# Tire cavity induced structure-borne noise study with experimental verification

Ray W. Herrick Laboratories,  
Purdue University, USA  
Rui Cao\* and J. Stuart Bolton  
August/27<sup>th</sup> 2018

# I. Introduction

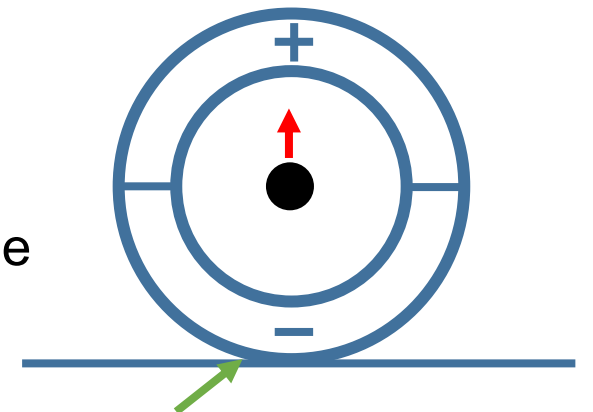

# I. Introduction

---

- High frequency interior noise is mostly airborne and usually is not associated with structural vibration from road excitation. However, low frequency noise, has a strong association with structural vibration and can be perceived by the passengers.
- A major component of structure-borne noise comes from the tire's acoustic cavity mode near 200 Hz

***Why do two tires of **same size** and geometry, from different manufacturers, have very **different responses**, in terms of cavity noise perception?***

- Study force transmission from contact patch excitation to rim center
- How the cavity resonance may affect force transmission
- Ways of identifying bad tires/good tires, in terms of structure-borne noise

## II. A previous finite element tire model

---

**A Finite Element structural-acoustical tire model was created to investigate the tire cavity-induced structure-borne noise**

Assembled model

Air cavity model

Meshed assembled model

A 245/40R20 tire was used for dimensions

## II. A previous finite element tire model

---

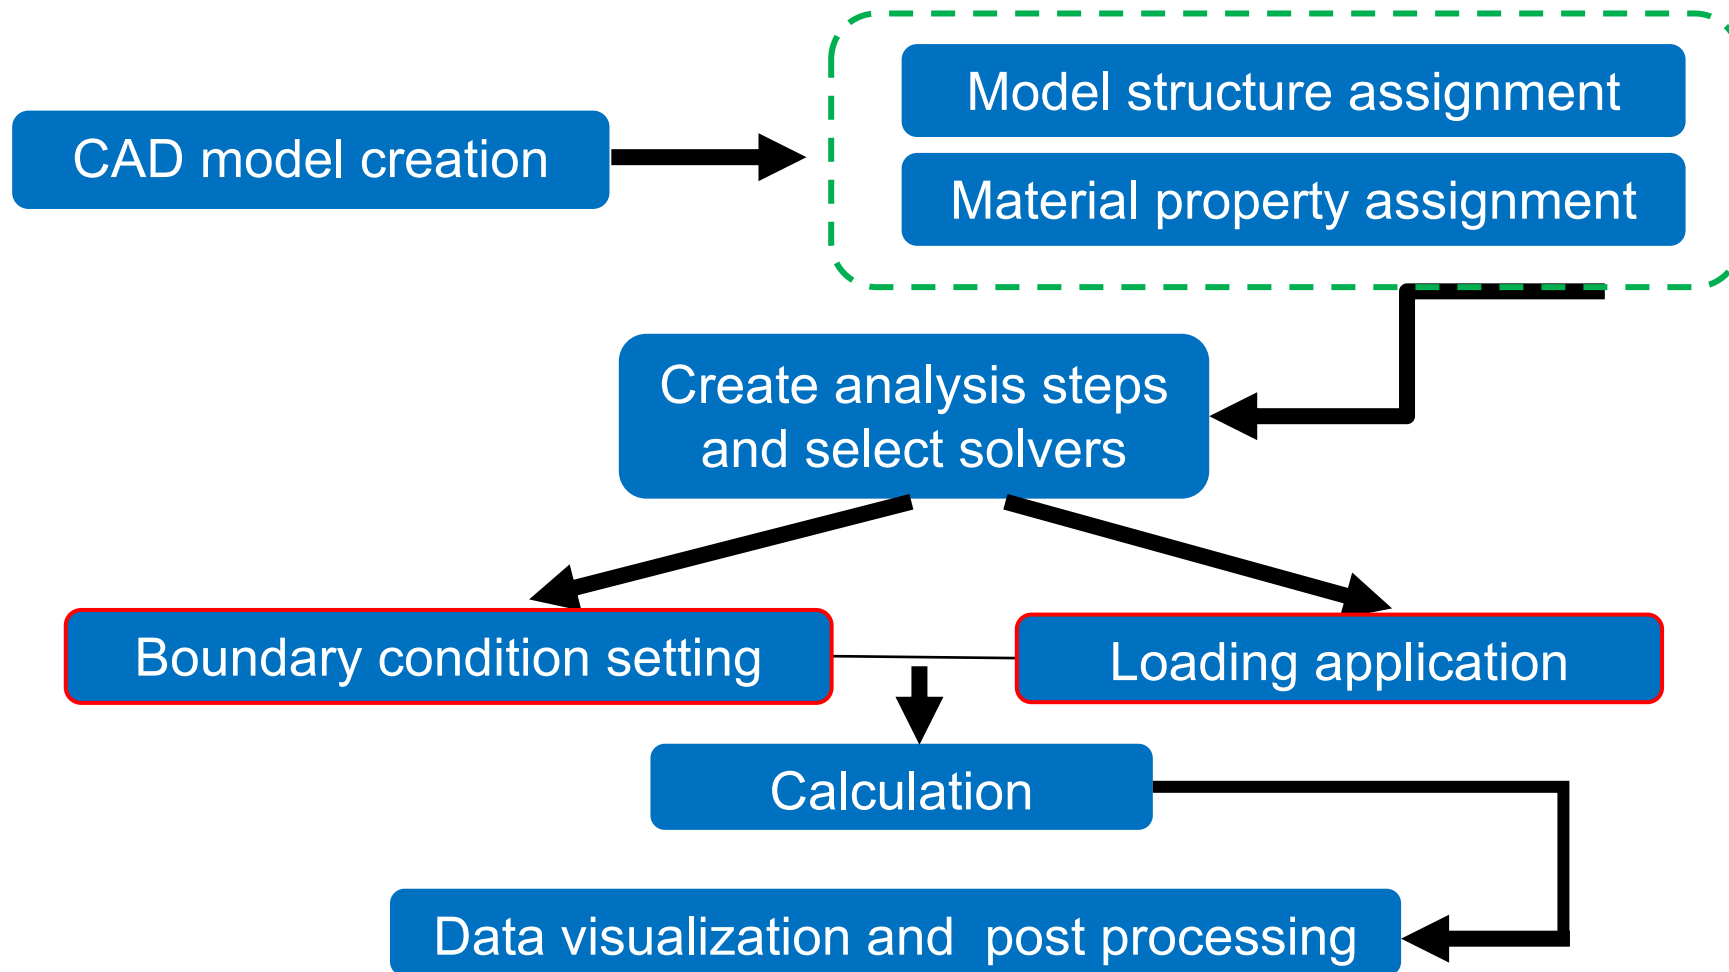

All parts are assumed homogeneous material

Part	Density [kg/m <sup>3</sup> ]	Modulus [Pa]	Thickness [mm]	Poisson's ratio
Rim	2700	$7 \times 10^{12}$	10	0.3
Tread	1200	$7.5 \times 10^8$	10	0.45
Sidewall	800	$5 \times 10^7$	8	0.45
Air	1.204	149180	N/A	N/A

- ❖ Material properties were simplified and approximated
- ❖ Rim was set to be very stiff, so its resonances were above the frequency of interest in this study
- ❖ Air bulk modulus was given at 97 °F

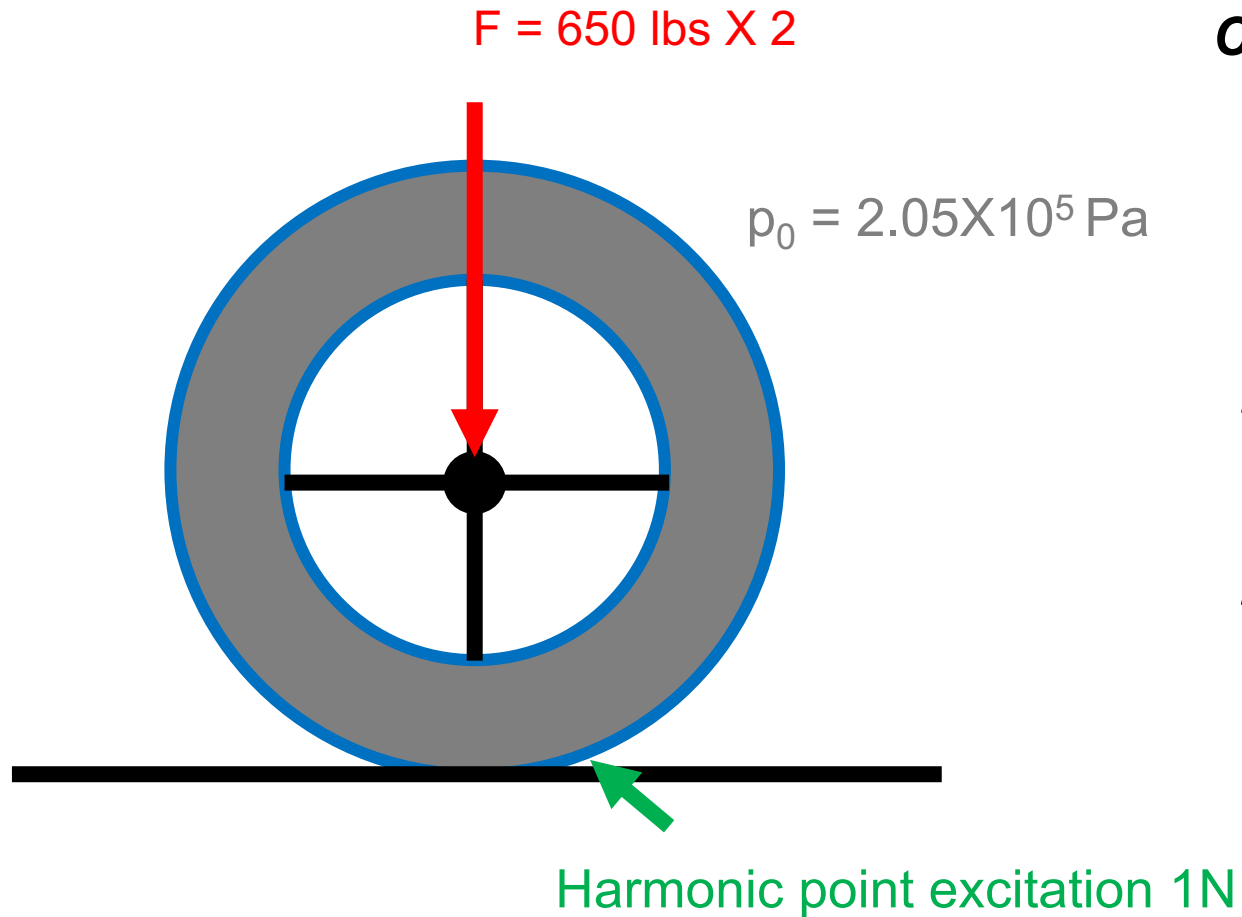

## II. A previous finite element tire model

---

## II. A previous finite element tire model

### Excitations and boundary conditions

**BC -**  
**Continuity boundary**  
**Contact boundary**

**Load -**  
**Vertical static loads**  
**Static inflation pressure**  
**Point harmonic excitation**

## II. A previous finite element tire model

Spatial Surface velocity  
- unloaded tire

Drive point

Velocity was measured at points  
along the tire tread centerline

Dispersion relations  
- unloaded tire

Dispersion was based on the  
wavenumber decomposition of  
the surface mobility data

## II. A previous finite element tire model

Vertical cavity mode (pressure distribution)

Horizontal cavity mode (pressure distribution)

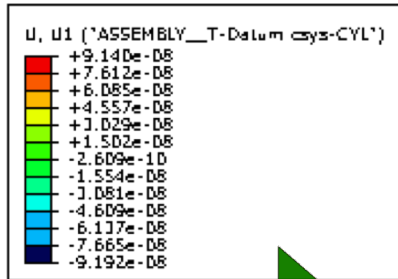

- ❖ Deformation causes cavity resonance split
- ❖ One occurs below undeformed cavity resonance (horizontal)
- ❖ One occurs above undeformed cavity resonance (vertical)

Undeformed resonance: 200.1 Hz; vertical mode: 201.4 Hz; horizontal mode: 199.3 Hz

## II. A previous finite element tire model

1<sup>st</sup> cavity mode - horizontal

Deformed Var: U Deformation Scale Factor: +3.000e+00

# II. A previous finite element tire model

## 9<sup>th</sup> structural mode

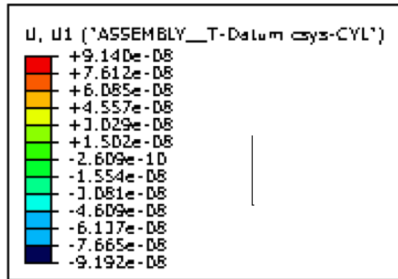

Side views

## II. A previous finite element tire model

9<sup>th</sup> structural mode

Top view

Motion on two sides cancel each other, except for the peak on top

ODB: Job-GYR20\_FreeAble\_PVW1.odb Abaqus/Standard 6.13-4 Wed Sep 20 10:48:12 Eastern Daylight Time 2017

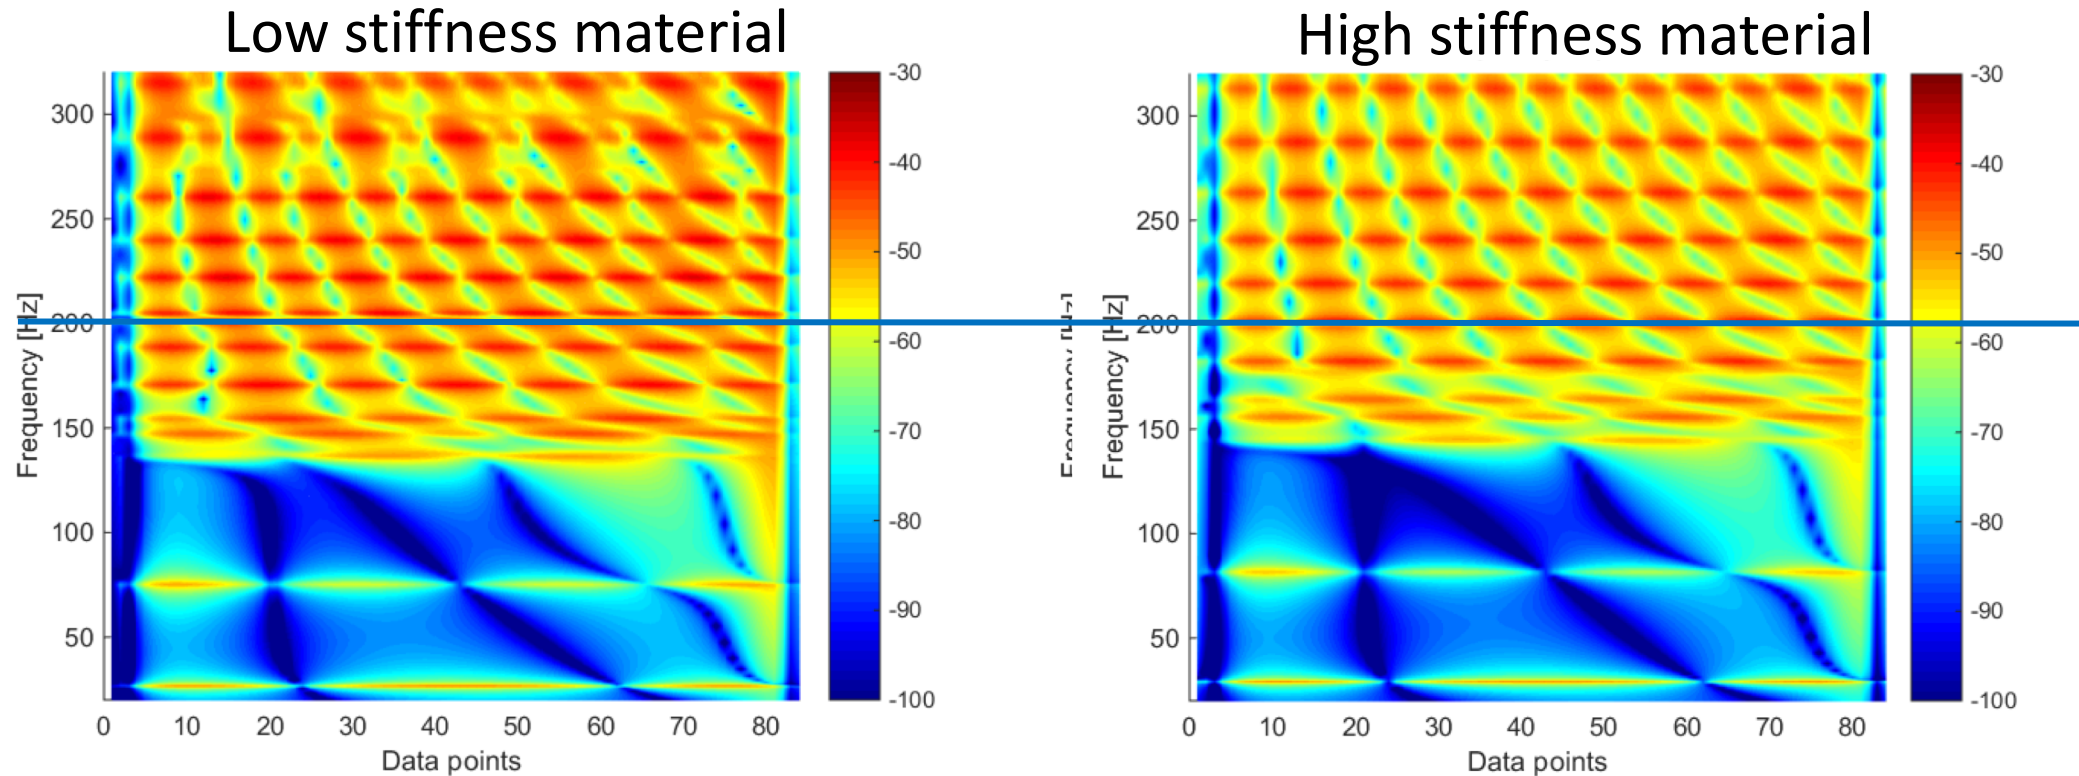

Step: Step-1  
Mode: 20; Value = 1.78211E+06 Freq = 212.52 (cycles/time)  
Primary Var: U, U1 ('ASSEMBLY\_\_T-Datum csys-CYL')  
Deformed Var: U; Deformation Scale Factor: +3.000e+00

When 9<sup>th</sup> circumferential structural mode has same frequency as the vertical cavity mode, large response is observed

## II. A previous finite element tire model

---

### Align the structural resonance with cavity resonance

## II. A previous finite element tire model

### Compare with a model without air cavity

**Low Stiffness**

Vertical cavity mode  
= 9<sup>th</sup> structural mode

**High Stiffness**

Vertical cavity mode  
= 8<sup>th</sup> structural mode

Without air – fore-aft motion is substantially reduced near 200 Hz for high stiffness case

## II. A previous finite element tire model

### Compare with a model without air cavity

**Low Stiffness**

Vertical cavity mode  
= 9<sup>th</sup> structural mode

**High Stiffness**

Vertical cavity mode  
= 8<sup>th</sup> structural mode

Without air - vertical motion is substantially reduced near 200 Hz

### III. Experiment verification

---

#### *Laser Doppler Vibrometry*

- Measure tire surface velocity

#### *Tire set up*

- Static tire mounted on a rig
- driven by a mini-shaker

# III. Experiment verification

## Test facility

Tire Pavement Testing Apparatus (TPTA)

at Ray W. Herrick Laboratories, Purdue University, West Lafayette, IN

- ❖ Tires run at 50 km/hr
- ❖ Loaded up to 6000 N, inflation set at 33 psi
- ❖ Tests run with and without fibrous lining in the cavity

## Sensors

Tri-axial accelerometer mounted on the rigid hub

- ❖ Z-direction – normal to the pavement surface
- ❖ Y-direction – axial direction
- ❖ X-direction – tire travel direction

# III. Experimental result

## Static dispersion results

- ❑ Static cavity resonance is close to an odd structural mode for Tire 1
- ❑ Static cavity resonance is close to an even structural mode for Tire 2

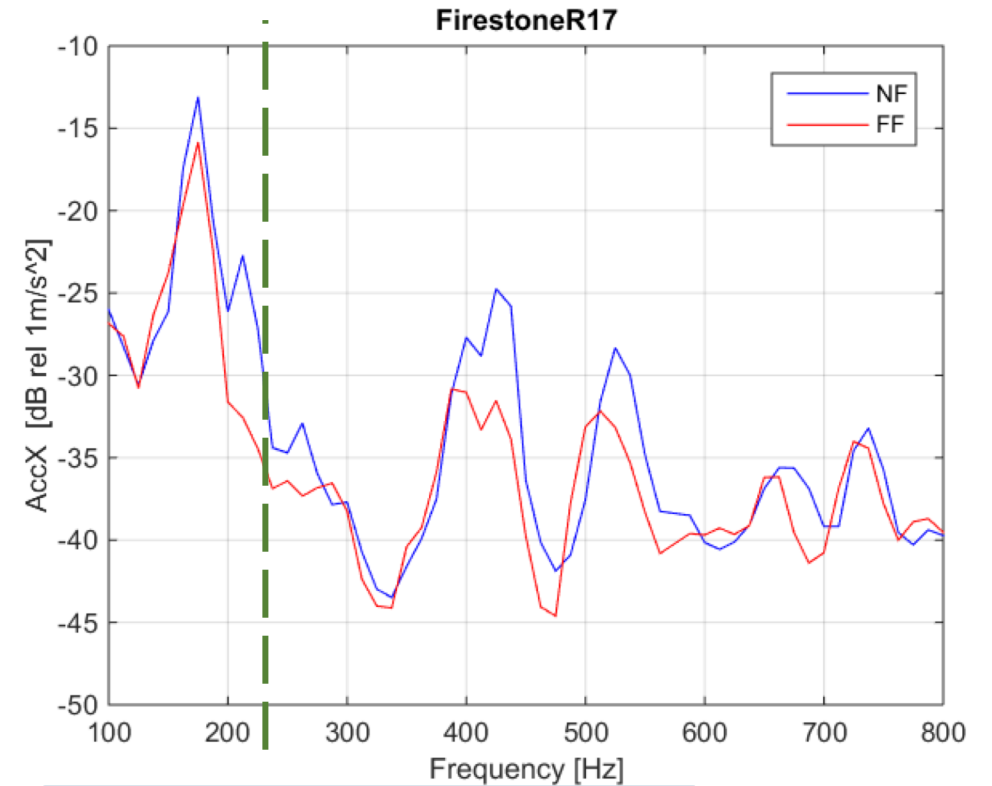

# III. Experimental result

## *Rim center accelerations – X-direction (fore-aft)*

Static cavity resonance: 205 Hz

Static cavity resonance: 211 Hz

- ❑ 5-10 dB reduction seen at resonance frequencies
- ❑ Larger reduction seen in Tire 2

### III. Experimental result

#### *Rim center accelerations – Z-direction (vertical)*

Static cavity resonance: 205 Hz

Static cavity resonance: 211 Hz

- Higher response compared to the x-direction
- Larger reduction seen in Tire 1

### **Conclusion**

- ❑ Both the finite element model and the tests confirmed that, if the **vertical cavity mode** couples with an **odd-number structural mode**, the rim center acceleration will be increased, especially in vertical directions
- ❑ If the **horizontal cavity mode** couples with an **even-number structural mode**, the rim center acceleration will be increased, especially in fore-aft directions
- ❑ The **acoustic material** was found to effectively **decouple** the cavity resonance from the structural resonance by absorbing the cavity resonance, thus substantially reducing the resultant narrow-band vibration levels around 200 Hz, in both fore-aft and vertical directions
