# ABSTRACT <br> JULIAN'S FORECASTING 

Krista Bowdle

This report focuses on developing a solution to a current problem faced at Julian's Cafe and Bistro. The problem is that inaccurate order quantities are leading to inventory shortage and surplus which is causing unnecessary profit loss. After accessing and analyzing historical sales data, several forecasts were created using various approaches. After assessing each method and applying a mean absolute percentage error to see how accurate the forecasts were, the seasonal forecast with removing outliers initially was the selected method. After, this method was used to forecast the top three selling items at Julian's and make demand predictions for busy times during the quarter versus non-busy time. The forecast for the coming year and the predictions can be used by the supervisor at Julian's to make quicker and more accurate ordering decisions.

## ACKNOWLEDGMENTS

I would like to thank my technical advisor, Dr. Nianpin Cheng, for the all the support, encouragement, time, and assistance she has given me throughout this project.

## I. Introduction

The subject of this report is inventory management and order optimization using forecasting at Julian's Cafe Bistro. The idea for this project originated from a previous group project in a different class. In IME 305 (Operations Research II), a group of student and I briefly looked into the current inventory tracking methods at Julian's by interviewing one of their employees. We gathered that there was no standardized or clear method that all employees followed which lead to disorganization and incorrect order quantities because current inventory levels were unclear and the supervisor was struggling to order the correct amounts of raw material. This seemed like an interesting problem to look into and design a solution for my senior project. The problem is that incorrect order quantities are causing inventory shortages and surpluses which leads to sale opportunity loss and wasted space in their small storeroom. The supervisor needs a better system when it comes to making ordering decisions. It is also difficult to predict how much to order because of the varying demand at Julian's. This variation comes from variables such as weather, time of day, time in the quarter, and special sale items. Depending on these factors, Julian's will sell more or less of certain items. This is an important problem to address because it currently leads to unnecessary inventory shortages and surpluses which ultimately wastes money for the business. Metrics to evaluate this problem are how long it takes the supervisor to make an order and the wasted product cost when a shortage or surplus occurs.

Some objectives for my project are as follows:

- Execute the project using IME curriculum such as operations research, inventory management, order quantity optimization, seasonal forecasting and process improvement
- Plan and manage the project using timelines and due dates
- Perform research on the IME topics I will be utilizing
- Measure forecasting error
- Design an engineering solution for Julian's
- Present results and recommendations
- Write a complete technical report
- Give a business plan presentation

To solve the problem at Julian's, an accurate current state analysis is needed to be made using flow process charts and data to quantify how much of a problem it is. This also involves interviewing the supervisor and getting her feedback on how relevant procedures and operations are currently done. Then, there is a need for adequate research and finding appropriate literature review resources in order to become an expert on the topics and see how other similar businesses are currently running their inventory management and ordering systems. Next, brainstorming and designing the best design and methodology for my solution is crucial. For this project, there is a developed solution to the problem, a technical report, and a business plan presentation. A deliverable from the work done is a seasonal forecast of the sales at Julian's to better aid the supervisor in making orders and help her understand the seasonal trends on campus. Another deliverable is a comparison of busy times in the library to non busy times and how that effect sales. The solution approach to be used to reach these objectives involve getting a clear understanding of what is useful to the supervisor, forming potential solutions, choosing the best
solution that is the most beneficial to Julian's and how it will save them money if they use it in the future. This report begins with background information and literature review, then moves onto the design section, followed by methodology and results.

## II. Background

This chapter contains background on Julian's, a current state report, and a summary of literature that pertains to my project. Julian's is located on the Cal Poly campus on the second floor of the Kennedy Library. They operate as a popular coffee and snack cafe for busy students as they are studying in the library. Some common items they sell are regular hot coffee, specialty coffee drinks, various snack items and pastries. Julian's operates under Campus Dining which operates under the Cal Poly Corporation. Recently, Julian's experienced many changes to their operations including a new supervisor and a new management software that the supervisor is expected to use. This software is called Order Management Software (OMS) and the supervisor at Julian's mainly uses it to keep track of inventory. Currently, the supervisor takes inventory about once a week by bringing a list to their storeroom and then counting and recording everything they have by hand. She then updates these inventory levels into OMS by Thursday to be reviewed by purchasing. For ordering, Julian's currently gets supplies from various vendors such as Sysco Corporation and LA \& SF Specialty, depending on the product needed. After viewing current inventory levels and using her best judgment from previous experience, the supervisor places an order approximately weekly, depending on the vendor's delivery availability. The flow process chart in figure 1 shows this current process.

Current state ordering process flow chart (done weekly)

Figure 1 Current state flow process chart.

Since there is not a standardized system in place for ordering, there can be shortages and surpluses which creates missed sales opportunity and wasted space in their limited stockroom.

Figure 2 shows a fishbone diagram to identify the root cause for these shortages and surpluses.

CAUSES OF INVENTORY SHORTAGE/SURPLUS

## Literature Review

The literature review for this report consists of references and information within those references that pertains to this project. This information has various case studies, definitions, and possible solutions to problems that are similar to the challenges faced at Julian's. The references stem from the overarching topics of inventory management and optimal order quantity. The literature review helped me come up with ideas for possible solutions to the inventory management problem at Julian's.

## Inventory Management

Proper inventory management is crucial for the success of a company, especially in a food service business like Julian's because they don't want any of their product to go bad and they also have a small storeroom so they can't afford excess inventory. There are five general types of inventory (Stevenson, 2005). The five most common are raw material and purchased goods, partially completed goods, finished goods, replacement parts, and goods-in-transit (Stevenson, 2005). Partially completed goods usually is classified as work in progress and finished goods can be a company's merchandise. The inventory types at Julian's are raw material, partially completed goods, and finished goods. The raw material are items such as coffee beans and chai latte powder while partially completed goods are drinks that are in the process of being made by the employees. Their inventory consists of mainly finished goods which are items such as cups, straws, and the food items that they order. The functions of inventory are to meet forecasted demand, smooth production requirements, decouple operations, avoid stock-out, take advantage of quality discounts and order cycles, and to help protect against price increases (Stevenson, 2005). Julian's mainly uses their inventory to meet forecasted
demand and avoid stock-out. The objective of inventory management is to achieve good customer service levels while keeping inventory costs low (Stevenson, 2005). These inventory costs usually consist of ordering and carrying costs. Effective inventory management leads to keeping track on current inventory levels, reliable forecasting of demand, knowledge of lead times, reasonable ordering, holding, and shortage cost estimates, and a proper classification system (Stevenson, 2005). The most important feature that effective inventory management can help improve Julian's is demand forecasting. There are many ways to keep track of inventory. Knowing accurate inventory levels can aid in accurate order quantities. The first inventory counting system is a periodic system when someone physically counts the items routinely (Stevenson 2005). This is what the supervisor at Julian's is currently doing. The next counting system is a perpetual inventory system which is when you accurately keep track of what comes out of inventory (Stevenson, 2005). That way you can know how much you need to replace on the next order. The next inventory counting system is a two-bin system. This is when each item in inventory has two containers that hold designated amounts and you reorder when the first container is empty (Stevenson, 2005). This is a method that might be useful at Julian's. The last inventory counting system is a universal barcode system where each item has a label that can be scanned on it with information pertaining to that item (Stevenson, 2005). These are all ways to keep more accurate current inventory levels which is crucial when deciding how much to order.

Inventory management in a foodservice organization can be particularly challenging because product has a shelf life and can go bad which is unwanted waste. You also don't want to order too much product because often there is limited storage space. In his paper, Spears discusses the flow of food through various food service options. Inventory control specifically
within food service organizations is crucial to keeping up with customer demand (Spears, 1995). There are many factor that go into the effectiveness of inventory management. After performing a study, Shiau Wei Chan found that "underproduction, overproduction, stockout situation, delays in the delivery of raw materials and discrepancy of records" are the main problems in inventory management (Chan, 2017). These can be seen in figure 3.

Figure 3 Main problems with inventory management.
Even though Julian's doesn't "produce" anything in the manufacturing sense, the concept still applies to when the supervisor over or under orders items. Chan also talks about how effective inventory management is important for a business to be more competitive. Common influencers on the effectiveness of inventory management are "the factors, documentation/store records, planning, and knowledge of employees/staff skill" (Chan, 2017). These are all important features to keep in mind when managing inventory.

Inventory management can also directly affect the daily operations at a company. There was a study done by Cham Springer to test a performance model that examined the relationship
between inventory management and firm operation performance. From the study, they found that "inventory efficiency and productivity significantly impact firm operating performance" and "firms that operate a leaner and more efficient inventory system significantly outperform competitors" (Springer, 2016). Dirk Pons in Management Control. A Survey of Production and Inventory Control Models in Theory and Practice also discusses the importance of inventory control while providing insight on production control objectives, sales and capacity planning, and integrated operating systems. He claims that "you should begin by raising the problem to a higher level and examining a great deal of the essential policy questions to be able to start working out the most suitable materials management system" (Pons, 51). All in all, adequate inventory management leads to a much more successful business with less waste.

## Optimal Order Quantity

There are many methods when it comes to deciding how much and how often to order depending on the industry, demand, and inventory size allotment. Getting the most optimal order quantity can yield great savings and in the end can make or break a company. At Julian's, optimal ordering is especially important because of their limited storage space and perishable items. This can be a difficult task though with the varying and sometimes unpredictable demand. Chih-Hsiumg Wang reiterates this and claims that "the reorder point plays a role in balancing the costs between the inventory holding and shortage" (Wang, 2010). There a many techniques that have been discovered over the years to tackle this reordering problem. In 1963, Hadley and Whitin initially developed a quantity and reorder point model to deal with varying demand where an order of $Q$ is placed once the inventory level reaches the reorder point $R$ (Wang, 2010). Later in 1996, Wang and Gerchak created a more general formula for order quantity and reorder point
with varying capacity (Want, 2010). Some variables in this formula include production cost per unit, inventory holding cost per unit, and order quantity (Wang, 2010). To deal with the varying demand, they introduced an X variable that represents the random demand during a replenishment lead time with a probability density function, cumulative distribution, and a survival distribution (Wang, 2010). The solution structure then depends on the distribution of the lead time demand. This method was proven to be useful in many inventory environments.

Using point of sales data to decide how much to order is also a useful and more methodological technique. Understanding what customers want and when they want it can be a major advantage to a company. Sethi claims that companies should obtain in advance information on their customer demand. He explains that there is an optimal Markov policy that is a modified base-stock policy (Sethi). This can be useful when deciding how much to order. He also says that "regrouping the forecasting effort from all sources such as firm orders received, preseasonal sale information, and point of sales data, has been remarkably effective in obtaining advanced demand information" (Sethi). When you know what your customers want, you can order properly ahead of time and optimize sales. Another example of a technique to evaluate what customers want is using MarketAnalyzer. Market Analyzer is an interactive visual analytics system to help vendors increase their competitive intelligence by analyzing present sale data, trends, and market share growth (Wiley). Wiley explains why this is important for a company to be successful by claiming that "competitive intelligence is a systematic approach for gathering, analyzing, and managing information to make informed business decisions. Many companies use competitive intelligence to identify risks and opportunities within markets". Using approaches
like MarketAnalyzer can help a company get insight on what their customers are going to want so they can accurately order ahead of time in preparation.

Several other models have been developed to help aid optimal ordering quantity when there are unknowns such as demand. The IEEE Conference Publication posted an article about economic order quantity (EOQ) with "fuzzy" demand. The term "fuzzy" refers to a variable that is unstable and varies. They use three types of variables to represent the uncertain demand and expected value of the total cost function is minimized. They explain that "fuzzy set theory is applied to represent uncertainties arising in demand or the cost coefficients. By using it, one can easily quantify the vagueness and imprecision in data" (De). They use lambda pessimistic and optimistic values for various L-R types of numbers in varying demand inventory models ( De ). Using a method like this could greatly benefit Julian's because they experience a similar varying demand that the model accounts for. Another method that stems from the traditional EOQ model was developed by Victoria Mabin and is a simple approach to ordering only involving the order size Q and the reorder point R (Mabin, 1989). This approach appeals to inventory controllers and management because it can obtain order quantity directly and it is an easy to understand approach so they trust it (Mabin, 1989). The model involves a total cost function of order quantity and reorder level which can be broken down to constants such as safety stock and holding cost (Mabin, 1989). In order to get the final solution, it classifies reorder level as being equal to an average constant plus safety stock (Mabin, 1989). This method is known to be quick but effective. It also saves on computer time since the model is so easy to use by supervisors and managers. Julian's could also greatly benefit from a simple model like this that the supervisor could run before doing her weekly orders.

This project is important in the context of this literature review because I will be coming up with a solution to optimize both inventory and ordering at Julian's. This literature review shows the importance of proper inventory management and optimal order quantities and how it can help a business save money and time. It also provides many methods and models that have been done in the past to try and tackle this problem. The insights from this literature review will be used to form a clear solution to the inventory and ordering challenges faced at Julian's.

## III. Design

This chapter will go through the design of solutions to the inventory problem faced at Julian's. After many meetings with the supervisor at Julian's to see what information and data was available, it seemed like their historical sales data was an underutilized resource. There was a clear need for a forecast at Julian's using their historical sales data so the supervisor could be more aware of trends throughout the quarter and make better order decisions accordingly. Some requirements for the design of the solution is that it uses valid data to make the forecast and that it accurately projects sales for the upcoming year. A constraint for the design is that it only uses the past four years of data in order to encompass a more manageable data size, but still enough to capture the seasonal trends.

To begin, the historical sales data was obtained from the supervisor at Julian's. I was given access to their Oracle MICROS system which captures all of the sales at Julian's. I decided to pull the weekly total amount of each item sold over the past four years because it captured the weekly varying demand that the project needed, but was still manageable for me to sort through. An example of the file that was exported from MICROS directly into Excel is shown on Table 1 in the appendix section. After creating 155 individual Excel files containing the weekly total sales, a VBA code was developed to pull the date, item, and quantity sold from each file and input it into four new Excel files for each of the four years. Then, the data was cleaned by removing duplicate and irrelevant data fields from the files.

Next, the data was to be visualized and analyzed. I combined all four years of data showing the item, quantity, and week period sold to one new Excel file. Then, I created a pivot table with the data sorted weekly and a seperate pivot table to analyze the data for monthly sales.

Table 2 in the appendix shows the total weekly sales data pivot table and Table 3 shows the total monthly sales data pivot table. After creating the pivot tables, the data was graphed to visually compare each year of sales to identify initial trends. The weekly and monthly graphs can be seen below in figure 4 and 5.

Figure 4 Weekly sales data.

Figure 5 Monthly sales data.
After analyzing the data, I decided to use the monthly sales data for the forecast because it was a more manageable data size that still captured the seasonal trends. I also knew the weekly sales data was available if I wanted to go back later and create an even more detailed forecast and analysis. By observing the graphs, the peaks occur during dead week and finals week which usually fall around week ten and eleven of the quarter. During these weeks of the quarter, more students are studying on campus and in the library and are more likely to purchase items at Julian's. The gaps in the graphs occur when classes are not in session such as winter or summer break when there are little to no customers at Julian's. The outliers in the data occur because throughout the past four years, the quarterly schedule hasn't been consistent. For example, one of the years we had three weeks off for winter break while another year we had four weeks off which created significantly less sales in December for that year.

To design the initial forecast, the data from the total items sold monthly at Julian's was used. A new Excel file was created that contained the month and corresponding total sales for that month in two columns. Then a "time" column was created as an ongoing time reference from 1 to 54 . Then, the seasonal average for each month was obtained by taking the average sales for every corresponding month. Next, the seasonal index was created by dividing the seasonal average value by the average of all the monthly demand values. After that, the data was deseasonalized by dividing the original demand for each month by the seasonal index. To find the trend, the regression function was used with the time column and deseasonalized data column to obtain a y-intercept and a slope value. Then, to find the final trend value, the time value was multiplied by the slope and added to the y-intercept value previously found. Finally, the forecast was created by multiplying the trend value by the corresponding seasonal index. The mean absolute percentage error was also created by taking the absolute value of the difference between the forecast and the actual demand for that month and dividing it by the same actual demand and multiplying it by 100 to make it a percentage. The table for my initial forecasting solution can be found in the appendix on table 4. Next, I graphed the data which can be seen below in figure 6, comparing the actual demand in blue to my forecast in orange.

Figure 6 Graph using seasonal forecasting to compare actual demand to forecasted demand.
In order to create and compare alternative solutions using different forecasting methods, a moving ranges forecast was also created on a new Excel sheet. It started with the same time, month, and demand column as the previous solution. Then, the moving average forecast was found by taking the average of the previous year's monthly demand. Next, the ratio of moving averages was created by dividing the demand by the moving average forecast previously found. Then, the unadjusted seasonal index for one entire year cycle was calculated by taking the average of the ratio moving averages for every corresponding month over the four years of total data. Next, the adjusted seasonal index was created by dividing the unadjusted seasonal index for each month in the year cycle by the average of all the unadjusted seasonal index for the months in that same year cycle. Then, a seasonally adjusted series was created by dividing the actual demand for every month by the previously calculated adjusted seasonal index. Then, the regression function was used with the time column and the seasonally adjusted series column to obtain a y-intercept and slope value. To find the trend forecast, the time value was multiplied by
the slope value and added to the y-intercept. Then finally, the seasonally adjusted forecast was calculated by multiplying the previously found trend forecast value by its corresponding adjusted seasonal index. The mean absolute percentage error was also calculated the same way as the previous solution in order to evaluate the accuracy of the measurements. The calculations and values for this forecasting solution can be found on table 5 in the appendix. The graph comparing the actual demand in blue, the seasonally adjusted forecast in grey and the trend forecast in orange can be seen in figure 7 below.

Figure 7 Graph using moving ranges forecasting to compare actual demand to trend and seasonally adjusted forecast.

The next alternative solution was similar to the first one but the outliers were removed from the data set initially. The outliers that were removed can be seen as the highlighted values in figure 8 below. They were selected because the month values were significantly different compared to the same month values over all four years.

| Month | 2014 | 2015 | 2016 | 2017 | 2018 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 1 | 19919 | 19411 | 21828 | 19593 | 14690 |
| 2 | 28041 | 26221 | 34127 | 24894 | 17689 |
| 3 | 26521 | 26816 | 30205 | 21768 | 14650 |
| 4 | 22967 | 24475 | 26473 | 24910 | 8062 |
| 5 | 39608 | 35702 | 30148 | 22432 |  |
| 6 | 6799 | 7733 | 12818 | 14216 |  |
| 9 | 9078 | 9156 | 5182 | 8362 |  |
| 10 | 27621 | 29269 | 30257 | 27954 |  |
| 11 | 31511 | 33589 | 17817 | 16175 |  |
| 12 | 9079 | 7785 | 16245 | 5792 |  |
|  |  |  |  |  |  |

Figure 8 Outliers removed from the data set.
After removing the outliers, the same calculations were made as the first seasonal forecasting solution. Table 6 in the appendix shows the calculations and values and figure 9 below shows the graph comparing the demand in blue to the forecasted demand in orange.

Figure 9 Graph using seasonal forecasting with outliers removed to compare actual demand to forecasted demand.

The final forecasting alternative solution was created by using a seasonal forecast with smoothing done first. A new Excel file was generated with the same time, month, and demand
columns as the previous solutions. Then, the smoothed demand was created with a damping factor of 0.9 by multiplying actual demand value by 0.1 and multiplying the previous smoothed demand value by 0.9 and then adding those two values together. Next, a seasonal average was created by taking the average of all the corresponding month values over the four years of data. Then, the seasonal index was found by dividing the previously found seasonal average value by the average of all the smoothed demand values. Then, the data was deseasonalized by dividing the smoothed data by the seasonal index. Then the trend, forecast, and mean absolute percentage error were calculated by using the same regression method and formulas as the first solution. The values for these calculations can be found on table 7 in the appendix and the graph can be seen below in figure 10 with the actual demand represented by the blue line, the smoothed demand in orange, and the forecast in grey.

Figure 10 Graph using seasonal forecasting with smoothing to compare actual demand to the smoothed demand and forecasted demand.

This chapter explains the design of the forecasting solutions for the project in detail.

There are four solutions revolving around seasonal forecasting. One is more traditional seasonal forecast, a moving ranges forecast, a seasonal forecast with outliers removed and a seasonal forecast with smoothing.

## IV. Methodology

This chapter will discuss the methods for testing the designs of project solutions and choosing the best solution. As discussed in the previous design chapter, the mean absolute percentage error was calculated for each solution. The average MAPE for each of the solutions can be seen in figure 11 below.

| Method | Seasonal | Moving ranges | Seasonal w/o outliers | Seasonal smoothing |
| :---: | :---: | :---: | :---: | :---: |
| MAPE | $21.1 \%$ | $84.2 \%$ | $14.2 \%$ | $3.7 \%$ |

Figure 11 Average MAPE for each solution.

By default, I was going to choose the solution with the lowest average MAPE value which would be the seasonal forecasting with smoothing. However, when looking at figure 9 above, the smoothed demand varies greatly from the actual demand and doesn't capture the variation seen at Julian's enough. Therefore, I chose the next lowest MAPE solution which is the seasonal forecasting with outliers removed. This chapter shows how a solution was selected to pursue for the rest of the project.

## V. Results and Discussion

This chapter will present the results of my project when applying the selected solution above. Next, I applied the seasonal forecasting with outliers removed solution to the top three selling items at Julian's. These items are iced coffees, 16 ounce hot coffees, and iced lattes. I used the initial pivot tables that I created to sort these three items individually sold monthly over the past four years. Then I created three new Excel files for each item.

Outliers were removed from the data set for each item which can be seen in the highlighted fields in tables 8, 9, and 10 in the appendix. Then I performed the chosen seasonal forecasting with outliers removed method to each item. The calculations and values can be found in the appendix section on tables 11,12 , and 13. The graph for the iced coffee solution can be seen below in figure 12.

Figure 12 Iced coffee forecast.

The blue line represents the actual demand while the orange line shows the forecasted demand.
The peaks occur during busy times in the library in addition to warm weather because people generally want iced drinks when it is hot outside. The graphs for the 16 ounce hot coffee and iced latte are shown below in figure 13 and 14 with the blue line being the actual demand and the forecasted demand in orange.

Figure 1316 oz . hot coffee forecast.

Figure 14 Iced latte forecast
Next, I extended the formulas to come up with the forecasted sales for the three top selling items. The results can be seen in figure 15 below.

| Month | Iced coffee forecast | 16 oz coffee forecast | Iced latte forecast |
| :---: | :---: | :---: | :---: |
| 1 | 2094 | 2145 | 544 |
| 2 | 2988 | 2802 | 870 |
| 3 | 3971 | 2239 | 1048 |
| 4 | 4049 | 2132 | 880 |
| 5 | 2218 | 2995 | 1220 |
| 6 | 1647 | 584 | 483 |
| 9 | 5258 | 2224 | 300 |
| 10 |  |  |  |

| 11 | 2903 | 2021 | 602 |
| :---: | :---: | :---: | :---: |
| 12 | 1236 | 960 | 277 |
| MAPE | $16.9 \%$ | $18.1 \%$ | $24.4 \%$ |

Figure 15 Projected forecast of top selling items.
There is a gap in between months 6 and 9 because of July and August when Julian's is closed are there is no sales data. The MAPE is also calculated at the bottom to show the accuracy of the calculations. As observed, the months containing busy times such as dead week and finals week, have a forecasted demand that is significantly higher. The supervisor at Julian's should anticipate this increase in sales and make sure to order accordingly beforehand. The results were as expected because they followed the seasonal trends that occur throughout the year when considering busier time such as finals week and slower times such as the first week in each quarter when not very many people have a lot of work to do so they are not in the library as often. It is a good design because of the relatively low mean absolute percentage error which shows that the results are valid.

In order to compare the top selling items during a regular week in the quarter, week 5 , and a busy time in the quarter, week 10, I looked found the top three selling items. In figure 16 below, it shows that iced coffee, 16 ounce hot coffee, and 12 ounce hot coffee are consistently the top selling items, regardless of the time in the quarter.

| Week/Item | Iced coffee | 16 oz. coffee | 12 oz. coffee |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 5 | 673 | 643 | 533 |  |  |  |  |
| $\%$ of total sales |  |  |  |  | $9.43 \%$ | $9.01 \%$ | $7.47 \%$ |
| 10 | 1173 | 739 | 577 |  |  |  |  |
| $\%$ of total sales |  |  |  |  | $12.94 \%$ | $8.15 \%$ | $6.37 \%$ |

Figure 16 Comparison of top selling items.
In addition, I wanted to compare the average total items sold during week 5 of the quarter to week 10 of the quarter to the supervisor can anticipate how much more to order during busy times in the library. Figure 17 below shows the total sales averages. By dividing the week 10 total sales by the week 5 total sales, it shows that the supervisor should order $231 \%$ more material during the busy times at the library. I predict with the aid of this forecast and analysis, it will take the supervisor at Julian's about half as long to place orders.

| Week 5 average total sales | Week 10 average total sales |
| :---: | :---: |
| 6583 | 15208 |

Figure 17 Busy vs. not busy comparison.
A difficulty that came up when interpreting the results was when the trends for various items didn't match month to month over the four years. This most likely occurred because of weather variability meaning when it's hot out people usually want iced drinks and when it's cold out people usually want hot drinks more. Another difficulty when interpreting the results was the presence of outliers in the data set because of varying quarter lengths. This inconsistency required careful attention, especially when applying the forecasting formulas in Excel.

Implementing this solution will help the supervisor at Julian's make more accurate and exact order quantity decisions. Based on the results, it can be predicted that the sales at Julian's
will follow the forecast and trends presented. Problems might occur when the supervisor adds new items to the menu because we don't have sales data on those new items yet so therefore, cannot make a forecast. However, the staple items such as cups, coffee beans, milk, and espresso beans have been ordered for years and years in the past and will continue to be ordered for many years to come. Implementing my project will have numerous impacts. The first is an organizational impact. Providing an accurate seasonal forecast will not only make Julian's more money because of the decrease in shortages and surpluses when it comes to ordering, but it will ultimately make the supervisor's job easier. The supervisor that I have be working with is very busy and it seems like employees are constantly coming to her asking questions or for help with various tasks during her time at Julian's. Not only is she suppose to be readily available for the student employee baristas, but she has many other tasks to be doing including going to meetings, answering emails, taking inventory, receiving shipments, and making orders. By referencing my forecast, the supervisor will spend less of her valuable time thinking about order quantities and varieties and can place orders quicker. Implementing this project will also have an environmental impact because there will be less surpluses and wasted raw material. This especially effects products that spoil quickly such as food and milk. Knowing the optimal amount of product to have in their store room will avoid ordering too much which later has to be thrown away. All in all, my project will reduce the carbon footprint at Julian's and create a more sustainable system with less waste.

## VI. Conclusions

This chapter will conclude the report and summarize the project. The calculated forecast will be helpful to the supervisor at Julian's in many ways. First, she can be more aware of the monthly sales trends at Julian's. She can also use the insights from the data visualization and analysis to make more accurate and educated ordering decisions of over 100 items sold at Julian's. For example, she knows now to order twice as many raw material for iced coffee during dead week and finals week compared to most other regular weeks during the quarter. These more accurate order quantities will create less shortage and surplus inventory waste and in the end help them make more profit. Throughout this project, I learned about data gathering and analysis and how to apply the data to create a forecast. I learned about forecasting in my classes, however that was usually with small amount of data points. It was interesting to use a vast amount of real data to apply forecasting techniques.

If I were to do some further studies at Julian's, I would look into forecasting all of the items sold at Julian's and not just the top 3 sellers. I would also try to convert the numbers of items sold to its raw material equivalence so that the supervisor knows exactly how many cups or espresso beans to order if they're expecting to sell 5,000 cappuccinos next March for example. I would also like to compare my forecast for the next year to the actual sales that happen over the next year and see how much the inventory shortage and surplus went down if the supervisor followed my order suggestions. I would also like to look into automatic forecasting for all the items sold at Julian's.
