.
		ungreedy	Regular expression flag option – Used to match as many characters as possible
searched_document	Holds a list of all documents scanned by a particular regular expression pattern during the current search	idregex_pattern	Primary key column for table (foreign key from regex_pattern table)
		idyear	Primary key column for table (foreign key from case_document table)
		idcase	Primary key column for table (foreign key from case_document table)
		idcase_document	Primary key column for table (foreign key from case_document table)
post_process (Table holds actual update and/or delete SQL statements that are used to filter out invalid indicators. For example, for the IPv4 data class, IP ranges such in 10.x.x.x or 192.168.x.x are of no particular intelligence value since they indicate internal network IP	Provides a means to filter out invalid instances of class data found within the documents	idpost_process	Primary key column for table (auto increment field)

Table Name (Note)	Table Purpose	Column Names	Column Purpose
ranges. These IP addresses can be easily deleted)			
		idregex_pattern	Primary key column for table (foreign key from regex_pattern table)
		sql_command	update or delete SQL statement that will be used to cleanse the indicator data.
matched_text (Instances of the matched text are related to the document they were extracted from. This table may hold many instances of the same matched text for each document and case.)	Holds all the instances of case indicators extracted from the case documents.	idmatched_text	Primary key column for table (auto increment field)
		idregex_pattern	Primary key column for table (foreign key from searched_document table)
		idyear	Primary key column for table (foreign key from searched_document table)
		idcase	Primary key column for table (foreign key from searched_document table)
		idcase_document	Primary key column for table (foreign key from searched_document table)
		matched_text	Holds the class data instance found and associated to the searched document.
unique_matched_text (Instances within this table have been cleansed by the filtering process and	Instances of unique indicators extracted from the documents.	idregex_pattern	Primary key column for table (foreign key from regex_pattern table)

Table Name (Note)	Table Purpose	Column Names	Column Purpose
condensed to just one instance of the matched text; however it is related to the case rather than the document.)			
		idcase	Primary key column for table (foreign key from case_file table)
		idyear	Primary key column for table (foreign key from case_file table)
		md5_value	Primary key column for table To assist in condensing multiple instances of matched text to just one instance, the matched text should also be part of the primary key, however; MySQL disallows a binary large object (BLOB) to be part of the primary key. To circumvent this limitation, the MD5 hash value of the matched text is calculated and saved. The composite key is now possible using the MD5 hash value in lieu of the actual matched text.
		unique_matched_text	The instance of the case indicator extracted from the documents and associated with its case.

Table 2

Database Schema, Table Indexes

Table Name	Index Name (Index Type)	Column(s)	Index Purpose
year	year_UNIQUE (Unique Index)	year	Ensures year value is not repeated.
case_file	case_number_UNIQUE (Unique Index)	case_number	Ensures case number value is not repeated.
case_document	udx_doc_name_type (Unique Index)	idcase iddocument_type document_name	Ensures unique document name/document type within a case
document_type	document_type_name_UNIQUE (Unique Index)	document_type_name	Ensures document type value is not repeated

Case Viewer Application

The case viewer is developed as a Windows application that accesses the MySQL database and provides the capability to create, delete, view and manipulate basic case related data and the associated case documents. Additionally, the case viewer also provides the capability to view case indicators that have been extracted from the case documentation. The viewer application organizes case files by year in descending order, and lists all the available cases beneath the year nodes. Furthermore, case documents are organized as nodes beneath the case. The source code for the case viewer application can be found in Appendix C.

To expand or collapse any node, a user may double click on the text of a node or simply click on the diamond prefacing the desired node. By clicking the right mouse button over a node, a context sensitive menu pops up showing the possible options allowed for that particular node.

By selecting the root node, a user can add a new year. Selecting a year node allows the addition of a new case, and by selecting the case node, a user can either view case related data or add a new document. Finally, by selecting a document node allows the deletion or editing of the selected document. Figure 3 shows the basic structure of the application's graphical user interface described.

Figure 3 – Case Viewer Application (Main Graphical User Interface)

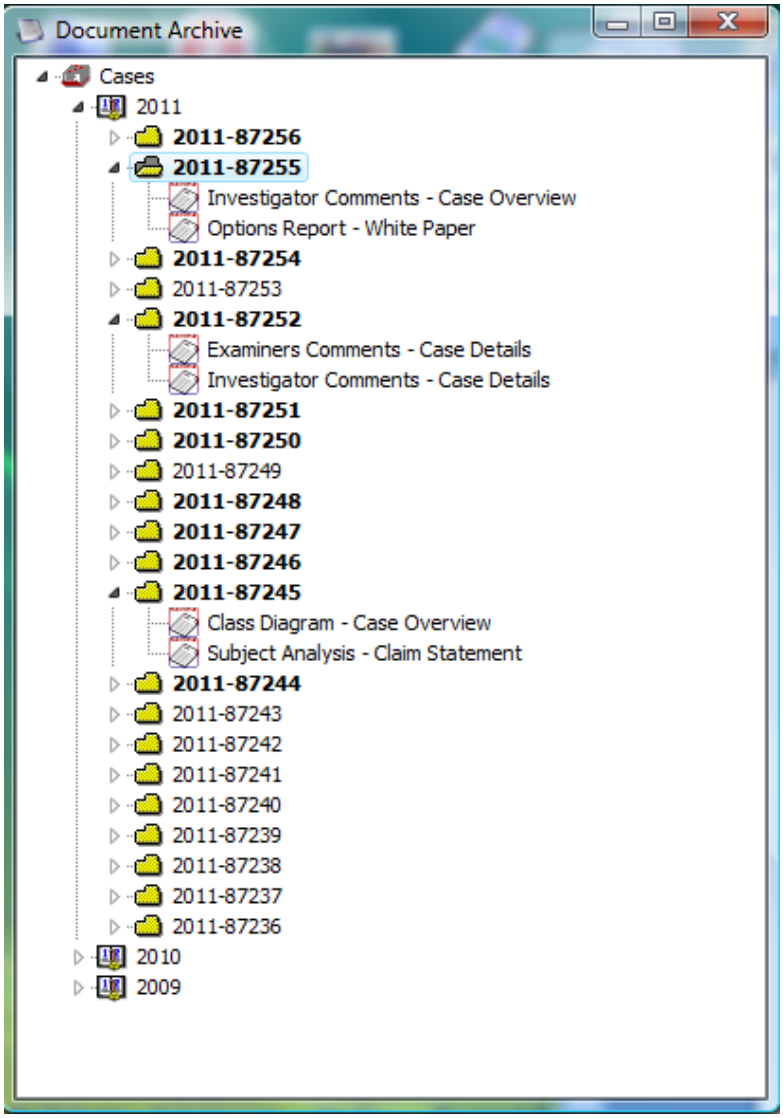

Figure 3. Main graphical user interface for the case viewer application. Each node is populated directly from the database tables. Users can use the right mouse button to cause a context sensitive menu to pop up providing options on how to view and/or manipulate the data.

Case Maintenance

To add a new case, a user need only right click on the appropriate year node, and select *New Case*. Once selected, the new case dialog box pops up already populated with the next sequential case number and the current date as the case start date. Upon acceptance, the new case is added to the list of cases under the selected year.

Figure 4 – Adding a New Case

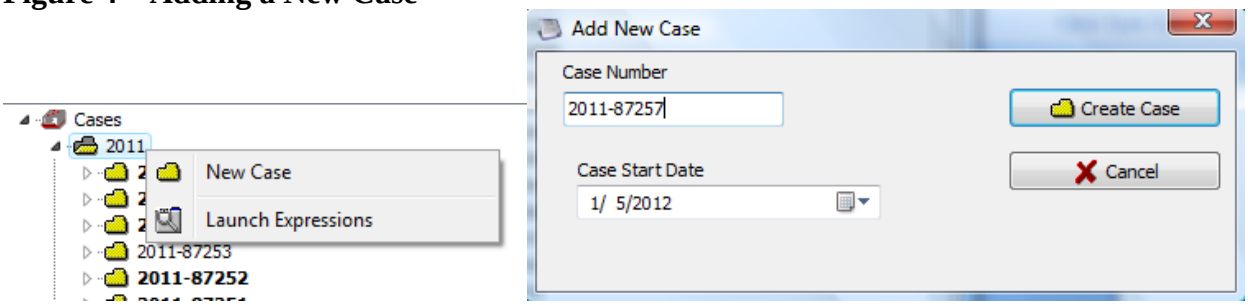

Figure 4. Cases are added as needed by an organization; each case can have multiple documents associated with it.

Document Maintenance

Documents can be imported, or created within the case viewer application. The application has been designed to allow documents to be imported if they are formatted as plain text (.txt), rich text format (.rtf), Microsoft Works documents (.wps), Microsoft Word documents (.doc or .docx) or finally, WordPerfect documents (.wpd). This allows an organization the freedom to use the tool of their choice to generate their documentation, and still maintain compatibility with the case viewer. To import a new document, simply right click on the appropriate case, and select *New Document* from the popup menu. From the import document dialog, enter a *document name*, and select a *document type*. If *Import Now* is checked, clicking the *Create Document* button allows a user to select an import file from the file system. If *Import Now* is not checked, a blank document is created and opened, ready to be edited by the user. The word processor control features many of the same advanced features available in many

professional word processors, such as Microsoft Word, however, the individual capabilities are not detailed here since it has little impact on the capabilities associated with this research project.

Figure 5 – Adding a New Document

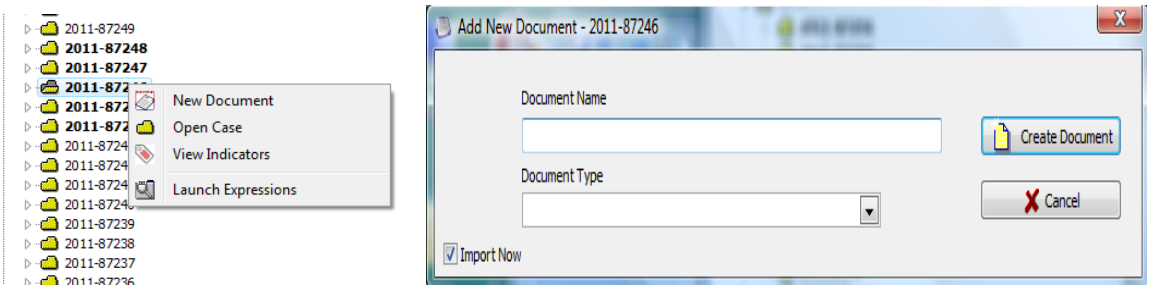

Figure 5. As an organization gains new documentation for a given case, it should be added to the database to allow access organization wide, and to allow it to be scanned by the parser.

To open a document for viewing or editing, right click on the desired document node and select *Open Document*. The application now extracts the document from the database, and loads it into an embedded word processor control on a secondary form. Changes to the document are also written directly to the database from the application.

Figure 6 – Viewing/Editing a Document

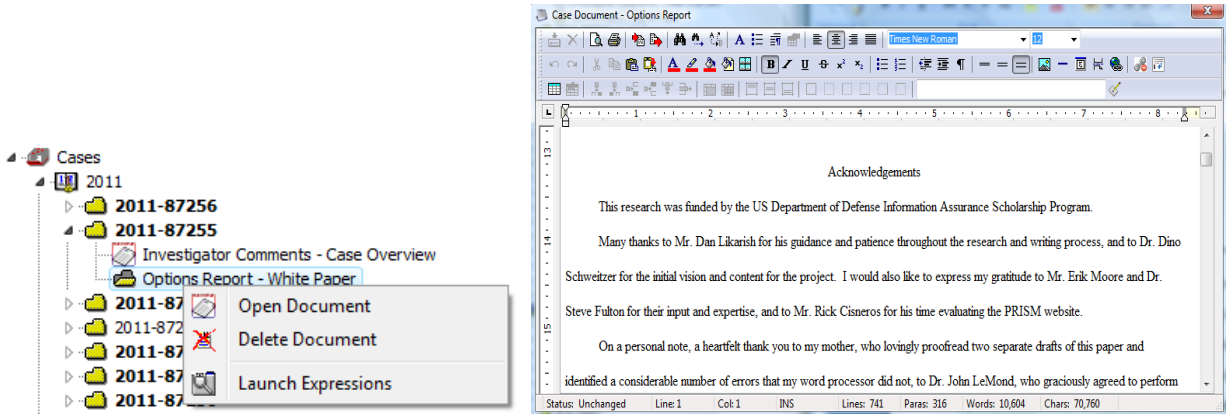

Figure 6. The application provides a full featured word processor which is important for an organization that needs to document more than is possible with a text editor like Notepad.

The database has been designed to track when a particular document is first added to the database, and then any subsequent changes made to it, to include being scanned for case

indicators. In concert with the database, the case viewer application ensures these data items are maintained accurately. When a document is created, either directly within the application or via document import, it automatically enters the current date and time into the datetime_created, datetime_last_accessed and datetime_last_modified fields of the case_document table. When a document is accessed via the case viewer application, the datetime_last_accessed is again updated with the current date and time. If modifications are made and saved to the document, the datetime_last_modified is then updated with the current date and time. These date time stamps will be used by the Windows service application, discussed later, to determine which documents need to be scanned. Once scanned, either by the regular expression parser application, or the Windows Service application, the datetime_last_scan field is updated with the current date and time of the scan.

Figure 7 – Date Time Status of Document Import

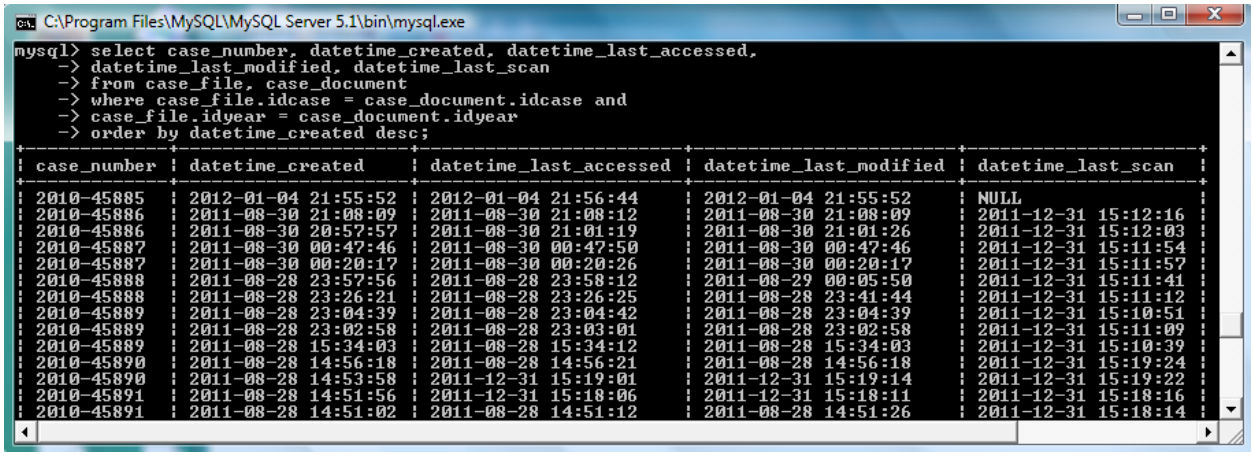

Figure 7. For imported document associated with case 2010-45885, the date time stamps for datetime_created, datetime_last_accessed and datetime_last_modified are shown to reflect the date and time the document was imported. Additionally, the document was subsequently accessed moments later, shown with an updated datetime_last_accessed. The datetime_last_scan value remains NULL until the document is actually scanned.

Viewing Case Indicators

Once the series of documents associated with a case has been scanned by the regular expression parser or regular expression service application to extract case indicators, the unique case indicators are populated into the unique_matched_text table, and available to be viewed within the case viewer application. There are two distinct case indicator views available to users of the application. Case indicators can be viewed either from the perspective of an individual case or all case indicators regardless of case.

Case related indicators can be brought up by right clicking the desired case and selecting *View Indicators*.

Figure 8 – Case Specific Indicator View

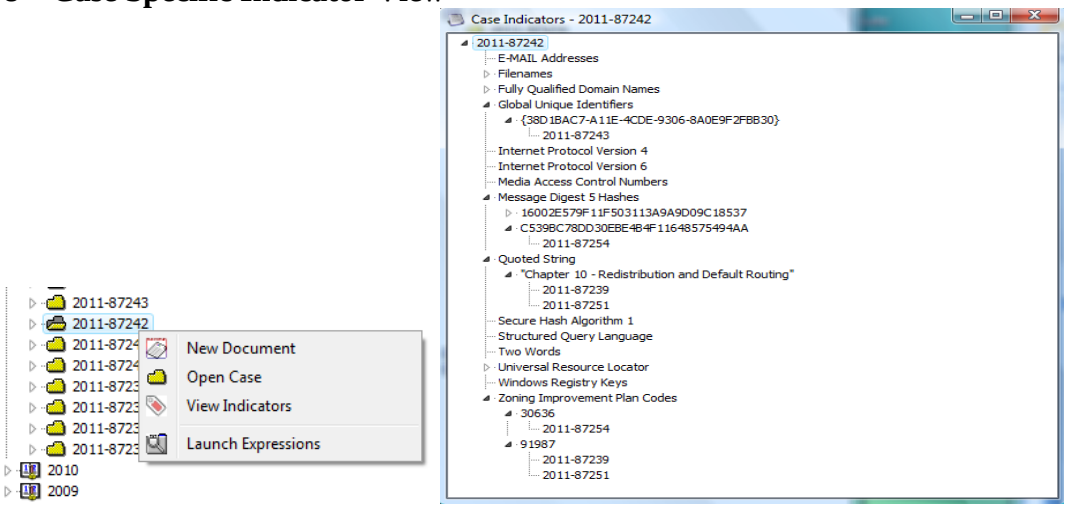

Figure 8. The Case Indicator view allows a user to view all the indicators, organized by type, for a selected case. If there are other cases that share that same indicator, it is shown as child nodes to the indicator. Clicking on the case opens a new case indicator view for the related case in a new window.

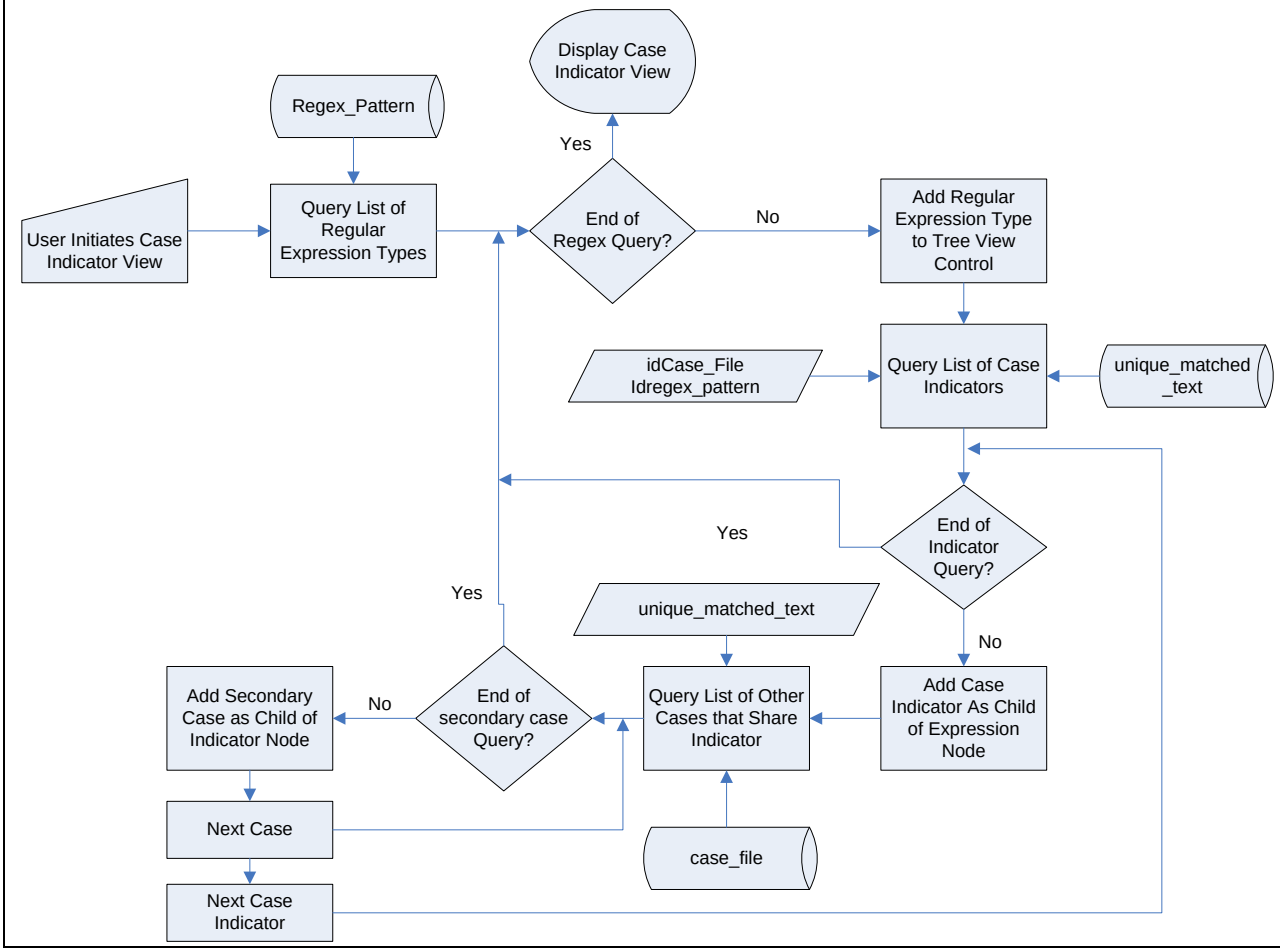
To populate the *Case Indicator* display, three distinct queries are necessary. The initial query result set is the list of pattern types from the regex_pattern table. Iterating through the list of patterns, the database is then queried for all case indicators associated with the case node selected in the case viewer and the pattern. A final step queries each individual case indicator to

find other cases that may share this piece of data. By clicking on the associated case node opens the same case indicator view for the selected case in a new window, allowing direct comparison to other case indicators. Figure 9 details the process used to create the Case Specific Indicator view.

Figure 9 – Case Specific Indicator View Process



To view case indicators from the perspective of all available indicators regardless of case association a user would right click on the root node and select *View All Indicators*.

Populating the *All Indicator* display presents some difficulties due to the sheer number of case indicators to manage. If the entire hierarchical tree structure were to be populated when the view is first opened, a user would have to wait a significant amount of time before it is displayed.

To circumvent this, the form merely populates the tree structure to the regular expression pattern level, and places a dummy node as a child to it. This ensures that the pattern node has the diamond indicator signifying that there are children nodes. When a user expands a particular pattern, the secondary query returns all the case indicators associated with the selected pattern. Once again a dummy node is inserted as a child to each node. By expanding any case indicator node, a follow-on query returns all cases that share that indicator. Finally, by clicking on the case node, opens the *Case Indicator* view in a new window.

Figure 10 – All Indicator View

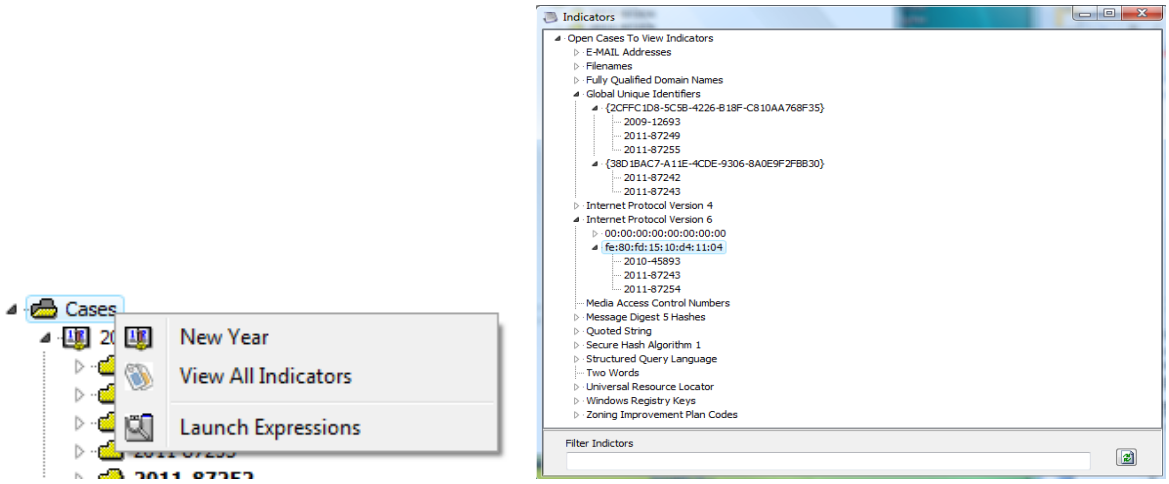


Figure 10. The All Indicator view allows a user to view all indicators, organized by type. Related cases to each case indicator are listed as child nodes, and by clicking on the case, it opens a Case Indicator View for the selected case in a new window. Additionally, the application can filter the indicators displayed with a filter.

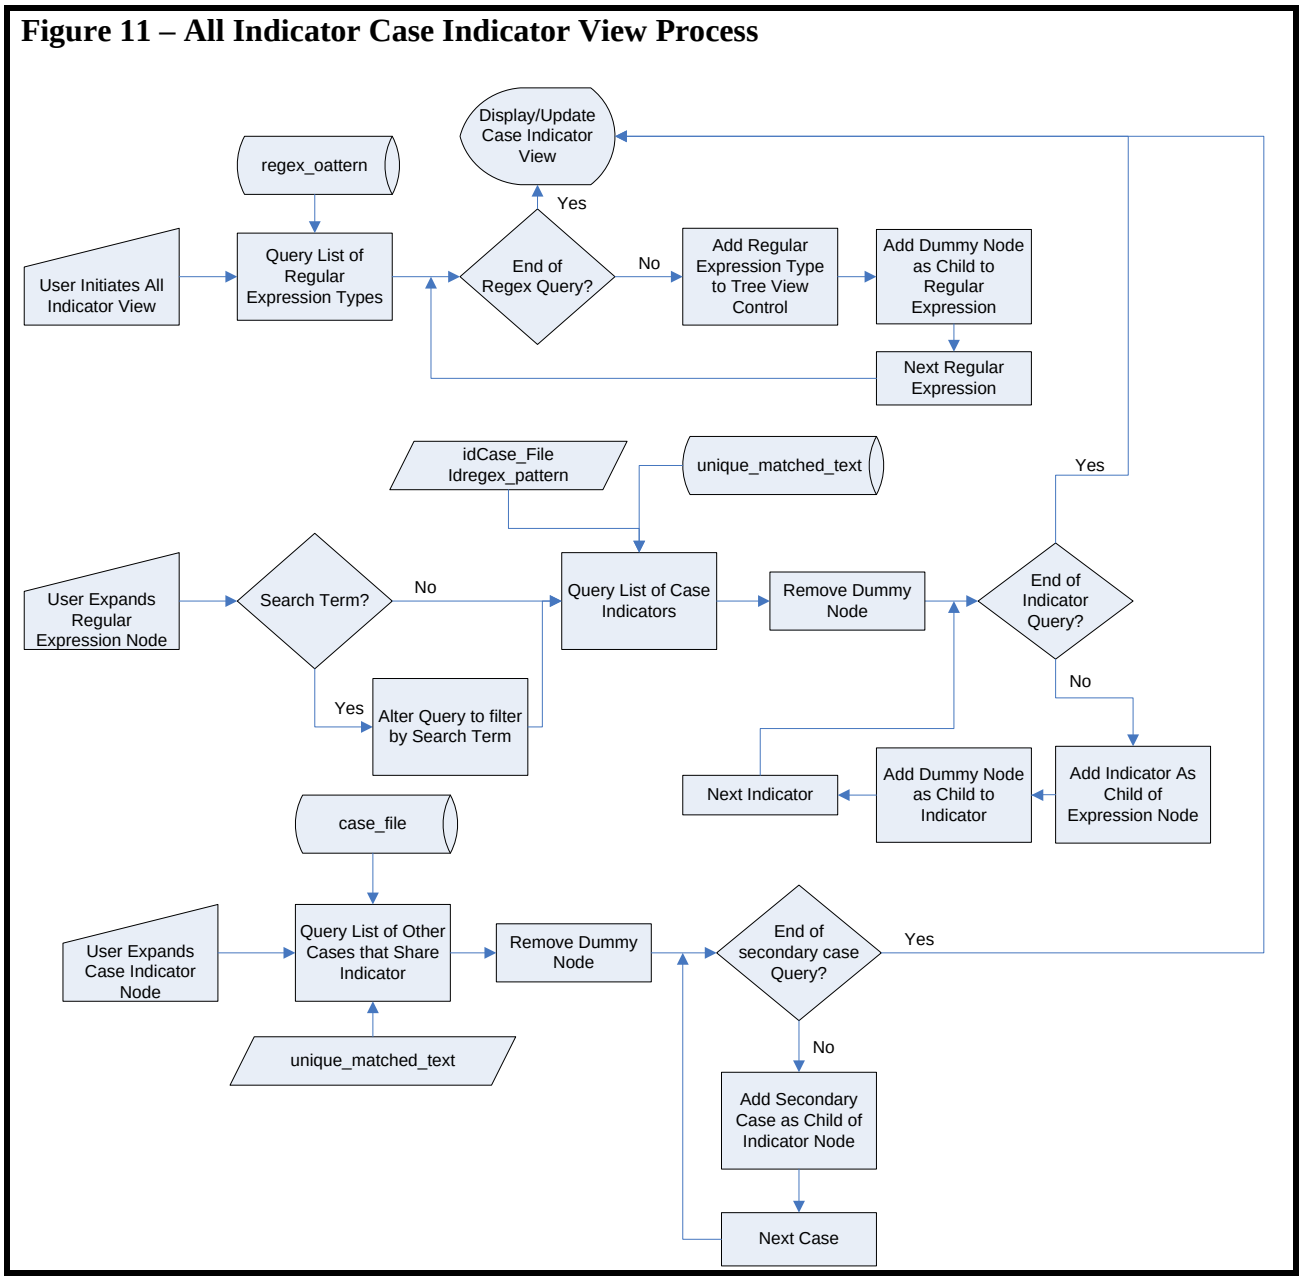
By populating each level dynamically allows for the possibility to search for specific case indicators as the indicators are queries from the database. To accomplish this, the query that returns case indicators is designed to take a parameter that is applied using an SQL *Like* against the text of the indicator. Additionally, if the parameter does not contain the '%' character, used as a wildcard match, the application automatically pads both the front and back of the parameter with the percent sign. If however, the parameter already contains this character, then the

parameter is not padded. This allows the user several options. By not including the percent sign, the query returns any indicator with the text of the search term anywhere in the indicator. By starting the parameter with a percent, only indicators that end with the search term are returned, and finally, ending with the percent returns indicators that start with the search term. Figure 11 details the process used to create the All Indicator view.

Figure 11 – All Indicator Case Indicator View Process



Connection with Regular Expression Parser

Finally, the case viewer is dependent on the Regular Expression Parser or the Regular Expression service application to extract the case indicators from the documents maintained within the database. While the regular expression parser is a stand-alone application, and can be launched directly, it can also be launched from the case viewer application. Users can launch the parser by right clicking anywhere within the client area of the case viewer application and selecting *Launch Expressions*. As stated, the Regular Expression Parser (Expressions application) is responsible for scanning the documents for the case indicators and will be discussed in detail below.

As a precaution to not have both the regular expression parser and the regular expression service application running at the same time, which could cause issues with simultaneous access to the matched_text table, each application has been made to first confirm if either are already active. The case viewer application is also aware if the service application is active, and if it is, the *Launch Expressions* popup menu may not be visible.

Figure 12 – Launching Regular Expression Parser

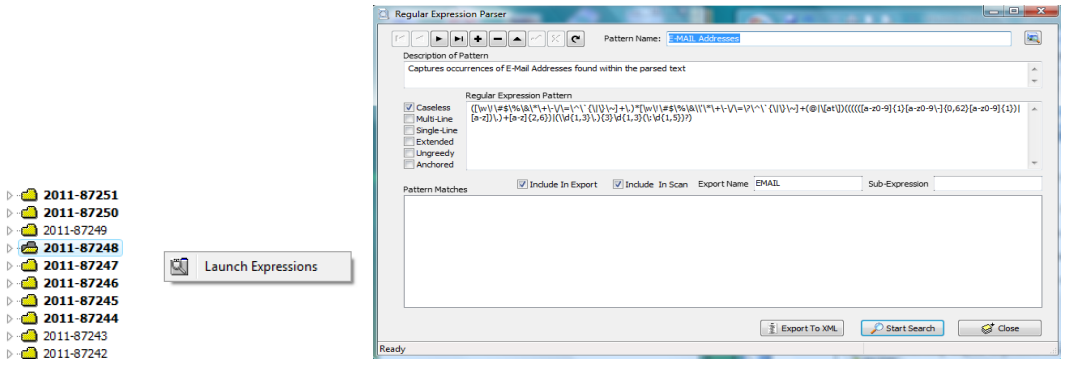


Figure 12. The regular expression parser is the heart of this research project, providing the ability to scan the documents and extract case indicators.

Regular Expressions

The actual mechanism to perform the searches utilizes regular expressions. Valid regular expressions had to be devised to extract each type of data class proposed by this research project. Specifically, regular expressions were designed that can effectively search for e-mail addresses, computer file names, fully qualified domain names, global unique identifiers, internet protocol version 4 and 6, media access control numbers, message digest five hash values, secure hash algorithm one digests, quoted strings, structured query language statements, universal resource locators, Microsoft Windows registry keys and zoning improvement plan codes were developed and tested.

It is worth noting that each regular expression was a compromise in what a particular data class allows, format wise, and what is possible to search for. Some examples that highlight the difficulty in designing a regular expression include that of searching for a file name. The file name regular expression uses a list of possible file extensions as a *token* to key the identification of a file name. The list of file extensions included to search for is quite extensive, but not exhaustive. Any file using a non-standard extension will not be flagged as a file. Additionally, both Microsoft Windows and MAC OS allow spaces as valid characters in a file name. If the regular expression were to also allow for spaces however, every character before an identified file extension could also presumably be part of the file name. E-mail address formats were also just as difficult to quantify. The user name portion of e-mail addresses allow for characters not normally associated with e-mail addresses. Even the @ character is allowed in the user name portion if encapsulated within quotes. The domain portion has several standard possibilities, such as .net or .com, however, if the regular expression is to also allow for international e-mail addresses, it must also allow for domains that include every country of the world, such as .ru for

Russia, or .us for United States. Forgoing a list of all possible domains, and strictly keying off of a period (.) followed by two or three characters in the range of a to z, again such as .ru or .com, restricts the possibility of longer domains, such as .museum, however, allowing for six characters, to allow for .museum, increases the chance for invalid matches.

Below is the list of regular expressions used by the regular expression parser application. The list also identifies some of the strengths and a few of the weaknesses associated with the regular expression, and also shows an example of a valid match.

Table 3

Regular Expressions

Data Class	Regular Expression Strength	Weakness Example Match
E-Mail Address	([\w\!\#$\%\&*\+\-\/\=\^\`{\|\}\~]+\.)*[\w\!\#$\%\&\\'*\+\-\/\=\?\^\`{|\}\~]+(@|\[at\])(((((([a-z0-9]{1}[a-z0-9\-]{0,62}[a-z0-9]{1})|[a-z])\.)+[a-z]{2,6})|(\\d{1,3}\.){3}\d{1,3}(\:\d{1,5})?)	
	Allows a wide range of valid characters for the user name portion. xxxxxxxx@gmail.com	1) Domain portion may allow more than just e-mail addresses register as a match. 2) Legal domains include IPs which are not matched.
File Names	([a-z0-9~\[\]_\-]+[a-z]?+[0-9a-z\(\)\[\]\=\/\^\%\!\{\}_\-\+~#@]?+\.(acl|asf|asm|asp|ba?k|bas|bat|bat\.tar\.gz|bcc|bcp|bd|bin|blt|bmp?|bpr|bup|cab|cad|cap|cb|cdr|cer|cfg|cgi|chm|chn|cla|cmd|cpl|cpp|csv|dat|dbf?|dcr|dcu|d1l|dll|dl_|docx?|drv|ds|dvr|ebs|egg|eml|enc|epj|evt|exe?|exe\.vir|exe\.vir\.[0-9]|exe.reg|ex_|gg|gif|gpl|gz|g?zip|h\+\+|hex|hke|hlp|hsc|hsl|ht|ico|idx|ime|inc|index\.dat\.txt|inf|ini|jar|java?|jpe?g?|jse?|jsfl|jsp|key|kog|lang|levels|lib|lnk|logs?|lpr|lrs|lzh?|mai|make?|map|mdb|mht|midi?|mpe?g|msi|nfo|oab|obj|oca|ocx|old|ora|pag|pas|pcap?|pd?f|pe|perl|pfx?|pgm|php|p?html?|pl|pm|png|ppk|pps|pps\.lnk|pptx?|pst|python|rar|raw|reg|res|rtf|sav|scr|session|\$?swf|sys|tar|tar\.gz|tcl|te?mp|tlb|txt|txt\.xls|uid|uue|vbe|vbx?|wav|xif|xlsx?|xml|xsd|wav|wma|wmv|wri|xwd|x11|00+[0-9]|7z))

	Allows for optional 4 digit extension to ZIP Code. 45221	Does not guarantee match is an actual ZIP Code in use by the Postal Service.

Regular Expression Parser Application

The regular expression parser application is the heart of this research project. It has a multipurpose role in that it manages the list of regular expressions, provides an avenue to test regular expressions as they are being developed, conducts the actual scan against the case documentation with the regular expressions and finally, can export the list of case indicators that

it has found in an extensible markup language (.xml) formatted export document. The application is designed as a Windows based application that can be executed directly from the Windows Start menu, or by double clicking the application icon, or by selecting *Launch Expressions* from the case viewer application popup menu. The source code for the Regular Expressio Parser can be found in Appendix D. The main graphical user interface allows a user to add, delete or modify regular expressions, and to set the options necessary to use the expression. It also allows the ability to turn on or off individual regular expressions for a particular scan as well as whether the case indicators for a particular data class should be included in the export .xml report. Below is a view of the application's main graphical user interface.

Figure 13 – Regular Expression Parser (Main Graphical User Interface)

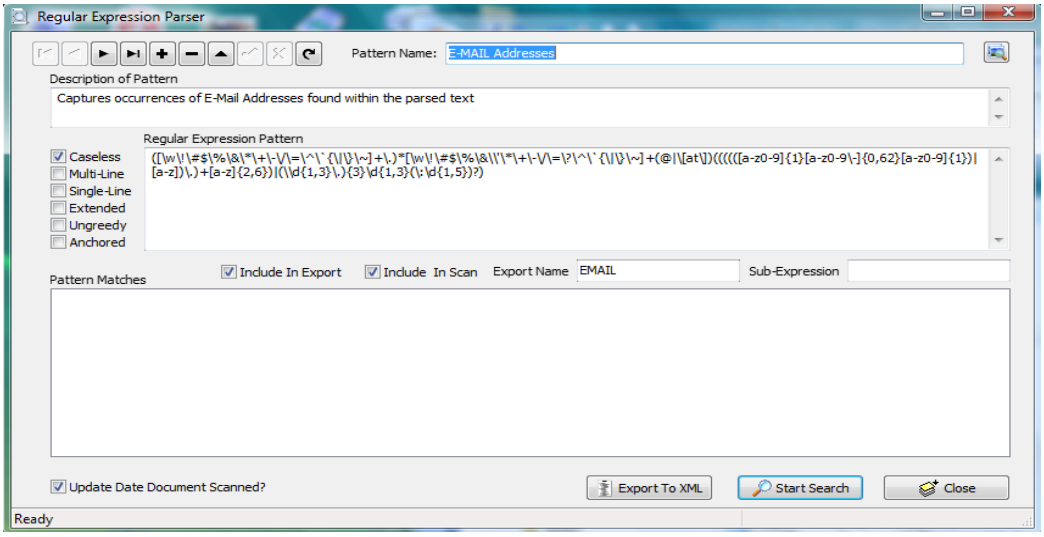

Figure 13. The application interface is divided into two main sections. The top half is dedicated towards the management of the regular expressions, while the bottom is geared toward displaying the results of the document scans.

Management of Regular Expressions

The regular expressions are a critical aspect of this project. Ensuring they are adequately maintained thus becomes an important requirement. To ensure this, they have been allocated a portion of the data model to maintain the data items associated with each regular expression.

Furthermore, the regular expression parser can access these tables to add, delete or modify each expression.

Adding a new regular expression can be done by clicking the plus (+) sign in the database navigator control in the upper left corner of the application. A *pattern name* must be entered, which is a shorthand notation to identify the type of data class the regular expression will attempt to match. The *description of pattern* is a more detailed explanation of the regular expression, and is saved within a binary large object, allowing for the possibility of maintaining detailed instructions for a particular expression. The *Include in Export* flag identifies if the case indicators it found associated with the regular expression should be included in the extensible markup language (.xml) export report, checked signifies that it should. The *Include in Scan* flag identifies if the regular expression should be included in a scan of the documents, again, checked signifies that it should. The *export name* field will be used in the .xml file to signify the data class type of the case indicators. The *sub-expression* field is used to return a substring of the entire matched text. This is important if a *token* is used to help find a match, however, the token itself should not be part of the case indicator. As an example, if it is known that names of individuals can always be found after the token '*Name:* ', then it would be reasonable to use this token to match and capture the name that follows it, however; the token itself would not be desired in the actual text of the case indicator. In this case, each sub-portion of the regular expression can be wrapped within parenthesis, and the order number of the relevant portion of the matched text is entered into the *sub-expression* field to limit the returned text. Additional aspects of a regular expression's meta-data include the selection of the options that include: *Caseless*, *Multi-Line*, *Single Line*, *Extended*, *Ungreedy* and *Anchored* which are all described in table one above. To cleanse the pattern matches, standard update and delete structured query language statements are

maintained in the post_process database table. Any regular expression can have as many queries as needed to cleanse the data as needed. These queries are also accessible from the regular expression parser application by clicking the control button located in the upper right corner of the application's graphical user interface. The queries are applied to the matched_text table before they are committed to the unique_matched_text table. This minimizes the process necessary to transfer data from the matched_text table to the unique_matched_text table, which is explained below.

Figure 14 – Example SQL Filter for Internet Protocol v.4 Pattern Matches

```
Delete From matched_text
Where (matched_text like "172.16.%" or matched_text like "172.016.%" or
        matched_text like "172.17.%" or matched_text like "172.017.%" or
        matched_text like "172.18.%" or matched_text like "172.018.%" or
        matched_text like "172.19.%" or matched_text like "172.019.%" or
        matched_text like "172.20.%" or matched_text like "172.020.%" or
        matched_text like "172.21.%" or matched_text like "172.021.%" or
        matched_text like "172.22.%" or matched_text like "172.022.%" or
        matched_text like "172.23.%" or matched_text like "172.023.%" or
        matched_text like "172.24.%" or matched_text like "172.024.%" or
        matched_text like "172.25.%" or matched_text like "172.025.%" or
        matched_text like "172.26.%" or matched_text like "172.026.%" or
        matched_text like "172.27.%" or matched_text like "172.027.%" or
        matched_text like "172.28.%" or matched_text like "172.028.%" or
        matched_text like "172.29.%" or matched_text like "172.029.%" or
        matched_text like "172.30.%" or matched_text like "172.030.%" or
        matched_text like "172.31.%" or matched_text like "172.031.%" or
        matched_text like "10.%" or matched_text like "192.168.%") and
        idregex_pattern =  (Select idregex_pattern From regex_pattern
                            Where pattern_name = 'Internet Protocol Version 4')
```

Figure 14. This query deletes IPs that would only match an organization's internal network. Connection with another cases based on these values would be superficial.

Finally, the regular expression itself is entered within the *regular expression pattern* field. This too is associated with a binary large object, allowing for arbitrarily long regular expressions.

Deleting a regular expression can be done by clicking the minus (-) sign in the database navigator in the upper left corner of the application. When clicked, the currently displayed regular expression is deleted from the database. Other operations possible from the database navigator include, go to first regular expression, go to previous, go to next and go to last. Additionally, buttons that initiate edits on the regex_pattern table, save edits to the current regular expression, cancels unsaved edits and finally, refresh the view of the regex_pattern table are available.

Testing Regular Expressions

Testing a regular expression involves the use of the *Include in Scan* flag associated with each regular expression. By simply turning off this flag for every regular expression except the one being tested, the application can parse the documents for text that matches the pattern. It is not inconceivable though, that there is in fact no match to the pattern being tested located in the database of documents. In a production environment, simply altering the documents to include text to match a pattern is not an option. It is recommended that, for a real-world solution, a test environment should be established that can be utilized to test regular expressions as they are being designed.

Scanning Procedure

The regular expression parser scans all the documents against all the regular expressions that are marked with the *Include in Scan* flag set. To start the scanning process, ensure all the regular expressions that should be included in the scan are selected and then simply click the *Start* button in the lower right corner of the application. The *pattern matches* display window is used by the application to show the actual instances of the text that is being matched while

simultaneously populating the matched_text table. The output is organized hierarchically by year, then by case and document, then by regular expression culminating in the matched text.

Figure 15 – Regular Expression Parser Output Display

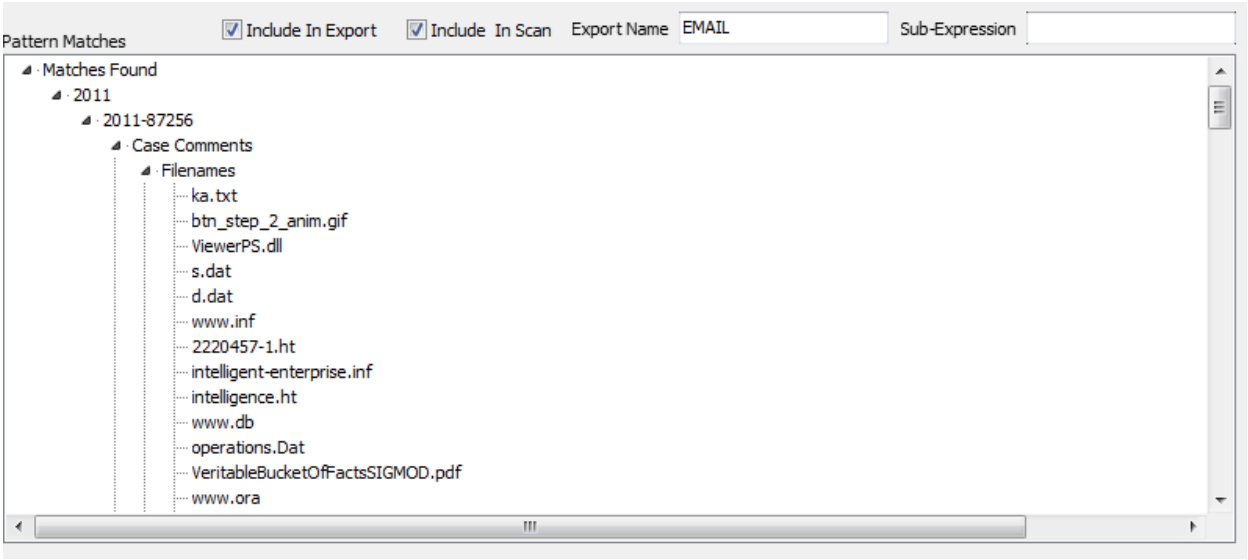

Figure 15. Every match to the regular expressions are output to the display, to include duplicates, in a hierarchical tree.

Once scanning is initiated, the application starts by querying the documents, order by year, then by case number, then by document name. By cycling through each document, it loads the document into the word processor control, which is purposely made to not be displayed on the application interface. Each document is scanned in turn, by each regular expression that is selected.

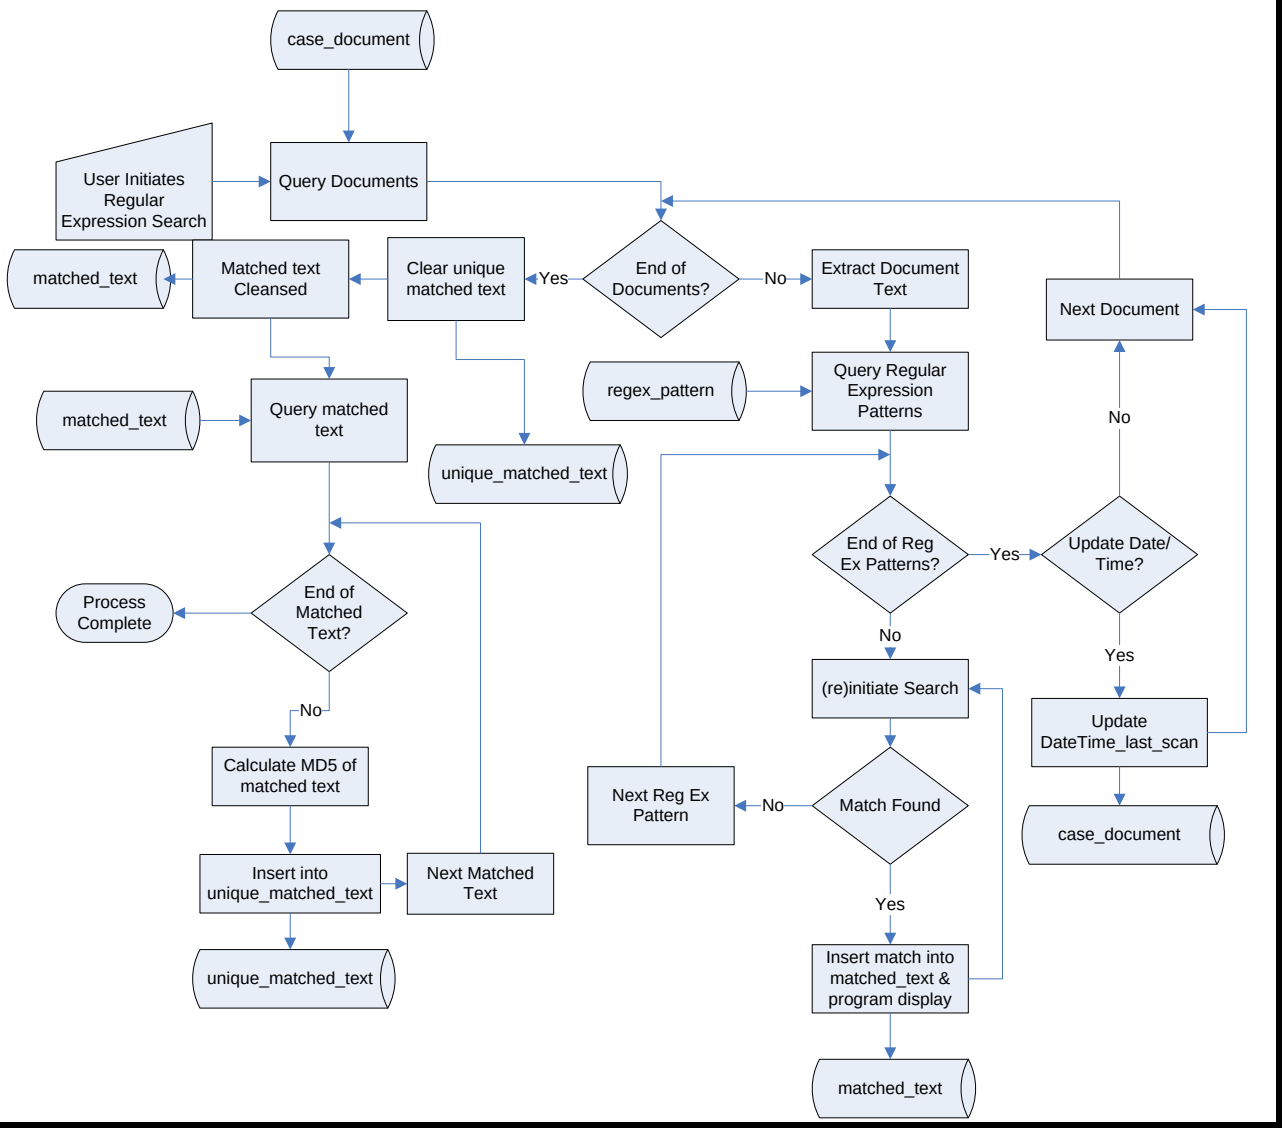
Unfortunately, documents loaded into the word processor control cannot be directly parsed as they currently are, since the document may have graphics or other embedded objects that could interfere with the scan. The word processor control has the capability to programmatically extract just the text of a document, either in ANSI or UNICODE format. For this research project, UNICODE text was extracted to be scanned. Once extracted it is assigned to the search text property of the regular expression software object within the application.

Additionally, each regular expression is also assigned to the expression property of the regular expression object individually. With both properties of the software object set, the application then initiate the search. As matches are captured, the value of the sub-expression is examined. If there are no values in the sub-expression field, a sub-expression value of zero is assumed, which defaults to the entire matched string, otherwise, only the selected substring is returned and inserted into the matched_text database table. If the *Update Date Document Scanned* flag is set, which is in the lower left corner of the application interface, the datetime_last_scan field of the case_document table is updated with the current date and time for each document scanned. Finally, when all cases have been completed, the matched text table will be populated with every string that matched the regular expression patterns. It is at this point that the filtering process executes the SQL associated with each regular expression to remove invalid instances of matched text.

The second phase of the parsing process can now commence, which is to remove duplicate instances of matched strings from the matched_text table. Starting from the first and then cycling through the entire contents of the matched_text table, the MD5 hash value of the matched text is calculated. The application then attempts to insert the value into the unique_matched_text table. Given the inclusion of the matched text's MD5 value being part of the primary key of the unique_matched_text table, a key violation error will enforce the uniqueness of matched strings in the table for a given case. The application is specifically programmed to react accordingly when the key violation occurs. This ensures that no error message is displayed to the user. Once complete, the contents of the matched_text table are emptied and all case indicators have been successfully inserted into the unique_matched_text table.

Below is a high level representation of the regular expression scanning process:

Figure 16 – Regular Expression Scanning Process



Exporting Case Indicators

An organization may have the need to share the case indicators found during the scanning process. Extensible markup language (.xml) format is an ideal format to export this type of data, since it can be easily viewed by any text editor or web browser. Pressing the *export to XML* button in the lower right corner of the application opens the export form in a new window. By pressing the *Create XML* button, the application opens the unique_matched_text table, and

produces the export report. The export report only reports on the case indicators associated with regular expressions that have the *Include in Export* flag set.

Figure 17 – XML Export Report

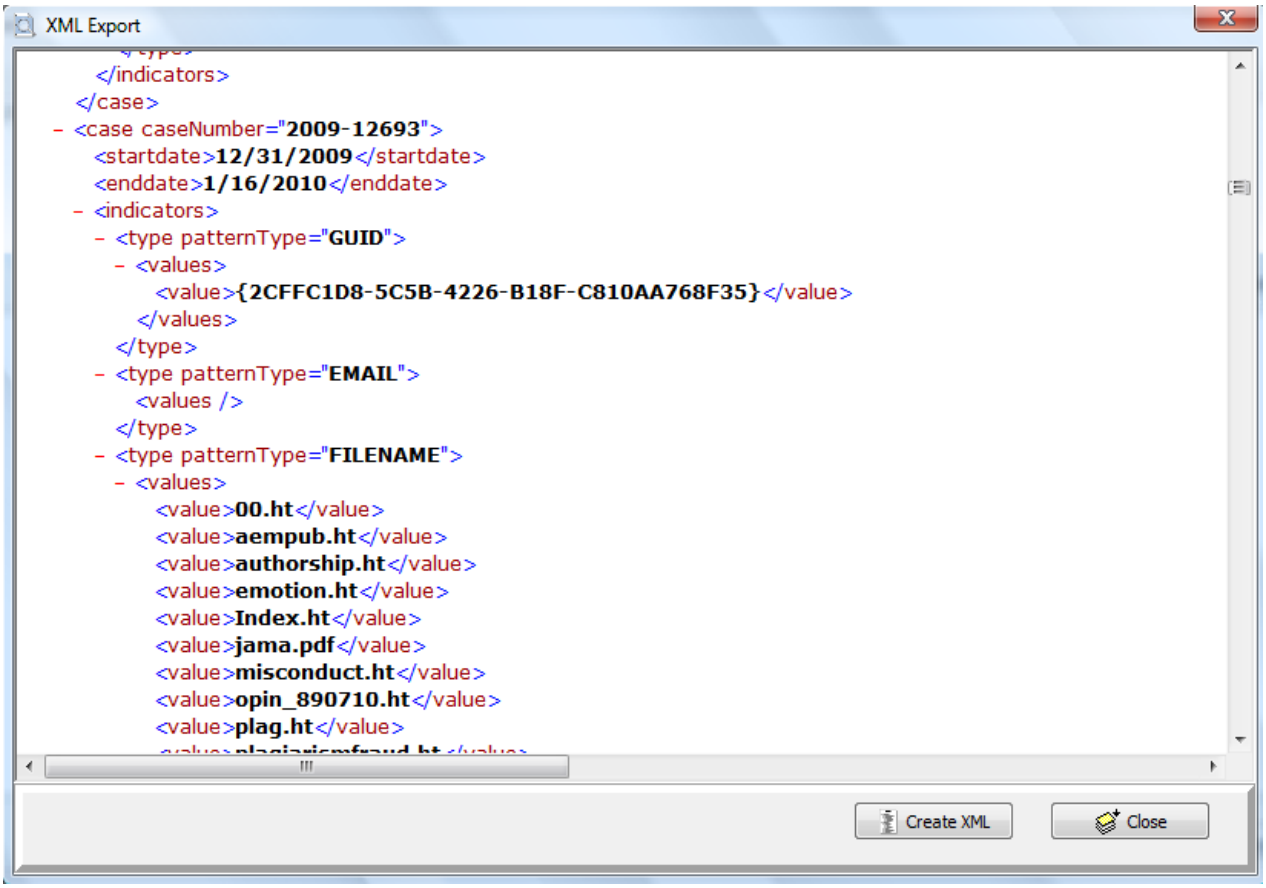


Figure 17. Export report identifies all the case indicators found associated with a case in an XML formatted document.

Regular Expression Service Application

The Regular Expression Service application is intended to replace the scanning capabilities of the regular expression parser application. For an organization that continually makes changes to their repository of documents, a manually launched scanner is a less than optimal solution. The results of a scan can be invalidated within minutes of a scan if a document were to be modified to remove text that had matched one of the regular expression patterns.

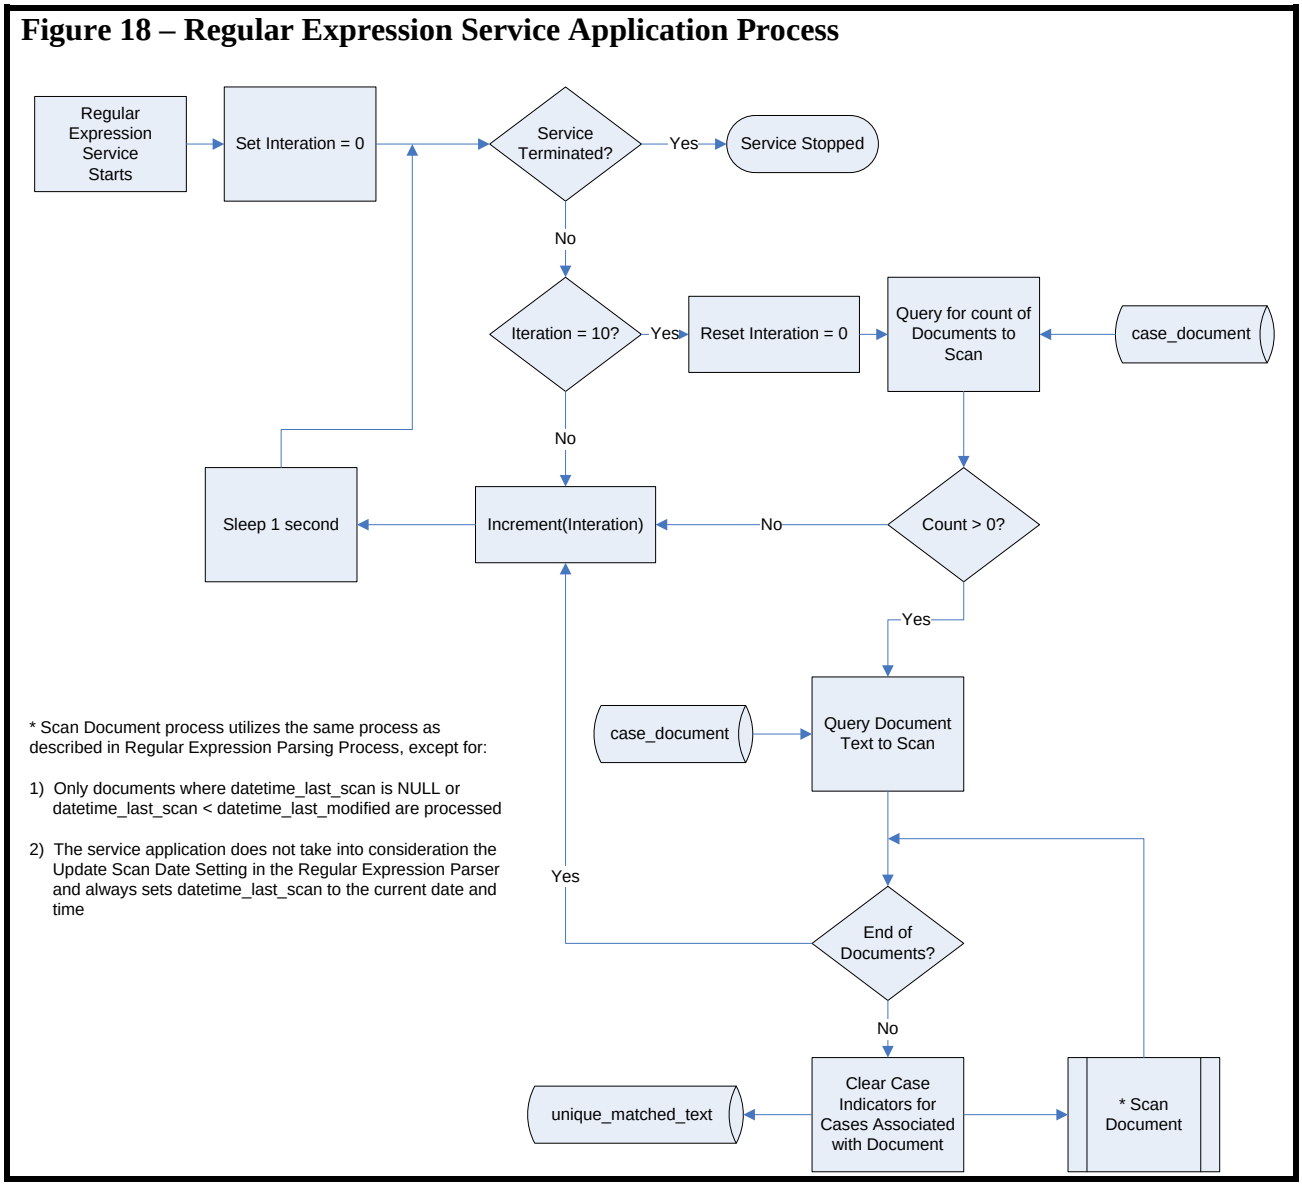
Similarly, new documents could possibly need to wait days to be scanned at all. Due to these limitations, a real-world solution would be an application that would be able to react to changes to the database as they happened. A Windows service application can provide these benefits. The source code for the service application can be found in Appendix E.

Since it is designed as a service application, it has no user interface and continually runs in the background; however, the actual method employed to conduct the scan is equivalent to the regular expression parser application. A new requirement brought about by the way the service operates is to develop a mechanism to identify which documents need to be scanned. This can easily be accomplished by selecting only those documents where the datetime_last_scan field is either NULL or has a date time stamp earlier than the datetime_last_modified. This is done by polling the database, although the process doing so is intricate. It is typical for a service application to accomplish a task, and then sleep until it needs to accomplish the task again. Having the service poll the database continually would put an undue strain on the server and the database; however, times between polling durations should not be too long causing changes to the database to go unprocessed for an extended period. For this research project, the time between polling was selected to be every ten seconds; however having the service sleep for ten seconds could make the service seem unresponsive, especially if an administrator wanted the service to be stopped, such as during a reboot. To fix this, the service actually only sleeps for one second increments, wakes and tests to see if it has been requested to terminate, and if not sleeps again, unless ten seconds have elapse, which prompts the application to poll the database once again. Another complication also arises on how new or modified documents are scanned. The validity of the case indicators held within the unique_matched_text table comes into question if a modified document has been altered to remove text that has been selected as a match to one of the

regular expressions. Due to this, when a document is added or modified within a case, all case indicators for that case are deleted from the unique_matched_text table, and every document associated with that case is rescanned. With the completion of the scan, the datetime_last_scan field for every scanned document is once again updated with the current date and time.

Below is a high level representation of the regular expression scanning process of the service application:

Figure 18 – Regular Expression Service Application Process



To utilize the service application, a server computer should be dedicated, which has access to the MySQL database instance. The application must be installed as a service on the computer and will automatically restart itself when the server is rebooted. A DOS window should be opened as an administrator to install the service. Navigating to the directory where the service is located and issuing the command: *ThesisSvc.exe /install* installs the service.

Figure 19 – Installing the Service Application

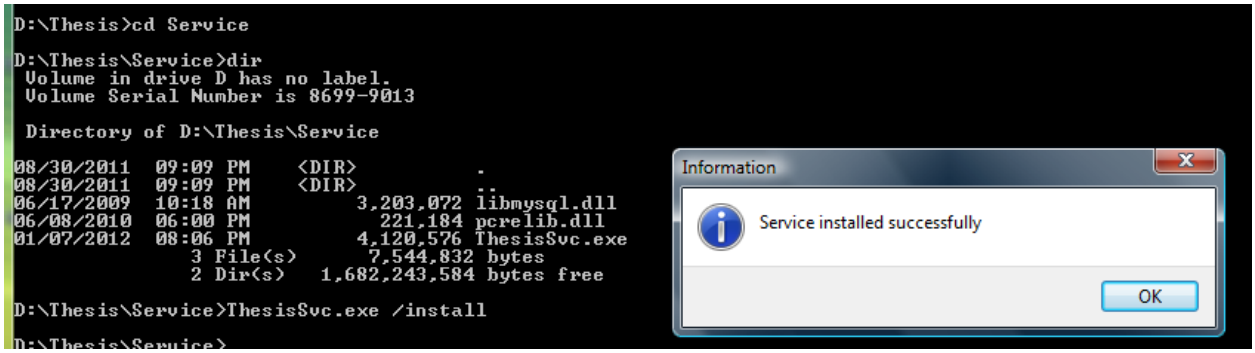


Figure 19. Installing the service makes it visible as a service in the Computer Management Window.

To uninstall a service, similarly, from a DOS windows issue the command: *ThesisSvc.exe /uninstall*.

Figure 20 – Uninstalling the Service Application

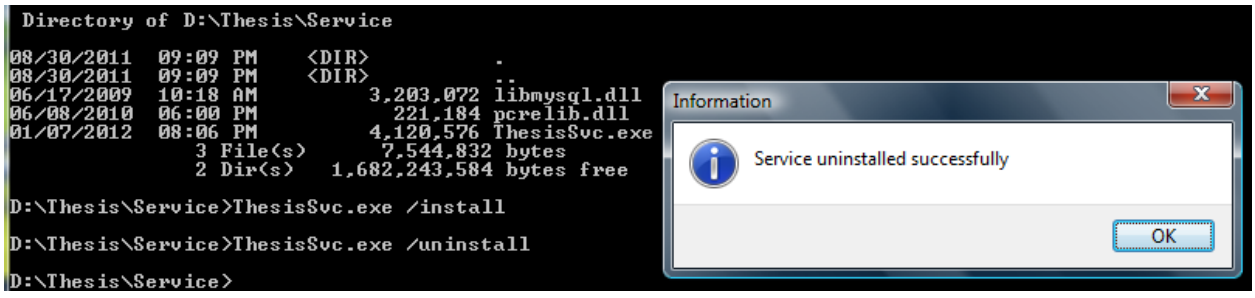

Figure 20. Uninstalling the service removes the service from the Computer Management Window.

The Windows Computer Management window can provide the status of the service application.

Figure 21 – Obtaining Service Status

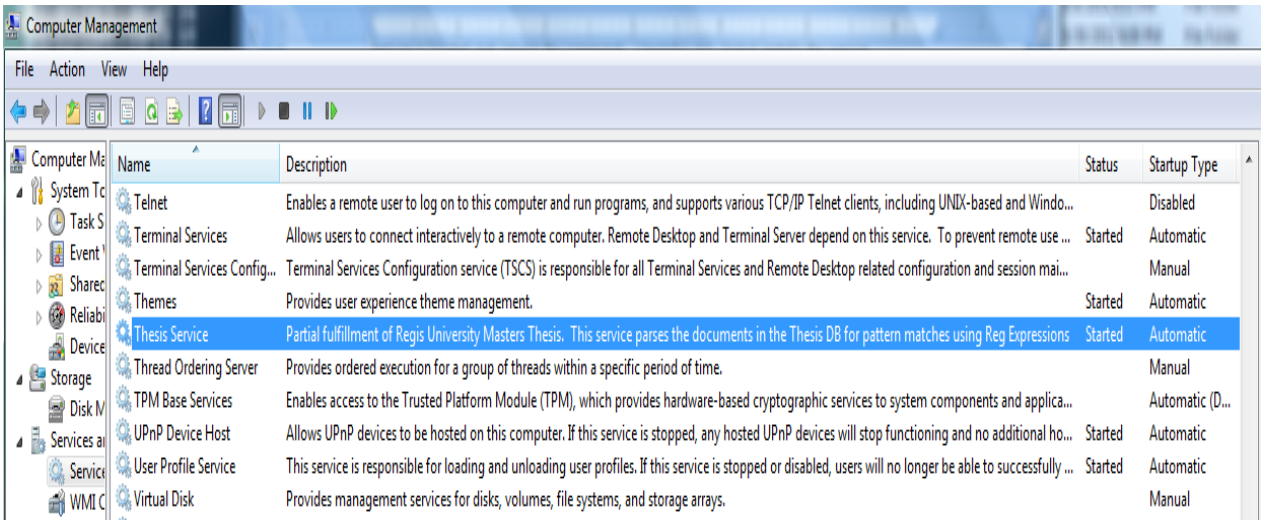

Figure 21. The service will be listed in the Computer Management window. The status should be Started, and the Startup Type should be Automatic.

A network administrator can use this view to monitor the status of the service application to ensure that it is started and that the startup type is automatic, which ensures that the service automatically restarts when the server is restarted.

Chapter 4 – Project Analysis and Results

According to the article, Data Mining Techniques, data mining efforts can be classified as generalized, characterization, association, classification, clustering or pattern matching (Han 1996). This research project attempts to utilize pattern matching, via regular expressions, to create associations among cases. The measure of success for this research project is whether the proposed process does in fact find correlations between cases where they exist, while simultaneously minimizing the possibility of connecting cases that are not related. Evaluating this research project's proposed process will involve identifying the process's strengths and weaknesses, coupled with reviewing the actual results of the document scan to see if the connections between the cases emerged naturally.

Process Fortes

An important aspect of the proposed process permits the cases and documents themselves to reveal any relevant connections without a priori knowledge of what should be searched for. This allows the relationships between cases to be discovered without any human biases a reviewer may bring with them. This not only saves an organization the man-hours involved in document reviews, but also eliminates any prior prejudices that may affect how the case documents are interpreted. Additionally, while no method can be as thorough as manually reading the documents, having an automated process, as this is, does pose a significant benefits, not gained by manually reading. Documents, once scanned, are still available for rescanning. Reprocessing can be prompted for many reasons, such as the modification of the document itself, but also possible are the refinement of the regular expression to better find its intended data class, or the definition of a new regular expression designed to find a new data classes not previously scanned for. Rescanning the entire contents of an organization's document repository is easily accomplished

via the regular expression parser, while manually re-reading the documents would be a major undertaking.

By classifying the case indicators by the regular expression (data class) that was used to identify it, gives the case indicators greater context than by simply collecting an uncategorized list of indicators. Categorization of the case indicators is accomplished within, the unique_matched_text table by having relationships with both the case_file table and the regex_pattern table. This allows for searches within the case indicators to be limited to one or more data classes. Furthermore, confidence on a correlation between different cases can be heightened by the existence of additional shared case indicators, both within or outside the scope of a single data class.

More interesting is the possibility of finding secondary correlations, through common case indicators, which results in a web of connections between cases. The results of the regular expression parsing process show that it is capable of identifying direct connections where they exist, and that it is also capable of also finding the secondary correlations between cases. Furthermore, in an actual production environment version of this research project's proposal, far beyond secondary level connections have been identified throughout multiple years of datasets. Analysts are now exploring these connections to validate if these connections are more than superficial associations.

Results Verifying Case Correlations

As described in Chapter 3, the case viewer application has two specific views that illustrate the case indicators categories by the regular expression used to find them. The first view is case centric, while the secondary takes on a more global view, providing all indicators, solely categorized by the regular expression used to find it. This next section will attempt to illustrate

different levels of connections using those views, followed by snapshots of relationship graphs generated by visualization software on actual datasets that show the web of connection that can be attained through the process proposed in this research project.

The case indicator view is used to view indicators, related to one case. By expanding any node that has children (indicators), it then shows the actual text found with the case that matched the regular expression.

Figure 22 – Case Related Indicators Showing Relationship to Secondary Case

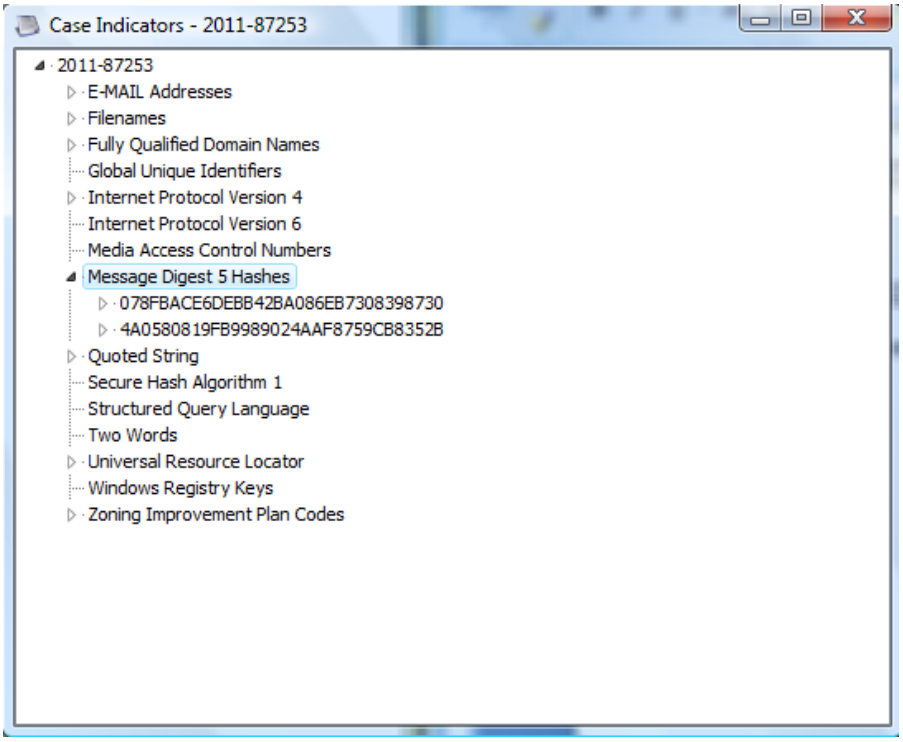

Figure 22. This view shows the indicators associated with case 2011-87253. The MD5 node has been expanded to illustrate actual matches extracted during the scan.

Each node that has related sub-nodes, are identified with diamonds. Expanding the nodes associated with the MD5 case indicators will show other cases that share that same indicator.

Figure 23 – Related Secondary Case

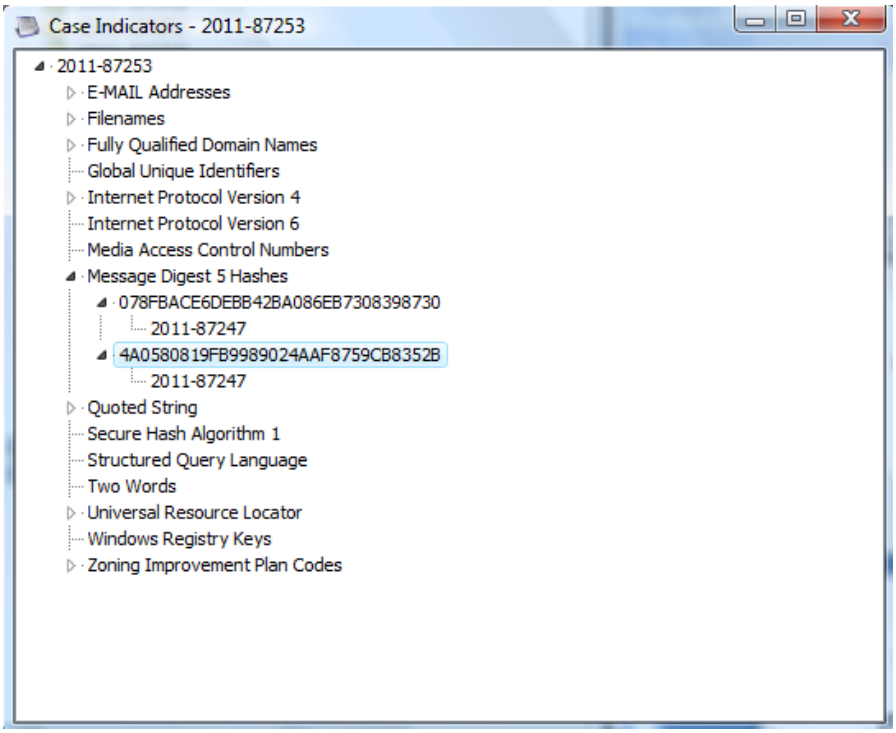

Figure 23. This view shows that case 2011-87247 share two instances of MD5 values with case 2011-87253.

By opening the same case indicator view for the related case, shows the same association to the original case using MD5 values as the link.

Figure 24 – Secondary Case, Confirmation of Association

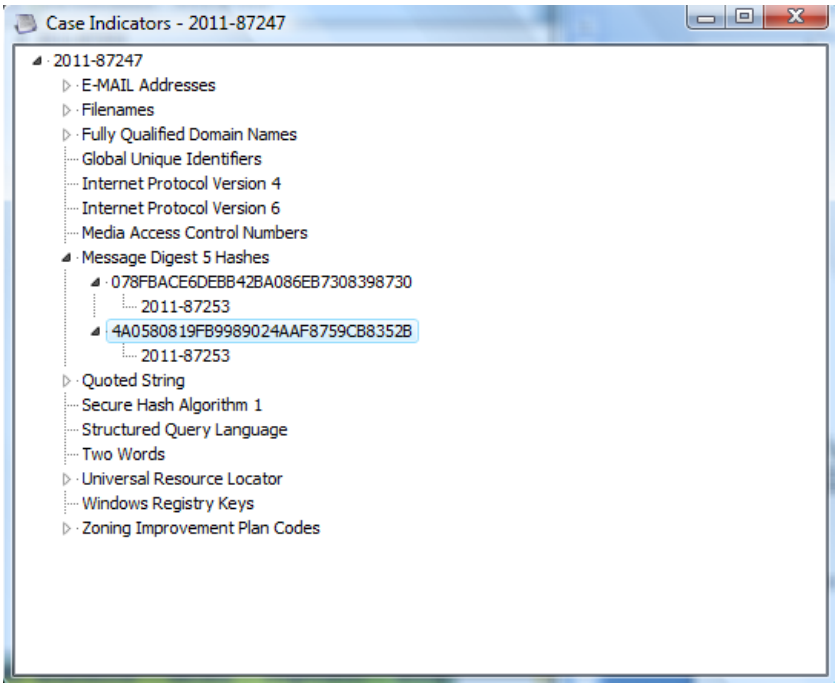

Figure 24. This view confirms that the relationship was established in both directions.

Illustrating secondary relationships are also possible using this view. Interestingly, the next examples, shows two cases that do not directly share any indicators, but are linked via a chain of indicators. In this example, the first two cases share a GUID, followed by the second case sharing an MD5 value with a third case, which chains to a final case using that same MD5 value.

Figure 25 – Demonstration of Relationship Chain

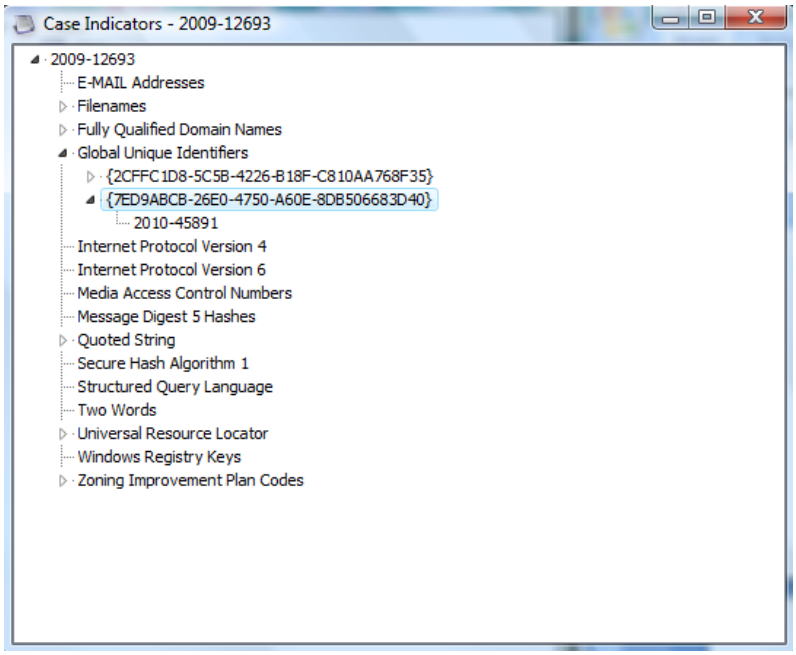

Figure 25. This view shows case 2009-12693 shares a GUID with case 2010-45891.

Figure 26 – Relationship Chain, Secondary Case

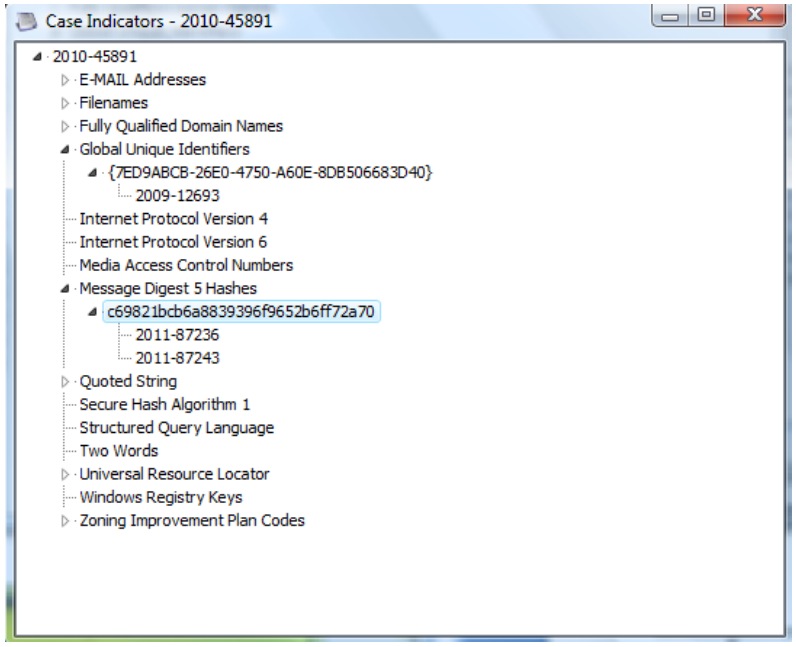

Figure 26. This view shows related case 2010-45891 that is also related to 2011-87342 via MD5.

Figure 27 – Relationship Chain, Related Case with no Direct Link to Original

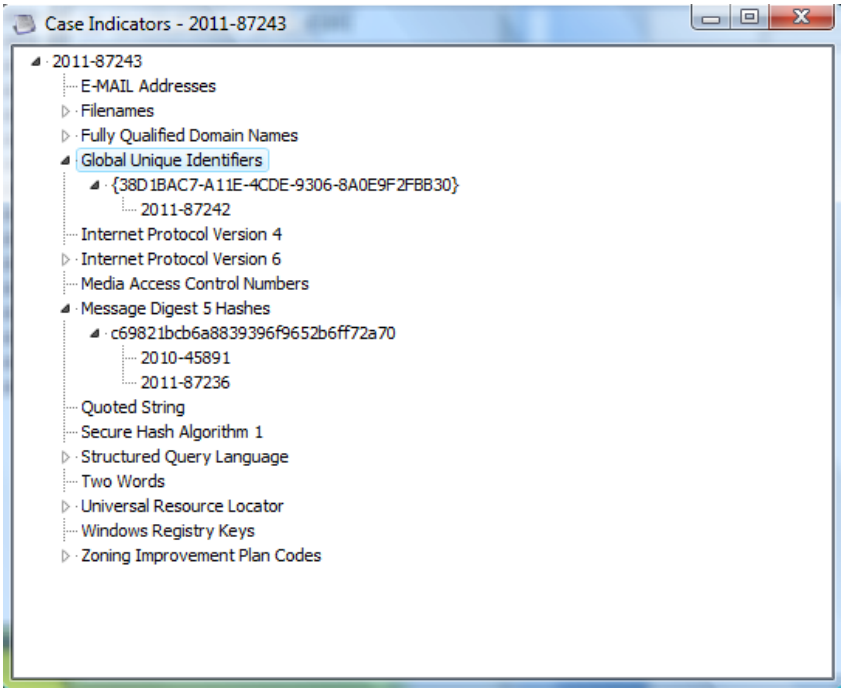

Figure 27. Finally, case 2011-87243 shows the same relationship with 2010-45891, but does not share GUID with original case. Following the link to 2011-87242 furthers the chain of relationships developing a web of relationships.

Finally, using visualization software, a true picture of the types of relationship webs that are extracted, can be fully illustrated. These relationship graphs detailed below were created using live data sets derived from the Department of Defense Cyber Crime Center's Defense Computer Forensics Laboratory, located in Linthicum Maryland. The Department of Defense Cyber Crime Center provides digital evidence processing, supporting fraud investigations and counter intelligence activities (Department of Defense Cyber Crime Center, 2012). The case indicators are related to cases of malware and network intrusions identified by Department of Defense contractors, which can pose a serious national security risk. Forensic examiners are responsible for determining the extent of the intrusion, or damage assessment of malware attacks, and create document artifacts that detail the findings of their examinations. These documents are scanned using a similar process proposed by this research project.

Figure 28 – MD5 Relationship Graph

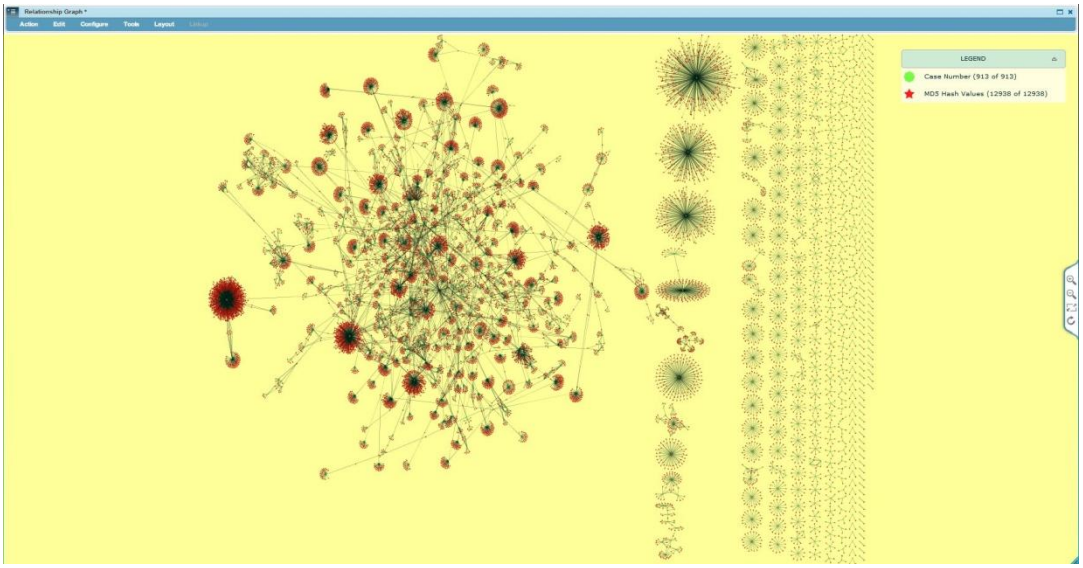

Figure 28. Green nodes represent cases, red nodes represent MD5 values. MD5 values are a major data point for forensic examinations. They can be associated with snippets of code, a file or series of files.

Figure 29 – URL Relationship Graph

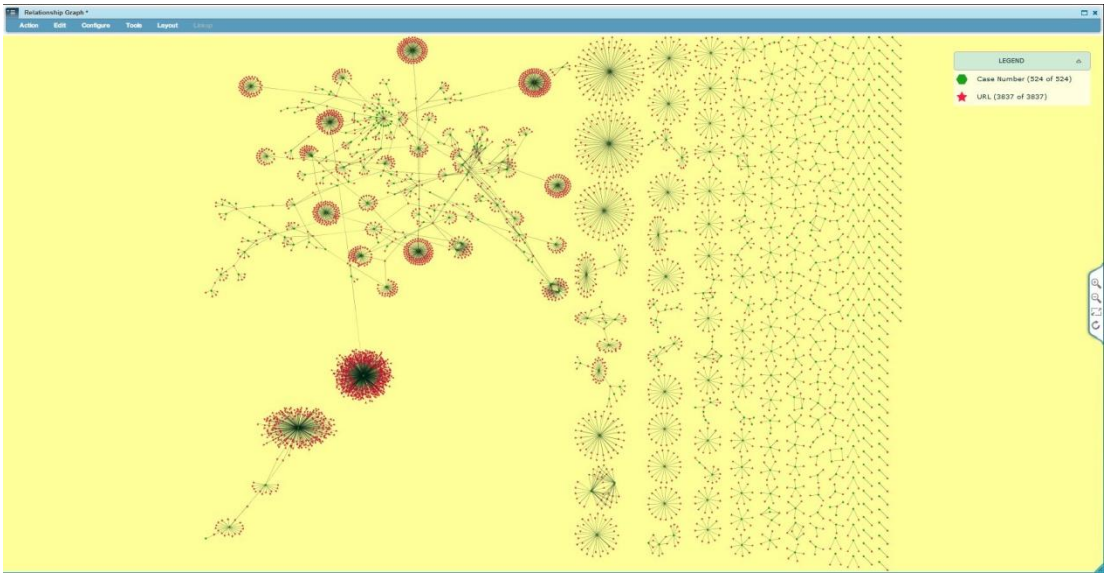

Figure 29. Greed nodes represent cases, red nodes represent URL values. URLs are often indicators of where network data is ex-filtrated to by malware and network intruders.

Process Weaknesses

The process proposed by this research project is not a fool proof method to find all related cases, nor does it guarantee that the relationship it does find is based on a true connection. For all their strengths, finding case indicators via regular expressions are susceptible to the idiosyncrasies of the underlying documents they search. Context of a particular term within a document can easily change the meaning of a relationship. An example that has been experience at the forensic laboratory is cases that identify a particular case indicator, such as URL. While the URL was easily found in the text, the context with the document would actually negate any relationship. Often, cases are forwarded to the laboratory for examination with a belief that it is related to other cases by the investigator. The indicators associated with the other suspected related case is routinely searched for by the examiner, and the outcome of their search is often part of the case documentation, even if the results of the search are negative.

The data class may also be of little intelligence value given the context for an organization. For an organization where most of their business is constrained within a particular geographic area, little, if any, intelligence is gained from links established based on a ZIP code data class. Any such connections could easily be explained by the limited number of values serviced by the organization. Additionally, certain values of a particular data class may also be of minimal importance. Examples of IPv.4 addresses with minimal intelligence value were already described in chapter three; however, these values are easily understood by IP domain experts. Another, not so obvious example may be the MD5 or SHA1 hash value for an empty file, which will always evaluate to D41D8CD98F00B204E9800998ECF8427E for MD5 or DA39A3EE5E6B4B0D3255BFEF95601890AFD80709 for the SHA. Any relationship based on these values is superficial, at best.

Chapter 5 – Conclusions

This research project has shown a proof of concept for utilizing regular expression to search unstructured text for data classes, followed with a method to use the indicators found as a gauge towards determining the likelihood of correlations between cases. As stated, the Department of Defense Computer Forensic Laboratory is already utilizing this method, and has disseminated to their customers, the indicator specific to the cases they have submitted. Defense contractors have used the information provided via .xml export files to harden their internal networks against future attack.

Future Work

Further refinements to this process may increase its success rate at finding case relationships or reveal new aspects of a case or series of cases. The following are specific areas that can be explored in that effort.

Case Tags

Introducing tags associated with cases may increase the confidence of possible relationship between cases. Case tags would be defined as key words discovered directly via human interaction as the document is created and entered into a central repository of tags. Any case could be associated with numerous tags, with tags also capable of being related to numerous cases. To exploit this new data point, case indicators realized through the regular expression search process could also be cross compared against the tags, adding the possibility of relationships discovered through the case indicator to tag connection.

Time Lines

Many of the relationships discovered at the forensics lab point to the evolution of malware through time. Many of these malware applications retain the core of their code, but incorporate

new functionality to circumvent countermeasures or simply to improve upon its operation. As a result of this natural evolution, it is not uncommon to have several versions of the same root malware. By plotting each related case chronologically as they happened with visualization software, a timeline graph may indicate how a particular malware has progressed.

The Case Viewer application was developed using Delphi Professional 2010, however; to recompile this application, additional components are needed. To connect to the MySQL database, the ZEOS database components version 7.0 were used. These components can be found here: http://zeos.firmos.at/. A database aware version of a date and time picker was utilized that can be found here: http://delphi.about.com/library/bluc/ucvcl.htm. Furthermore, the wordprocessing capabilities built into the application were possible through the use of the TRichView components Version 12.0 that can be found here: http://www.trichview.com/, with an added capability to count the number of paragraphs, words, letters contained within a document, which needs RVWordEnum.pas which can be downloaded from http://www.trichview.com/resources/spell/rvspell.zip

The Regular Expression Parser application was developed using Delphi Professional 2010, however; to recompile this application, additional components are needed. To connect to the MySQL database, the ZEOS database components version 7.0 were used. These components can be found here: http://zeos.firmos.at/. To calculate the MD5 Hash values necessary to save matched text to the unique_matched_text table, the dcpCrypt components were used, which can be found here: http://www.cityinthesky.co.uk/opensource/dcpcrypt. To conduct the regular expression searches, the PCRE Regex component was used, and can be found here: http://www.regular-expressions.info/delphi.html. Finally, while wordprocessing capabilities were not part of this application, the TRichView components Version 12.0 were still utilized specifically to extract the pure text from the documents and can be found here: http://www.trichview.com/.
