2 Patients with symptoms suggestive of acute myocardial infarction (AMI) account for  
3 about 10% of all emergency department (ED) presentations.(1) The majority of  
4 patients are finally found to have diagnoses other than AMI.(2) Thus, the expeditious  
5 evaluation of such patients is important as delays in ruling out AMI may interfere with  
6 the detection of other underlying diseases. The 0/1hour(h)-algorithm and the 0/3h-  
7 algorithm are both recommended by the European Society of Cardiology (ESC) with  
8 a class I recommendation for the early rule-out of AMI.(1) The 0/1h- and the 0/3h-  
9 algorithm are completely different protocols. While the 0/1h-algorithm uses high-  
10 sensitivity cardiac troponin (hs-cTn) concentrations at presentation and absolute  
11 changes within the first hour, and hence takes optimal advantage of the increased  
12 diagnostic accuracy and precision of hs-cTn assays, the 0/3h-algorithm uses a fixed  
13 threshold protocol based on the 99<sup>th</sup> percentile at presentation and 3h in conjunction  
14 with clinical criteria (Global Registry of Acute Coronary Events (GRACE) score below  
15 140 and the need to be pain-free). It is currently unknown whether one algorithm is  
16 preferable to the other.

17 The aim of this study was to directly compare safety quantified by the negative  
18 predictive value (NPV) and the negative likelihood ratio (LR) for the presence of AMI,  
19 and efficacy quantified by the proportion of patients triaged towards rule-out in a  
20 large diagnostic multicenter study enrolling patients presenting with suspected AMI to  
21 the ED (NCT00470587). The study was carried out according to the principles of the  
22 Declaration of Helsinki and approved by the local ethics committees. Written  
23 informed consent was obtained from all patients. Patients presenting with ST-  
24 Segment-Elevation MI were excluded. Triage towards rule-out by the 0/1h- or the  
25 0/3h-algorithm was compared against the final adjudication performed by two  
26 independent cardiologists using all information including cardiac imaging and serial

27 hs-cTnT measurements. Analyses were performed using hs-cTnT and hs-cTnI. NPV  
28 and efficacy were compared using McNemar's test, respectively Pearson  $\chi^2$  test.  
29 95%-Confidence intervals were calculated using the Wilson score method without  
30 continuity correction.

31       Among 2547 patients eligible for analysis using hs-cTnT, AMI was the final  
32 adjudicated diagnosis in 387 patients (15%). The 0/1h-algorithm provided similar  
33 safety compared to the 0/3h-algorithm (NPV 99.8% (95%CI 99.4-99.9%) and  
34 negative LR 0.01 (95%CI 0.00-0.03) versus 99.7% (95%CI 99.2-99.9%) and 0.02  
35 (95%CI 0.00-0.05)), but allowed to rule-out significantly more patients as compared  
36 to the 0/3h-algorithm (60% vs. 44%,  $p<0.001$ ). Among 2197 patients eligible for  
37 analysis using hs-cTnI, AMI was the final diagnosis in 327 patients (15%). The 0/1h-  
38 algorithm provided higher safety compared to the 0/3h-algorithm (NPV 99.6%  
39 (95%CI 99.1-99.9%) and negative LR 0.02 (95%CI 0.01-0.05) vs. 97.8% (95%CI  
40 96.7-98.5%) and 0.13 (95%CI 0.09-0.19)), and allowed to rule-out a similar portion of  
41 patients as compared to the 0/3h-algorithm (52% vs. 51%,  $p=0.507$ , Figure 1).

42       Overall, 711 patients (28%) presented within the first two hours from chest  
43 pain onset (CPO). Safety for the 0/1h- and 0/3h-algorithm using hs-cTnT was very  
44 high (NPV 99.6% (95%CI 98.4-99.9%) versus 100% (95%CI 98.9-100%) and  
45 comparable to late presenters (CPO>2h) with 99.9% (95%CI 99.5-100%) versus  
46 99.6% (95%CI 98.9-99.9%), respectively. The 0/1h-algorithm allowed to rule-out  
47 more patients compared to the 0/3h-algorithm in early presenters (64% versus 49%  
48  $p<0.001$ ) and in late presenters (59% versus 42%,  $p<0.001$ ). Findings were  
49 confirmed using hs-cTnI as well as using 30-days survival as an additional outcome  
50 measure for safety with survival rates of 99.9%-100% for patients triaged towards  
51 rule-out by both algorithms.

52           These findings corroborate and extend previous work on the development and  
53 validation of safe and effective rule-out strategies for AMI and have important clinical  
54 implications.(3–5) The excellent safety achieved with both algorithms documents the  
55 suitability of most of these patients for early discharge and outpatient management.  
56 Beyond the more favorable combination of safety and efficacy by the 0/1h-algorithm  
57 versus the 0/3h-algorithm, the following features may help physicians and institutions  
58 in the selection of their preferred triage algorithm. First, the 0/1h-algorithm has the  
59 obvious and important additional advantage of allowing clinical decision-making two  
60 hours earlier as compared to the 0/3h-algorithm. As most patients triaged towards  
61 early rule-out are also candidates for direct discharge from the ED, it is very likely  
62 that it will reduce time to discharge and treatment cost in the ED. Second, the 0/1h-  
63 algorithm does not require the use of a specific risk score, which further increases its  
64 feasibility. Previous studies have documented that omitting any of the three elements  
65 of the 0/3h-algorithm (hs-cTn, GRACE-score, pain-free criteria) in an effort to simplify  
66 the approach would worsen its safety and is therefore discouraged.(3) When putting  
67 our findings into clinical perspective, it is important to highlight that the 0/1h-algorithm  
68 and the 0/3h-algorithm should always be used in conjunction with all clinical  
69 information available. This is of paramount importance as among patients presenting  
70 with acute chest discomfort to the ED, the rule-out of AMI is related to the possibility  
71 of rapid discharge and outpatient management, but not identical to it.

72           In conclusion, the 0/1h-algorithm is superior to the 0/3h-algorithm using hs-  
73 cTnT as well as hs-cTnI, as it more favorably combines safety with efficacy.

## 77 **Funding**

The study was supported by research grants from the Swiss National Science Foundation, the European Union, the Swiss Heart Foundation, Abbott, Beckman Coulter, BRAHMS, Roche, Siemens, 8sense, Nanosphere, Alere and the Department of Internal Medicine, University Hospital Basel.

## **Conflict of interests**

The authors designed the study, gathered and analyzed the data, vouched for the data and analysis, wrote the paper, and decided to publish. Drs. Badertscher, Boeddinghaus, and Mueller had full access to all the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis. All

authors have read and approved the manuscript. The sponsors had no role in designing or conducting the study and no role in gathering or analyzing the data or writing the manuscript. The manuscript and its contents have not been published previously and are not being considered for publications elsewhere in whole or in part in any language, including publicly accessible web sites or e-print servers.

We disclose that Dr. Boeddinghaus received speaker honoraria from Siemens and research grants from the University of Basel and the Department of Internal Medicine. Dr. Twerenbold has received research support from the Swiss National Science Foundation (P300PB\_167803), the University of Basel, the University Hospital of Basel and the Cardiovascular Research Foundation Basel as well as speaker honoraria/consulting honoraria from Roche, Abbott, Brahms, Siemens and Singulex. Dr. Rubini received speaker honoraria from Abbott and the research support from the Swiss Heart Foundation. Dr. Reichlin has received research grants from the Goldschmidt-Jacobson-Foundation, the Swiss National Science Foundation (PASMP3-136995), the Swiss Heart Foundation, the Professor Max Cloëtta Foundation, the Uniscientia Foundation Vaduz, the University of Basel and the Department of Internal Medicine, University Hospital Basel as well as speaker honoraria from Brahms and Roche. Dr. Mueller has received research support from the Swiss National Science Foundation, the Swiss Heart Foundation, the KTI, the Stiftung für kardiovaskuläre Forschung Basel; Abbott, Alere, Astra Zeneca, Beckman Coulter, Biomerieux, Brahms, Roche, Siemens, Singulex, Sphingotec, and the Department of Internal Medicine, University Hospital Basel, as well as speaker honoraria/consulting honoraria from Abbott, Alere, Astra Zeneca, Biomerieux, Boehringer Ingelheim, BMS, Brahms, Cardiorientis, Novartis, Roche, Siemens, and Singulex.

All other authors declare that they have no conflict of interest with this study. The investigated hs-cTn assay were donated by the manufacturers, who had no role in the design of the study, the analysis of the data, the preparation of the manuscript, or the decision to submit the manuscript for publication.

**Figure 1** Direct comparison of the 0/1h- and 0/3h-algorithm for early rule-out of AMI using hs-cTnT (A) and hs-cTnI (B)

The figure is illustrating both co-primary endpoints: safety, as quantified by the negative predictive value (%), and efficacy (proportion of patients assigned to ruled-out, %). Bars represent 95% confidence intervals, hs-cTn = high sensitivity cardiac troponin. AMI = acute myocardial infarction.
