# DECLARATION OF CO-AUTHORSHIP AND PREVIOUS PUBLICATION

## *Co-Authorship*

I hereby declare that this dissertation incorporates material that is a result of joint research, as follows:

**Chapter 2** of the dissertation contains results published in the original research communication “2,6-Bis(benzimidazol-2-yl)pyridines as more electron-rich and sterically accessible alternatives to 2,6-bis(imino)pyridine for group 13 coordination chemistry” (Swidan, A.; Binder, J. F.; St. Onge, P. B.; Suter, R.; Burford, N.; Macdonald, C. *Dalton Trans.* **2019**, 1284–1291). Mr. St. Onge contributed to the synthesis and characterization of some of the reported compounds, Mr. Binder contributed to the computational studies, Dr. Macdonald and Dr. Suter helped in the writing and editing of the manuscript.

**Chapter 3** of the dissertation contains results published in the original research article “2,6-Bis(benzimidazol-2-yl)pyridine Complexes of Group 14 Elements” (Swidan, A.; St. Onge, P. B.; Binder, J. F.; Suter, R.; Burford, N.; Macdonald, C. *Dalton Trans.* **2019**, 48, 7835-7843). Mr. St. Onge contributed to the synthesis and characterization of some the reported compounds, Mr. Binder contributed to the computational studies, Dr. Macdonald helped in the writing, editing and provided ideas to investigate and include in the manuscript.

**Chapter 5** of the dissertation contains results published in the original research article “Tris(benzoimidazol)amine (L) complexes of pnictogen(III) and pnictogen(V) cations and assessment of the  $[LP]^{3+}/[LPF_2]^{3+}$  redox couple” (Swidan, A.; Suter, R.; Macdonald, C. L. B.; Burford, N. **2018**, 5837–5841). Dr. Suter contributed to the synthesis and characterization of some of the reported compounds as well as in the computational studies, writing, and editing of the manuscript. Dr. Macdonald contributed to the computational studies, writing, and editing of the manuscript.

I am aware of the University of Windsor Senate Policy on Authorship and I certify that I have properly acknowledged the contribution of other researchers to my dissertation and have obtained written permission from each of the co-author(s) to include the above material(s) in my dissertation. I certify that, with the above qualification, this dissertation, and the research to which it refers, is the product of my own work.

### ***Previous Publication***

This dissertation includes 3 original papers that have been previously published/submitted for publication in peer-reviewed journals, as follows:

<b>Dissertation Chapter</b>	<b>Publication title/full citation</b>	<b>Publication status</b>
Chapter 2	"2,6-Bis(benzimidazol-2-yl)pyridines as more electron-rich and sterically accessible alternatives to 2,6-bis(imino)pyridine for group 13 coordination chemistry" Swidan, A.; Binder, J. Chapter 3	"2,6-Bis(benzimidazol-2-yl)pyridine Complexes of Group 14 Elements" Swidan, A.; St. Onge, P. B.; Binder, J. F.; Suter, R.; Burford, N.; Macdonald, C. <i>Dalton Trans.</i> <b>2019</b> , 48, 7835-7843.	Published
Chapter 5	"Tris(benzoimidazol)amine (L) complexes of pnictogen(III) and pnictogen(V) cations and assessment of the [LP]3+/[LP2]3+ redox couple" Swidan, A.; Suter, R.; Macdonald, C. L. B.; Burford, N. <b>2018</b> , 5837–5841.	Published

I certify that I have obtained written permission from the copyright owner(s) to include the above published material(s) in my dissertation. I certify that the above material describes work completed during my registration as a graduate student at the University of Windsor.

### ***General***

I declare that, to the best of my knowledge, my dissertation does not infringe upon anyone's copyright nor violate any proprietary rights and that any ideas, techniques, quotations, or any other material from the work of other people included

*DECLARATION OF CO-AUTHORSHIP AND PREVIOUS PUBLICATION*

in my dissertation, published or otherwise, are fully acknowledged in accordance with the standard referencing practices. Furthermore, to the extent that I have included copyrighted material that surpasses the bounds of fair dealing within the meaning of the Canada Copyright Act, I certify that I have obtained written permission from the copyright owner(s) to include such material(s) in my dissertation.

I declare that this is a true copy of my dissertation, including any final revisions, as approved by my dissertation committee and the Graduate Studies office and that this dissertation has not been submitted for a higher degree to any other University or Institution.

## ABSTRACT

2,6-bis(benzimidazol-2-yl)pyridine derivative (G-BZIMPY, G = NBn, N(3,5-CF<sub>3</sub>)Bn, N-allyl and O) have been used as pincer ligands to coordinate and isolate various group 13-15 complexes. For Group 13, treatment of G-BZIMPY with two equivalents of GaCl<sub>3</sub> results in the self-ionization products [G-BZIMPYGaCl<sub>2</sub>][GaCl<sub>4</sub>]. This Ga(III) complex can be reduced to a Ga(I) centre using K<sub>2</sub>[Fe(CO)<sub>4</sub>] as a reducing agent to result in the Ga(I) complex [(NBn-BZIMPY)(Cl)Ga-Fe(CO)<sub>4</sub>] (Chapter 2).

Group 14 complexes of G-BZIMPY have been synthesized in a similar fashion through the self-ionization reactions of G-BZIMPY with two equivalents of MCl<sub>2</sub> (M = Ge, Sn) to yield [G-BZIMPYMCl][MCl<sub>3</sub>]. Attempts to reduce these complexes into the M(0) centre were not successful. Other reactivities and UV-vis studies are detailed in this dissertation (Chapter 3). Comparison of group 13 and 14 complexes of G-BZIMPY to complexes of the structurally similar bis(imino)pyridine (DIMPY) are studied and reveal G-BZIMPY as a stronger donor than DIMPY for group 13 coordination. For group 15 elements, treatment of PnCl<sub>3</sub> (Pn = P, As, Sb) with G-BZIMPY does not yield any reactivity, however, the addition of TMS-OTf (Trimethylsilyl trifluoromethanesulfonate) results in the isolation of [G-BZIMPYPnCl][OTf]<sub>2</sub> (Chapter 4).

In-addition, a tetradentate ligand tris((1-ethyl-benzoimidazol-2-yl)methyl)amine (BIMe<sub>3</sub>) has been investigated. A series of cationic complexes involving a pnictogen(III) (Pn = P, As, Sb) centre coordinated to BIMe<sub>3</sub> have been synthesized and comprehensively characterized. Oxidation of [P(BIMe<sub>3</sub>)]<sup>3+</sup> with

*ABSTRACT*

XeF<sub>2</sub> provides access to [PF<sub>2</sub>(BIMe<sub>3</sub>)]<sup>3+</sup> representing the first structurally characterized example of a phosphorus(V) centred trication (Chapter 5).

Attempts to synthesize an anionic carbon(0) are detailed in chapter 6. Although obtaining an anionic carbon(0) was not successful, it led to a series of interesting compounds and results. Compounds containing carbon centre behave differently than their heavier group-14 analogues of the same bidentate anionic bisphosphine ligand.

# **DEDICATION**

*To Family and Science!*

## ACKNOWLEDGEMENTS

My academic journey would not have been possible if it wasn't for the support of my community. My community has provided me with the necessary environment and tools to be successful and for that, I am eternally grateful and will always be indebted to this loving and caring community.

My supervisor, Dr. Charles L. B. Macdonald, has been very supportive throughout the years and I am very thankful to have him as my mentor and for giving me the opportunity to join his research group. Despite his busy schedule, Chuck is always available, even after moving to Carleton, Chuck is available to answer questions and would free-up time to be there for the group. Working with Chuck allowed me opportunities that helped me improve by building on my experiences and skills. Different collaborations and taking part in developing a course are among the many opportunities that were made available to me by Chuck, and for that, I am very thankful.

The Macdonald group members have made this journey an enjoyable one and for that, I would like to thank all the past and present group members. Special thanks to Blake whom I mentored in his 410 project and by having him on-board, he helped make significant advances. Although I was mentoring and training Blake, I myself have learned a lot from Blake. I would like to thank Justin for the continued collaborations we had over the years and for all the good times spent together in and out of the lab. When it comes to chemistry discussions between Justin and myself, if there is one thing we agree on, it is to disagree! I would also like to thank Brad for the

## *ACKNOWLEDGEMENTS*

numerous conversations and hangouts we had. Lastly, I would like to thank Steph, Max and Loue for making the lab a fun place to be in and for the amazing memories that I will cherish forever.

I would like to thank our collaborators, Dr. Neil Burford and Dr. Riccardo Suter for the amazing collaborations we had over the last two years. Meeting Dr. Suter at the Toronto CSC conference in 2017, little did I know the extent this collaboration will have, and I am very pleased in the turnout of this fruitful collaboration between the two groups.

In the chemistry department, I would like to thank Dr. Matthew Revington for his help and training in the NMR instruments. Dr. Janeen Auld for her help in the set-up of elemental analysis instruments, making it always available and ready to go. A special thanks to Marlene Bezaire, our graduate secretary, for keeping me on track to graduate and for all the love and support she shows to graduate students. She is very caring and wants all students to be successful, she tries her best to make this happen. In addition, I would like to thank our undergraduate laboratory coordinators, Una Lee and Nedhal Al-Nidawy, for the opportunity to teach and mentor undergraduate students over the years.

I would like to thank my committee members, not only for agreeing to be on my committee but also for providing guidance and assistance throughout my degree. Dr. Green is always my go to when I have any questions or problems with synthesis or any organic related problems. Whenever I have any questions regarding transition metals or coordination chemistry, Dr. Johnson is always there to help, guide and

## ACKNOWLEDGEMENTS

clarify. Working with Dr. Johnson on the inorganic chemistry tutorials is something I really enjoyed, and I looked forward to GAing the course year after year. I would like to thank Dr. Maeva for agreeing to be my outside-of-department reader at the beginning of my PhD. I would like to thank Dr. Joel Gagnon for agreeing to fill-in for Dr. Maeva and really appreciate his time and willingness to be on my committee. I would like to thank Dr. Richeson for agreeing to be my external examiner and really appreciate his time and the trouble of travel. Dr. Richeson's research has been of great interest to me and some of the research results in this dissertation were a direct inspiration of work reported by Dr. Richeson. Additionally, I would like to thank Dr. Peter T. Wolczanski for being a great mentor during time at Cornell University as a graduate student. Pete is very supportive, and I have learned a lot in the short span of time I spent with Pete.

Last but not least, I would like to thank my wife who has been supportive and understanding. Having to leave in the middle of the night to mount the next crystal when it's our turn on the diffractometer is something I had to do frequently, and my wife has been very supportive throughout my PhD journey and I would like to thank her for that.

# CHAPTER 1: Introduction

## 1.1 General Introduction

The renaissance of Main Group Chemistry was born in the mid-1980s with the October issue of *Chemical Reviews* in 1985 entitled “Main Group Chemistry”.<sup>1</sup> Main group chemistry is made up of both s- and p- block elements. s- and p- block elements make up more than 90% of the elemental composition of the Earth’s crust.<sup>2</sup> Additionally, elements like carbon, hydrogen, nitrogen, oxygen, phosphorus, and sulfur are the most common elements found in biological organisms.<sup>3</sup> The periodic table is organized in different groups (columns) labeled 1-18 (using Arabic numerals) or IA-VIIIA (using Roman numerals). Our group is mainly interested in p-block elements, more specifically, groups 13-15 elements in lower than usual oxidation states.

Group 13 elements, also known as the boron group or triels, contain boron (B), aluminium (Al), gallium (Ga), indium (In) and thallium (Tl) with more attention given to boron through indium due to the high toxicity of thallium. Triels contain three valence electrons and have many industrial applications. For example, boron is commonly used in fiberglass, ceramics, and bleach. Aluminium is used in various electrical devices, construction materials and is widely used for food storage for its inertness towards food products.<sup>4</sup> Gallium arsenides are used in semiconductors, solar cells and make up a major component of LEDs (Light Emitting Diodes).<sup>5</sup> Indium

is usually used as an alloy with other metals for various applications, mainly conductive coating for displays like LCDs (liquid crystal displays).<sup>6</sup>

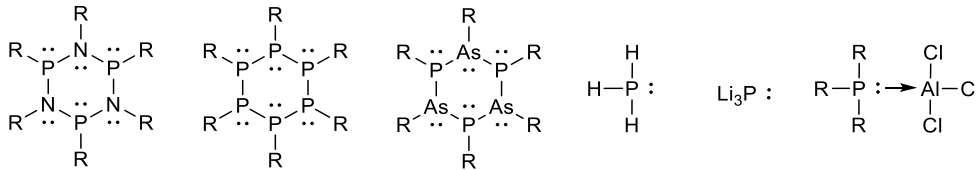

Group 14 elements, also known as the carbon group or tetrels, contain carbon (C), silicon (Si), germanium (Ge), tin (Sn) and lead (Pb). Tetrels contain four valence electrons with +4 as the most common oxidation state found (for C, Si, and Ge). Carbon exists in various allotropes that include amorphous carbon, graphite, diamond, fullerenes, buckyballs, nanotubes, nanobuds and nanofibers.<sup>7</sup> Carbon is of particular interest in organic chemistry because it's the backbone for organic compounds and living organisms in general. Carbon is smaller than its group 14 analogs and can have a more effective overlap of p-orbitals making it possible for carbon to obtain double and triple bonds. Uses of carbon vary depending on the form used, for example, crude oil containing hydrocarbon chains and charcoal are used as fuel sources, while diamond is considered very precious and expensive. Silicon is the second most abundant element in earth's crust with various applications that range from use in toothpaste to being a major component of glass.<sup>8</sup> Germanium oxide is mainly used in fiber optics (microscopes, camera lenses, etc.) due to its high index of refraction and low optical dispersion.<sup>9</sup> Tin's most common use is in soldering where solder is used to create a permanent bond between metal pieces like copper pipes or binding a wire to a circuit board.<sup>8</sup> When it comes to lead, most of the lead produced is used in the creation of lead-acid batteries. Just like thallium, lead is toxic and the use of lead decreased over time due to concerns of its toxicity.

Group 15 elements, also known as the nitrogen family or pnictogens, contain nitrogen (N), phosphorus (P), arsenic (As), antimony (Sb) and bismuth (Bi). Pnictogens contain 5 valence electrons and exist mainly in +3 and +5 oxidation states. In their elemental forms, the physical and chemical properties of these pnictogens vary considerably. Nitrogen is found as a non-metal diatomic gas, phosphorus exists as different allotropes and is a non-metal solid in most of these allotropes, arsenic and antimony are metalloids and bismuth is considered a metal. Nitrogen (N<sub>2</sub>) makes up most of the atmosphere on Earth and can be isolated by fractional distillation of air. With a boiling point of -196 °C, nitrogen is commonly used as a cryogenic liquid.<sup>10</sup> Both nitrogen and phosphate are used in fertilizers and elemental phosphorus is used in the making of matches.<sup>10</sup> Arsenic is highly toxic, as a result, one of its uses is as an insecticide. Another use is in the form of an alloy with gallium in the making of LEDs as mentioned above.

## 1.2 Oxidation States

Oxidation state is an integer number assigned to an atom which provides a charge indicating the degree of oxidation. The degree of oxidation refers to the number of electrons that have been removed from a neutral atom. French chemist, Antoine Lavoisier was the first to use the term oxidation in reference to a reaction of a substance with oxygen. The definition has been extended to include all reactions in which electrons are lost.<sup>11</sup>

An oxidation state is used to assign electrons to individual atoms within a molecule and thus can give an insight into the electron rich, poor and neutral sites within a molecule. There are numerous ways of assigning oxidation states, but most commonly, oxidation state is determined by disregarding the concept of shared electrons (in covalent bonds) and assigning those electrons merely on the basis of electronegativity where the more electronegative atom is assigned the electrons in a chemical bond.<sup>12</sup> Another term used, valence state, is based on the number of electrons involved in bonding while taking charges into consideration. Both terms are sometimes used interchangeably to describe the same thing which can be confusing in many cases.

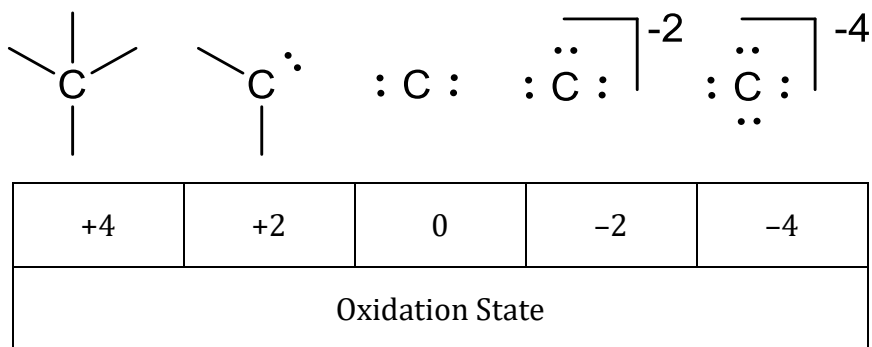

Oxidation State	+3	+1	-1	-3	-3	±3
Valence State	3	3	3	3	3	5

**Figure 1.1.** Oxidation states of phosphorus in different molecules showing how oxidation state is not always consistent with valence state.

By examining the different phosphorus compounds shown in **Figure 1.1**, one can see how oxidation state is not always in agreement with valence state. Oxidation state itself is not always consistent and/or representative of the reactivity of a compound. Comparing the first three compounds that contain pnictogens in a cyclohexyl arrangement, one can observe that the phosphorus centres are assigned

very different oxidation states when they are similar in nature and bonding. Comparing phosphine (PH<sub>3</sub>) and phosphide (Li<sub>3</sub>P), based on oxidation state rules, they are assigned the same oxidation state (-3) when they are very different compounds.

In the Macdonald group, we like using a more convenient model that is based on the number of lone pairs in a given atom.<sup>13,14</sup> In the case of phosphorus, phosphorus with no lone pairs is in the +5 oxidation state (P<sup>V</sup>), phosphorus with one lone pair is in the +3 oxidation state (P<sup>III</sup>) and phosphorus with two lone pairs is in the +1 oxidation state (P<sup>I</sup>). This model can be extended to other main group elements and is particularly useful for group 13-15 main group elements. **Figure 1.2** shows the assignment of oxidation state for carbon using this model where carbon with no lone pairs, one lone pair, two lone pairs, three lone pairs and four lone pairs are assigned as carbon(+4), carbon(+2), carbon(0), carbon(-2) and carbon(-4), respectively.

**Figure 1.2.** A more convenient model to assigning an oxidation state based on the number of lone pairs present on a given atom.

Every system has its shortcomings, and in this case, as the assignment depends on the number of lone pairs present, it'll heavily depend on the structure drawn. A

Lewis structure can be ambiguous as it's possible to draw more than one plausible structure for a given system. In the case of a carbodiphosphorane for example, two phosphines are bound to a carbon centre as shown in **Figure 1.3**. The oxidation state assignment can vary greatly depending on the way the structure is drawn. Lewis structure is a tool to help illustrate basic connectivity of a given molecule, but to be able to obtain more accurate electron density delocalization, computational methods would be an ideal way of figuring out and assigning the presence or absence of lone pairs on a given atom.<sup>15</sup>

**Figure 1.3.** Different Lewis drawings of carbodiphosphorane showing how the assignment of oxidation state on the carbon centre can be different depending on the way the Lewis structure is drawn.

### 1.3 Chemical Bonding: The Covalent Bond

The concept of a molecule dates to the seventeenth century, but it wasn't until the twentieth century that chemists got a better understanding of the structure of a molecule. Gilbert Newton Lewis (1875–1946), was an American chemist that discovered the covalent bond and the concept of an electron pair. He postulated the idea of atoms sharing one or more electrons and developed a dot system to help keep

track of electrons. Lewis also devised the octet rule which states that any non-hydrogen atom will tend to form bonds until the octet rule is satisfied meaning it'll be surrounded by eight valence electrons.<sup>16,17</sup>

The Lewis model gave chemists a rationale for molecule formation, covalent bonding and a way to help predict molecular geometries, but it didn't answer the question as to why molecules come together. Likewise, the octet rule was believed to only work for the first two rows of the periodic table with the reasoning that atoms in third shell or higher have access to d-orbitals, allowing for hybridization (orbital mixing) yielding new orbitals capable of expanding beyond the octet rule. Firstly, d-orbitals are high in energy and inaccessible to an atom like phosphorus and secondly, there are examples of first and second row elements breaking the octet rule and forming hypervalent compounds.<sup>18</sup> Another downside to the Lewis model is the fact that a Lewis structure of O<sub>2</sub> (**Figure 1.4**) does not explain the paramagnetic properties observed in liquid oxygen. This was the case until the introduction of quantum mechanics.

**Figure 1.4.** A Lewis structure of a dioxygen atom (O<sub>2</sub>).

Molecular Orbital Theory (MO theory) is a method that describes a molecular structure by combining atomic orbitals into orbitals that describe the bonding in a molecule as a whole rather than assigning electrons to individual bonds between atoms. By considering two overlapping 1s atomic orbitals (H<sub>2</sub> molecule), MO theory

dictates that the combination of these two orbitals would result in two molecular orbitals, one bonding, and one anti-bonding. This is in accordance with Pauli exclusion principle where no two electrons in a molecule can have the same set of quantum numbers. Therefore, it's necessary that the two originating atomic orbitals be split into two molecular orbitals as shown in **Figure 1.5**.

**Figure 1.5.** Molecular orbital diagram of dihydrogen.

MO theory not only helps in rationalizing bonding but also explains why bonding happens. Sharing of electrons can help stabilize a given molecule by bringing down the energy of electrons as shown in **Figure 1.5**. Going back to the O<sub>2</sub> example, sketching the MO diagram (**Figure 1.6**) will make it clear why dioxygen is paramagnetic. According to Hund's rule, every orbital within a subshell is singly occupied before an orbital is doubly occupied, thus, with two electrons to fill the doubly degenerate π\* orbital, each orbital must be filled with an electron before pairing electrons and this is why dioxygen is paramagnetic.

**Figure 1.6.** Molecular orbital diagram of an  $O_2$ .

## 1.4 Pincer Ligands

Early work in organometallic chemistry focused on monodentate and chelate ligands; recent work, however, showed a lot of interest in pincer ligands due to their versatility and ease of use. The term ‘pincer’ dates back to 1989 in which van Koten used the term to describe tridentate ligands with an anionic carbon centre.<sup>19</sup> Over the past 15 years, the term pincer broadened to generally refer to any tridentate (three-coordinate) ligand with adjacent binding sites that usually adopt a meridional (*mer-*) geometry but can also be found with facial (*fac-*) geometry (butterfly-like) in some cases. There are examples of pincer complexes adapting a fluxional process between

the two geometries.<sup>20</sup> **Figure 1.7** illustrates an [ONO] type ligand that is fluxional in the sense that it can be present in a T-shaped geometry or a bent geometry, more details to follow in section 1.5.<sup>21</sup>

**Figure 1.7.** Arduengo's 10-As-3 T-shaped complex (*mer*-, left) and in the bent shape (*fac*-, right).

Due to their broadened definition, there is ambiguity regarding the classification and nomenclature of pincer ligands. In a recent review, Peris and Crabtree<sup>20</sup> classify pincer ligands based on the charge and symmetry of the pincer ligand. The term palindromic is used to describe symmetric donor arms (regardless of the central donor), thus, coordinating atoms like [N,N,N], [O,N,O] and [P,C,P] are all considered to be palindromic, as long as the substituents on terminal donors are the same. In cases where the two terminal arms have differing donor atoms like [N,N,P], or different substituents like [LN,N,NL'], the ligand is considered to be non-palindromic. Regardless of the palindromicity of the pincer ligand, it can also be further classified based on the overall charge of the ligand. It can be neutral ( $L_3$ ), anionic ( $XL_2$ ), dianionic ( $X_2L$ ) or trianionic ( $X_3$ ) as illustrated in **Figure 1.8**.

**Figure 1.8.** Classification of pincer ligands based on the overall charge of the pincer ligand, neutral ( $L_3$ ), anionic ( $XL_2$ ), dianionic ( $X_2L$ ) or trianionic ( $X_3$ ).

The use of pincer ligands with transition metals gained a lot of interest due to the stability pincer ligands, the ease of tunability and cooperativity (through non-innocent pincer ligands). Non-innocent ligands are redox active ligands that can accept or lose electrons in its  $\pi$ -system resulting in significant change in the internal bond distances of the ligand. This allows for the coordinated metal to maintain its starting oxidation state or undergo reactivity that otherwise would not be possible. Pincer ligands are very robust, which makes them a great choice in reactions that require harsh conditions. Goldman and Brookhart<sup>22</sup> reported the production of *n*-alkanes using an iridium pincer catalyst (**Figure 1.9**) that can undergo extreme reaction conditions, such as in the metathesis of *n*-decane that requires heating at 175 °C for nine days. Another example of the robustness of such systems is the Ni(II) complex, **Figure 1.9** (right), that is very thermally stable to the point that it can be sublimed in air at 240 °C in air without decomposition.<sup>23</sup>

**Figure 1.9.** Goldman and Brookhart's Iridium(III) catalyst (left) and Moulton's Nickel(II) (right) are examples of robust metal pincer catalysts.

Pincer ligands also allow for tunability of the ligand framework, which gives chemists a handle to manipulate the reactivity of the overall catalyst by modifying the pincer ligand. The importance of pincer ligand design is illustrated in the Ni(II) catalyst shown in **Figure 1.10** that is used in the Sonogashia coupling between terminal alkynes and alkyl halides. Dissociation of an amine sidearm is the rate determining step of the reaction, a more labile amine (right) results in the catalyst being active at room temperature, while a more rigid amine group (left) results in the catalyst requiring temperatures exceeding 100 °C for the dissociation of the amine to occur and for the catalyst to become active.<sup>24</sup>

**Figure 1.10.** An example of how the tuning of pincer ligand can affect the reactivity of the catalyst.

Another interesting aspect of pincer ligands is the possibility of introducing chirality into the ligand design, allowing for enantioselective catalysis. Anionic [N,N,N] pincer ligands like the ones depicted in **Figure 1.11** have shown to yield

highly enantioselective transformations. The high kinetic stability of the resulting catalysts allow for reduced catalyst loadings.<sup>25</sup>

**Figure 1.11.** Examples of chiral [N,N,N] pincer ligands.

Although pincer complexes are generally viewed as stable compounds, where the ligand framework remains unchanged under harsh reaction conditions, there are cases where the pincer ligand itself undergoes transformations resulting in unusual reactivities. This occurs in cases where there is a great delocalization of electron density over multiple aromatic rings resulting in a lowered HOMO–LUMO gap, that is ligand based, allowing it to participate in electron transfer reactions.<sup>20</sup> In such cases, the ligand is considered to be “non-innocent” and is redox active. **Figure 1.12** illustrates the reaction of a Ta(V) complex with a phenyl azide yielding in a nitrene transfer onto the metal centre. The oxidation state of the tantalum centre does not change, where tantalum maintains its preferred +5 oxidation state; however, the pincer ligand goes from being a trianionic ( $X_3$ ) ligand to a monoanionic ( $XL_2$ ) ligand, meaning, the ligand underwent a two-electron oxidation.<sup>26</sup>

**Figure 1.12.** An example of a redox non-innocent ligand that allows Ta(V) undergo reaction with nitrene without changing the preferred oxidation state of the metal centre.

## 1.5 Pincer Complexes of Group 15 Elements and Their Role in Modern Main Group Chemistry

Main group elements combined with various types of pincer ligands resulted in some of the most interesting complexes to appear in the literature over the past decade.<sup>25,27</sup> In the 1980s, Arduengo was a pioneer in multidentate pnictogen complexes.<sup>21,28–31</sup> In the 1990s, he went on to synthesize the first stable carbene that will be further discussed in Chapter 6 of this dissertation.<sup>32</sup> Arduengo reported the phosphorus complex of 5-aza-2,8-dioxa-3,7-di-tert-butyl-1-phospha-bicyclo[3.3.0]octa-3,6-diene (ADPO), which is referred to as a 10-P-3 complex if it assumes T-shaped geometry (**Figure 1.13**, left).<sup>30</sup> The 10 denotes the number of  $\pi$ -electrons in the system and the 3 refers to the number of coordination sites. If the complex assumes a bent geometry, then there are 8  $\pi$ -electrons in the system and the system is referred to as an 8-P-3 complex (**Figure 1.13**, right).

**Figure 1.13.** Arduengo's 10-P-3 T-shaped complex and its different resonance structures (left), and 8-P-3 bent complex (right).

Arduengo additionally reported the complexation of other pnictogens to the same ligand (ADPnO). Arsenic and antimony both adapted the 10-Pn-3 T-shape geometry<sup>21,28</sup> while bismuth reacted with three equivalents of the ligand to yield a 20-Bi-9 complex (**Figure 1.14**, right).<sup>31</sup> Upon treatment of ADPnO with silver, Arduengo observed that, in the cases of arsenic and antimony, the ligand system maintained the T-shaped geometry resulting in a 10-Pn-4 complex, while in the case of phosphorus, the coordination resulted in bent structure yielding an 8-Pn-4 system.<sup>33</sup>

**Figure 1.14.** Pnictogens with 10-Pn-3 system, P, As and Sb (left), and 20-Bi-9 system (right).

ADPnO complexes have interesting reactivities, starting with the ADSbO, as treatment with hexafluoro-2-butyne afforded an unprecedented addition of a substrate to hypervalent species as shown in **Scheme 1.1**, where two acetylenes add across the antimony and carbon backbone. The reaction of ADSbO with hexafluorobiacyetyl results in the 4-coordinate adduct shown in the scheme below (10-Sb-4) where two oxygens add across the antimony centre with an appended arm of the tridentate ligand. In the case of arsenic, ADAso reacts with bis(trifluoromethyl)dithiete in a similar manner to that of the hexafluorobiacyetyl (with ADSbO) where the two sulfurs add across the arsenic centre; except that the resulting complex is 5-coordinate (12-As-5).

**Scheme 1.1.** The Reaction of ADSbO with hexafluoro-2-butyne (right) and with hexafluorobiacyetyl (left). The reaction of bis(trifluoromethyl)dithiete with ADAso (bottom).

In light of recent advancements in main group chemistry in the activation of dihydrogen and other small molecules using Frustrated Lewis Pairs (FLPs),<sup>34</sup>

chemists have been searching for other ways to activate small molecules using main group elements. The ADPO complex that was first synthesized by Arduengo has been recently investigated by Radosevich for possible catalytic activity.<sup>30,35,36</sup> Practically, tricoordinate P(III) compounds will tend to adopt a pyramidal geometry (**Figure 1.15**, left); however, through appropriate ligand design, it's possible to deviate from such geometry and by doing so, change the reactivity at the phosphorus centre. Lowering the symmetry of a phosphine results in a smaller HOMO–LUMO gap that results from destabilization of the HOMO and the stabilization of the LUMO. This gives rise to a biphilic phosphorus centre capable of behaving as an electron donor and an electron acceptor at the same site.<sup>35,36</sup>

**Figure 1.15.** Different geometries adapted by tricoordinate phosphorus:  $C_{3v}$ ,  $C_s$  and  $C_{2v}$  respectively.

Radosevich demonstrated that Arduengo's phosphine (ADPO) is capable of activating N–H and O–H bonds of small molecules across the phosphorus centre. Calculations show that this reaction does not undergo a concerted oxidative addition via a three-centre transition; rather, an amine molecule would bind first to the electrophilic phosphorus followed by a heterolytic cleavage of the N–H bond and a proton transfer from N to P.<sup>36</sup> ADPO is also capable dehydrogenating an ammonia–borane complex (**Scheme 1.2**) to yield a P(V)–H<sub>2</sub> complex, which can also be accessed via the treatment of a P(V)–Cl<sub>2</sub> complex with sodium cyanoborohydride.

**Scheme 1.2.** Radosevich's synthesis of P(V)-H<sub>2</sub> complex.

The resulting pentacoordinate P(V)-H<sub>2</sub> complex can transfer hydrogens onto an unsaturated organic substrate. The reaction was shown to be catalytic in the presence of both ammonia-borane and azobenzene. A 10 mol% catalyst loading of P(V)-H<sub>2</sub> can transfer hydrogenate onto azobenzene substrate in yields exceeding 80% at room temperature. The difference between this method of transfer hydrogenation and FLPs is that in the case of an FLP, the phosphorus acts as an electron donor and requires the presence of a Lewis acid to act as an electron acceptor. In the case of ADPO, however, both the electron donor and acceptor are on the same site making it possible to perform two-electron redox transformations that are observed in transition metal catalysts.<sup>35</sup> The proposed mechanism for this transformation is shown in **Scheme 1.3** with an equilibrium between P(III) and P(V) that illustrates the redox capability of the phosphorus centre. Other recent work by Radosevich showed evidence of the formation of pentacoordinate phosphorus via a concerted cyclic transition suggesting the potential of organophosphorus catalysis via its biphilic centre.<sup>37</sup>

**Scheme 1.3.** Proposed mechanism of transfer hydrogenation catalysis of ADPO catalyst.

Pincer ligands have been used in the isolation of other various low valent main group elements. In 2006, Cowley demonstrated that upon treating  $\text{AsCl}_3$  with  $\text{SnCl}_2$ , the arsenic is reduced to the arsenic(I) species (“AsCl”) that can be isolated by treatment of the resulting suspension with an  $\alpha,\alpha'$ -diiminopyridine ligand (also known as diiminopyridine, DIMPY and DIP), resulting in the arsenic(I) salt as shown in **Scheme 1.4**.<sup>38</sup> Ragona later illustrated that the same ligand can be used in the isolation of a phosphorus(I) salt by treatment of DIMPY ligand with  $\text{PI}_3$  resulting in a P(I) centre and an  $\text{I}_3^-$  as the counterion ( $^{31}\text{P}$   $\delta = 169$  ppm). Ragona reported that the use of  $\text{PCl}_3$  and  $\text{PBr}_3$  resulted in either no reaction or in indiscernible mixtures. Including a halide abstracting agent like cyclohexene in the presence of  $\text{PCl}_3$  didn't show any reactivity; however, there was conversion into product in the case of  $\text{PBr}_3$

with cyclohexene with much smaller yields (28% compared to >80% in the case of  $\text{PI}_3$ ).<sup>39</sup>

**Scheme 1.4.** Examples of Group 15 low valent pincer complexes.

## 1.6 Pincer Complexes of Group 14 Elements and Their Role in Modern Main Group Chemistry

The use of pincer ligands with group 14 elements dates back to 1985, before the term pincer was even adopted, where Archer and co-workers reported the synthesis of a tripyridine tin(II)chloride (**Figure 1.16**).<sup>39</sup> Reid and co-workers reported the synthesis of a germanium(II) salt of a triamine, pmdta ( $\text{MeN}(\text{CH}_2\text{CH}_2\text{NMe}_2)_2$ ) (**Figure 1.16**) by treatment of pmdta with 2 equivalents of  $\text{GeX}_2$  ( $\text{X} = \text{Cl}, \text{Br}$ ) yielding to the self-ionization of the  $\text{GeX}_2$  centre into a  $\text{GeX}^+$  and  $\text{GeX}_3^-$  fragments.<sup>40</sup> Although this is a more flexible ligand and is capable of adopting a facial geometry, it rather adopts a planar meridional geometry.

**Figure 1.16.** Early examples of pincer-type complexes of group 14 main group elements.

As mentioned earlier, one of the reasons pincer ligands are attractive ligands is the possibility to tune the ligand, thus, asymmetry can be introduced into the ligand yielding a chiral metal centre. Evans and co-workers demonstrated this via the use of a chiral ligand PYBOX (bis(oxazoline)pyridine) in the isolation of a chiral tin(II) Lewis acid (Figure 1.17) that is capable of catalyzing aldol condensation reactions.<sup>42</sup> With 10 mol% loading, aldol reactions can be performed between ethyl glyoxylate and silylketene acetals to yield respective products in good yields in greater than 90% ee.

Figure 1.17. Evans' tin(II) chiral Lewis acid complex.

DIMPY ligands have been important in development of group 14 low-valent main group chemistry, Roesky reported that using such ligands, one is able to isolate the self-ionization product of germanium(II) and tin(II) (Scheme 1.5).<sup>43</sup> Nikonov later reported that the treatment of a DIMPY-Ge(II) complex with two equivalents of potassium graphite (KC<sub>8</sub>) in benzene results in a germanium(0) complex as illustrated in Scheme 1.5.<sup>44</sup> Other variants of the M(II) DIMPY (M = Ge, Sn) have also been reported.<sup>45,46</sup>

**Scheme 1.5.** Roesky's DIMPY- $M(\text{II})$  complex ( $M = \text{Ge}, \text{Sn}$ ) and Nikonov's reduced  $\text{Ge}(0)$  complex.

Although  $\text{Sn}(0)$  has not been synthesized in the same manner (reduction from  $\text{Sn}(\text{II})$  to  $\text{Sn}(0)$ ) as in the case of germanium, Flock and co-workers were successful using a different variant of DIMPY ligand with  $\text{Sn}[\text{N}(\text{SiMe}_3)_2]_2$  resulting in a transamination reaction that yields a  $\text{Sn}(0)$  complex by eliminating two amine equivalents (**Scheme 1.6**).<sup>47</sup>

**Scheme 1.6.** Mechanism of the transamination reaction of DIMPY ligand with  $\text{Sn}[\text{N}(\text{SiMe}_3)_2]_2$  to yield a  $\text{Sn}(0)$  complex.

Zaitsev's group reported a different variant of dianionic tridentate complexes of group 14 elements and have demonstrated that the main group element centre is

reactive and can undergo reactions like oxidative addition and transition metal coordination (**Scheme 1.7**).<sup>48-50</sup> Coordination of germanium and tin complexes to tungsten and molybdenum carbonyl compounds have been successful. In addition, both germanium and tin complexes are capable of oxidatively adding small molecules like MeI, Br<sub>2</sub>, and Ph<sub>2</sub>S<sub>2</sub>. Furthermore, DIMPY-Sn(II) complexes have been employed in various transition metal coordination as a result of the work of Jambor and co-workers.<sup>51,52</sup>

**Scheme 1.7.** Zaitsev's tridentate complexes and reactivity.

## 1.7 Pincer Complexes of Group 13 Elements and Their Role in Modern Main Group Chemistry

Pincer complexes of group 13 main group elements are more prominent in literature in comparison to either group 14 and 15, particularly, after their recent advancement as supporting ligands (metalloligand scaffold) for transition metal catalysts.<sup>53</sup> An example of this is the use of metalloligand pincer scaffolds' of group 13 elements that forms an overall pincer ligand with a group 13 element as the central atom (**Scheme 1.8**).<sup>54-56</sup>

**Scheme 1.8.** Zwitterionic complexes containing ambiphilic pincer ligands.

The presence of a Lewis acid (e.g. boron or aluminium containing compounds) at or near transition metals results in altered reactivity of the metal centre.<sup>57</sup> Lewis acids have been used in conjunction with transition metal catalysts as external activators or co-catalysts. Only recently have Lewis acids been incorporated within ligand motif resulting in ambiphilic ligands where the Lewis acid acts as a  $\sigma$ -acceptor (Z-type) ligand. The different donor types can be described as L (2-electron donor), X (1 electron donor) and Z (2-electron acceptor) type ligands.  $\sigma$ -acceptors can have different goals in coordinating transition metals, they can be used to generate a reactive electron-deficient metal centre and can also be used in cooperative metal-ligand activation of small molecules.<sup>57-59</sup> Having a group 13 element acting as a  $\sigma$ -acceptor have mostly been investigated in use as an external activator or a co-catalyst, but not until recently has it been investigated as part of a ligand scaffold to yield a Z-type ligand (**Figure 1.17**).<sup>60</sup> Z-type ligands are considered Lewis acids and when coordinated to a metal centre, both electrons come from the metal centre. Recent

studies show that the use of Lewis acids or Z-type donors in general at or near transition metals result in increased reactivity of the metal centre.<sup>34,53,60,61</sup>

**Figure 1.18.** MO diagram depicting the difference between an L- and a Z-type ligand coordinating to a transition metal.

One example that illustrates this altered reactivity by incorporating a group 13 element is the work of Takaya and Iwasawa.<sup>53</sup> The palladium(II) complex proposed contains a group 13 main group element (E) within the ligand scaffold that's directly coordinated to palladium as illustrated in **Figure 1.19**. This catalyst is used towards the hydrosilylation of CO<sub>2</sub> and depending on the main group element incorporated, the resulting reactivity of the catalyst was altered. Aluminium showed the highest reactivity in the group 13 series and was much more reactive in comparison to either gallium or indium. The aluminium containing catalyst exhibited the highest catalyst activity reported for hydrosilylation of CO<sub>2</sub> to be reported at the time. This result shows a promising future for the development of new catalysts with various tunable metalloligands.

**Figure 1.19.** Takaya and Iwasawa's palladium(II) catalyst with  $E = Al, Ga$  and  $In$ .

Although pincer metalloligands have gained popularity over the past decade due to the altered reactivity, the use of pincer ligands with group 13 elements have been useful in the isolation of various +1 and +3 group 13 elements. Diiminopyridine (DIMPY) ligands that were introduced earlier have been used in the isolation of group 14 and 15 main group elements in various oxidation states. Attempts to isolate gallium(I) using DIMPY ligand by employing "GaI" as a gallium(I) source by Mills and Richeson yielded mixtures of gallium(III) and gallium(II) radical species as shown in **Scheme 1.9**.<sup>62,63</sup> Initially it wasn't clear as to why this was the case, however, solid-state analysis by Ragona's group presented that the simple mixing of gallium metal with half an equivalent of iodine does not yield the anticipated "GaI", rather, a mixture with an overall formula of  $[Ga^0]_2[Ga^+]_2[Ga_2I_6^{2-}]$  was observed. Varying the reaction time would result in a different mixture; for example, a shorter reaction time (40 minutes) yields the overall formula:  $[Ga^0]_2[Ga^+][GaI_4^-]$ .<sup>64</sup> Treatment of DIMPY with two equivalents of  $GaI_3$  or  $AlCl_3$  results in the clean isolation of self-ionized products  $[DIMPY-MX][MX_4]$  (**Scheme 1.9**).

**Scheme 1.9.** Reaction of DIMPY ligand with  $GaI$ ,  $2GaI_3$  or  $2AlCl_3$ .

Mills reported that the treatment of two equivalents of  $InCl$  with DIMPY ligand results in the deposition of indium metal and the coordination of  $InCl_3$  to DIMPY.<sup>63</sup> Later work by Richeson demonstrated that using a more appropriate  $In(I)$  source ( $InOTf$ ) with DIMPY ligand results in the isolation of  $[In-DIMPY][OTf]$  as shown in **Scheme 1.10**.<sup>65</sup> Additionally, Richeson showed that the indium(III) complex of DIMPY can be conveniently prepared by treatment of DIMPY with two equivalents of  $InCl_3$  to yield the self-ionized product shown in the scheme below.

**Scheme 1.10.** Reaction of DIMPY ligand with  $InOTf$  (left) and two equivalents of  $InCl_3$  (right).

DIMPY complexes of aluminium are more common than either indium or gallium, which is due to the fact that DIMPY-Al complexes have been useful in the activation of small molecules and play an important role in studies of catalytic reactions like Ziegler–Natta catalysis.<sup>66–68</sup> Among the very first examples of DIMPY-Al complexes was the work of Gambarotta and co-workers where they isolated paramagnetic Al complexes of DIMPY via treatment of DIMPY– $FeCl_2$  with either  $AlMe_3$

or  $\text{AlEt}_3$  in an attempt to study the mechanism involved in this Ziegler-Natta catalyst where aluminium is used as a cocatalyst (**Scheme 1.11**).<sup>69</sup>

**Scheme 1.11.** Reaction of DIMPY- $\text{FeCl}_2$  with  $\text{AlMe}_3$  and  $\text{AlEt}_3$ .

Berben et. al. reported the synthesis of two square planar complexes of DIMPY-AlX (X = Cl, H).<sup>68</sup> These complexes were synthesized by initially reducing the ligand by 2 electrons using sodium metal, followed by the introduction of aluminium trichloride or dichloroaluminum, respectively, to yield the square planar complexes shown in **Scheme 1.12**. The hydride complex is capable of activating N-H bonds via a metal-ligand cooperative mechanism.<sup>67</sup> In-addition, Berben demonstrated that the same aluminium hydride catalyst can promote selective dehydrogenation of formic acid to  $\text{H}_2$  and  $\text{CO}_2$  via an aluminium-ligand cooperative mechanism (**Scheme 1.12**).<sup>66</sup>

# CHAPTER 2: 2,6-Bis(benzimidazol-2-yl)pyridine as More Electron-Rich and Sterically Accessible Alternatives to 2,6-bis(imino)pyridine for Group 13 Coordination Chemistry

## 2.1 Introduction

Pincer ligands have proven to be vital in transition metal chemistry and have been studied to a great extent.<sup>1</sup> The use of a neutral trinitrogen donor ligand such as bis(imino)pyridine (DIMPY) with iron and cobalt resulted in highly active catalysts for ethylene polymerization.<sup>2</sup> This ligand has proven to be redox active, which is useful for metal-ligand cooperative catalysis.<sup>3,4</sup> The use of pincer ligands with main group (MG) elements has not been exploited to the same extent as with transition metals but there are some noteworthy reports. In particular, DIMPY ligand (**A**) has been used to isolate different low valent MG species including In(I)<sup>5</sup>, As(I)<sup>6</sup>, P(I)<sup>7</sup>, Ge(0)<sup>8</sup> and Sn(0)<sup>9</sup>.

**Scheme 2.1.** DIMPY complexes of group 13 elements.

Reports of ‘Ga(I)’ with DIMPY ligands yielded mixtures of Ga(III) ([DIMPYGaI<sub>2</sub>][GaI<sub>4</sub>]) and radical Ga(II) species ([<sup>i</sup>PrDIMPYGaI<sub>2</sub>]<sup>•</sup>); similarly with AlCl<sub>3</sub> the corresponding [DIMPYAlCl<sub>2</sub>][AlCl<sub>4</sub>] is formed.<sup>10,11</sup> Richeson however,

showed that using an appropriate In(I) source like InOTf yielded the complex [DIMPYIn(I)][OTf].<sup>5</sup> In the case of aluminium, the two square planar complexes of DIMPY-AlX (X = Cl, H) are formed by first reducing the ligand with two electrons, followed by the treatment with aluminium trichloride or dichloroaluminum as shown in **Scheme 2.2**.<sup>12</sup> The hydride complex was shown to activate N–H bonds via a metal–ligand cooperative mechanism<sup>13</sup> and is capable of promoting selective dehydrogenation of formic acid to H<sub>2</sub> and CO<sub>2</sub>.<sup>14</sup>

**Scheme 2.2.** The synthesis of square planar Al(III) complexes.

Aluminium cocatalysts are used to activate late transition metal DIMPY complexes in polymerization reactions. To that end, Gambarotta and co-workers studied the reaction of [<sup>i</sup>PrDIMPYFeCl<sub>2</sub>] with AlMe<sub>3</sub> and AlEt<sub>3</sub> as shown in **Scheme 2.3**.<sup>15</sup> Both resulting complexes are paramagnetic and contain trivalent aluminium centres.

**Scheme 2.3.** Reaction of  $[{}^{\text{Pr}}\text{DIMPYFeCl}_2]$  with  $\text{AlMe}_3$  and  $\text{AlEt}_3$ .

In this work, we explore the coordination of group 13 elements to bisbenzimidazole ligands **B** shown in **Figure 2.1** with  $G = \text{NH}$ ,  $\text{NMe}$ ,  $\text{NEt}$ ,  $\text{NBn}$ ,  $\text{N}(3,5\text{-CF}_3)\text{Bn}$ ,  $\text{N-Allyl}$  and  $\text{O}$ . These ligands are more rigid than their DIMPY counterparts and they have been used in transition metal chemistry for supramolecular self-assembly,<sup>16</sup> photoinduced CO release in biological systems,<sup>17</sup> anti-cancer agents,<sup>18</sup> and catalysts for transfer hydrogenation of ketones.<sup>19</sup> Coordination of BZIMPY ligand to indium have been previously reported,<sup>20,21</sup> among other group 14 complexes.<sup>22-29</sup> This work presented herein represents its first application to gallium. Similar imidazole and benzimidazole tripodal ligand coordination to MG elements have been previously investigated.<sup>30-32</sup>

**Figure 2.1.** DIMPY ligand, B: BZIMPY ligand ( $G = \text{NH}$ ,  $\text{NBn}$ ,  $\text{N}(3,5\text{-CF}_3)\text{Bn}$ ,  $\text{N-Allyl}$  and  $\text{O}$ ).

## 2.2 Results and Discussion

### 2.2.1 Synthesis and Characterization

Initial attempts to coordinate group 13 halides,  $MCl_3$  ( $M = Al, Ga, In$ ) to NH-BZIMPY (Compound **B** with  $G = NH$ ) resulted in the precipitation of coloured materials that were insoluble in common organic solvents. These reactions were carried out in dichloromethane, acetonitrile and tetrahydrofuran with one or two equivalents of  $MCl_3$ . In all cases, the resulting materials could not be characterized by NMR spectroscopy or X-ray crystallography. To increase the solubility of the resulting complexes, the NH nitrogen sites were substituted using different alkylating agents to introduce Me, Et, Allyl, Bn and (3,5- $CF_3$ )Bn derivatives. While the methyl and ethyl substituted ligands exhibit increased solubility compared to the free NH ligand, the resultant coordination complexes remained poorly soluble in common organic solvents. Fortunately, the use of allyl and benzyl (Bn) substituents allowed for the isolation of soluble materials that could be characterized by heteronuclear NMR spectroscopy and grown into single crystals suitable for X-ray diffraction analysis (**Figure 2.2**).

**Figure 2.2.** Solid state structure of the cations in  $[\text{NBn-BZIMPYGaCl}_2][\text{GaCl}_4]$  (**1**, left) and  $[\text{NAllyl-BZIMPYGaCl}_2][\text{GaCl}_4]$  (**3**, right). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms, solvent molecules and counter anions are omitted for clarity. Selected bond distances and angles are given in **Table 2.1**.

First we studied the known self-ionization process ( $\text{L} + \text{MCl}_3 \rightarrow [\text{LMCl}_2][\text{MCl}_4]$ ) which is evident and well-studied in combination with the structurally related DIMPY ligands.<sup>11,33</sup> These reactions went to completion by using two equivalents of metal halide, the halide displacement at the coordinated MG element was always observed regardless of the stoichiometry added (**Scheme 2.4**). The products (**1**, **2** and **3**) ( $[\text{G-BZIMPYGaCl}_2][\text{GaCl}_4]$ ) were obtained by treating G-BZIMPY with two equivalents of  $\text{GaCl}_3$  in dichloromethane (DCM), resulting in an immediate clear yellow solution. DCM was removed under reduced pressure and the resulting solid is suspended in toluene, filtered, dried under vacuum and collected to yield yellow solid in almost quantitative yields. Slow evaporation from a DCM solution yields yellow crystals of (**1**, **2** and **3**) suitable for X-ray diffraction.

**Scheme 2.4.** Self-ionization reactions of  $\text{GaCl}_3$  with G-BZIMPY ligands.

The uncoordinated 2,6-bis(benzoxazol-2-yl)pyridine (O-BZIMPY) is very poorly soluble in common organic solvents; however, treating the ligand with two equivalents of  $\text{GaCl}_3$  in DCM and sonicating for 24 hours yielded a yellow/green insoluble material with yellow microcrystals of complex **4**, [O-BZIMPY $\text{GaCl}_2$ ][ $\text{GaCl}_4$ ] (**Figure 2.3**). A dilute solution in  $\text{CD}_3\text{CN}$  allowed for NMR spectral analysis of the compound.

**Figure 2.3.** Solid state structure of the cation in [O-BZIMPY $\text{GaCl}_2$ ][ $\text{GaCl}_4$ ] (**4**). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms, solvent molecules and counter anion are omitted for clarity. Selected bond distances and angles are given in **Table 2.1**.

Next, we were interested in comparing the coordination of Ga halides to G-BZIMPY to that of DIMPY. [ $i\text{Pr}$ DIMPY $\text{GaI}_2$ ][ $\text{GaI}_4$ ] ( $i\text{Pr}$ DIMPY = 2,6-Bis-[1-(2,6-diisopropylphenylimino)ethyl]pyridine) has already been reported by Mills as a disproportionation product from  $\text{GaI}$  treated with  $i\text{Pr}$ DIMPY.<sup>11</sup> To our knowledge, there are no reports of the chloride equivalent of gallium complex

of  $i\text{PrDIMPY}$ , therefore, the ligand was treated with two equivalents of  $\text{GaCl}_3$ . This resulted in the clean and quantitative formation of  $[\text{iPrDIMPYGaCl}_2][\text{GaCl}_4]$  (**5**) (**Figure 2.4**, left).  $[\text{iPrDIMPYAlCl}_2][\text{AlCl}_4]$  has been reported by Budzelaar as a 1:1 mixture with the free ligand  $i\text{PrDIMPY}$ .<sup>33</sup> Treatment of  $i\text{PrDIMPY}$  with two equivalents of  $\text{AlCl}_3$  resulted in the clean and quantitative formation of  $[\text{iPrDIMPYAlCl}_2][\text{AlCl}_4]$  (**6**) (**Figure 2.4**, right), which upon crystallizing from DCM yielded crystals that were solvomorphous to the structure reported by Budzelaar.

**Figure 2.4.** Solid state structure of the cations in  $[\text{iPrDIMPYGaCl}_2][\text{GaCl}_4]$  (**5**, left) and  $[\text{iPrDIMPYAlCl}_2][\text{AlCl}_4]$  (**6**, right). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms, solvent molecules and counter anions are omitted for clarity. Selected bond distances and angles are given in **Table 2.1**.

**Table 2.1.** Selected bond distances ( $\text{\AA}$ ) and angles ( $^\circ$ ) of complexes **1-7**.

The M-N bond distances in the DIMPY complexes are significantly shorter for the pyridine interaction M-N2 (M = Ga, Al) than the ones to the imine side arms (M-N1 and M-N3) (**Table 2.1**). This is probably attributable to the steric hindrance of the bulky imine donors. In the case of G-BZIMPY, the bond distances for the pyridine interaction and the side arms are similar with slight asymmetry of the side arms due to the more rigid nature of the ligand forcing the gallium to be slightly off-centre. Although the M-N2 interaction with pyridine is shorter in DIMPY (**5**) than G-BZIMPY (**1-4**), the imidazole donors feature shorter distances to the gallium centre than the imine donors of DIMPY. This suggests that G-BZIMPY is a better donor ligand than DIMPY; this postulate is corroborated by the snapping energy calculations detailed below.

## 2.2.2 Reduction of Ga(III) to Ga(I)

Germanium(0) and tin(0) complexes of DIMPY ligand have been isolated, but there have been no reports of DIMPY stabilized group 13 metals in the +1 oxidation state apart from the unique example prepared by Richeson described earlier.<sup>5,8,9</sup> To this end, we were interested in reducing the [G-BZIMPYGaCl<sub>2</sub>][GaCl<sub>4</sub>] to Ga(II), Ga(I) or even Ga(0). Treatment of [NBn-BZIMPYGaCl<sub>2</sub>][GaCl<sub>4</sub>] with 1, 2 or 3 equivalents of K<sub>2</sub>C<sub>8</sub>, potassium or sodium naphthalide in THF have all resulted in reduction of the gallium centre to gallium metal and the release of the free NBn-BZIMPY ligand. This is likely attributable to the relative absence of steric protection on the front end of the BZIMPY ligand; however, we reasoned that the lack of steric bulk could allow for a nucleophilic attack with a redox active nucleophile. In this context K<sub>2</sub>[Fe(CO)<sub>4</sub>] was added stoichiometrically to a solution of **1** in THF at -50 °C, which resulted in an immediate colour change to a red/purple solution with the formation of a precipitate. Single crystals grown from the filtered reaction mixture identified the product as a reduced gallium species with a direct gallium iron bond (**Scheme 2.5**).

**Scheme 2.5.** Reaction of [NBn-BZIMPYGaCl<sub>2</sub>][GaCl<sub>4</sub>] with K<sub>2</sub>[Fe(CO)<sub>4</sub>] in THF to yield [(NBn-BZIMPY)(Cl)Ga—Fe(CO)<sub>4</sub>] (**7**).

The two metal centres in [(NBn-BZIMPY)(Cl)Ga—Fe(CO)<sub>4</sub>] (**7**, **Figure 2.5**) are best described as a Ga(I) centre coordinated to an Fe(0) centre (LGa<sup>I</sup>→Fe(CO)<sub>4</sub>). This structure is reminiscent to that of a gallium complex reported by Driess featuring a biscarbene ligand.<sup>34</sup> The Ga(I)-Fe bond distance reported by Driess (2.4010(12) Å) is slightly longer than that observed in complex **7** (2.3861(7) Å). Complex **7** has a trigonal bipyramid geometry at the iron centre with an <sub>ax</sub>CO-Fe-Ga angle of 179.09(13)°. The gallium centre sits 0.610 Å above the plane of the ligand with Ga-N bond distances significantly longer than in the parent compound **1** and has a distorted trigonal bipyramid geometry with N1-Ga-N2 angle being 137.29(11)°. The Ga-Cl distance of 2.2477(10) Å is significantly longer than any of those observed for the gallium(III) complexes and is consistent with the 2.2463(6) Å value reported by Driess for their analogous complex<sup>34</sup> and that of 2.269(2) Å reported by Fischer for the complex [(tmeda)(Cl)Ga—Co(CO)<sub>5</sub>].<sup>35</sup>

Reduction of **1** to **7** resulted in an increase of the Ga–N bond distances by approximately 0.11 Å (**Table 2.2**). No significant change was observed in the bond distances within the ligand framework suggesting in innocent BZIMPY ligand with the electron pair of the monovalent gallium delocalized in the dative Ga<sup>I</sup>→Fe bond. DIMPY's square planar aluminium (<sup>i</sup>PrDIMPY-AlCl) complex reported by Berben<sup>12</sup> involves an initial reduction of DIMPY ligand with sodium metal followed by the introduction of aluminium trichloride. Comparing bond distances of the two complexes shows a decrease in the Al-N bond distances (opposite to that observed in NBn-BZIMPY) and a significant

change in the bond distances within the ligand. The changes observed in the ligand are reflective of the redox non-innocent nature of DIMPY resulting in a dianionic ligand making the aluminium centre more appropriately described as an Al<sup>III</sup> centre. Finally, the Ga-Cl distance is also consistent with the assignment of a +1 oxidation state to gallium.

	<b>1</b>	<b>7</b>	<b>[DIMPY-AlCl<sub>2</sub>]<sup>+</sup> (6)</b>	<b>[DIMPY-AlCl]<sup>12</sup></b>

**Table 2.2.** Selected bond distances (Å) of [NBn-BZIMPYGaCl<sub>2</sub>][GaCl<sub>4</sub>] (**1**), [(NBn-BZIMPY)(Cl)Ga—Fe(CO)<sub>4</sub>] (**7**), [<sup>i</sup>PrPDIAICl<sub>2</sub>][AlCl<sub>4</sub>] (**6**) and Berben's [<sup>i</sup>PrPDIAICl].

**Figure 2.5.** Solid state structure of  $[(NBn-BZIMPY)(Cl)Ga-Fe(CO)_4]$  (**7**). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms and solvent molecules are omitted for clarity. Selected bond distances (Å) of **7**: Ga-Fe 2.3861(7), Ga-Cl 2.2477(10),  $_{ax}C-O$  1.148(5),  $_{eq}C-O$  1.160(4), 1.152(5), 1.162(5). Selected bond distances (Å) of Driess' complex: Ga-Fe 2.4010(12), Ga-Cl 2.2463(6),  $_{ax}C-O$  1.149(3),  $_{eq}C-O$  1.168(3), 1.157(2), 1.156(3). Other selected bond distances and angles of **7** are given in **Table 2.2**.

IR absorption bands for complex **7** ( $\nu_{CO} = 2072(w), 1980(s)$  and  $1865(s)$   $cm^{-1}$ ) are slightly more spread out in comparison to that reported by Fischer for  $[(tmeda)(Cl)Ga-Fe(CO)_4]$  ( $\nu_{CO} = 2011, 1928$  and  $1881$   $cm^{-1}$ ). Overall,  $\nu_{CO}$  absorptions of complex **7** are shifted hypsochromic by  $\sim 60-80$   $cm^{-1}$  in comparison to the chloro and alkyl derivatives of the tmeda complexes (**Table 2.3**). Other metal carbonyl ( $M = Fe, W, Cr$  and  $Mo$ ) complexes of gallium and aluminium have been reported where the carbonyl absorption bands generally range between  $1863$  and  $2050$   $cm^{-1}$ .<sup>35-37</sup>

### 2.2.3 Computational Studies

Density functional theory calculations (M062X/cc-pVTZ) were performed on simplified models of DIMPY (model **A** with R=R'=H) and BZIMPY (model **B** with G=NH and imidazoles in-place of benzimidazoles) in an effort to help rationalize the electronic differences between the two ligands. Selected molecular orbitals of both simplified ligand sets and their optimized geometries are depicted in **Figure 2.6**. The HOMOs of both ligands are  $\pi$ -type MOs and the energy of this MO is significantly higher for BZIMPY, suggesting that this ligand should be a stronger donor. This conclusion is also consistent with the shorter imidazole N-Ga distances in **1-3** (determined crystallographically and reproduced computationally) as compared to the imine N-Ga distances in **5**. It is worthy to note however that the energies of the MOs corresponding to the pyridine "lone pair" are energetically very similar for both ligands. The LUMO of DIMPY is significantly lower in energy than that of BZIMPY (-0.89 eV vs -0.47 eV), which suggests that BZIMPY should be a worse electron-acceptor than DIMPY, which is reputed for its non-innocence. Snapping energies of the [LGaCl<sub>2</sub>]<sup>+</sup> (L = BZIMPY or DIMPY ligands) complexes were calculated from optimized complex models and indicate that BZIMPY forms a stronger complex with the [GaCl<sub>2</sub>]<sup>+</sup> fragment than does DIMPY by approximately 75 kcal/mol. This result suggests that, while DIMPY complexes benefit significantly from kinetic stabilization (as discussed previously), the BZIMPY ligand forms more thermodynamically stable complexes with [GaCl<sub>2</sub>]<sup>+</sup>

that are not as sterically cumbersome. We postulate that this combination should facilitate further chemistry at the metal site.

**Figure 2.6.** Optimized geometries and selected molecular orbitals of simplified models of DIMPY and BZIMPY (M062X/cc-pVTZ).

## 2.3 Conclusions

We report Ga(III) coordination to 2,6-Bis(benzimidazol-2-yl)pyridine (G-BZIMPY, G = NBn, N(3,5-CF<sub>3</sub>)Bn, N-Allyl and O) ligands. The G-Bzimpy

ligands proved to be more electron-rich and sterically accessible alternatives to 2,6-bis(imino)pyridine (DIMPY) ligands for Group 13 coordination. Compound **1** can be readily reduced to Ga(I) using  $K_2[Fe(CO)_4]$  which results in the bimetallic complex  $NBn-BZIMPYGaClFe(CO)_4$  (**7**) that contains a rare Ga(I)-Fe(0) linkage with a sterically accessible GaCl that may be available for further chemistry.

## 2.4 Experimental

### 2.4.1 General Remarks

All manipulations were carried out using standard inert-atmosphere techniques. All reagents and chemicals were obtained from Sigma-Aldrich. All reagents were used without further purification.  $MeCN-d_3$  was dried over calcium hydride or phosphorus pentoxide, and dichloromethane- $d_2$  was dried over phosphorus pentoxide. All other solvents were dried on a series of Grubbs-type columns and were degassed prior to use.<sup>40</sup> All glassware was stored in a 170 °C oven for several hours and was degassed prior to use. 2,6-Bis(benzimidazol-2-yl)pyridine (NH-BZIMPY),<sup>41</sup> 2,6-bis(benzoxazol-2-yl)pyridine (O-BZIMPY)<sup>42</sup> and  $K_2[Fe(CO)_4]$ <sup>43</sup> were all prepared according to the literature procedures.

NMR spectra were recorded at room temperature on Bruker Avance III 500 MHz, Bruker Avance Ultrashield 300 MHz, and Bruker Avance DPX 300 MHz spectrometers. Chemical shifts are reported in parts per million relative to

internal standards for  $^1\text{H}$  and  $^{13}\text{C}$  (the given deuterated solvent) and external standards for  $^{19}\text{F}$  ( $\text{CFCl}_3$ ). Coupling constants  $|J|$  are given in hertz. Elemental analysis was performed at the University of Windsor Mass Spectrometry Service Laboratory using a Perkin-Elmer 2400 combustion CHN analyzer. Infrared spectra were recorded using the neat solids on a Bruker ALPHA FT-IR spectrometer using a Platinum ATR sampling module. Stretching frequencies ( $\nu$ ) are reported in  $\text{cm}^{-1}$  and intensities are reported using the following abbreviations: vw = very weak, w = weak, m = medium, s = strong, vs = very strong.

### 2.4.2 Synthesis

Alkylation reactions of NH-BZIMPY were carried according to general procedure for the synthesis of NBn-BZIMPY.<sup>55</sup> Similar procedures were carried out to isolate the NAllyl, N(3,5- $\text{CF}_3$ )Bn derivatives:

**[N(3,5- $\text{CF}_3$ )Bn-BZIMPY]** A 100 mL round bottom flask was charged with NH-BZIMPY (600 mg, 1.93 mmol) and KOH (249 mg, 4.44 mmol) in 30 mL acetone. The reaction mixture was refluxed at 60 °C for one hour before adding 3,5-bis(trifluoromethyl)benzyl bromide (0.78 mL, 4.26 mmol) and was further refluxed for another 12 hours. Volatiles were removed under reduced pressure, and the residue was treated with dichloromethane (20 mL) and filtered.

Filtrate was dried under vacuum and the resulting precipitate was suspended in hexane and collected by filtration to yield N(3,5-CF<sub>3</sub>)Bn-BZIMPY as an off-white precipitate. Ligand was further dried in a vacuum oven at 60 °C for 16 hours (1.31 g, 89%). <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.44 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.10 (t, 1H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.88 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.78 (b, 2H), 7.38 (s, 6H), 7.30 (m, 2H), 7.18 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 5.80 (s, 4H). <sup>13</sup>C{<sup>1</sup>H} NMR δ: 150.05, 150.03, 143.46, 140.21, 139.13, 136.41, 132.52 (<sup>2</sup>J<sub>CF</sub> = 33 Hz), 126.96, 126.54, 124.67, 123.78, 123.34 (<sup>1</sup>J<sub>CF</sub> = 272 Hz), 122.23, 120.99, 110.61, 47.88. <sup>19</sup>F{<sup>1</sup>H} NMR δ: -63.47.

**[Nallyl-BZIMPY]** A 100 mL round bottom flask was charged with NH-BZIMPY (800 mg, 2.57 mmol) and KOH (331 mg, 5.90 mmol) in 30 mL acetone. The reaction mixture was refluxed at 60 °C for one hour before adding allyl bromide (0.5 mL, 5.77 mmol) and was further refluxed for another 12 hours. Volatiles were removed under reduced pressure, and the residue was treated with dichloromethane (20 mL) and filtered. Filtrate was dried under vacuum and the resulting precipitate was suspended in hexane and collected by filtration to yield Nallyl-BZIMPY as a white precipitate. Ligand was further dried in a vacuum oven at 60 °C for 16 hours (762 g, 76%). <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.40 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.03 (t, 1H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.83 (m, 2H), 7.46 (m, 2H), 7.33 (m, 4H), 5.96 (ddt, 2H, <sup>3</sup>J<sub>HH</sub> = 18 Hz, <sup>3</sup>J<sub>HH</sub> = 10 Hz, <sup>4</sup>J<sub>HH</sub> = 5 Hz), 5.45 (m, 4H), 5.12 (dd, 2H, <sup>3</sup>J<sub>HH</sub> = 10 Hz, <sup>2</sup>J<sub>HH</sub> = 2 Hz), 4.92 (dd, 2H, <sup>3</sup>J<sub>HH</sub> = 18 Hz, <sup>2</sup>J<sub>HH</sub> = 2 Hz). <sup>13</sup>C{<sup>1</sup>H}

NMR  $\delta$ : 150.29, 143.30, 138.34, 136.98, 133.48, 125.90, 123.82, 123.04, 120.46, 116.96, 111.28, 47.82.

**[NBn-BZIMPYGaCl<sub>2</sub>][GaCl<sub>4</sub>] (1)** A 100 mL Schlenk flask was charged with NBn-BZIMPY (500 mg, 1.02 mmol) and GaCl<sub>3</sub> (360 mg, 2.04 mmol). To that was added 40 mL of dichloromethane resulting in an immediate formation of a yellow solution. After 2 hours of stirring, the solvent was evaporated under reduced pressure and the resulting solid was suspended in toluene (20 mL), collected and washed with toluene (2×10 mL) yielding **1** as a pale-yellow solid (788 mg, 92%). Slow evaporation from dichloromethane yielded crystals suitable for X-ray Diffraction. <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 8.50 (t, 1H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.33 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.17 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.63 – 7.75 (m, 6H), 7.34 – 7.41 (m, 6H), 7.17 (d, 4H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 6.01 (s, 4H). <sup>13</sup>C{<sup>1</sup>H} NMR  $\delta$ : 149.05, 143.01, 140.85, 138.09, 135.56, 132.27, 130.21, 129.51, 128.60, 128.11, 125.76, 125.02, 119.30, 112.21, 49.81. Anal. Calc. for C<sub>33</sub>H<sub>25</sub>Cl<sub>6</sub>Ga<sub>2</sub>N<sub>5</sub> (843.75 g/mol): C, 46.98; H, 2.99; N, 8.30. Found: C, 46.97; H, 3.09; N, 8.06.

**[N(3,5-CF<sub>3</sub>)Bn-BZIMPYGaCl<sub>2</sub>][GaCl<sub>4</sub>] (2)** A 20 mL vial was charged with N(3,5-CF<sub>3</sub>)BnBZIMPY (40 mg, 0.052 mmol) and GaCl<sub>3</sub> (19 mg, 1.04 mmol). 5 mL

of CD<sub>3</sub>CN was added, resulting in the formation of a yellow solution. The solution was stirred for 1 hr and the solvent was then evaporated under reduced pressure resulting in a yellow solid. Slow evaporation from DCM/CH<sub>3</sub>CN mix resulted in **2** as yellow crystals suitable for X-ray Diffraction (44 mg, 91%). <sup>1</sup>H NMR (CD<sub>3</sub>CN) δ: 8.53 (t, 1H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.32 (b, 2H), 8.24 (t, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.06 (s, 2H), 7.90 (s, 4H) 7.69-7.77 (m, 6H), 6.18 (s, 4H). <sup>13</sup>C{<sup>1</sup>H} NMR δ: 147.97, 145.15, 144.53, 137.93, 136.62, 131.96 (<sup>2</sup>J<sub>CF</sub> = 33 Hz), 128.04, 127.59, 127.21, 127.15, 124.95, 123.25 (<sup>1</sup>J<sub>CF</sub> = 272 Hz), 122.80, 118.51, 112.79, 48.77. <sup>19</sup>F{<sup>1</sup>H} NMR δ: -63.45. Anal. Calc. for C<sub>37</sub>H<sub>21</sub>Cl<sub>6</sub>F<sub>12</sub>Ga<sub>2</sub>N<sub>5</sub> (1115.74 g/mol): C, 39.83; H, 1.90; N, 6.28. Found: C, 39.56; H, 1.85; N, 5.97.

**[Nallyl-BZIMPYGaCl<sub>2</sub>][GaCl<sub>4</sub>] (3)** A 20 mL vial was charged with NallylBZIMPY (30 mg, 0.08 mmol) and GaCl<sub>3</sub> (29 mg, 0.16 mmol). 5 mL of CD<sub>2</sub>Cl<sub>2</sub> was added, resulting in the formation of a yellow solution. The solution was allowed to stir overnight and was then left to slowly evaporate resulting in **3** as yellow crystals (50 mg, 85%). <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.83 (t, 1H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.42 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.28 (m, 2H), 7.72 (b, 6H), 6.27 (ddt, 2H, <sup>3</sup>J<sub>HH</sub> = 18 Hz, <sup>3</sup>J<sub>HH</sub> = 10 Hz, <sup>4</sup>J<sub>HH</sub> = 4 Hz), 5.50 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 10 Hz), 5.43 (b, 4H), 5.14 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 18 Hz). <sup>13</sup>C{<sup>1</sup>H} NMR δ: 149.02, 142.88, 141.35, 137.89, 135.77, 129.34, 128.71, 128.23, 125.15, 119.90, 119.20, 112.48, 48.78. Anal. Calc. for

**NBn-BZIMPYGaClFe(CO)<sub>4</sub> (7)** A 20 mL vial was charged with **1** (30 mg, 0.036 mmol) and  $K_2[Fe(CO)_4]$  (9 mg, 0.036 mmol). 5 mL of pre-cooled ( $-40\text{ }^\circ\text{C}$ ) THF was added resulting in an immediate formation of a dark red/purple solution. The solution stirred for 1 hr before filtration. The filtrate was collected and left at  $-40\text{ }^\circ\text{C}$  for two days to yield (**7**) as deep red crystals suitable for X-ray Diffraction (15 mg, 56%). IR ( $\nu_{CO}$ ,  $\text{cm}^{-1}$ ): 2072(w), 1980(s) and 1865(s).  $^1\text{H}$  NMR (THF- $d_3$ )  $\delta$ : 8.55 (d, 2H,  $^3J_{\text{HH}} = 8\text{ Hz}$ ), 8.28 (t, 1H,  $^3J_{\text{HH}} = 8\text{ Hz}$ ), 8.17 (d, 2H,  $^3J_{\text{HH}} = 8\text{ Hz}$ ), 7.62 (d, 2H,  $^3J_{\text{HH}} = 8\text{ Hz}$ ), 7.47 (m, 4H), 7.33 (m, 6H), 7.22 (d, 4H,  $^3J_{\text{HH}} = 8\text{ Hz}$ ), 6.07 (s, 4H).  $^{13}\text{C}\{^1\text{H}\}$  NMR  $\delta$ : 220.08, 149.84, 142.70, 138.54, 138.21, 135.78, 130.15, 129.89, 129.19, 128.61, 127.81, 126.50, 125.54, 121.95, 111.55, 48.97. Anal. Calc. for  $C_{37}H_{25}ClFeGaN_5O_4$  (765.65 g/mol): C, 58.12; H, 3.30; N, 9.16. Found: C, 56.71; H, 3.46; N, 8.90.

### 2.4.3 Computational Details

Calculations were performed with the Gaussian 09 suite of programs<sup>44</sup> using Compute Canada's Shared Hierarchical Academic Research Computing Network (SHARCNET). Model complexes were fully optimized with no symmetry constraints using the M06-2X density functional method,<sup>45</sup> in

conjunction with the cc-pVTZ basis set.<sup>46,47</sup> Geometry optimizations were started using models in which the relevant non-hydrogen atoms were placed in positions found experimentally by X-ray crystallography using Gaussview.<sup>48</sup> Frequency calculations were also performed at the same level of theory in order to confirm that the optimized structures were minima on the potential energy hypersurface and to determine thermochemical and vibrational information. Natural bond orbital (NBO) analyses<sup>49</sup> to determine orbital contributions, Wiberg Bond Indices and orbital energies were obtained using the routine included in the Gaussian distributions.<sup>50</sup> Visualizations of the Kohn-Sham orbitals and optimized geometries were made using Gaussview.<sup>48</sup> Snapping energies were calculated by subtracting the sum of the single point energies of the GaCl<sub>2</sub><sup>+</sup> and ligand fragments (separately) from the energy of their optimized complexes.

#### **2.4.4 X-ray Crystallography**

Crystals for investigation were covered in Paratone<sup>®</sup>, mounted onto a goniometer head, and then rapidly cooled under a stream of cold N<sub>2</sub> of the low-temperature apparatus (Oxford Cryostream) attached to the diffractometer. The data were then collected using the APEXII (Bruker AXS) software suite on a Bruker Photon 100 CMOS diffractometer using a graphite monochromator with MoK<sub>α</sub> ( $\lambda = 0.71073 \text{ \AA}$ ). For each sample, data were collected at low temperature. APEXII software was used for data reductions and SADABS (Bruker AXS) was used for absorption corrections (multi-scan; semi-empirical

from equivalents). XPREP was used to determine the space group and the structures were solved and refined using the SHELX<sup>51</sup> software suite as implemented in the WinGX<sup>52</sup> or OLEX2<sup>53</sup> program suites. Validation of the structures was conducted using PLATON<sup>54</sup> and the structures have been deposited in the Cambridge Structural Database (CCDC 1857723-1857729).

# CHAPTER 3: 2,6-Bis(benzimidazol-2-yl)pyridine Complexes of Group 14 Elements

## 3.1 Introduction

Neutral trinitrogen donor ligands such as bis(imino)pyridine ( $R'DIMPY$ , **A**) have played an important role in transition metal chemistry and have generated highly active catalysts<sup>1-3</sup> for ethylene polymerisation.<sup>4</sup> In several instances, variously substituted  $R'DIMPY$  ligands bound to main group elements have allowed for the isolation of different low valent fragments including: Ge(0)<sup>5</sup>, Sn(0)<sup>6</sup>, As(I)<sup>7</sup>, P(I)<sup>8</sup>, and In(I)<sup>9</sup>.

**Scheme 3.1.** Top:  $DIMPY$  (**A**) vs  $G-BZIMPY$  ( $G = NH, NBn, N(3,5-CF_3)Bn, NAllyl$  and  $O$ ). Bottom:  $DIMPY$  complexes of group 14 elements.

The use of pincer ligands with group 14 elements dates back to 1985 - before the term “pincer” was even adopted - where Archer and co-workers reported the synthesis of a tripyridine tin(II)chloride complexes.<sup>10</sup> Pincer

ligands are very tuneable allowing for the introduction of asymmetry in the ligand producing a chiral catalyst. Evans and co-workers reported the tin(II) chiral Lewis acid shown in **Figure 3.1** that have been used in aldol condensation reactions, resulting in good yields with greater than 90% ee.<sup>11</sup>

**Figure 3.1.** Evans tin(II) chiral Lewis acid catalyst.

DIMPY ligands have also been important in the development of group 14 low-valent chemistry. Roesky reported the self-ionization products of <sup>i</sup>PrDIMPY with the corresponding GeCl<sub>2</sub> and SnCl<sub>2</sub><sup>12</sup> to yield [<sup>i</sup>PrDIMPYMCl][MCl<sub>3</sub>] (M = Ge, Sn). Nikonov later showed that treating the germanium complex with 2 equivalents of potassium graphite (KC<sub>8</sub>) in benzene results in a Ge(0) complex [<sup>i</sup>PrDIMPYGe(0)] as shown in **Scheme 3.2**.<sup>5</sup> Other variants of the <sup>R</sup>DIMPYE(II) (E = Ge, Sn) have also been reported.<sup>13,14</sup>

**Scheme 3.2.** Nikonov's synthesis of [<sup>i</sup>PrDIMPYGe(0)].

In this work, we explore the coordination of group 14 elements to different variants of G-BZIMPY (ligands **B**, **Scheme 3.1**). These ligands are

more rigid than their DIMPY analogues and there have been a few examples of complexes reported featuring transition metals.<sup>15-18</sup> We recently reported the coordination of different G-BZIMPY ligands to Ga(III) centres, and determined that G-BZIMPY are electron-rich and sterically accessible alternatives to DIMPY ligands for group 13 coordination chemistry.<sup>19</sup> Complexes of BZIMPY ligands with indium<sup>20,21</sup> and lead have also been investigated.<sup>22-28</sup> Recent work by Schmedake<sup>29</sup> and co-workers reported the synthesis of a  $\text{Si}(\text{BZIMPY})_2$  complex (**Scheme 3.3**) as a potential electron transport layer and electroluminescent layer in organic electronic devices.

**Scheme 3.3.** Synthesis of  $\text{Si}(\text{BZIMPY})_2$ .

The parent ligand, NH-BZIMPY can be easily prepared and functionalized at the nitrogen atom of the benzimidazole allowing for tuning of the electronic and steric properties. Analogous imidazole and benzimidazole tripodal ligand coordination to main group elements have also been investigated.<sup>30-34</sup>

## 3.2 Results and Discussion

### 3.2.1 Synthesis and Characterization

Treatment of the parent ligand NH-BZIMPY with  $MCl_2$  ( $M = Ge, Sn$ ) resulted in coloured materials that were insoluble in common organic solvents and thus, further characterisation was not possible. To increase the solubility of the resulting complexes, NH nitrogen sites were substituted using different alkylating agents to introduce allyl, Bn and (3,5- $CF_3$ )Bn derivatives. These derivatives allowed for increased solubility and thus, characterisation by means of heteronuclear NMR spectroscopy and X-ray crystallography (**Figure 3.2**).

**Figure 3.2.** Solid state structure of the cations in  $[NBn-BZIMPYGeCl][GeCl_3]$  (**1**, left) and  $[NBn-BZIMPYSnCl][SnCl_3]$  (**2**, right). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms, solvent molecules and counterions are omitted for clarity. Selected bond distances and angles are listed in **Table 3.1**.

The self-ionization process ( $L + 2 MCl_2 \rightarrow [LMCl][MCl_3]$ ) has been previously reported for the structurally related DIMPY ligands.<sup>12-14</sup> A 1:1 reaction of BZIMPY and  $MCl_2$  results in 50% yield of the self-ionized product,  $[BZIMPYMCl][MCl_3]$ ; thus, it was necessary to use two equivalents of metal halide for the reaction to go to completion (**Scheme 3.4**). Products **1** and **2**

[[NBn-BZIMPYMC1][MCl<sub>3</sub>]] were obtained in high yields (>85%) and large scales by treating NBn-BZIMPY with two equivalents of MCl<sub>2</sub> in dichloromethane (DCM), resulting in an immediate intense yellow solution for **1** (M = Ge) and a slower more pale-yellow solution for **2** (M = Sn). Slow evaporation from a DCM solution yields yellow crystals of **1** and **2** suitable for X-ray diffraction. Compounds **3** and **4** [[N(3,5-CF<sub>3</sub>)Bn-BZIMPYMC1][MCl<sub>3</sub>]] were obtained by treatment of N(3,5-CF<sub>3</sub>)Bn-BZIMPY with two equivalents of MCl<sub>2</sub> in CD<sub>3</sub>CN. Similarly, reaction with GeCl<sub>2</sub> resulted in a faster and more intense yellow colour than SnCl<sub>2</sub>. Crystals of **3** and **4** suitable for X-ray diffraction were obtained from slow evaporation of CD<sub>3</sub>CN solutions.

**Scheme 3.4.** Self-ionization reactions of MCl<sub>3</sub> (M = Ge, Sn) with G-BZIMPY ligands.

G-BZIMPY complexes of germanium are more soluble than their tin counterparts. As a result, G-BZIMPY ligands with G = NAllyl and O were very poorly soluble when coordinated to tin and only slightly soluble in the case of germanium. [NAllyl-BZIMPYGeCl][GeCl<sub>3</sub>] (**5**) and [O-BZIMPYGeCl][GeCl<sub>3</sub>] (**6**) were obtained by treating two equivalents of GeCl<sub>2</sub> with the corresponding G-BZIMPY followed by sonication for 24 hours to yield a sparingly soluble yellow

solution. Crystals suitable for X-ray diffraction were obtained by slow evaporation of a dilute solution of **5** and **6**.

**Table 3.1.** Selected bond distances (Å) and angles (°) of complexes **1-6**, and  $[{}^i\text{PrDIMPYMCl}]^+$  ( $M = \text{Ge}, \text{Sn}$ )<sup>12</sup>.

**Figure 3.3.** Solid state structure of the cations in [Allyl-BZIMPYGeCl][GeCl<sub>3</sub>] (**5**, left) and [O-BZIMPYGeCl][GeCl<sub>3</sub>] (**6**, right). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms, solvent molecules and counterion are omitted for clarity.

Next, we were interested in comparing the G-BZIMPY complexes of germanium and tin to those of <sup>i</sup>PrDIMPY. [<sup>i</sup>PrDIMPYMCl][MCl<sub>3</sub>] complexes of germanium and tin were reported by Roesky as the products of the reaction of <sup>i</sup>PrDIMPY with two equivalents of the corresponding GeCl<sub>2</sub> and SnCl<sub>2</sub>.<sup>12</sup> The germanium and tin coordination complexes of <sup>i</sup>PrDIMPY have a shorter bond distance to the pyridine (M-N2) than the imine donors (M-N1 and M-N3) (**Table 3.1**). This trend was also observed in group 13 complexes of <sup>i</sup>PrDIMPY and is likely due to the steric hindrance of the bulky imine donors.<sup>19</sup> Complexes **1** and **2** contain shorter M-N1 and M-N3 distances (benzimidazole donors) than their <sup>i</sup>PrDIMPY counterparts (imine donors) suggesting a stronger BZIMPY donor ligand than <sup>i</sup>PrDIMPY. This was also observed and confirmed by computational analysis with group 13 complexes of G-BZIMPY.<sup>19</sup>

Complex **3** shows slight asymmetry in the solid state with the germanium coordinating closer to N1 and N2 (M-N1: 2.149(4)Å and M-N2:

2.169(4)Å) than to N3 (M-N3: 2.306(3)Å). This asymmetry is not observed in the room temperature proton NMR spectrum, which is likely due to the Ge centre exchanging between N1 and N3 at a rate faster than the NMR time scale. This asymmetry could be a result of crystal packing effects in the solid state. Asymmetry in the solid-state structure is also observed in [O-BZIMPYGeCl][GeCl<sub>3</sub>], complex **6** (Table 3.1). Complex **5** shows an intermolecular interaction between the Ge–Cl fragment of the cation and a Ge–Cl fragment of the anion (Figure 3.3, left). These interactions (3.3961(7) Å and 3.543(1) Å) are within the Van der Waals radii expected for Ge (2.13 Å) and Cl (1.89 Å) (Ge–Cl= 4.02 Å).<sup>35</sup>

As introduced earlier, Evans' chiral Lewis acid contains a dicationic tin(II) pincer complex with two triflate anions.<sup>11</sup> In an effort to produce a similar Lewis ([G-BZIMPY-M][OTf]<sub>2</sub>), complex **1** was treated with 1, 2 and 5 equivalents of trimethylsilyl trifluoromethanesulfonate (TMS-OTf) in CD<sub>3</sub>CN yielding the monocationic complex [NBn-BZIMPYGeCl][OTf] (**7**, Figure 3.4, left) where the [GeCl<sub>3</sub>] anion is exchanged by a triflate anion [OTf]. Treatment of the commercially available Sn(OTf)<sub>2</sub> with an equivalent of NBn-BZIMPY in CD<sub>3</sub>CN results in the dicationic tin complex, [NBn-BZIMPYSn][OTf]<sub>2</sub> (**8**, Figure 3.4, right). Slow evaporation of both complexes from an acetonitrile solution results in yellow crystals suitable for X-ray diffraction.

**Figure 3.4.** Solid state structure of the cations in  $[\text{NBn-BZIMPYGeCl}][\text{OTf}]$  (**7**, left) and  $[\text{NBn-BZIMPYSn}][\text{OTf}]_2$  (**8**, right). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms and solvent molecules are omitted for clarity. Selected bond distances and angles are listed in **Table 3.2**.

The Lewis acidity of the resulting complexes was assessed using the Gutmann-Beckett method.<sup>36,37</sup> A  $\text{CH}_3\text{CN}$  solution was prepared containing an equivalent of triethylphosphine oxide and **8**. This solution exhibited a singlet in the  $^{31}\text{P}\{^1\text{H}\}$  NMR at  $\delta = 76.5$  ppm, which is significantly shifted from the free phosphine oxide ( $\Delta\delta = 35.5$  ppm). Using the Gutmann-Beckett method, this shift corresponds to an acceptor number of 78. To put this into perspective, other commonly used boron containing Lewis acids have the following acceptor numbers:  $\text{B}(\text{C}_6\text{F}_5)_3$  (82)  $<$   $\text{BF}_3$  (89)  $<$   $\text{BCl}_3$  (106)  $<$   $\text{BBr}_3$  (109)  $<$   $\text{BI}_3$  (115).<sup>38</sup> This suggests that the Lewis acidity of **8** is slightly weaker than that of  $\text{B}(\text{C}_6\text{F}_5)_3$  (BCF). As a result of the Lewis acidic tin, the two triflate anions coordinate to the tin centre in the solid state resulting in a pseudo-square pyramidal geometry around tin. Assessing the Lewis acidity of **7** using the same method results in a more significant shift in the  $^{31}\text{P}\{^1\text{H}\}$  NMR with a singlet at  $\delta$

= 91.9 ppm. This shift of  $\Delta\delta = 50.9$  ppm (from free phosphine oxide) yields an acceptor number of 112, suggesting that **7** is a very strong Lewis acid and is comparable to other strong  $BX_3$  (X = Cl, Br, and I) Lewis acids.

Complexes **1** and **7** have similar bond distances around the germanium and within the ligand framework. Complex **1** is more soluble in dichloromethane while complex **7** is more soluble in acetonitrile. In the case of tin, comparing complexes **2** to **8** where the chloride is absent in the latter, the bond distances of the tin centre to the ligand are similar, however, the two triflate anions are now bound to the tin centre forming a pseudo-square pyramidal geometry around the tin centre unlike complex **7** where the triflate was non-coordinating.

*Table 3.2. Selected bond distances (Å) and angles (°) of complexes 7-10.*

### 3.2.2 UV-vis Studies

UV-vis absorption spectra of complexes **1-8** were collected in dichloromethane (DCM). Complex **1** in DCM gives a yellow solution that shows intense absorption band at 322 nm ( $\epsilon = 23,000 \text{ L mol}^{-1} \text{ cm}^{-1}$ ) and a moderate band at 375 nm ( $\epsilon = 9,700 \text{ L mol}^{-1} \text{ cm}^{-1}$ ). Absorption bands are assigned in accordance with other BZIMPY metal complexes reported in literature where the high-energy intense band is attributed to an intra-ligand (IL) transition, while the low-energy band is assigned to a metal-to-ligand charge-transfer

(MLCT).<sup>39,40</sup> Increasing the polarity of the solvent in **1** (CH<sub>3</sub>CN) results in negative solvatochromism of the low-energy band. **Figure 3.5a** illustrates this blue-shift of the CT band resulting in a single overlapping band at 314 nm ( $\epsilon = 29,000 \text{ L mol}^{-1} \text{ cm}^{-1}$ ). The same observation was made in **6** (**Figure 3.5c**) where a DCM solution yielded two bands at 376 nm ( $\epsilon = 6,200 \text{ L mol}^{-1} \text{ cm}^{-1}$ ) and 321 nm ( $\epsilon = 31,000 \text{ L mol}^{-1} \text{ cm}^{-1}$ ); while in CH<sub>3</sub>CN, negative solvatochromism of the low-energy band shifts and disappears under the IL band at 316 nm ( $\epsilon = 37,200 \text{ L mol}^{-1} \text{ cm}^{-1}$ ). [NBn-BZIMPYSnCl][SnCl<sub>3</sub>] (**2**) exhibits a MLCT band at 370 nm with a molar absorptivity of  $\epsilon = 19,600 \text{ L mol}^{-1} \text{ cm}^{-1}$  that is significantly stronger than its germanium counterparts. Using a more polar solvent (CH<sub>3</sub>CN) with **2** does not result in a significant change to the MLCT, 364 nm ( $\epsilon = 19,400 \text{ L mol}^{-1} \text{ cm}^{-1}$ ) as shown in **Figure 3.5b**. IL band of **2** in DCM (318 nm,  $\epsilon = 23,600 \text{ L mol}^{-1} \text{ cm}^{-1}$ ) does not shift upon increasing the polarity of the solvent (317 nm,  $\epsilon = 24,500 \text{ L mol}^{-1} \text{ cm}^{-1}$ ). It is worth noting that the different group-14 element bound to G-BZIMPY not only results in a difference in the intensity of the MLCT band, but it can dictate whether or not negative solvatochromism is observed. In light of the differences between the UV-vis spectra of the germanate (**1**) and triflate (**7**) salts of an identical cation, the solvent effects observed for the germanium-containing complexes are likely primarily a consequence of differing cation-anion-solvent interactions.

For both the germanium and tin complexes, changing the R group in the NR-BZIMPY ligands has a negligible effect on the observed absorbance. Germanium complexes of NR-BZIMPY (**1**, **3** and **5**) have an IL band at 311-322

nm ( $\epsilon = 20,800\text{-}21,200 \text{ L mol}^{-1} \text{ cm}^{-1}$ ) and a MLCT band at 375-384 nm ( $\epsilon = 9,600\text{-}12,800 \text{ L mol}^{-1} \text{ cm}^{-1}$ ). Tin counterparts (**2** and **4**) have a relatively similar IL band at 318-320 nm ( $\epsilon = 21,200\text{-}23,600 \text{ L mol}^{-1} \text{ cm}^{-1}$ ) but a significantly more intense MLCT band at 365-370 nm ( $\epsilon = 17,900\text{-}19,600 \text{ L mol}^{-1} \text{ cm}^{-1}$ ).

To study the impact of changing the counter-ion and the abstraction of the chloride on absorption bands, UV-vis spectra of **7** and **8** were collected in DCM. The low-energy band in **7** is likely blue-shifted and not observed, as a result, a single broad absorption is observed at 319 nm with a molar absorptivity of  $\epsilon = 31,100 \text{ L mol}^{-1} \text{ cm}^{-1}$  (**Figure 3.5a**). The absorption bands in **8** (368 nm,  $\epsilon = 23,900 \text{ L mol}^{-1} \text{ cm}^{-1}$  and 318 nm,  $\epsilon = 29,300 \text{ L mol}^{-1} \text{ cm}^{-1}$ ) do not shift in comparison to **2**, confirming that Sn(II)-BZIMPY complexes are not sensitive to polarity of the solvent nor the environment surrounding the tin(II) centre.

**Figure 3.5.** a) UV-vis absorption of **1** in DCM vs  $\text{CH}_3\text{CN}$  along with **7** in DCM. b) UV-vis absorption of **2** in DCM vs  $\text{CH}_3\text{CN}$  along with **8** in DCM. c) UV-vis absorption of **6** in DCM vs  $\text{CH}_3\text{CN}$ . d) UV-vis absorption of **3-5** in DCM. Spectra collected in  $\text{CH}_3\text{CN}$  are indicated by the dashed line.

### 3.2.3 Reduction Attempts

Reduction of the  $[\text{iPr}^{\text{D}}\text{DIMPYGe}(\text{II})\text{Cl}]^+$  into the Ge(0) complex was reported by Nikonov as noted above (**Scheme 3.2**).<sup>5</sup> We thus investigated similar reactions in which complexes **1** and **2** were treated with different reducing agents including  $\text{KC}_8$ , potassium, or sodium naphthalide in THF; each of these reactions resulted in the deposition of the main group element and the release of the free NBn-BZIMPY ligand. We recently reported the successful reduction of Ga(III) to Ga(I) BZIMPY complex using Collman's reagent

( $K_2[Fe(CO)_4]$ ) to yield of  $[(NBn-BZIMPY)(Cl)Ga-Fe(CO)_4]$ .<sup>19</sup> Again, attempts to extend this chemistry to group 14 complexes by treating complexes **1** or **2** with an equivalent of  $K_2[Fe(CO)_4]$  in THF results in the free NBn-BZIMPY ligand along with an insoluble precipitate. Using an equivalent of  $[Ni(COD)_2]$ , we anticipated the reduction of the main group element and the oxidation of the Ni(0) centre to Ni(II). Although the nickel centre is indeed oxidized, it displaces the main group element to yield  $[(NBn-BZIMPY)_2Ni][MCl_3]_2$  ( $M = Ge$  (**9**), Sn (**10**), **Figure 3.6**).

**Figure 3.6.** Solid state structure of the cations in  $[(NBn-BZIMPY)_2Ni][GeCl_3]_2$  (**9**, left) and  $[(NBn-BZIMPY)_2Ni][SnCl_3]_2$  (**10**, right). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms and solvent molecules are omitted for clarity. Selected bond distances and angles are listed in **Table 3.2**.

These reactions were repeated using half an equivalent of  $Ni(COD)_2$  to yield **9** and **10** in 34-37% yields (**Scheme 3.5**). The crystal structures of **9** and **10** are isomorphous, having the same unit cell parameters with the tin replacing the germanium in complex **10**.

**Scheme 3.5.** Reduction attempt of complexes **1** and **2** using  $\text{Ni}(\text{COD})_2$  to yield complexes **9** and **10** respectively ( $R = \text{Bz}$ ).

In an effort to elucidate possible reasons for the observed G-BZIMPY ligand behaviour in reducing conditions, cyclic voltammetry experiments of NBn-BZIMPY were undertaken. From the voltammograms (**Figure 3.7**), it was determined that there is a single irreversible reduction that occurs at  $-0.902 \text{ V}$  (versus  $\text{Fc}/\text{Fc}^+$ ).

**Figure 3.7.** Overlapping CVs of  $0.01\text{M}$  solution of ferrocene ( $\text{Fc}/\text{Fc}^+$ ) in black and  $0.01\text{M}$  solution of ferrocene/NBn-BZIMPY in red. Both solutions were prepared in DCM with  $0.1\text{M}$   $[\text{NBu}_4][\text{PF}_6]$ . Working and counter electrodes were Pt, the reference electrode was  $\text{Ag}/\text{AgCl}$ , and the scan rate was  $100 \text{ mVs}^{-1}$ .

### 3.2.4 Computational Studies

Gas phase geometry optimizations on simplified NH-BZIMPY models (2,6-di(1H-imidazol-1-yl)pyridine) of compound **1** and **2** (**1'** and **2'** corresponding to Ge and Sn complexes of the simplified ligand, respectively) performed at the M062X/cc-pVTZ level of theory result in models with near perfect *C*<sub>s</sub> symmetry and metrical parameters that are close to the values determined experimentally using single crystal X-ray diffraction. Inspection of the molecular orbitals of **1'** reveal that the HOMO has significant contributions from germanium, corresponding to the “lone pair”. The energy of the HOMO (–10.89 eV) is significantly higher than the HOMO of the model [ClGe(<sup>H</sup>DIMPY)]<sup>1+</sup> calculated at the same level of theory (–11.48 eV) and suggests that **1'** should be a superior donor. Interestingly, NBO analyses corroborate the conclusion regarding germanium “lone pair” energies but suggest that the donor abilities of NH-BZIMPY and <sup>H</sup>DIMPY are similar. The HOMO–1 and HOMO–2 of **1'** are  $\pi$ -type ligand-based MOs with A'' and A' symmetry, respectively, and the HOMO–3 and HOMO–4, represent the “lone pairs” on the chlorine atom. The LUMO has A' symmetry, but does not exhibit any metal-ligand anti-bonding character and thus does not explain why reduction attempts were unsuccessful. Models of the putative Ge(0) species [Ge(NH-BZIMPY)] and [Ge(<sup>H</sup>DIMPY)] exhibit similar structural features and HOMO-LUMO energy differences and do not provide any obvious electronic rationale for the instability of the NH-BZIMPY variant. Given the foregoing, it is likely that kinetic instability of the putative reduced compound precludes its isolation.

*Figure 3.8. Optimized geometry and selected occupied molecular orbitals of 1' (M062X/cc-pVTZ).*

### 3.3 Conclusions

We presented Ge(II) and Sn(II) coordination to 2,6-Bis(benzimidazol-2-yl)pyridine (G-BZIMPY, G = NBn, N(3,5-CF<sub>3</sub>)Bn, NAllyl and O) ligands. Some of the salts were assessed to be potent Lewis acids using the Gutman-Beckett method. UV-vis absorption spectra of these complexes feature an intense high-energy intra-ligand band and a moderate low-energy MLCT band. Negative solvatochromism was observed in germanium-containing complexes upon increasing polarity of the solvent, but this was not observed in those of tin. Attempts to reduce these M(II) complexes into low-valent M(0) complexes were not successful; this is likely attributable to kinetic instability of the resulting reduced compounds.

## 3.4 Experimental

### 3.4.1 General Remarks

All manipulations were carried out using standard inert-atmosphere techniques. All reagents and chemicals were obtained from Sigma-Aldrich. All reagents were used without further purification. MeCN-*d*<sub>3</sub> was dried over calcium hydride or phosphorus pentoxide, and dichloromethane-*d*<sub>2</sub> was dried over phosphorus pentoxide. All other solvents were dried on a series of Grubbs-type columns and were degassed prior to use.<sup>41</sup> All glassware was stored in a 170 °C oven for several hours. 2,6-Bis(benzimidazol-2-yl)pyridine (NH-BZIMPY),<sup>42</sup> 2,6-bis(benzoxazol-2-yl)pyridine (O-BZIMPY),<sup>43</sup> NBn-BZIMPY,<sup>44</sup> N(3,5-CF<sub>3</sub>)Bn-BZIMPY,<sup>19</sup> Nallyl-BZIMPY,<sup>19</sup> and K<sub>2</sub>[Fe(CO)<sub>4</sub>]<sup>45</sup> were all prepared according to the literature procedures.

NMR spectrum was recorded at room temperature on Bruker Avance III 500 MHz, Bruker Avance Ultrashield 300 MHz, and Bruker Avance DPX 300 MHz spectrometers. Chemical shifts are reported in parts per million relative to internal standards for <sup>1</sup>H and <sup>13</sup>C (the given deuterated solvent) and external standards for <sup>19</sup>F (CFCl<sub>3</sub>). Coupling constants  $|J|$  are given in hertz. Elemental analysis was performed at the University of Windsor Mass Spectrometry Service Laboratory using a Perkin-Elmer 2400 combustion CHN analyzer.

Cyclic voltammetry was performed in dry CH<sub>2</sub>Cl<sub>2</sub> solutions using [NBu<sub>4</sub>][PF<sub>6</sub>] (0.1 M) as the electrolyte with analyte concentration of approximately 0.01 M. A platinum electrode, a platinum wire, and 1.0 M

Ag/AgCl electrode were used as the working, auxiliary, and reference electrodes, respectively. The experiments were run with a scan rate of 100 mV/s and a sensitivity of 100  $\mu$ A/V and the potentials reported are referenced to ferrocene/ferrocenium ( $E_{1/2} = 0.0$  V).

### 3.4.2 Synthesis

**[NBn-BzimpyGeCl][GeCl<sub>3</sub>] (1)** A 100 mL Schlenk flask was charged with NBn-BZIMPY (465 mg, 0.95 mmol) and GeCl<sub>2</sub>-dioxane (438 mg, 1.9 mmol). To that was added 40 mL of dichloromethane resulting in an immediate formation of a yellow/green solution. After 2 hours of stirring, the solvent was evaporated under reduced pressure and the resulting solid was suspended in toluene (20 mL), collected and washed with toluene (2 $\times$ 10 mL) yielding **1** as a yellow solid (630 mg, 85%). Slow evaporation from dichloromethane yielded yellow crystals suitable for X-ray Diffraction. <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>)  $\delta$ : 8.45 (t, 1H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.20 (b, 4H), 7.65 (m, 4H), 7.37 (b, 4H), 7.24 (b, 8H), 6.02 (s, 4H). <sup>13</sup>C{<sup>1</sup>H} NMR  $\delta$ : 145.81, 145.38, 144.47, 137.88, 137.31, 133.96, 130.07, 129.18, 127.91, 126.75, 126.23, 125.10, 119.20, 112.32, 50.10. Anal. Calc. for C<sub>33</sub>H<sub>25</sub>Cl<sub>4</sub>Ge<sub>2</sub>N<sub>5</sub> (778.68 g/mol): C, 50.90; H, 3.24; N, 8.99. Found: C, 50.59; H, 3.12; N, 8.82.

**[NBn-BzimpySnCl][SnCl<sub>3</sub>] (2)** A 100 mL Schlenk flask was charged with NBn-BZIMPY (500 mg, 1.0 mmol) and SnCl<sub>2</sub> (386 mg, 2.0 mmol). To that was added 40 mL of dichloromethane resulting in an immediate formation of a yellow solution. After allowing the reaction to stir overnight, the solvent was evaporated under reduced pressure and the resulting solid was suspended in toluene (20 mL), collected and washed with toluene (2×10 mL) yielding **2** as a pale-yellow solid (910 mg, 98%). Slow evaporation from dichloromethane yielded yellow crystals suitable for X-ray Diffraction. <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.27 (t, 1H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.16 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.07 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.62 (m, 5H), 7.42 (m, 5H), 7.13 – 7.26 (m, 6H), 6.03 (s, 4H). <sup>13</sup>C{<sup>1</sup>H} NMR δ: 148.32, 144.93, 144.48, 137.89, 134.26, 130.08, 129.09, 127.48, 126.70, 126.55, 126.20, 125.50, 119.11, 112.35, 50.50. Anal. Calc. for C<sub>33</sub>H<sub>25</sub>Cl<sub>4</sub>Sn<sub>2</sub>N<sub>5</sub>(toluene)<sub>0.5</sub> (916.89 g/mol): C, 47.81; H, 3.19; N, 7.64. Found: C, 48.01; H, 3.25; N, 7.16.

**[N(3,5-CF<sub>3</sub>)Bn-BzimpyGeCl][GeCl<sub>3</sub>] (3)** A 20 mL vial was charged with N(3,5-CF<sub>3</sub>)Bn-BZIMPY (40 mg, 0.052 mmol) and GeCl<sub>2</sub>-dioxane (24 mg, 1.0 mmol). 5 mL of CD<sub>3</sub>CN was added, resulting in the formation of a yellow solution. The

solution was allowed to stir overnight and was then left to evaporate resulting in **3** as yellow crystals (47 mg, 85%).  $^1\text{H}$  NMR ( $\text{CD}_3\text{CN}$ )  $\delta$ : 8.46 (t, 1H,  $^3J_{\text{HH}} = 8$  Hz), 8.22 (m, 4H), 8.02 (s, 2H), 7.85 (s, 4H), 7.62-7.74 (m, 6H), 6.15 (s, 4H).  $^{13}\text{C}\{^1\text{H}\}$  NMR  $\delta$ : 148.04, 146.55, 144.60, 138.32, 137.74, 132.82 ( $^2J_{\text{CF}} = 33$  Hz), 128.48, 128.04, 127.97, 127.36, 125.87, 124.20 ( $^1J_{\text{CF}} = 272$  Hz), 123.52, 119.55, 113.24, 49.65.  $^{19}\text{F}\{^1\text{H}\}$  NMR  $\delta$ : -64.40. Anal. Calc. for  $\text{C}_{37}\text{H}_{21}\text{Cl}_4\text{F}_{12}\text{Ge}_2\text{N}_5$  (1050.65 g/mol): C, 42.30; H, 2.01; N, 6.67. Found: C, 42.08; H, 2.20; N, 6.33.

**[N(3,5- $\text{CF}_3$ )Bn-BzimpySnCl][ $\text{SnCl}_3$ ]** (**4**) A 20mL vial was charged with N(3,5- $\text{CF}_3$ )Bn-BZIMPY (40 mg, 0.052 mmol) and  $\text{SnCl}_2$  (20 mg, 1.0 mmol). 5 mL of  $\text{CD}_3\text{CN}$  was added to the vial, resulting in the formation of a pale-yellow solution. The solution was allowed to stir overnight and was then left to evaporate resulting in **4** as yellow crystals (58 mg, 97%).  $^1\text{H}$  NMR ( $\text{CD}_3\text{CN}$ )  $\delta$ : 8.24 (t, 1H,  $^3J_{\text{HH}} = 8$  Hz), 8.21 (m, 2H), 8.13 (d, 2H,  $^3J_{\text{HH}} = 8$  Hz), 8.03 (s, 2H), 7.85 (s, 4H), 7.62-7.68 (m, 6H), 6.13 (s, 4H).  $^{13}\text{C}\{^1\text{H}\}$  NMR  $\delta$ : 147.97, 144.80, 144.25, 137.68, 137.25, 131.90 ( $^2J_{\text{CF}} = 33$  Hz), 127.23, 127.15, 127.09, 126.30, 125.38, 123.40 ( $^1J_{\text{CF}} = 272$  Hz), 122.58, 118.63, 112.24, 48.94.  $^{19}\text{F}\{^1\text{H}\}$  NMR  $\delta$ : -62.63 (s). Anal. Calc. for  $\text{C}_{37}\text{H}_{21}\text{Cl}_4\text{F}_{12}\text{Sn}_2\text{N}_5$  (1142.81 g/mol): C, 38.89; H, 1.85; N, 6.13. Found: C, 39.11; H, 2.12; N, 6.35.

**[NAllyl-BZIMPYGeCl][GeCl<sub>3</sub>] (5)** A 20mL vial was charged with NAllyl-BZIMPY (20 mg, 0.051 mmol) and GeCl<sub>2</sub>-dioxane (24 mg, 0.10 mmol). 5 mL of CD<sub>3</sub>CN was added to the vial, resulting in the formation of a yellow precipitate. The solution was sonicated overnight to yield a pale-yellow solution with yellow precipitate. Solvent was evaporated to yield **5** as yellow precipitate (26 mg, 75%). Crystals were formed by dissolving a few milligrams of **5** in CH<sub>3</sub>CN and leaving the solution to slowly evaporate yielding yellow crystals suitable for X-ray diffraction. <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>) δ: 8.67 (t, 1H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.47 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.13 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.81 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.66 (m, 4H), 6.30 (b, 2H), 5.29 – 5.47 (m, 6H), 5.09 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 18 Hz). Compound is not soluble enough to obtain a <sup>13</sup>C NMR. Anal. Calc. for C<sub>25</sub>H<sub>21</sub>Cl<sub>4</sub>Ge<sub>2</sub>N<sub>5</sub> (678.54 g/mol): C, 44.25; H, 3.12; N, 10.32. Found: C, 43.81; H, 2.96; N, 9.98.

**[O-BZIMPYGeCl][GeCl<sub>3</sub>] (6)** A 20mL vial was charged with O-BZIMPY (20 mg, 0.064 mmol) and GeCl<sub>2</sub>-dioxane (30 mg, 0.13 mmol). 4 mL of CD<sub>3</sub>CN and 1 mL of CD<sub>2</sub>Cl<sub>2</sub> were added to the vial, resulting in the formation of a yellow solution. The solution was allowed to stir overnight, and slow evaporation of the solvent yielded yellow crystals of **6** (35 mg, 92%). <sup>1</sup>H NMR (CD<sub>2</sub>Cl<sub>2</sub>/CD<sub>3</sub>CN (1:4)) δ: 8.69

(m, 3H), 8.08 (d, 2H,  $^3J_{\text{HH}} = 8$  Hz), 7.91 (d, 2H,  $^3J_{\text{HH}} = 8$  Hz), 7.76 (t, 2H,  $^3J_{\text{HH}} = 8$  Hz), 7.66 (t, 2H,  $^3J_{\text{HH}} = 8$  Hz).  $^{13}\text{C}\{^1\text{H}\}$  NMR  $\delta$ : 159.88, 152.01, 145.02, 143.55, 137.90, 129.56, 127.90, 127.47, 120.57, 113.06.; Anal. Calc. for  $\text{C}_{19}\text{H}_{11}\text{Cl}_4\text{Ge}_2\text{N}_3\text{O}_2(\text{CH}_3\text{CN})_{0.33}$  (613.89 g/mol): C, 38.46; H, 1.97; N, 7.59. Found: C, 38.83; H, 1.85; N, 7.28.

**[NBn-BzimpyGeCl][OTf] (7)** A 20 mL vial was charged compound **1** (50 mg, 0.064 mmol). 5 mL of  $\text{CD}_3\text{CN}$  was added, followed by excess TMSOTf (0.035 mL, 0.19 mmol). The solution was stirred for an hour and left to slowly evaporate yielding **7** as yellow crystals (45 mg, 94%).  $^1\text{H}$  ( $\text{CD}_3\text{CN}$ )  $\delta$ : 8.39 (t, 1H,  $^3J_{\text{HH}} = 8$  Hz), 8.25 (d, 2H,  $^3J_{\text{HH}} = 8$  Hz), 8.18 (m, 2H), 7.62 (m, 4H), 7.76 (m, 2H), 7.66 (m, 2H), 7.33 – 7.40 (m, 6H), 7.20 (d, 2H,  $^3J_{\text{HH}} = 8$  Hz), 6.01 (s, 4H).  $^{13}\text{C}\{^1\text{H}\}$  NMR  $\delta$ : 146.21, 145.64, 144.26, 142.12, 138.16, 137.47, 134.74, 130.06, 128.18, 127.07, 126.57, 123.72 ( $^1J_{\text{CF}} = 313$  Hz), 119.17, 112.99, 49.94.  $^{19}\text{F}\{^1\text{H}\}$  NMR  $\delta$ : -77.83. Anal. Calc. for  $\text{C}_{34}\text{H}_{25}\text{F}_3\text{N}_5\text{O}_3\text{SGe}$  (748.74 g/mol): C, 54.54; H, 3.37; N, 9.35. Found: C, 54.09; H, 3.10; N, 9.22.

**[NBn-BzimpySn][OTf]<sub>2</sub> (8)** A 20 mL vial was charged with NBn-BZIMPY (40 mg, 0.082 mmol) and Sn(OTf)<sub>2</sub> (35 mg, 0.084 mmol). 5 mL of CD<sub>3</sub>CN was added, resulting in the formation of a yellow solution. The solution was allowed to stir overnight and was then left to evaporate resulting in **8** as yellow crystals (59 mg, 80%). <sup>1</sup>H NMR (CD<sub>3</sub>CN) δ: 8.31 (t, 1H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.22 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.19 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.74 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.62 (m, 4H), 7.35 (m, 6H), 7.17 (d, 4H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 6.03 (s, 4H). <sup>13</sup>C{<sup>1</sup>H} NMR δ: 149.42, 145.40, 144.79, 138.61, 138.36, 135.15, 130.32, 129.39, 127.95, 127.23, 126.99, 126.33, 122.07 (<sup>1</sup>J<sub>CF</sub> = 316 Hz), 119.40, 113.39, 50.32. <sup>19</sup>F{<sup>1</sup>H} NMR δ: -79.50 Anal. Calc. for C<sub>35</sub>H<sub>25</sub>F<sub>6</sub>N<sub>5</sub>O<sub>6</sub>S<sub>2</sub>Sn (908.43 g/mol): C, 46.28; H, 2.77; N, 7.71. Found: C, 45.88; H, 3.02; N, 7.59.

**[(NBn-BZIMPY)<sub>2</sub>Ni][GeCl<sub>3</sub>]<sub>2</sub> (9)** A 20 mL vial was charged with compound **1** (36 mg, 0.046 mmol) and Ni(COD)<sub>2</sub> (7 mg, 0.025 mmol). 5 mL of THF (precooled to -40 °C) was added resulting in a colour change from yellow to deep brown/red solution. The reaction was allowed to warm up to room

temperature and stir for 1 hr before filtering. 1 mL of hexane was added to the filtrate and was allowed to sit at room temperature overnight, resulting in deep brown crystals of **9** (12 mg, 37%). Anal. Calc. for  $C_{66}H_{50}Cl_6Ge_2N_{10}Ni$  (1399.85 g/mol): C, 56.63; H, 3.81; N, 10.01. Found: C, 56.60; H, 3.81; N, 9.75.

**[(NBn-BZIMPY)<sub>2</sub>Ni][SnCl<sub>3</sub>]<sub>2</sub> (10)** A 20 mL vial was charged with compound **2** (48 mg, 0.055 mmol) and Ni(COD)<sub>2</sub> (8 mg, 0.029 mmol). 5 mL of THF (precooled to -40 °C) was added resulting in a colour change from yellow to a deep brown solution. The reaction was allowed to warm up to room temperature and stir for 1 hr before filtering. 1 mL of hexane was added to the resulting filtrate and was allowed to sit at room temperature overnight, resulting in light brown crystals of **10** (14 mg, 34%). Anal. Calc. for  $C_{66}H_{50}Cl_6Sn_2N_{10}Ni$  (1492.20 g/mol): C, 53.13; H, 3.38; N, 9.39. Found: C, 49.81; H, 3.23; N, 8.68.

**Gutmann-Beckett method:**

Reaction of **7** with OPET<sub>3</sub>; A 20 mL vial was charged with **7** (14 mg, 0.019 mmol) and OPET<sub>3</sub> (3 mg, 0.022 mmol) in 1 mL CH<sub>3</sub>CN. Reaction mixture was stirred for 30 minutes before collecting phosphorus NMR. <sup>31</sup>P{<sup>1</sup>H} NMR (CH<sub>3</sub>CN) δ: 91.9.

Reaction of **8** with OPET<sub>3</sub>; A 20 mL vial was charged with **8** (34 mg, 0.037 mmol) and OPET<sub>3</sub> (5 mg, 0.037 mmol) in 1 mL CH<sub>3</sub>CN. Reaction mixture was stirred for 30 minutes before collecting phosphorus NMR. <sup>31</sup>P{<sup>1</sup>H} NMR (CH<sub>3</sub>CN) δ: 76.5.

### **3.4.3 Computational Details**

Calculations were performed with the Gaussian 09 suite of programs<sup>46</sup> using Compute Canada's Shared Hierarchical Academic Research Computing Network (SHARCNET). Model complexes were fully optimized with no symmetry constraints using the M06-2X density functional method,<sup>47</sup> in conjunction with the cc-pVTZ basis set.<sup>48,49</sup> The cc-pVQZ-PP basis set employing a relativistic small-core pseudopotential was used for tin.<sup>50</sup> Geometry optimizations were started using models in which the relevant non-hydrogen atoms were placed in positions found experimentally by X-ray crystallography using Gaussview.<sup>51</sup> Frequency calculations were also performed at the same level of theory in order to confirm that the optimized structures were minima on the potential energy hypersurface and to determine thermochemical and vibrational information. Natural bond orbital (NBO) analyses<sup>52</sup> to determine orbital contributions, Wiberg Bond Indices and orbital energies were obtained using the routine included in the Gaussian distributions.<sup>53</sup> Visualizations of the Kohn-Sham orbitals and optimized geometries were made using Gaussview.<sup>51</sup>

### **3.4.4 X-ray Crystallography**

Crystals for investigation were covered in Paratone®, mounted onto a goniometer head, and then rapidly cooled under a stream of cold N<sub>2</sub> of the low-temperature apparatus (Oxford Cryostream) attached to the diffractometer. The data were then collected using the APEXIII (Bruker AXS) software suite on

a Bruker Photon 100 CMOS diffractometer using a graphite monochromator with MoK $\alpha$  ( $\lambda = 0.71073 \text{ \AA}$ ). For each sample, data were collected at low temperature. APEXIII software was used for data reductions and SADABS (Bruker AXS) was used for absorption corrections (multi-scan; semi-empirical from equivalents). XPREP was used to determine the space group and the structures were solved and refined using the SHELX<sup>54</sup> software suite as implemented in the WinGX<sup>55</sup> or OLEX2<sup>56</sup> program suites. Validation of the structures was conducted using PLATON<sup>57</sup> and the structures have been deposited in the Cambridge Structural Database (CCDC 1895464-1895473).

# CHAPTER 4: 2,6-Bis(benzimidazol-2-yl)pyridine Complexes of Group 15 Elements

## 4.1 Introduction

Trinitrogen donors have played an important role in the development of recent main group chemistry.<sup>1-11</sup> Among these notable ligands is the redox-active bis(imino)pyridine (DIMPY) that is useful in preparing highly active transition metal catalysts.<sup>12-14</sup> Cowley and Reeske reported that treatment of DIMPY to a mixture of  $\text{AsCl}_3$  with  $\text{SnCl}_2$  generates the arsenic(I)-DIMPY complex shown in **Scheme 4.1**, right.<sup>4</sup> Later work by Ragona resulted in the isolation of a P(I) cation using  $\text{PI}_3$  and DIMPY (**Scheme 4.1**, left).<sup>3,5</sup>

**Scheme 4.1.** Low valent P(I) and As(I) complexes of DIMPY. Dipp = 2,6-diisopropylphenyl.

Stephan and co-workers reported the synthesis of a P(III) dicationic complex of tripyridine that can be prepared as shown in **Scheme 4.2**.<sup>15</sup> The resulting Lewis acid has proven to be useful in catalytic hydrodefluorination (HDF) of unactivated fluoroalkanes.

**Scheme 4.2.** Stephan's dicationic P(III) catalyst.

Tridentate ligands, in general, have led to many interesting pnictogen containing compounds.<sup>16–32</sup> In particular, early work by Arduengo presented new and unusual bonding in 10-P-3 ADPO allowing for the idea of a shape-shifting compound.<sup>33</sup> Recently, work by Radosevich and co-workers illustrated that such compounds with distorted tricoordinate phosphorus result in an active phosphorus centre capable of transfer hydrogenation and small molecule activation.<sup>34,35</sup> An example containing a trinitrogen ligand (**Figure 4.1**) can readily activate E-H (O-H and N-H) bonds to yield a phosphorus(V) centre that is reversible to the phosphorus(III) centre at elevated temperatures.<sup>36</sup>

**Figure 4.1.** Arduengo's 10-P-3 (*T-shaped*) and 8-P-3 (*bent*) phosphines.

In this work, we explore the coordination of group 15 elements to bisbenzimidazole (BZIMPY) ligands **B** shown in **Figure 4.2** with  $\text{G} = \text{NBn}$ . These

BZIMPY ligands are more rigid than their DIMPY counterparts and have been used to a much lesser extent with transition metals.<sup>37-40</sup> We have recently reported that BZIMPY ligands are more electron-rich and sterically accessible alternatives to DIMPY ligands for group 13 and 14 coordination chemistry.<sup>9,41</sup> Other literature main group complexes of BZIMPY contain indium,<sup>42,43</sup> lead,<sup>44-50</sup> and silicon.<sup>51</sup> Parent NH-BZIMPY ligand allows for the introduction of different substituents to tune the electronic and steric properties. Analogous imidazole and benzimidazole tripodal ligand coordination to MG elements have also been investigated.<sup>52-56</sup>

**Figure 4.2.** A: DIMPY ligand, B: BZIMPY ligand ( $G = \text{NH}$ , NBn,  $N(3,5\text{-CF}_3)\text{Bn}$ , N-Allyl and O).

## 4.2 Results and Discussion

### 4.2.1 Synthesis and Characterization

Coordination of group 13 and 14 elements to G-BZIMPY has proven to be successful by treatment of G-BZIMPY with two equivalents of group 13 or 14 metal halides ( $\text{MCl}_3$  and  $\text{MCl}_2$ ) yielding the self-ionized products:  $[\text{G-BZIMPYMCl}_2][\text{MCl}_4]$  and  $[\text{G-BZIMPYMCl}][\text{MCl}_3]$ , respectively. Extending this approach to group 15 metal halides,  $\text{MCl}_3$  ( $\text{M} = \text{P}$ , As and Sb), does not result in any reactivity or any indication of coordination to G-BZIMPY.

As noted above, Cowley<sup>4</sup> and Ragogna<sup>5</sup> were successful in isolating the As(I) and P(I) complexes of DIMPY using  $\text{AsCl}_3/\text{SnCl}_2$  and  $\text{PI}_3$ , respectively. Attempts to implement this method with NBn-BZIMPY resulted in grey insoluble materials with  $\text{PCl}_3/\text{SnCl}_2$  and orange insoluble materials with  $\text{PI}_3$ . The only materials collected and characterized from these reactions were those of free NBn-BZIMPY ligand.

On the other hand, following Stephan's<sup>15</sup> work, the introduction of excess TMS-OTf to a solution containing NBn-BZIMPY and  $\text{PCl}_3$  in DCM/ $\text{CH}_3\text{CN}$  results in an immediate intense yellow colour (**Scheme 4.3**). After allowing the reaction mixture to stir overnight, solvents were removed under reduced pressure and the resulting solid was suspended in toluene, filtered and dried under vacuum to yield  $[\text{NBn-BZIMPYPCl}][\text{OTf}]_2$  (**1**) as a yellow solid in good yield (79%). Slow evaporation from a DCM/ $\text{CH}_3\text{CN}$  mixture yields yellow crystals of **1** suitable for X-ray diffraction (**Figure 4.3**). A similar procedure was carried out to prepare and isolate  $[\text{NBn-BZIMPYAsCl}][\text{OTf}]_2$  (**2**) and  $[\text{NBn-BZIMPYSbCl}][\text{OTf}]_2$  (**3**) in decent yields (65-83%).

**Scheme 4.3.** Reaction of  $\text{MCl}_3$  ( $M = \text{P}, \text{As}, \text{Sb}$ ) with Bn-BZIMPY to yield complexes **1**, **2** and **3**.

**Figure 4.3.** Solid state structure of the  $[\text{NBn-BZIMPYPCl}][\text{OTf}]_2$  (**1**, top),  $[\text{NBn-BZIMPYAsCl}][\text{OTf}]_2$  (**2**, left), and  $[\text{NBn-BZIMPYSbCl}][\text{OTf}]_2$  (**3**, right). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms and solvent molecules are omitted for clarity. Selected bond distances and angles of complexes **1-3** are in **Table 4.1**.

The phosphorus centre in **1** is binding symmetrically to both benzimidazole donors with P-N bond distances of 1.913(2) and 1.916(2) Å. The P-N bond distance to the pyridine nitrogen (1.855(2) Å) is significantly shorter, which is different from that observed in group 13 and 14 complexes where the M-N bond distances to pyridine nitrogen are longer than M-N bond distances to benzimidazole nitrogens. To assess the planarity of complex **1**, the pyridine para-carbon, pyridine nitrogen and phosphorus angle is examined. For complex **1**, C5-N2-P angle is 175.8(1)°, which is close to 180°, suggesting a planar complex. As the binding element increases in size going to As and Sb, this angle decreases as the main group element sits slightly above the plane of

the ligand, resulting in slight distortion to the planarity and the C5-N2-M angles being 164.0(4)° for arsenic and 166.2(1)° for antimony.

As a result of this distortion in planarity, the solid-state structure is not symmetric, resulting in differences in the M-N bond distances to the two benzimidazole arms. In arsenic, the As-N bond distances to benzimidazoles are 2.089(7) and 2.130(7) Å, while the As-N bond distance to the pyridine nitrogen is 2.002(7) Å, consistent with the observation made in **1**, having a shorter M-N bond distance to pyridine. Similarly, antimony binding results in slight distortion in the planarity of the ligand with the antimony centre sitting closer to N1 and N2 (2.253(2) and 2.260(2) Å, respectively) compared to N3 (2.292(2) Å).

**Table 4.1.** Selected bond distances ( $\text{\AA}$ ) and angles ( $^\circ$ ) of complexes **1**, **2** and **3**.

While the reaction has a distinct colour change from colourless to yellow upon the addition of TMS-OTf, the  $^1\text{H}$  NMR spectrum exhibits a clear downfield shift of the ligand protons upon binding of the metal centre which can be used as a handle to confirm coordination. The C5-H proton in particular is very sensitive to pnictogen binding and this sensitivity is dependent on the main group element bound. The downfield shift,  $\Delta\delta$ , observed increases going from Sb to As to P as shown in **Figure 4.4**. Thus, going up the periodic table results in greater influence on the shift of the ligand protons.

CH<sub>3</sub>CN solutions were prepared containing an equivalent of triethylphosphine oxide with **1**, **2** and **3**. These solutions exhibited a significant shift ( $\Delta\delta \sim 51$  ppm) in the <sup>31</sup>P{<sup>1</sup>H} NMR spectrum from the free phosphine oxide ( $\delta = 41.0$  ppm). Using the Gutmann-Beckett method, these shifts correspond to acceptor numbers of 112-113 for complexes **1-3**. To put this into perspective, other commonly used boron containing Lewis acids have the following acceptor numbers: B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> (82) < BF<sub>3</sub> (89) < BCl<sub>3</sub> (106) < BBr<sub>3</sub> (109) < BI<sub>3</sub> (115). This suggests that complexes **1-3** are very strong Lewis acid and are comparable to other strong BX<sub>3</sub> (X = Cl, Br, and I) Lewis acids.

**Figure 4.4.** <sup>1</sup>H NMR of **1** (red), **2** (green), **3** (blue), and free NBn-BZIMPY ligand (black).

### 4.3 Conclusions

We present group 15 (P, As, and Sb) coordination to 2,6-Bis(benzimidazol-2-yl)pyridine (NBn-BZIMPY) ligand. The resulting complexes are characterized by FT-

NMR and SC X-ray Diffraction. Further chemistry and reactivity are currently under way.

## 4.4 Experimental

### 4.4.1 General Remarks

All manipulations were carried out using standard inert-atmosphere techniques. All reagents and chemicals were obtained from Sigma-Aldrich. All reagents were used without further purification. MeCN-*d*<sub>3</sub> was dried over calcium hydride or phosphorus pentoxide, and dichloromethane-*d*<sub>2</sub> was dried over phosphorus pentoxide. All other solvents were dried on a series of Grubbs-type columns and were degassed prior to use.<sup>57</sup> All glassware was stored in a 170 °C oven for several hours and was degassed prior to use. 2,6-Bis(benzimidazol-2-yl)pyridine (NH-BZIMPY),<sup>58</sup> and the alkylation of NBn-BZIMPY<sup>59</sup> were prepared according to literature procedures. Alkylation reactions of NH-BZIMPY were carried according to general procedure reported.  
9,59

NMR spectra were recorded at room temperature on Bruker Avance III 500 MHz, Bruker Avance Ultrashield 300 MHz, and Bruker Avance DPX 300 MHz spectrometers. Chemical shifts are reported in parts per million relative to internal standards for <sup>1</sup>H and <sup>13</sup>C (the given deuterated solvent) and external standards for <sup>19</sup>F (CFCl<sub>3</sub>) and <sup>31</sup>P (85% H<sub>3</sub>PO<sub>4</sub>). Coupling constants |J| are given in hertz. Elemental analysis was performed at the University of Windsor Mass

Spectrometry Service Laboratory using a Perkin-Elmer 2400 combustion CHN analyzer.

#### 4.4.2 Synthetic Information

**[NBn-BZIMPYCl][OTf]<sub>2</sub> (1)** To 100 mL Schlenk flask charged with NBn-Bzimpy (305 mg, 0.62 mmol) in 40 mL CH<sub>3</sub>CN, PCl<sub>3</sub> (56 μL, 0.62 mmol) was added followed by TMSOTf (0.45 mL, 2.5 mmol). This resulted in an immediate formation of a yellow solution that was allowed to stir for 18 hours. Solvents were removed under reduced pressure and the resulting solid was suspended in Et<sub>2</sub>O (20 mL), collected and washed with Et<sub>2</sub>O (2×10 mL) yielding **1** as a yellow solid (420 mg, 79%). Slow evaporation from dichloromethane yielded crystals suitable for X-ray Diffraction. <sup>1</sup>H NMR (CD<sub>3</sub>CN) δ: 8.99 (t, 1H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.82 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.45 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.99 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.88 (m, 4H), 7.40 (m, 10H), 6.18 (s, 4H). <sup>13</sup>C{<sup>1</sup>H} NMR δ: 152.62 (d, J<sub>CP</sub> = 5 Hz) 141.63, 140.77 (d, J<sub>CP</sub> = 13 Hz) 138.62 (d, J<sub>CP</sub> = 8 Hz), 133.61, 132.63, 130.75, 130.41, 129.94 (d, J<sub>CP</sub> = 13 Hz), 127.83, 127.72, 127.26 (d, J<sub>CP</sub> = 7 Hz), 119.75 (q, <sup>1</sup>J<sub>CF</sub> = 315 Hz), 118.48, 115.08, 50.89. <sup>19</sup>F{<sup>1</sup>H} NMR δ: -78.56. Anal. Calc. for C<sub>35</sub>H<sub>25</sub>ClF<sub>6</sub>N<sub>5</sub>O<sub>6</sub>PS<sub>2</sub> (856.15g/mol): C, 49.10; H, 2.94; N, 8.18. Found: C, 48.91; H, 3.23; N, 8.05.

**[NBn-BZIMPYAsCl][OTf]<sub>2</sub> (2)** To a 20 mL vial was charged with NBn-Bzimpy (30 mg, 0.06 mmol) in 5 mL CD<sub>3</sub>CN, AsCl<sub>3</sub> (5.3 μL, 0.06 mmol) was added followed by TMSOTf (44 μL, 0.24 mmol). This resulted in an immediate formation of a yellow solution that was allowed to stir for 18 hours. The solution was then slowly evaporated to yield **2** as yellow crystals (36 mg, 65%). <sup>1</sup>H NMR (CD<sub>3</sub>CN) δ: 8.75 (t, 1H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.58 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 8.33 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.94 (d, 2H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.84 (m, 4H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 7.38 (m, 6H), 7.27 (d, 4H, <sup>3</sup>J<sub>HH</sub> = 8 Hz), 6.15 (s, 4H). <sup>13</sup>C{<sup>1</sup>H} NMR δ: 151.10, 143.75, 142.45, 138.57, 135.02, 133.81, 130.44, 130.16, 130.03, 129.80, 129.55, 127.60, 127.20, 119.98 (q, <sup>1</sup>J<sub>CF</sub> = 318 Hz), 118.70, 114.50, 50.66. <sup>19</sup>F{<sup>1</sup>H} NMR δ: -78.58. Anal. Calc. for C<sub>35</sub>H<sub>25</sub>ClF<sub>6</sub>N<sub>5</sub>O<sub>6</sub>AsS<sub>2</sub> (900.10g/mol): C, 46.70; H, 2.80; N, 7.78. Found: C, 47.26; H, 3.12; N, 7.76.

**[NBn-BZIMPYSbCl][OTf]<sub>2</sub> (3)** To a 20 mL vial was charged with NBn-Bzimpy (30 mg, 0.06 mmol) in 5 mL CD<sub>3</sub>CN, SbCl<sub>3</sub> (14 mg, 0.06 mmol) was added followed by TMSOTf (44 μL, 0.24 mmol). This resulted in an immediate formation of a yellow solution that was allowed to stir for 18 hours. The solution was then slowly evaporated to yield **3** as yellow crystals (48 mg, 83%).

$^1\text{H}$  NMR ( $\text{CD}_3\text{CN}$ )  $\delta$ : 8.59 (t, 1H,  $^3J_{\text{HH}} = 8$  Hz), 8.48 (d, 4H,  $^3J_{\text{HH}} = 8$  Hz), 7.88 (d, 2H,  $^3J_{\text{HH}} = 8$  Hz), 7.75 (p, 4H,  $^3J_{\text{HH}} = 8$  Hz), 7.38 (m, 6H), 7.23 (d, 4H,  $^3J_{\text{HH}} = 8$  Hz), 6.14 (s, 4H).  $^{13}\text{C}\{^1\text{H}\}$  NMR  $\delta$ : 148.63, 146.93, 142.55, 138.46, 136.56, 134.06, 130.44, 129.70, 129.52, 128.92, 127.85, 127.06, 119.58 (q,  $^1J_{\text{CF}} = 317$  Hz), 119.20, 114.04, 50.79.  $^{19}\text{F}\{^1\text{H}\}$  NMR  $\delta$ : -78.46. Anal. Calc. for  $\text{C}_{35}\text{H}_{25}\text{ClF}_6\text{N}_5\text{O}_6\text{SbS}_2$  (946.94 g/mol): C, 44.39; H, 2.66; N, 7.40. Found: C, 44.34; H, 2.97; N, 7.29.

#### **Gutmann-Beckett method:**

General Method; A 20mL vial was charged with **1**, **2** or **3** (0.02 mmol) and  $\text{OPEt}_3$  (0.02 mmol) in 1 mL  $\text{CH}_3\text{CN}$ . Reaction mixture was stirred for 30 minutes before collecting phosphorus NMR spectrum.  $^{31}\text{P}\{^1\text{H}\}$  NMR (**1** +  $\text{OPEt}_3$ ) ( $\text{CH}_3\text{CN}$ )  $\delta$ : 110.2 (P-Cl), 92.0 ( $\text{OPEt}_3$ ).  $^{31}\text{P}\{^1\text{H}\}$  NMR (**2** +  $\text{OPEt}_3$ ) ( $\text{CH}_3\text{CN}$ )  $\delta$ : 92.0.  $^{31}\text{P}\{^1\text{H}\}$  NMR (**3** +  $\text{OPEt}_3$ ) ( $\text{CH}_3\text{CN}$ )  $\delta$ : 91.9.

#### **4.4.3 X-ray Crystallography**

Crystals for investigation were covered in Paratone<sup>®</sup>, mounted onto a goniometer head, and then rapidly cooled under a stream of cold  $\text{N}_2$  of the low-temperature apparatus (Oxford Cryostream) attached to the diffractometer. The data were then collected using the APEXIII (Bruker AXS) software suite on a Bruker Photon 100 CMOS diffractometer using a graphite monochromator with  $\text{MoK}\alpha$  ( $\lambda = 0.71073$  Å). For each sample, data were collected at low temperature. APEXIII software was used for data reductions and SADABS (Bruker AXS) was used for absorption corrections (multi-scan; semi-empirical from equivalents). XPREP was used to determine the

*CHAPTER 4*

space group and the structures were solved and refined using the SHELX<sup>60</sup> software suite as implemented in the WinGX<sup>61</sup> or OLEX2<sup>62</sup> program suites. Validation of the structures was conducted using PLATON<sup>63</sup> and the structures have been deposited in the Cambridge Structural Database (CCDC 1900124-1900126).

# CHAPTER 5:

## Tris(benzoimidazol)amine (L) complexes of pnictogen(III) and pnictogen(V) cations and the $[LP]^{3+}/[LPF_2]^{3+}$ redox couple

### 5.1 Introduction

Phosphorus(III) centres can undergo reversible oxidative addition of N-H and O-H bonds and have potential application as catalysts in organic transformations. This traditional Lewis basic reactivity extends to pnictogen(III) centres in general, but has been challenged by the realization of the Lewis acid “umpolung” made possible by the introduction of a cationic charge.<sup>2</sup> A variety of pnictogen(III) based cations have been synthesized by halide abstraction from  $PnX_3$  derivatives in the presence of various ligands and weakly coordinating anions.<sup>3</sup> The cationic charge not only lowers the energy of the pnictogen based LUMO but also lowers the energy of the HOMO, so that oxidation is impeded. Consequently, examples of redox couples of the type  $[Pn(III)]^{3+} : [Pn(V)R_2]^{3+}$  have not been reported. The fluorophilicity of phosphonium cations<sup>4</sup> and dications<sup>5</sup> is well established and has led to the discovery of effective catalysts for hydrofluorination reactions.<sup>6</sup> The Lewis acidity of  $[LPR]^{2+}$  with L = terpyridine is an active catalyst for dehydrofluorination of fluoroalkanes, suggesting a substantial fluoride affinity.<sup>7</sup>

We have recently shown that the multidentate  $BIMe_3$  ligand encapsulates a germanium dication that is readily oxidized to  $[BIMe_3GeF_2][OTf]_2$ , and have now exploited the versatility of this ligand to synthesise  $[P(BIMe_3)][OTf]_3$ .<sup>8</sup> As an analogue of the Verkade superbases (I),<sup>9</sup> the trication adopts a proazaphosphatrane

type cage structure, and is oxidized by  $XeF_2$  to give  $[P(BIMEt_3)F_2][OTf]_3$ , which represents a rare example of a cationic Pn(V) centre with a charge  $> +2$ .<sup>10</sup> (e.g. for +2 charge  $[Ph_3PnL_x][OTf]_2$ , Pn = As<sup>11</sup>, Sb, Bi<sup>12</sup>; and +3 charge  $[Ph_2SbL_x][OTf]_3$ <sup>13</sup>). The synthesis and characterization of the heavier tricationic pnictogen salts  $[BIMEt_3Pn][OTf]_3$  (Pn = As, Sb) are also reported.

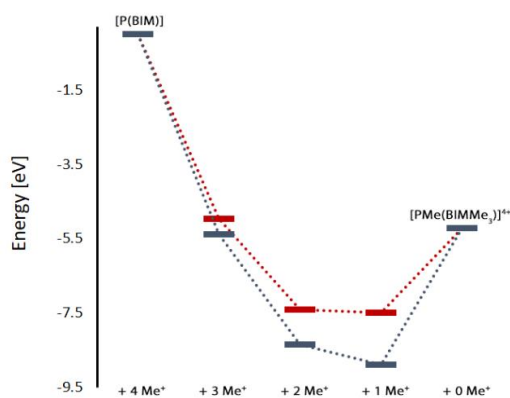

**Figure 5.1.** Highlight of the phosphorus containing compounds synthesized (left),  $BIMH_3$  ligand (right).

## 5.2 Results and Discussion

$P(BIM)$  was synthesized from the reaction of  $BIMH_3$ <sup>14</sup> (**Figure 5.1**) and  $PCl_3$  in the presence of a slight excess of NaH in THF at room temperature. Quantitative formation of  $P(BIM)$  was evidenced by a single peak in the  $^{31}P$  NMR spectrum ( $^{31}P$   $\delta$  = 44.7 ppm). Crystals of  $P(BIM)$  were obtained by slow evaporation of the solvent from a DCM/MeCN solution. In the solid state structure (**Figure 5.2a**), two enantiomers are present in the unit cell, with the benzoimidazole groups arranged

either in their S or R enantiomer. The geometry at N1 is essentially planar (319.48° and 317.75°, respectively) and features a pre-ordered N1 --- P bond with an average distance of 2.925 Å. The P - N3 bonds (1.721 Å) are significantly longer than those observed in **I** (e.g. 1.694 Å for N(CH<sub>2</sub>-CH<sub>2</sub>-NR)<sub>3</sub>P with R = CH(Me)Ph).<sup>15</sup> The nucleophilic behaviour of P(BIM) was explored by reactions involving a variety of stoichiometric ratios of methyl triflate. In each case the <sup>31</sup>P-NMR spectrum of the reaction mixture indicated the formation of several products which we speculate to result from simultaneous methylation of the nitrogen and phosphorus atoms. We have modelled the energetic profile of the reactions using DFT calculations at the PBEPBE/6-311+G(d,p) level of theory.<sup>16</sup> Structure optimizations for each complex imply that methylation is favoured at the imino nitrogen atoms (coloured blue). In the gas phase each methylation of an imino centre is exergonic. Similar results were obtained with MeCN as a solvent model but an energetic minimum was not evident for [PMe(BIMMe<sub>3</sub>)]<sup>4+</sup> (**Table 4.1** and SI), and consistently, complicated reaction mixtures are observed for MeOTf and P(BIM). Nevertheless, addition of excess MeOTf resulted in a colourless precipitate (insoluble in common organic solvents) which suggests for the potential formation of [PMe(BIMMe<sub>3</sub>)]<sup>4+</sup>.

N-methylation	eV	P-methylation	eV
P(BIM) + 4 Me <sup>+</sup>	0	P(BIM) + 4 Me <sup>+</sup>	0
[P(BIMMe)] <sup>+</sup> + 3 Me <sup>+</sup>	-5.38	[PMe(BIM)] <sup>+</sup> + 3 Me <sup>+</sup>	-4.96
[P(BIMMe <sub>2</sub> )] <sup>2+</sup> + 2 Me <sup>+</sup>	-8.34	[PMe(BIMMe)] <sup>2+</sup> + 2 Me <sup>+</sup>	-7.40
[P(BIMMe <sub>3</sub> )] <sup>3+</sup> + 1 Me <sup>+</sup>	-8.90	[PMe(BIMMe <sub>2</sub> )] <sup>3+</sup> + 1 Me <sup>+</sup>	-7.49
[PMe(BIMMe <sub>3</sub> )] <sup>4+</sup>	-5.21	[PMe(BIMMe <sub>3</sub> )] <sup>4+</sup>	-5.21

**Table 5.1.** Summary of Gibbs free energies for optimized gas phase structures for the stepwise methylation of [P(BIM)] at the PBEPBE/6-311+G(d,p) level of theory. N-methylation in blue and P-methylation in red.

Based on the modelled stability of [P(BIMMe<sub>3</sub>)]<sup>3+</sup>, we examined the reaction of BIMe<sub>3</sub><sup>17</sup> with “P(OTf)<sub>3</sub>” by mixing PCl<sub>3</sub> and AgOTf acetonitrile in the presence of BIMe<sub>3</sub>. A singlet at  $\delta = 56.1$  ppm in the <sup>31</sup>P NMR spectrum indicates the quantitative formation of [P(BIMe<sub>3</sub>)]<sup>3+</sup>[OTf]<sub>3</sub>, which has been separated from the AgCl by filtration, and crystallized by layering the reaction mixture with diethyl ether. As TMSOTf is a relatively weak halide abstracting agent, reactions of AsCl<sub>3</sub> with BIMe<sub>3</sub> and excess TMSOTf formed primarily [AsCl(BIMe<sub>3</sub>)]<sup>3+</sup>[OTf]<sub>2</sub>, which has been isolated in small quantities. The heavier analogue [SbF(BIMe<sub>3</sub>)]<sup>3+</sup>[OTf]<sub>2</sub> can be formed quantitatively by reaction with SbF<sub>3</sub> and two equivalents of TMSOTf. The dications in derivatives of

[MX(BIMe<sub>3</sub>)](OTf)<sub>2</sub> exhibit one set of signals for the benzoimidazole groups in the <sup>1</sup>H-NMR spectrum consistent with a labile ligand in solution, as observed for analogous germanium complexes.<sup>8</sup> Salts of the trications [As(BIMe<sub>3</sub>)](OTf)<sub>3</sub> and [Sb(BIMe<sub>3</sub>)](OTf)<sub>3</sub> were isolated in a similar fashion to the phosphorus analogue using three equivalents of AgOTf as the halide abstractor.

**Figure 5.2.** (a) Solid state structure of one of two independent molecules of P(BIM). (b) Solid state structure of the cation in [P(BIMe<sub>3</sub>)](OTf)<sub>3</sub>·(MeCN)<sub>2</sub>. (c) Solid state structure of the cation in [PF<sub>2</sub>(BIMe<sub>3</sub>)](OTf)<sub>3</sub>·MeCN. Thermal ellipsoids are shown at a 50% probability level. Hydrogen atoms, solvent molecules and triflate anions are omitted for clarity. Inter-atomic distances and angles are summarized in **Table 5.2**.

[P(BIMe<sub>3</sub>)](OTf)<sub>3</sub>·(MeCN)<sub>2</sub> crystallizes in the space group P-1 (See **Figure 5.2b**). The three triflate anions are remote from the phosphorus centre (3.58 - 3.92 Å). The unique apex nitrogen atom ( $\angle \Sigma_{N1} = 350.5$ ) is significantly bent out of plane

towards the phosphorus centre consistent with a cross ring bonding interaction. Nevertheless, N1---P(2.866(2) Å) is only slightly shorter than those in P(BIM) (2.912(2) and 2.938(2) Å). In the solid state, [As(BIMEt<sub>3</sub>)]+[OTf]<sub>3</sub><sup>-</sup> and [Sb(BIMEt<sub>3</sub>)]+[OTf]<sub>3</sub><sup>-</sup> (**Figure 5.3c,d**) exhibit a significantly different geometry around the pnictogen centre. The polygon described by the ligands is best described as a pentagonal bipyramid with three nitrogen atoms (N1, N2 and N3), one triflate oxygen atom and the lone pair in the plane. A second triflate oxygen atom and one nitrogen (N4) atom occupy the axial positions. This geometry enables significantly shorter Pn-N1 bond (As-N1 2.104(4) and Sb-N1 2.389(2) and 2.370(2) Å, respectively) compared to that in [P(BIMEt<sub>3</sub>)]+[OTf]<sub>3</sub><sup>-</sup> (P-N1 2.879 Å). Two of the three triflate anions have a weak interaction with the pnictogen centre (**Table 5.3**). The mono-halide derivatives [SbF(BIMEt<sub>3</sub>)]+[OTf]<sub>2</sub><sup>-</sup> and [AsCl(BIMEt<sub>3</sub>)]+[OTf]<sub>2</sub><sup>-</sup> crystallise as dimeric structures. The antimony fluoride is linked by two triflate anions and the arsenic chloride is linked by chlorine substituents (As-Cl 2.3342(7) and 3.913(2) Å). The antimony centre adopts a tetragonal pyramidal geometry with two oxygen atoms from the triflate anions (Sb---OTf 2.551(2) and 2.793(2) Å) and two nitrogen atoms (Sb-N 2.214(2) and 2.165(2) Å) with the antimony 0.486 Å above this plane.

*Tris(benzoimidazol)amine (L) complexes of pnictogen(III) and pnictogen(V) cations and the [LP]3+/[LPF2]3+ redox couple*

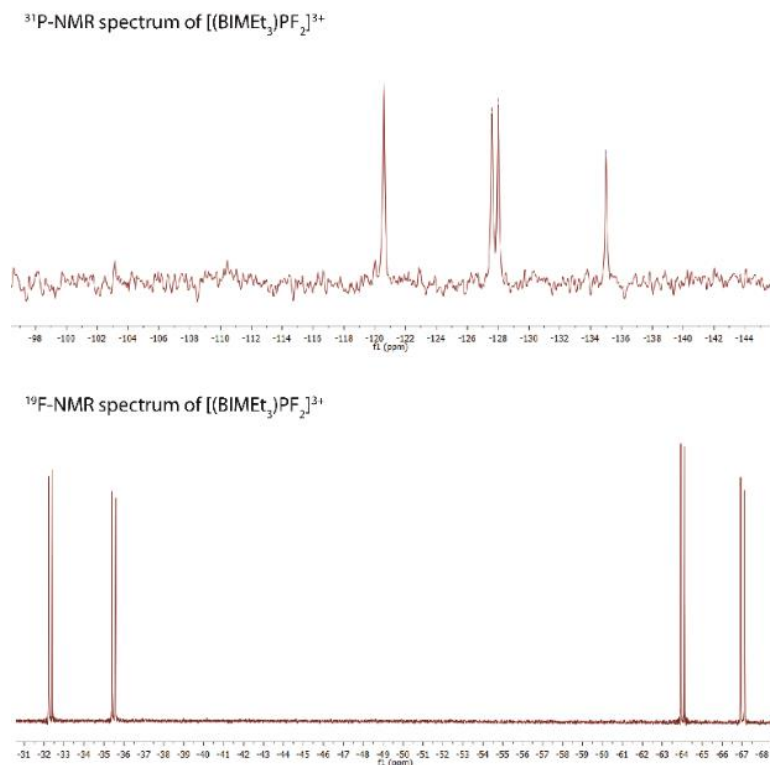

**Figure 5.3.** Solid state structure of (a)  $[\text{AsCl}(\text{BIMeEt}_3)]^{2+}$ , (b)  $[\text{SbF}(\text{BIMeEt}_3)]^{2+}$ , (c)  $[\text{As}(\text{BIMeEt}_3)]^{3+}$  and (d)  $[\text{Sb}(\text{BIMeEt}_3)]^{3+}$ . Thermal ellipsoids are shown at a 50% probability level. Oxygen atoms of the triflate anions that interact with the pnictogen centres are shown, but the other atoms of the anions are omitted for clarity as well as the hydrogen atoms and solvent molecules. Interatomic distances and angles are summarized in **Table 5.3**.

Equimolar mixtures of  $\text{PCl}_5$  and  $\text{BIMeEt}_3$  with three equivalents of  $\text{AgOTf}$  give a mixture of products as evidenced by the  $^{31}\text{P}$  NMR spectrum of the reaction mixture. Isolation of  $[\text{P}(\text{BIMeEt}_3)][\text{OTf}]_3$  from this mixture implicates formation of  $[\text{PCl}_2(\text{BIMeEt}_3)][\text{OTf}]_3$ , which is subsequently reduced. In this context, we have studied the oxidation of  $[\text{P}(\text{BIMeEt}_3)][\text{OTf}]_3$  with the expectation to form cationic compounds analogous to  $[\text{PPh}_3\text{I}][\text{I}_3]$ <sup>18</sup> or  $[\text{Ph}_3\text{P-I-I}]$ <sup>19</sup> However, reaction of addition of  $[\text{P}(\text{BIMeEt}_3)][\text{OTf}]_3$  with a large excess of  $\text{I}_2$  caused only a small chemical shift in the

$^{31}\text{P}$  NMR spectrum and a product could not be isolated. Nevertheless, Stephan's approach for oxidation of phosphonium cations<sup>4</sup> was applied using equimolar mixtures of  $[\text{P}(\text{BIMEt}_3)][\text{OTf}]_3$  and  $\text{XeF}_2$  in acetonitrile to yield a mixture of products with a prominent doublet of doublets resonance in the  $^{31}\text{P}$ -NMR spectrum ( $^{31}\text{P}$   $\delta = -127.8$  ppm;  $^1J_{\text{PF}} = 899.3$  and  $849.7$  Hz) and consistently, two doublet of doublet resonances in the  $^{19}\text{F}$  NMR spectrum ( $\delta = -65.5$  and  $-33.9$  ppm;  $^2J_{\text{FF}} = 52.0$  Hz). Attempts to scale up the reaction yielded several different fluorinated phosphorus species. Rapid crystallization from a saturated acetonitrile solution at  $-35$  °C layered with diethyl ether yielded small amounts of fragile crystals, that have been characterized as  $[\text{PF}_2(\text{BIMEt}_3)][\text{OTf}]_3$ . Consistent with the solution NMR spectra (**Figure 5.4**), the solid state structure reveals, inequivalent fluorine substituents at phosphorus (**Figure 5.2c**) and two different benzoimidazole environments.

CHAPTER 5  
*Tris(benzoimidazol)amine (L) complexes of pnicogen(III) and pnicogen(V) cations and the  
 [LP]3+/[LPF2]3+ redox couple*

**Figure 5.4.** NMR spectra for  $[PF_2(BIMEt_3)]^+[OTf]_3^-$  in  $CD_3CN$ .

The N1-P distance (1.893(13) Å) is significantly shorter than that in  $[P(BIMEt_3)][OTf]_3$ . The P-F1 bond *trans* to the tertiary amine is longer [1.577(9) Å] than P-F2 [1.604(9) Å]. Consequently, the pseudo  $C_{3V}$ -geometry of the cation in  $[P(BIMEt_3)][OTf]_3$  adjusts to  $C_s$  symmetry in the octahedral frame in  $[PF_2(BIMEt_3)][OTf]_3$ . Moreover, P-N1 in  $[PF_2(BIMEt_3)][OTf]_3$  is shorter than that in  $[P(BIMEt_3)][OTf]_3$  and the other P – N bonds are longer (**Table 5.2**). This substantive change in geometry is also evidenced by  $^{31}P$  NMR spectroscopy ( $[PF_2(BIMEt_3)]^{3+} \delta = -127.8$  ppm) with a chemical shift difference of 184 ppm upon oxidation. There are no close interactions of the phosphorus centre with any of the triflate anions, so that the cation in  $[PF_2(BIMEt_3)][OTf]_3$  represents the first fully characterized tricationic P(V) $^{3+}$  species.

**Table 5.3.** Selected bond distances in Å for [AsCl(BIMe<sub>3</sub>)]<sub>2</sub>[OTf]<sub>2</sub>, [SbF(BIMe<sub>3</sub>)]<sub>2</sub>[OTf]<sub>2</sub>, [As(BIMe<sub>3</sub>)]<sub>3</sub>[OTf]<sub>3</sub> and [Sb(BIMe<sub>3</sub>)]<sub>3</sub>[OTf]<sub>3</sub>.

## 5.3 Conclusions

We have presented a versatile and facile synthetic approach to a number of pnictogen(III) cations in the BIMEt<sub>3</sub> ligand scaffold. The phosphorus derivative [P(BIMEt<sub>3</sub>)](OTf)<sub>3</sub> can be readily oxidized to form the first tricationic phosphorus(V) complex, [LP<sup>V</sup>F<sub>2</sub>]<sup>3+</sup>. A fundamental study for general use of such pnictogen salts in Lewis acid catalysis, small molecule activation or as catalytic fluorination agents is ongoing.

## 5.4 Experimental

### 5.4.1 General Remarks

All air- and moisture-sensitive manipulations were carried out using standard vacuum line Schlenk techniques or in an MBraun Labmaster inert atmosphere dry-box containing an atmosphere of purified nitrogen. THF-*d*<sub>8</sub>, CD<sub>2</sub>Cl<sub>2</sub> and C<sub>6</sub>D<sub>6</sub> were purchased from Sigma Aldrich. CD<sub>2</sub>Cl<sub>2</sub> was dried over CaH<sub>2</sub> and distilled, THF-*d*<sub>8</sub> and C<sub>6</sub>D<sub>6</sub> were distilled over potassium. All glassware was stored in a 170 °C oven for several hours and was degassed prior to use. Solvents were distilled over the appropriate drying agent. Anhydrous grade MeCN was obtained from Sigma-Aldrich and used without distillation but stored over 3 Å molecular sieves. Solvents were additionally tested using a ketyl test to guarantee oxygen and moisture free

conditions. TMSOTf (99%) was distilled before use. BIMH<sub>3</sub><sup>20</sup> and BIMe<sub>3</sub><sup>21</sup> were synthesized following literature procedures.

NMR tubes fitted with J-Young valves were charged and sealed inside the glovebox. <sup>1</sup>H NMR spectra were recorded on Bruker spectrometers operating at 300, 360 MHz, <sup>13</sup>C NMR at 76 MHz. <sup>31</sup>P NMR at 121.6 MHz, <sup>19</sup>F NMR at 282.5 MHz. All <sup>1</sup>H and <sup>13</sup>C NMR chemical shifts are reported relative to SiMe<sub>4</sub> using the <sup>1</sup>H (residual) and <sup>13</sup>C chemical shifts of the solvent as a secondary standard.

Infrared spectra were obtained on a Perkin Elmer Frontier instrument. Elemental analysis was performed at the University of Windsor Mass Spectrometry Service Laboratory using a Perkin Elmer 2400 combustion CHN analyser. All quantum chemical calculations were carried out using Gaussian 16.<sup>22</sup>

### 5.4.2 Synthesis

**P(BIM):** A 100 mL Schlenk flask was charged with BIMH<sub>3</sub> (500 mg, 1.23 mmol) and NaH (90 mg, 3.74 mmol) in 30 mL THF at room temperature. After bubbling stops, the reaction was left to stir for 30 mins followed by the addition of PCl<sub>3</sub> (0.117 mL, 1.28 mmol) yielding in white precipitate. The reaction mixture was allowed to stir for 24 hours before solvent was removed under reduced pressure. DCM (30 mL) was

added and the resulting suspension was filtered through Celite® and washed with DCM (2 x 10 mL). Solvent from the filtrate was removed under reduced pressure to result in P(BIM) as a colourless solid, 0.367 g (69 %). Slow evaporation from THF or acetonitrile yields colourless crystals suitable for X-ray diffraction  $C_{24}H_{18}N_7P \cdot THF$ , MW = 507.53 g/mol, MP = 185 (dec.), EA [calc.]: C, 66.26; H, 5.16; N, 19.32 EA [found.]: C, 66.23; H, 5.04; N, 18.87.  $^1H$  NMR (300 MHz,  $CDCl_3$ )  $\delta$  = 8.00 (d, 3H,  $^3J_{HH}$  = 6.6 Hz), 7.70 (d, 3H,  $^3J_{HH}$  = 7.8 Hz), 7.37 (m, 6H), 4.59 (s, 6H).  $^{13}C\{^1H\}$  NMR (75.5 MHz,  $CDCl_3$ )  $\delta$  = 154.42 (d,  $J_{CP}$  = 8.7 Hz), 144.23 (d,  $J_{CP}$  = 7.2 Hz), 137.59 (d,  $J_{CP}$  = 36.9 Hz), 128.7 (d,  $J_{CP}$  = 61.2 Hz), 124.36 (d,  $J_{CP}$  = 9.2 Hz), 120.31 (s), 111.41 (d,  $J_{CP}$  = 24.5 Hz), 51.16 (s).  $^{31}P\{^1H\}$  NMR (121.5 MHz,  $CDCl_3$ )  $\delta$  = 44.74 (s).

**[P(BIMeEt<sub>3</sub>)]<sup>3+</sup>[OTf]<sub>3</sub>**: To a rapidly stirred suspension of  $PCl_3$  (0.2 mmol, 18  $\mu$ L) and  $BIMeEt_3$  (0.2 mmol, 100 mg) in 3 mL of MeCN,  $TMSOTf$  (0.50 mmol, 100  $\mu$ L) was added to yield a blue solution. The solution was left to stir for 10 mins.  $AgOTf$  (0.6 mmol, 154 mg) was added, producing a cloudy blue mixture due to precipitation of  $AgCl$ . The mixture was then filtered and the clear solution was layered with 6 mL of diethyl ether and placed in the freezer at  $-35$  °C. Colourless blocks were isolated from after 72 hours. Yield: 204 mg (94 %) of the composition  $C_{33}H_{33}F_9N_7O_9PS_3 (MeCN)_3$  MW = 1093.0 g/mol, MP = 184 °C (brown) – 241 °C (black) (dec.) EA [calc.]  $C_{33}H_{33}F_9N_7O_9PS_3$ :

Traces of moisture leads to decomposition of the product and the formation of [HBIMe<sub>3</sub>][PF<sub>6</sub>] indicated by the formation of a *septed*-resonance in the <sup>31</sup>P-NMR spectrum for the PF<sub>6</sub>-anion (-144.6 ppm, <sup>1</sup>J<sub>P,F</sub> = 706.3 Hz). Scaling up the reaction only yielded several side products. Decomposition of the product in solution was observed if left in MeCN overnight, crystallization has to be initiated right after addition of XeF<sub>2</sub> to isolate crystalline material of the [PF<sub>2</sub>(BIMe<sub>3</sub>)]<sub>3</sub>[OTf]<sub>3</sub>.

### 5.4.3 X-ray Crystallography

Crystals for investigation were covered in Paratone<sup>®</sup>, mounted onto a goniometer head, and then rapidly cooled under a stream of cold N<sub>2</sub> of the low-temperature apparatus (Oxford Cryostream) attached to the diffractometer. The data were then collected using the APEXII (Bruker AXS) software suite on a Bruker Photon 100 CMOS diffractometer using a graphite monochromator with MoK<sub>α</sub> (λ = 0.71073 Å). For each sample, data were collected at low temperature. APEXII software was used for data reductions and SADABS (Bruker AXS) was used for absorption corrections (multi-scan; semi-empirical from equivalents). XPREP was used to determine the space group and the structures were solved and refined using the SHELX<sup>23</sup> software suite as implemented in the WinGX<sup>24</sup> or OLEX2<sup>25</sup> program suites. Validation of the structures was conducted using PLATON and the structures have been deposited in the Cambridge Structural Database (CCDC 1578584-1578587).<sup>26</sup>

# CHAPTER 6: Towards the Synthesis of an Anionic Carbon(0)

## 6.1 Introduction

Carbon contains four valence electrons and is most stable in the +4 oxidation state. Carbon in the +2 oxidation state (carbenes) has played an important role in transient intermediates of organic and organometallic chemistry since the 1950s. The first stable carbene (**Scheme 6.1**) was in the form of a stable *N*-heterocyclic carbene (NHC) reported in 1991 by Arduengo and co-workers.<sup>1</sup> Carbenes can exist in the singlet state with two non-bonding electrons having an opposite spin or in the triplet state where the two non-bonding electrons have the same spin. Knowing the multiplicity of the ground-state is important in determining the reactivity of the carbene.<sup>2</sup>

**Scheme 6.1.** Synthesis of the first stable *N*-heterocyclic carbene.

After their discovery, carbenes and alkylidenes (a carbon(II) without a heteroatom substituent on the alpha carbon) have played a significant role in metal catalysts. Among these notable examples is the second-generation Grubbs' catalyst (**Figure 6.1**) that is used for olefin metathesis.<sup>3</sup> Robert H. Grubbs was a co-recipient of the 2005 Nobel Prize in Chemistry for his work on olefin metathesis. *N*-heterocyclic

carbenes were necessary for recent developments in the field of main group chemistry; some notable examples include some of the first examples of low valent group 13-15 complexes (**Figure 6.1**).<sup>3-6</sup>

**Figure 6.1.** Grubbs' second-generation catalyst (top), and some notable examples of the use of *N*-heterocyclic carbenes in the stabilization of low-valent group 13-15 elements.

Carbon in the zero-oxidation state contains four non-bonding electrons (i.e. all of the carbon's four valence electrons). **Figure 6.2** illustrates the difference in electron configuration between a C(IV), C(II) and C(0); this method of oxidation state assignment has been introduced in section 1.2 of Chapter 1.

**Figure 6.2.** Depiction of carbon centres in the +4 (left), +2 (centre) and 0 (right) oxidation states.

A crucial difference between a carbon(+2) and a carbon(0) is in the degenerate p-type orbitals,  $p_x$  and  $p_y$ . In carbenes, one of the two p-orbitals contains a pair of

electrons (singlet carbenes) making it a  $\sigma$ -donor, while the orthogonal p-orbital is empty and serves as a  $\pi$ -acceptor. A carbon(0) on the other hand, contains a lone pair of electrons in each of the two p-orbitals, resulting in both p-orbitals as electron donors.

**Figure 6.3.** Frontier orbital difference between a carbon(+2) (left) and a carbon(0) (right). The carbon(+2) shown is assuming a singlet state.

Having two lone pairs would allow for one lone pair to be a  $\sigma$ -type donor while the other can either be  $\sigma$ - or  $\pi$ -donating, depending on the type of complex formed. **Figure 6.4** demonstrates the two different binding modes of a carbon(0) centre with  $\sigma$ - and  $\pi$ -donors and with two  $\sigma$ - donors.

Alcarazo and co-workers<sup>7</sup> reported that the use of a carbodiphosphorane as a donor ligand revealed the capability of simultaneous  $\sigma$ - and a  $\pi$ -donation. This was evident by the stabilization observed in the reactive dihydrido borenium cation shown in **Figure 6.4** (left). With the B–C bond distance (1.5030 Å) being closer to a B=C double bond (1.35–1.45 Å) than a B–C single bond (1.58–1.62 Å), it can be deduced that this is a clear indication of the  $\pi$ -type contribution from the second lone pair of electrons into the B–C bond bringing stabilization to the reactive borenium centre.<sup>7</sup> Additionally, Alcarazo reported the chiral heterobimetallic complex shown in

**Figure 6.4** (right) that demonstrates the capability of a carbon(0) centre to serve as a two  $\sigma$ -donor site.<sup>8</sup>

**Figure 6.4.** An example of carbon(0) with a  $\sigma$  and a  $\pi$ -donor (left), with two  $\sigma$ -donor orbitals (right).

The first carbon(0) was reported in 1961, which was a carbodiphosphorane (CDP) of the form,  $\text{Ph}_3\text{P} \rightarrow \text{C} \leftarrow \text{PPh}_3$ .<sup>9</sup> It was not until recently that further studies of these compounds gained interest as ligands for transition metals and main group elements.<sup>10–17</sup> **Figure 6.5** highlights a few examples of these carbodiphosphorane coordination complexes.

**Figure 6.5.** Selected examples of carbodiphosphorane complexes of transition metals and main group elements.

Carbodiphosphanes are supported by two phosphine donors coordinating to the carbon(0) centre. Another form of carbon(0) ligands is those stabilized by carbene donors resulting in a carbodicarbene compound. Carbodicarbenes (CDC) were theoretically studied by Frenking in 2006<sup>18,19</sup> and synthesized a year later by Bertrand and co-workers as shown in **Scheme 6.2**.<sup>20</sup>

**Scheme 6.2.** Bertrand's synthesis of the first carbodicarbene.

Despite the fact that the first stable carbon(0) was reported three decades before Arduengo's work on stable carbenes, carbenes gained larger popularity and have been investigated to a much greater extent than carbon(0) ligands.<sup>18</sup> Carbodicarbenes, in particular, were predicted to be better donors than either carbenes or phosphines solely based on  $\nu_{CO}$  stretching frequencies of *cis*-[RhCl(CO)<sub>2</sub>(L)] as reported by Bertrand (**Table 6.1**).<sup>20</sup>

L	PR <sub>3</sub>	NHC	CDC
$\nu_{CO}$ (cm <sup>-1</sup> )	2070–2090	2036–2058	2014

**Table 6.1.**  $\nu_{CO}$  stretching frequencies *cis*-[RhCl(CO)<sub>2</sub>(L)] complexes where L = PR<sub>3</sub>, NHC and CDC.

In hopes of creating better carbon(0) donors, we propose that an anionic carbon(0) ligand would be a better  $\sigma$ - and  $\pi$ - donor than its neutral counterpart making it more attractive as a ligand for coordination chemistry. This would be feasible by having an anionic bisphosphine ligand bind a carbon(0) centre giving it an overall negative charge. To this end, Jonas Peters ligand (**Scheme 6.4**, JCP-Li, JCP<sup>-</sup>) was predicted to be a good candidate to investigate the isolation of an anionic carbon(0) ligand.<sup>21</sup> JCP<sup>-</sup> ligands have been previously employed in the isolation of heavier group 14 elements as illustrated in **Scheme 6.3**.<sup>6</sup> JCP<sup>-</sup> ligand has also been used as a new class of ligand for metal catalysts due to its strong  $\sigma$ - donation ability demonstrated by carbonyl frequency studies compared to other phosphines.<sup>22</sup> In addition, metal complexes of JCP<sup>-</sup> ligand have proven to be useful in copolymerization reactions of CO and ethylene (in the case of JCP-Pd)<sup>23</sup> and the activation of C-H bonds of benzene (using JCP-Pt).<sup>22</sup>

**Scheme 6.3.** JCP-Tl ligand reactivity with heavier group 14 elements (Ge and Sn).

## 6.2 Results and Discussion

### 6.2.1 Attempted Synthesis of an Anionic Carbodiphosphorane

The overall synthetic steps to obtain JCP-Li are shown in **Scheme 6.4**. Phosphine reagent, **I**, is prepared by the deprotonation of methyl-diphenylphosphine using  $n\text{BuLi}$  and TMEDA (tetramethylethylenediamine).<sup>24</sup> **II** is prepared by heating the neat reaction mixture of tribromoborane with two equivalents of trimethyl(phenyl)silane to yield diphenylbromoborane (**II**).<sup>25</sup> The desired bis(phosphino)borate is prepared by mixing two equivalents of **I** with an equivalent of **II** in diethylether at  $-78\text{ }^\circ\text{C}$ , yielding JCP-Li.<sup>22</sup>

*Scheme 6.4. Synthesis of Peters' ligand, JCP-Li.*

We postulate that the treatment of JCP-Li in neat  $\text{CH}_2\text{Br}_2$  should liberate  $\text{LiBr}$  salt and yield the fragment  $[\text{JCPCH}_2][\text{Br}]$  (**IV**) as shown in **Scheme 6.5**. **IV** would then be treated with two equivalents of a base to doubly deprotonate the methylene bridge resulting in an overall anionic carbodiphosphorane,  $[\text{K}][\text{JCP}(\text{C})]$  (**V**) as shown in the scheme below.

**Scheme 6.5.** Proposed synthesis of an anionic carbodicarbene using JCP-Li as the starting ligand.

Experimentally, treatment of JCP-Li with  $\text{CH}_2\text{Br}_2$  results in a mixture of products in the  $^{31}\text{P}\{^1\text{H}\}$  NMR and characterization of the resulting products was not successful. It is likely that the presence of  $\text{Li}^+$  or TMEDA results in side reactions with the anticipated product and/or resulting intermediates. As a result, finding another cation was desirable and can be achieved by salt metathesis reactions. One option is to prepare the thallium(I) salt of JCP that was used by Ragoana and co-workers for their heavier group 14 complexes introduced earlier (**Scheme 6.3**).<sup>6</sup> While this cation might be a good candidate considering its success with heavier group 14 analogues, due to the toxicity of thallium, we were inclined to find another counterion to experiment with. Among the other variants reported by Peters, one particular example is JCP-ASN<sup>22</sup> (ASN = 5-Azoniaspiro[4.4]nonane), which can be easily prepared by the salt metathesis reaction of JCP-Li with ASNBr in methanol to yield JCP-ASN in high yields (>90%).

Upon preparing the ASN salt of JCP, treatment of JCP-ASN with dibromomethane results in clean reactivity with a single product peak observed in the  $^{31}\text{P}\{^1\text{H}\}$  NMR (+25 ppm). The resulting peak decomposes over time, however, and thus, subsequent deprotonation of **IV** was performed *in situ*. Addition of excess (2.5

equivalents) NaNH<sub>2</sub> to a THF solution of **IV** results in immediate bubbling of ammonia. Filtration through Celite and removal of solvent from the filtrate under reduced pressure results in an off-white solid. Dissolving the resulting crude materials in THF and allowing for slow evaporation results in colourless crystals suitable for X-ray diffraction. The resulting structure was that of the singly deprotonated neutral product, JCP-CH (**1**, **Scheme 6.6**).

**Scheme 6.6.** Synthetic route to isolate neutral compound **1**. Base = NaNH<sub>2</sub>

Compound **1** (**Figure 6.6**) is overall neutral with the geometry at the carbon being sp<sup>2</sup> hybridized. The <sup>31</sup>P{<sup>1</sup>H} NMR shows a single peak at +20 ppm. **Scheme 6.6** illustrates the overall scheme of the reaction and the base used in the deprotonation to **1** is sodium amide (NaNH<sub>2</sub>). Irrespective of the stoichiometry used (1-5 equivalents of base), the only product observed and isolated in all cases is **1**. Other bases have been employed in an attempt to deprotonate the remaining proton to yield an anionic carbodiphosphorane but were not successful. Bases like NaNH<sub>2</sub>, <sup>n</sup>BuLi, <sup>t</sup>BuLi, KHMDS, NaH and LiAlH<sub>4</sub> have all resulted in no reactivity towards **1**. Transition metal complexes like Zr(Bn)<sub>4</sub>, Ag(OAc), Pd(OAc)<sub>2</sub> and Cu(OAc) are known to abstract protons (internal bases) by activating C-H bonds and yielding organometallic complexes.<sup>26</sup> Attempts to generate the anionic carbodiphosphorane and coordinating

it to a transition metal in-situ did not work in all of these cases; no reactivity was observed.

**Figure 6.6.** Solid state structure of **1** (left). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms and solvent molecules are omitted for clarity. Selected bond distances and angles are given in **Table 6.2**. <sup>31</sup>P{<sup>1</sup>H} NMR of **1** (right).

Deprotonation of **1** has proven to be a challenge and thus, an alternative method to arrive at the anionic carbodiphosphorane was desired. A C–Br fragment in-place of C–H would, in theory, be easier to break as a C–Br bond (~285 kJ/mol) is significantly weaker than a C–H bond (~411 kJ/mol)<sup>27</sup> making it a good candidate to undergo reduction of the C(II) centre using mild reducing conditions.

Treating JCP-ASN with CBr<sub>4</sub>, it was anticipated that ASNBr would be eliminated resulting in the product [JCP-CBr<sub>2</sub>][Br]; this was not observed, and the <sup>31</sup>P{<sup>1</sup>H} NMR spectrum showed a mixture of at least 10 different phosphorus containing fragments. This is likely due to the generation of free bromine molecules in solution reacting with the product and intermediates leading to the different side products. To avoid this, excess of zinc powder was added to the reaction mixture prior to the addition of CBr<sub>4</sub> to abstract free bromine molecules as they are generated

during the course of the reaction. The reaction mixture was stirred for 2 days in THF, followed by filtration through Celite. The filtrate was dried under reduced pressure to yield **2** as a colourless solid (**Scheme 6.7**).

**Scheme 6.7.** Synthetic route to isolate JCP-CBr (**2**) with and without the presence of Zn<sup>0</sup> powder.

Dissolving **2** in THF and allowing it to slowly evaporate yields crystals suitable for X-ray diffraction (**Figure 6.7**). Next, we were interested in reducing **2** to the anionic carbodiphosphorane using various reducing agents like Mg<sup>0</sup>, Zn<sup>0</sup>, Ni(COD)<sub>2</sub> and <sup>n</sup>BuLi. All of these reagents did not yield any reactivity towards **2**, and the use of stronger reducing agents like K<sub>2</sub>C<sub>8</sub>, Na<sup>0</sup> and K<sup>0</sup> result in decomposition of **2**, determined by observing multiple peaks in the <sup>31</sup>P NMR spectrum.

**Figure 6.7.** Solid state structure of **2**. Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms and solvent molecules are omitted for clarity. Selected bond distances and angles are given in **Table 6.2**.

Both **1** and **2** are similar crystallographically in-terms of the internal bond distances within the phosphine ligand. Both structures assume a half-chair conformation with the bridging carbon (C1) in plane with the ligand and the boron sitting out of plane. This is due to having the carbon's lone pair delocalized in the P-C bonds and not localized on the carbon centre (C1). The sum of angles around C1 in **2** add-up to  $\sum_{C1}: 358.35^\circ$ ; which is very close to  $360^\circ$  (for a planar system). This is very different compared to Ragoana's germanium and tin complexes of JCP where the sum of angles around the germanium and tin are  $\sum_{Ge}: 280.15^\circ$  and  $\sum_{Sn}: 272.94^\circ$  respectively. This is a result of the lone pair being delocalized on germanium and tin centres resulting in the chloride pointing out of plane as shown in **Figure 6.8**. This is further illustrated by examining the P-C1 bond distances in **1** and **2** ( $\sim 1.71 \text{ \AA}$ ) being significantly shorter than that expected for a P-C single bond ( $\sim 1.80\text{--}1.85 \text{ \AA}$ ) and more consistent with a P-C double bond ( $\sim 1.6\text{--}1.7 \text{ \AA}$ ) supporting the idea of a delocalized lone pair making an ylide in **1** and **2**.<sup>28</sup>

## 6.2.2 Attempted Synthesis of an Anionic Carbodicarbene

The resulting decomposition from the reduction attempts raised the question of whether or not JCP ligand is a suitable candidate for the isolation of an anionic carbodiphosphorane. Our group previously reported the triphosphenium salt depicted in **Scheme 6.8**, which contains a phosphorus(I) centre stabilized by a dppe (1,2-Bis(diphenylphosphino)ethane) donor ligand.<sup>29</sup> Having phosphine donors to stabilize the P(I) centre did not provide enough support and stabilization for the P(I) centre to undergo further reactivity without decomposition. Work performed during my master's research (**Scheme 6.8**) consisted of introducing a carbene donor to displace the weaker dppe ligand, resulting in a P(I) centre that is stabilized by two carbenes. This change gave rise to a more stable P(I) centre that can undergo further chemistry without decomposition.<sup>30-33</sup>

**Scheme 6.8.** Reaction scheme showing the synthesis of triphosphenium P(I) cation and the subsequent ligand exchange reaction with N-heterocyclic carbenes.

Carbodicarbenes have been first reported by Bertrand and co-workers as mentioned previously, following the synthetic route shown in **Scheme 6.2**.<sup>20</sup> Carbene donors are stronger and more stabilizing than phosphines, therefore, we became interested in synthesizing an anionic carbodicarbene (as an alternative to an anionic carbodiphosphorane) in hopes of obtaining a stable anionic carbon(0) centre. Using

the same starting ligand as Bertrand's, (**VI**, **Scheme 6.9**), we attempted to add a negative overall charge by adding a dialkylbromoborane to **VI** in THF, which resulted in the formation of white precipitate that is insoluble in solvents like DCM, THF and CH<sub>3</sub>CN. The precipitate was collected by filtration and washed with ether to yield **3** and **4** ( $[(\text{NMeBz})_2\text{CH}_2\text{BR}_2][\text{Br}]$ ) in great yields (82% and 85% respectively).

**Scheme 6.9.** Synthesis of compounds **3**, **4**, **6**, and **7**. G = NR, S or O, for VI, G = NMe.

Compounds **3** and **4** were treated with 2.5 equivalents of KHMDS (potassium hexamethyldisilazide) in THF and were allowed to stir for 16 hours yielding pale-yellow solutions and yellow precipitate (**Scheme 6.9**). The resulting compounds have poor solubility, but slow evaporation of the dilute yellow solutions resulted in yellow crystals suitable for X-ray diffraction. Structures of **6** and **7** were obtained (**Figure 6.9**); both structures show planar geometry throughout the compound with the boryl-R groups pointing above and below the plane of the compound. Unlike the half chair confirmation adapted by compounds **1** and **2**, compounds **6** and **7** have a planar core with C1-N1-N2-C2 dihedral angles of 1.01° in **6** and 0.00° in **7**.

**Figure 6.9.** Solid state structure of **6** (left) and **7** (right). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms and solvent molecules are omitted for clarity. Selected bond distances and angles are given in **Table 6.3**.

**Table 6.3.** Selected bond distances (Å) and angles (°) of compounds VI and **6-8**.

Other variants of the Ligand have been investigated ( $[(\text{GBz})_2\text{CH}_2\text{BR}_2][\text{Br}]$ ) where G = NR, S and O (**Scheme 6.9**). In cases where G = NR, compounds **3** and **4** were isolated, but as mentioned above, poor solubility did not allow for characterization by NMR spectroscopy or X-ray crystallography. Ligands with G = O or S were insoluble in common organic solvents; however, counter-ion exchange using TMSOTf resulted in increased solubility of the ligand with G = S to yield  $[(\text{SBz})_2\text{CH}_2\text{BR}_2][\text{OTf}]$  (**5**) as shown in **Scheme 6.10**.

After isolating the neutral compounds **6** and **7**, attempts to further deprotonate the compounds were not successful. A similar library of bases as used with **1** and **2** was employed but no reactivity was observed. Despite the failed attempt to obtain an anionic carbodicarbene, compounds **6** and **7** have dye like properties (**Figure 6.10**, right) with a core similar to that of boron-dipyrromethene (BODIPY, **Figure 6.10**, left) that are useful fluorescent dyes.<sup>34</sup>

**Figure 6.10.** Core structure of BODIPY (left) and a suspension of compound **6** in dark (middle) and under UV-light (right).

**Scheme 6.10.** Reaction scheme showing synthesis of **8**.

Although carbodicarbenes have been predicted to be better donors solely based on  $\nu_{\text{CO}}$  stretching frequencies of  $\text{cis-}[\text{RhCl}(\text{CO})_2(\text{L})]$  as mentioned earlier;<sup>20</sup> recent work by Grubbs and co-workers show that carbodicarbenes are weaker donors than carbenes.<sup>35</sup> **Figure 6.11** displays a series of ruthenium-based olefin metathesis catalysts where the catalyst on the left is Grubbs second generation that generally has higher activity and stability than Grubbs first generation catalyst. The middle catalyst contains a bis(NHC) ruthenium catalyst that is slow to initiate due to the strong NHC donors making it harder for ligand dissociation to take place and result in an active catalyst. The bis(NHC) ruthenium catalyst only showed modest reactivity at elevated temperatures.<sup>35</sup> Lastly, a mixed system of NHC–CDC ruthenium catalyst was prepared by Grubbs and it was anticipated to be an even slower reaction due to the strong donor ability of CDC. To their surprise and mine, the CDC ligand was the labile ligand, readily dissociating to yield an active catalyst at room temperature. This illustrates that the donor ability of a ligand is not the only factor in play and that

$\nu_{\text{CO}}$  stretching frequencies can be used to predict donor strengths of similar systems, but cannot be reliable to compare different systems.

*Figure 6.11. A series of ruthenium-based catalysts reported by Grubbs.*

## 6.3 Conclusions

We successfully synthesized compounds **1** and **2** that represent the first examples of six-membered ring systems with this specific arrangement of atoms. Although further deprotonation was not successful, these compounds show the different behaviour adopted by the carbon in comparison to heavier group-14 analogues of the same ligand. Compounds **6** and **7** have interesting features and the central arrangement resembles that of BODIPY making it a potential fluorescent dye.

## 6.4 Experimental

### 6.4.1 General Remarks

All manipulations were carried out using standard inert-atmosphere techniques. All reagents and chemicals were obtained from Sigma-Aldrich. All reagents were used without further purification. MeCN-*d*<sub>3</sub> was dried over calcium

hydride or phosphorus pentoxide, and dichloromethane- $d_2$  was dried over phosphorus pentoxide. All other solvents were dried on a series of Grubbs-type columns and were degassed prior to use.<sup>36</sup> All glassware was stored in a 170 °C oven for several hours and was degassed prior to use. **I**<sup>24</sup>, **II**<sup>25</sup>, JCP-Li<sup>22</sup>, JCP-ASN<sup>22</sup>, **VI**<sup>37</sup>, and [(SBz)<sub>2</sub>CH<sub>2</sub>BR<sub>2</sub>] (**VII**)<sup>38</sup> were all prepared according to the literature procedures.

NMR spectra were recorded at room temperature on Bruker Avance III 500 MHz, Bruker Avance Ultrashield 300 MHz, and Bruker Avance DPX 300 MHz spectrometers. Chemical shifts are reported in parts per million relative to internal standards for <sup>1</sup>H and <sup>13</sup>C (the given deuterated solvent) and external standards for external standards (85% H<sub>3</sub>PO<sub>4</sub> for <sup>31</sup>P). Coupling constants |J| are given in hertz. Elemental analysis was performed at the University of Windsor Mass Spectrometry Service Laboratory using a Perkin-Elmer 2400 combustion CHN analyzer.

### 6.4.2 Synthesis

**[Ph<sub>2</sub>B(CH<sub>2</sub>PPh<sub>2</sub>)<sub>2</sub>CH] (1)** A 100 mL Schlenk flask was charged with JCP-ASN (600 mg, 0.87 mmol) in 3 mL CH<sub>2</sub>Br<sub>2</sub>. After 5 minutes of stirring, all the precipitate disappeared and solvents were removed under reduced pressure. THF (40 mL) was added followed by NaNH<sub>2</sub> (170 mg, 4.34 mmol) resulting in bubbling of NH<sub>3</sub>. The mixture was refluxed for 4 hours, cooled down to room temperature and filtered through Celite. Solvents were removed from the filtrate under reduced pressure to yield **1** as

an off-white precipitate (280 mg, 56%).  $^1\text{H}$  NMR ( $d_8$ -THF)  $\delta$ : 7.67 (t, 8H,  $^3J_{\text{HH}} = 9$  Hz), 7.34 (m, 12H), 6.86 (b, 4H), 6.62 (m, 6H), 1.94 (d, 4H,  $^2J_{\text{PH}} = 16$  Hz), 1.24 (t, 1H,  $^2J_{\text{PH}} = 4$  Hz).  $^{13}\text{C}\{^1\text{H}\}$  NMR  $\delta$ : 136.93 (vt,  $J_{\text{PC}} = 84$  Hz), 133.45, 131.92 (vt,  $J_{\text{PC}} = 10$  Hz), 131.08, 128.95 (vt,  $J_{\text{PC}} = 11$  Hz), 126.52, 123.33, 16.93 (b), 1.63 (m).  $^{31}\text{P}\{^1\text{H}\}$  NMR  $\delta$ : 20.24 (s).  $^{11}\text{B}\{^1\text{H}\}$  NMR  $\delta$ : -13.41 (s). Anal. Calc. for  $\text{C}_{39}\text{H}_{35}\text{BP}_2$  (576.47 g/mol): C, 81.26; H, 6.12; N, 0.00. Found: C, 80.76; H, 5.85; N, 0.04.

**[Ph<sub>2</sub>B(CH<sub>2</sub>PPh<sub>2</sub>)<sub>2</sub>CBr] (2)** A 100 mL Schlenk flask was charged with JCP-ASN (2.0 g, 2.90 mmol), CBr<sub>4</sub> (962 mg, 2.90 mmol) and zinc powder (240 mg, 3.7 mmol) in THF. The reaction mixture was refluxed for 2 days before cooling down to room temperature and filtering through Celite. Solvents were removed from the filtrate under reduced pressure resulting in **2** as an off-white solid. (800 mg, 44%).  $^{31}\text{P}\{^1\text{H}\}$  NMR  $\delta$ : 22.58 (s). Anal. Calc. for  $\text{C}_{39}\text{H}_{34}\text{BBrP}_2$  (655.36 g/mol): C, 71.48; H, 5.23; N, 0.00. Found: C, 71.56; H, 5.01; N, 0.10.

General synthesis of **[(NMeBz)<sub>2</sub>CH<sub>2</sub>BPh<sub>2</sub>][Br] (3)**, **[(NMeBz)<sub>2</sub>CH<sub>2</sub>BMe<sub>2</sub>][Br] (4)** and **[(SBz)<sub>2</sub>CH<sub>2</sub>BMe<sub>2</sub>][Br] (5)** To a 100 mL Schlenk flask charged with **VI** (450 mg, 1.63 mmol) in 40 mL Et<sub>2</sub>O, (400 mg, 1.63 mmol) of BPh<sub>2</sub>Br was added resulting in a

white suspension. After allowing the reaction mixture to stir for 18 hours, the corresponding product was collected by filtration to yield **3** (712 mg, 85%) as a colourless solid. Similar procedure was carried out using (230 mg, 0.83 mmol) of **VI** and (0.081 mL, 0.83 mmol)  $\text{BMe}_2\text{Br}$  to yield **4** (270 mg, 82%) as a colourless solid; **VII** (247 mg, 0.87 mmol) and  $\text{BMe}_2\text{Br}$  (0.085 mL, 0.87 mmol) to yield **5** (338 mg, 99%) as a yellow solid. Poor solubility of these compounds did not allow for characterization via NMR or the formation of crystals suitable for X-ray diffraction.

General synthesis of  $[(\text{NMeBz})_2\text{CHBPh}_2]$  (**6**) and  $[(\text{NMeBz})_2\text{CHBMe}_2]$  (**7**) A 100 mL Schlenk flask charged with 0.27 mmol of **3** or **4** and KHMDS (106 mg, 0.53 mmol) in 40 mL THF was sonicated for 18 hours to result in yellow precipitate and small yellow crystals on the glass walls. These crystals were suitable for X-ray diffraction and allowed for the identification of the resulting structures of **6** and **7**. These compounds are very poorly soluble that no NMR data was collected for either compound.

$[(\text{SBz})_2\text{CH}_2\text{BMe}_2][\text{OTf}]$  (**8**) **5** (40 mg, 0.10 mmol) was suspended in a in  $\text{CH}_3\text{CN}$  in a 20 mL vial followed by the addition of TMSOTf (0.036 mL, 0.20 mmol). The reaction mixture was allowed to stir for 18 hours before decanting the dilute solution to

another vial to slowly crystalize yielding yellow crystals of **8** suitable for X-ray diffraction. The resulting product is poorly soluble to obtain NMR data.

### **6.4.3 X-ray Crystallography**

Crystals for investigation were covered in Paratone<sup>®</sup>, mounted onto a goniometer head, and then rapidly cooled under a stream of cold N<sub>2</sub> of the low-temperature apparatus (Oxford Cryostream) attached to the diffractometer. The data were then collected using the APEXII (Bruker AXS) software suite on a Bruker Photon 100 CMOS diffractometer using a graphite monochromator with MoK<sub>α</sub> ( $\lambda = 0.71073$  Å). For each sample, data were collected at low temperature. APEXII software was used for data reductions and SADABS (Bruker AXS) was used for absorption corrections (multi-scan; semi-empirical from equivalents). XPREP was used to determine the space group and the structures were solved and refined using the SHELX<sup>39</sup> software suite as implemented in the WinGX<sup>40</sup> or OLEX2<sup>41</sup> program suites. Validation of the structures was conducted using PLATON<sup>42</sup>.

# CHAPTER 7:

## Conclusions and Future Work

### 7.1 Dissertation Overview

This dissertation revolves around the idea of using chelating ligands to coordinate group 13-15 elements to create new and unique complexes. Three types of ligands have been discussed, a bidentate ligand in the attempted synthesis of an anionic carbon(0), a tridentate (pincer) ligand in the coordination to group 13-15 elements<sup>1</sup>, and a tetradentate (tripod) ligand used for group 15 elements,<sup>2</sup> and with our collaborators, we have been successful in expanding this ligand system to group 14 as well.<sup>3,4</sup> The outlook for these new complexes is to be able to create new systems capable of activating small molecules and carrying out different catalytic transformations.

### 7.2 Bidentate Ligands

#### 7.2.1 Bidentate Ligands Toward the synthesis of an Anionic Carbon(0)

As highlighted in Chapter 6, the attempted synthesis of an anionic carbon(0) involved two types of bidentate ligands, an anionic bisphosphine (JCP-ASN) and an anionic biscarbene. In both cases, the ligands did not yield the anticipated anionic carbon(0); however, new interesting materials were created and characterized in the process.

The JCP ligand has been used by Ragogna's group for the coordination of group 14-15 elements as mentioned earlier.<sup>5-7</sup> Our group illustrated that using a different anionic bisphosphine ligand can result in the zwitterionic triphosphenium compound shown in **Scheme 7.1**.<sup>8,9</sup> In cases where R = PPh<sub>2</sub>, further reactivity at the P(I) centre was hindered by the presence of a backbone phosphine that readily reacts before the P(I) centre. Introducing a <sup>t</sup>Bu group instead allowed for further chemistry and coordination at the P(I) centre.

**Scheme 7.1.** Synthetic route for zwitterionic triphosphenium compound.

The presence of a Cp ring in the backbone of the anionic bisphosphine would bring further rigidity and stability to the overall donor ligand and would be a more suitable choice in comparison to the anionic JCP ligand. **Scheme 7.2** depicts the two different pathways that can lead to the anionic carbodiphosphorane using this Cp based ligand instead. Treatment of [Li][<sup>t</sup>BuCp(PPh<sub>2</sub>)<sub>2</sub>] with CH<sub>2</sub>Br<sub>2</sub> followed by excess base (like KHMDS) or treatment with tetrabromomethane followed by a reducing

Initial reactivity studies of  $[\text{Li}][\text{R-Cp}(\text{PPh}_2)_2]$  with group 14 metal halides were successful. Treatment of  $[\text{Li}][\text{tBuCp}(\text{PPh}_2)_2]$  with either  $\text{GeCl}_2$  or  $\text{SnCl}_2$  in THF results in an immediate yellow solution yielding  $\text{tBuCp}(\text{PPh}_2)_2\text{GeCl}$  (**2**) and  $\text{tBuCp}(\text{PPh}_2)_2\text{SnCl}$  (**3**), respectively. The  $^{31}\text{P}\{^1\text{H}\}$  of  $[\text{Li}][\text{tBuCp}(\text{PPh}_2)_2]$  shows a singlet at  $-20.7$  ppm, and upon treatment with an equivalent of  $\text{GeCl}_2$  or  $\text{SnCl}_2$ , the  $^{31}\text{P}\{^1\text{H}\}$  shows a new singlet at  $5.9$  ppm for **2** and  $4.1$  ppm for **3**. Recrystallization of these products by means of slow evaporation from a THF solution yield yellow crystals of **2** and **3** suitable for X-ray diffraction (**Figure 7.1**).

**Figure 7.1.** Solid state structure of  $\text{tBuCp}(\text{PPh}_2)_2\text{GeCl}$  (**2**, left) and  $\text{tBuCp}(\text{PPh}_2)_2\text{SnCl}$  (**3**, right). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms and solvent molecules are omitted for clarity. Selected bond distances and angles are listed in **Table 7.1**.

Compounds **2** and **3** were a result of using  $[\text{Li}][\text{R-Cp}(\text{PPh}_2)_2]$  with  $\text{R} = \text{tBu}$ . The use of a ligand with  $\text{R} = \text{PPh}_2$  with an equivalent of  $\text{GeCl}_2$ :dioxane results in the backbone phosphine coordinating to a second  $\text{GeCl}_2$  (**4**, **Figure 7.2**). This is consistent with the observations made by our group with P(I) coordination where having a backbone phosphine results in the backbone phosphine being readily open to reactivity and coordination. Selected bond distances and angles of **4** are in **Table 7.1**.

**Figure 7.2.** Solid state structure of  $(\text{GeCl}_2)\text{PPh}_2\text{Cp}(\text{PPh}_2)_2\text{GeCl}$  (**4**). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms and solvent molecules are omitted for clarity.

	$\text{tBuCp}(\text{PPh}_2)_2$ $\text{GeCl}$ ( <b>2</b> )	$\text{GeCl}_2\text{PPh}_2\text{Cp}$ $(\text{PPh}_2)_2\text{GeCl}$ ( <b>4</b> )	$[\text{Ph}_2\text{B}(\text{CH}_2\text{PP}$ $\text{h}_2)_2\text{GeCl}]$	$\text{tBuCp}(\text{PPh}_2)_2$ $\text{SnCl}$ ( <b>3</b> )	$[\text{Ph}_2\text{B}(\text{CH}_2\text{PP}$ $\text{h}_2)_2\text{SnCl}]$
<b>M-Cl</b>	2.259(1)	2.2646(9)	2.2895(9)	2.461(2)	2.460(1)
<b>M-P</b>	2.2467(1); 2.2480(1)	2.4840(7); 2.4851(7)	2.4567(9); 2.4565(9)	2.672(2); 2.698(2)	2.672(1); 2.7005(9)
<b>P-C1</b>	1.755(5); 1.757(4)	1.761(2); 1.760(2)	1.812(3); 1.809(3)	1.755(9); 1.755(7)	1.811(4); 1.799(3)
<b>P-M-P</b>	81.99(3)	80.17(2)	85.50(3)	76.97(6)	81.74(3)
<b>P-M-Cl</b>	92.92(4); 91.96(4)	92.36(3); 97.33(3)	99.77(3); 94.88(3)	88.74(6); 76.97(6)	97.43(4); 93.77(4)
$^\circ\Sigma_{\text{M}}$	266.87	269.86	280.15	242.68	272.94

**Table 7.1.** Selected bond distances ( $\text{\AA}$ ) and angles ( $^\circ$ ) of compounds **2**, **3**, and **4** along with Ragogna's  $[\text{Ph}_2\text{B}(\text{CH}_2\text{PPh}_2)_2\text{MCl}]$  ( $M = \text{Ge}, \text{Sn}$ ).

The chloride in compounds **2-4** is pointing away from the plane of the ligand, similar to structures reported by Ragogna of JCP-GeCl and JCP-SnCl (discussed in chapter 6).<sup>7</sup> Compounds **2** and **4** have very similar bond distances and angles; however, it is noteworthy that in compound **4** the Ge-P bond distance of the P-GeCl<sub>2</sub>

backbone (2.4666(7)) is slightly shorter than the Ge-P bond distance of the GeCl bond to the bisphosphine (2.4840(7) and 2.4851(7)). The sum of angles around the Ge and Sn centres (266.87 and 242.68° respectively) are smaller than those observed in JCP-GeCl (280.15°) and JCP-SnCl (272.94°) which is likely due to the R-Cp(PPh<sub>2</sub>)<sub>2</sub>-MCl ligand forming a 5-membered ring with the main group element compared to the cyclohexyl chair confirmation adapted by JCP-MCl. The packing of compounds **2** and **4** are similar in the sense that both compounds have intermolecular interactions of the M-Cl fragments resulting in packing of these compounds as dimers in the solid state. These interactions are on the order of 3.3776(9)/3.4235(9) Å in **2**, and 3.236(2)/3.236(2) Å in **4**; the germanium and tin centres also interact with the phenyl ring of the adjacent compound (**Figure 7.1**) with an M-η<sup>6</sup>-Ph distance of 3.851 Å in **2** and 3.705 Å in **4**. These intermolecular interactions are not observed in Ragona's structures, [Ph<sub>2</sub>B(CH<sub>2</sub>PPh<sub>2</sub>)<sub>2</sub>MCl] (M = Ge, Sn), which is likely due to the bulky phosphine donors that make these group 14 centres sterically inaccessible for intermolecular interactions. Compound **3** contains intermolecular interaction between a GeCl of one compound and the backbone GeCl<sub>2</sub> of the neighbouring compound (3.4226(8) Å) as shown in **Figure 7.3**.

**Figure 7.3.** Grown structure of **3** showing the intermolecular interaction present between the GeCl fragment and the neighbouring GeCl<sub>2</sub> fragment.

### 7.2.3 Bidentate Ligands for Group 13 and 14 Coordination – Part 2

Another bidentate ligand we propose for coordination of group 14 elements is the ligand used towards the synthesis of anionic carbodicarbenes in chapter 6 ((NMeBz)<sub>2</sub>CH<sub>2</sub>). Deprotonation of the ligand yields a [(GBz)<sub>2</sub>CH]<sup>-</sup> (G = NMe, O, or S) anion that is structurally similar to that of NacNac (**Figure 7.4**, left). The use of NacNac ligands with group 13 and 14 elements have lead to many interesting and unique results.<sup>10-24</sup> Coordination of [(GBz)<sub>2</sub>CH]<sup>-</sup> ligand (**Figure 7.4**, right) with group 13 have been recently studied by Stalke and co-workers using different ligand variants that include G = NR, S, and O.<sup>25-27</sup> To the best of our knowledge there has been no reports of the coordination of this ligand to group 14 elements.

**Figure 7.4.** NacNac ligand (left) and  $[(GBz)_2CH]^-$  (right).

Our proposal is to treat  $(GBz)_2CH_2$  with an equivalent of base followed by the addition of  $GeCl_2$ -dioxane or  $SnCl_2$  to yield  $(GBz)_2CHMCl$  ( $M = Ge$ , or  $Sn$ ) as shown in **Scheme 7.4**. Initial reactivity studies involved the reaction of  $(NMeBz)_2CH_2$  with KHMDS followed by  $SnCl_2$  in THF to result in a deep brown solution. Upon filtration of the solution and slow evaporation of the filtrate, orange/brown crystals suitable for X-ray diffraction were isolated of  $(NMeBz)_2CH_2SnCl$  (**5**, **Figure 7.5**) in low yields (<20%). Selected bond distances and angles of **5** are in **Table 7.2**.

**Scheme 7.4.** Proposed reaction of  $(GBz)_2CH_2$  with group 14 metal halides ( $MX_2$ ,  $M = Ge$ , or  $Sn$ ;  $X = F, Cl, Br$  or  $I$ ) to yield  $(GBz)_2CHMX$ .

When comparing compound **5** to compounds discussed in chapter 6 with  $BR_2$  backbone,  $[(NMeBz)_2CHBPh_2]$  and  $[(NMeBz)_2CHBMe_2]$ , the internal bond distances within the ligand do not change, regardless if the bound element is boron or tin. This ligand is very rigid in nature, yet very accessible, allowing the metal centre to be open for further reactivity. Full characterization of this compound, synthesis of the

germanium adducts, and studies of the potential reactivity are all part of the future work proposal.

**Figure 7.5.** Left: Packing of **5** showing the intermolecular interactions present in the solid state. Right: Solid state structure of (NMeBz)<sub>2</sub>CH<sub>2</sub>SnCl (**5**). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms and solvent molecules are omitted for clarity.

### 7.3 Neutral Pincer (Tridentate) Ligand Donor for Groups 13-15

In chapter 4, we reported group 15 adducts of the form, [NBn-BZIMPYMC1][OTf]<sub>2</sub> (M = P, As, and Sb). Unfortunately, these compounds are air sensitive and decompose when covered in Paratone<sup>®</sup> on the microscope slide (going from yellow crystals to colourless non-crystalline material) over the course of a few hours. Stephan's work with the tripyridine donor<sup>28</sup> (**Scheme 7.5**) yielded an air-stable Lewis acid useful for catalytic hydrodefluorination (HDF) of unactivated fluoroalkanes as mentioned earlier.

**Scheme 7.5.** Stephan's dicationic P(III) catalyst.

In chapter 3, we discussed Evans work on a Sn(II) chiral Lewis acid (**Figure 7.6**) that has been used in aldol condensation reactions in good yields with greater than 90% ee.<sup>29</sup>

**Figure 7.6.** Evans tin(II) chiral Lewis acid catalyst.

For this part of chapter 7, we propose combining Stephan's work discussed in chapter 4 with Evans' ligand discussed in chapter 3 to yield the catalyst shown in **Scheme 7.6**. These ligands are commercially available, bis(oxazoline) ligands (BOX) with CH<sub>2</sub> (BOX) or Py (PYBOX) linkers. Treatment of R-PYBOX with PCl<sub>3</sub> or PhPCl<sub>2</sub> and excess TMSOTf should yield R-PYBOX-PX (X = Cl, Ph). The resulting complex would serve as a chiral catalyst that can be useful in substrate selectivity.

**Scheme 7.6.** Proposed complex using R-PYBOX with PCl<sub>2</sub>X (X = Cl, Ph) and excess TMSOTf to yield R-PYBOX-PX.

## 7.4 Trianionic Pincer (Tridentate) Ligand Donor for Phosphorus

Aside from working with neutral tridentate ligands, we became interested in investigating trianionic nitrogen donor ligands similar to those used by Arduengo and Radosevich.<sup>30-32</sup> Radosevich have shown that such ligands containing phosphorus as the central atom are capable of small molecule activation. Thus, to this end, we propose the use of the BZIM ligand (**Figure 7.7**) that contains two benzimidazole donors as with the parent NH-BZIMPY ligand, but with the difference here is in the central donor nitrogen being NH rather than pyridine. This key difference would allow for a more flexible ligand, permitting for the distortion needed to create an active phosphorus centre and for an anionic nitrogen to give an overall trianionic ligand.

Figure 7.7. Structure of BZIMPY (left) and BZIM (right).

In terms of introducing the phosphorus centre, we first attempted a transamination reaction between BZIM and  $(\text{Et}_2\text{N})_2\text{PCl}$  to promote the release of two molecules of  $\text{Et}_2\text{NH}$  and the coordination of phosphorus to BZIM creating a cation similar to the one shown in **Scheme 7.7**. In theory, this reaction is similar to the transamination work reported by Verkade and co-workers in their synthesis of the superbase depicted in **Scheme 7.7**.<sup>33</sup>

Scheme 7.7. Synthesis of Verkade's superbase.

This transamination process would be equivalent to deprotonation of the proton followed by the introduction of the phosphorus centre. The BZIM ligand is very poorly soluble, creating a suspension in DCM until the addition of  $(\text{Et}_2\text{N})_2\text{PCl}$  that results in an immediate uptake of the precipitate into the DCM solution. Allowing the reaction mixture to stir for an hour at room temperature results in a pale-yellow solution. The  $^{31}\text{P}\{^1\text{H}\}$  NMR shows a singlet at 96 ppm that is believed to correspond to the cationic phosphorus shown in **Scheme 7.8**.

**Scheme 7.8.** Proposed outcome of reacting BZIM with (Et<sub>2</sub>N)<sub>2</sub>PCl followed by KHMDS (right) vs. actual product isolated (left).

Dissolving the collected materials in DCM and allowing the solvent to slowly evaporate results in colourless crystals suitable for X-ray diffraction. The resulting structure, H-BZIMP(Et<sub>2</sub>N) (**6**, **Figure 7.8**), is a result of BZIM reacting with (Et<sub>2</sub>N)<sub>2</sub>PCl releasing an equivalent of Et<sub>2</sub>NH and an HCl. The protonated arm of the ligand is flexible and should have the ability to freely rotate and interact with the amide to form a diethylamine and the pincer phosphine; however, this was not observed at room temperature and was not made possible at elevated temperatures.

**Figure 7.8.** Solid state structure of the H-BZIMP(Et<sub>2</sub>N) (**6**). Thermal ellipsoids are shown at 50% probability level. Hydrogen atoms and solvent molecules are omitted for clarity.

The transamination approach showed an interesting result, however, to generate the compound of interest (BZIMP) other means of reactivity were investigated. In particular, deprotonation of the ligand followed by the introduction of PCl<sub>3</sub> to yield the desired phosphine was carried out. Treatment of BZIM with 3 equivalents of NaH in THF results in the immediate evolution of H<sub>2</sub> gas. Addition of PCl<sub>3</sub> to the resulting mixture results in a pale-yellow solution with white precipitate that was separated by centrifugation. The solvent of the filtrate (supernatant) was removed under reduced pressure to result in colourless precipitate. <sup>31</sup>P{<sup>1</sup>H} of the starting material (Et<sub>2</sub>N)<sub>2</sub>PCl, consists of a singlet at 155 ppm, compound **6** shows a singlet at 96 ppm and the materials resulting from this reaction gave rise to a singlet at 126 ppm. The proton-coupled NMR spectrum results in a pentet with a <sup>3</sup>J<sub>CP</sub> of 25 Hz that is likely due to the phosphorus centre coupling to the two CH<sub>2</sub> methylenes of the BZIM ligand framework. This shift in the phosphorus NMR spectrum is believed to correspond to the compound of interest, BZIMP (**7**). Attempts to crystallize **7** to

obtain crystals suitable for X-ray diffraction were not successful and the  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra show the presence of other non-phosphorus containing fragments. To this end, we hope to pursue further chemistry, first by making compound **7** cleanly and fully characterizing it, secondly, by testing out its reactivity towards small molecules.

**Figure 7.9.** Stacked NMR spectra of BZIMP (**7**) showing  $^{31}\text{P}\{^1\text{H}\}$  in red and  $^{31}\text{P}$  in blue.

## 7.5 Conclusions

This dissertation consists of the use of various chelating ligand towards the coordination of group 13-15 main group elements. In principle, these coordination reactions are successful and create new complexes with unique physical and chemical properties. The next step is to use these complexes in applications geared towards small molecule activations and other chemical transformations that are of importance to organic and inorganic chemists.

## 7.6 Experimental

### 7.6.1 General Remarks

All manipulations were carried out using standard inert-atmosphere techniques. All reagents and chemicals were obtained from Sigma-Aldrich. All reagents were used without further purification. MeCN- $d_3$  was dried over calcium hydride or phosphorus pentoxide, and dichloromethane- $d_2$  was dried over phosphorus pentoxide. All other solvents were dried on a series of Grubbs-type columns and were degassed prior to use.<sup>34</sup> All glassware was stored in a 170 °C oven for several hours and was degassed prior to use. [K][PPh<sub>2</sub>Cp(PPh<sub>2</sub>)<sub>2</sub>]<sup>35</sup>, [Li][<sup>t</sup>BuCp(PPh<sub>2</sub>)<sub>2</sub>]<sup>8,36</sup>, (NMeBz)<sub>2</sub>CH<sub>2</sub>,<sup>37</sup> and N,N-bis(1H-benzimidazol-2-ylmethyl)-N-amine (BZIM)<sup>38</sup> were all prepared according to the literature procedures.

NMR spectra were recorded at room temperature on Bruker Avance III 500 MHz, Bruker Avance Ultrashield 300 MHz, and Bruker Avance DPX 300 MHz spectrometers. Chemical shifts are reported in parts per million relative to internal standards for <sup>1</sup>H and <sup>13</sup>C (the given deuterated solvent) and external standards for <sup>19</sup>F (CFCl<sub>3</sub>) and <sup>31</sup>P (85% H<sub>3</sub>PO<sub>4</sub>). Coupling constants |J| are given in hertz. Elemental analysis was performed at the University of Windsor Mass Spectrometry Service Laboratory using a Perkin-Elmer 2400 combustion CHN analyzer.

## 7.6.2 Synthesis

**<sup>t</sup>BuCp(PPh<sub>2</sub>)<sub>2</sub>GeCl (2)** A 100 mL Schlenk flask was charged with [Li][<sup>t</sup>BuCp(PPh<sub>2</sub>)<sub>2</sub>] (400 mg, 0.73 mmol) and GeCl<sub>2</sub>·dioxane (169 mg, 0.73 mmol). 30 mL Toluene was added to result in a yellow solution. The resulting mixture was allowed to stir for overnight before filtering through Celite to result in a clear pale-yellow solution. Solvents were removed under reduced pressure to yield **2** as a yellow solid (350 mg, 81%). Slow evaporation from dichloromethane yielded crystals suitable for X-ray Diffraction. <sup>31</sup>P{<sup>1</sup>H} NMR δ: 5.91.

**(GeCl<sub>2</sub>)PPh<sub>2</sub>Cp(PPh<sub>2</sub>)<sub>2</sub>GeCl (3)** A 20 mL vial was charged with [K][PPh<sub>2</sub>Cp(PPh<sub>2</sub>)<sub>2</sub>] (31 mg, 0.047 mmol) and GeCl<sub>2</sub>·dioxane (11 mg, 0.047 mmol). 5 mL of DCM was added, resulting in the formation of a yellow solution. The solution was stirred for 1 hr, filtered through a pipette stuffed with cotton/kimwipes and the filtrate was then slowly evaporated to result in **3** as yellow crystals suitable for X-ray Diffraction. <sup>31</sup>P{<sup>1</sup>H} NMR δ: 6.62 (s, 1P), -14.21 (s, 2P).

CHAPTER 7  
Conclusions and Future Work

**<sup>t</sup>BuCp(PPh<sub>2</sub>)<sub>2</sub>SnCl (4)** A 20 mL vial was charged with [Li][<sup>t</sup>BuCp(PPh<sub>2</sub>)<sub>2</sub>] (40 mg, 0.073 mmol) and SnCl<sub>2</sub> (14 mg, 0.073 mmol). 5 mL of DCM was added, resulting in the formation of a yellow solution. The solution was stirred for 1 hr, filtered through a pipette stuffed with cotton/kimwipes and the filtrate was then slowly evaporated to result in **4** as yellow crystals suitable for X-ray Diffraction. <sup>31</sup>P{<sup>1</sup>H} NMR δ: 4.13.

**(NMeBz)<sub>2</sub>CH<sub>2</sub>SnCl (5)** A 20 mL vial was charged with (NMeBz)<sub>2</sub>CH<sub>2</sub> (40 mg, 0.14 mmol), SnCl<sub>2</sub> (34 mg, 0.15 mmol) and KHMDS (58 mg, 0.29 mmol). 5 mL of THF was added, resulting in the formation of an orange solution. The solution was stirred for overnight, 5 mL of DCM was added, and the resulting suspension was centrifuged with the resulting filtrate/supernatant slowly evaporated to yield **5** as deep orange/brown crystals suitable for X-ray Diffraction.

**H-BZIMP(Et<sub>2</sub>N) (6)**. A 20 mL vial was charged with BZIM (40 mg, 0.14 mmol) in 5 mL CH<sub>3</sub>CN. (Et<sub>2</sub>N)<sub>2</sub>PCl (32 μL, 0.15 mmol) was added using a microsyringe resulting in a clear solution as the insoluble BZIM ligand goes in solution. The solution was allowed

to slowly evaporate to yield 6 as colourless crystals suitable for X-ray diffraction.  $^{31}\text{P}\{^1\text{H}\}$  NMR ( $\text{CDCl}_3$ )  $\delta$ : 93.21 (s).  $^{31}\text{P}$  NMR ( $\text{CDCl}_3$ )  $\delta$ : 93.13 (b).

**BZIMP (7)** A 20 mL vial was charged with BZIM (40 mg, 0.14 mmol) and NaH (11 mg, 0.45 mmol). 5 mL of THF was added resulting in the evolution of  $\text{H}_2$  gas. After allowing the reaction mixture to stir for 15 minutes,  $\text{PCl}_3$  (16  $\mu\text{L}$ , 0.17 mmol) was added via a microsyringe resulting in a yellow cloudy solution. The solution was centrifuged, and the supernatant was slowly evaporated to yield off-white microcrystalline materials.  $^{31}\text{P}\{^1\text{H}\}$  NMR ( $\text{CDCl}_3$ )  $\delta$ : 125.17.  $^{31}\text{P}$  NMR ( $\text{CDCl}_3$ )  $\delta$ : 125.70 (q,  $^3J_{\text{PH}} = 25$  Hz).

### 7.6.3 X-ray Crystallography

Crystals for investigation were covered in Paratone<sup>®</sup>, mounted onto a goniometer head, and then rapidly cooled under a stream of cold  $\text{N}_2$  of the low-temperature apparatus (Oxford Cryostream) attached to the diffractometer. The data were then collected using the APEXII (Bruker AXS) software suite on a Bruker Photon 100 CMOS diffractometer using a graphite monochromator with  $\text{MoK}\alpha$  ( $\lambda = 0.71073$  Å). For each sample, data were collected at low temperature. APEXII software was used for data reductions and SADABS (Bruker AXS) was used for absorption corrections (multi-scan; semi-empirical from equivalents). XPREP was used to determine the space group and the structures were solved and refined using the SHELX<sup>39</sup> software suite as implemented in the WinGX<sup>40</sup> or OLEX2<sup>41</sup> program suites. Validation of the structures was conducted using PLATON.<sup>42</sup>

## VITA AUCTORIS

NAME: Alaaeddeen Swidan

PLACE OF BIRTH: Amman, Jordan

YEAR OF BIRTH: 1989

EDUCATION: J. L. Forster S. S., High School, Windsor, ON, 2007

University of Windsor, B.Sc., Windsor, ON, 2011

University of Windsor, M.Sc., Windsor, ON, 2013  
-Dr. Charles L. B. Macdonald

Cornell University, Grad. Studies, Ithaca, NY, 2015  
-Dr. Peter T. Wolczanski

University of Windsor, Ph.D. Windsor, ON, 2019  
-Dr. Charles L. B. Macdonald

## LIST OF PUBLICATIONS

1. "2,6-Bis(benzimidazol-2-yl)pyridine Complexes of Group 14 Elements"  
**Swidan, A.**; Binder, J. F.; St. Onge, P. B. J.; Suter, R.; Burford, N.; Macdonald, C. L.  
*B. Dalton Trans.*, **2019**, Published.
2. "Halogen and sulfur oxidation of germanium and tin dications" Suter, R.;  
**Swidan, A.**; Macdonald, C. L. B.; Burford, N.; Ferguson, M. *Inorg. Chem.* **2019**,  
*58* (9), 6238-6245.

3. "2,6-Bis(benzimidazol-2-yl)pyridine as More Electron-Rich and Sterically Accessible Alternatives to 2,6-bis(imino)pyridine for Group 13 Coordination Chemistry" **Swidan, A.**; Binder, J. F.; St. Onge, P. B. J.; Suter, R.; Burford, N.; Macdonald, C. L. B. *Dalton Trans.*, **2019**, 48, 1284-1291.
4. "Phosphonium-Templated Iodoplumbates" Omahen, E. H., Binder, J. F., Jacobs, B. F.; **Swidan, A.**; Macdonald, C. L. B., *ACS Omega*, **2018**, 3 (12), 17077-17082.
5. "Diphosphoniodiphosphene Formation by Transition Metal Insertion into a Triphosphenium Zwitterion" Kosnik, S. C.; Binder, J. F.; Nascimento, M. C.; **Swidan, A.**; Macdonald, C. L. B. *Chem. Eur. J.* **2019**, 25, 1208.
6. "Synthesis, characterization and mass-spectrometric analysis of [LSn(IV)F<sub>4-x</sub>]<sup>x+</sup> salts [L = tris ((1-ethyl-benzoimidazol-2-yl)methyl)amine, x = 1-4]" Suter, R.; **Swidan, A.**; Zijlstra, H.S.; Macdonald, C.L.B; McIndoe, J. S.; Burford, N., *Dalton Trans.* **2018**, 47 (46), 16729–16736.
7. "Synthesis of Heteroleptic Phosphorus(I) Cations by P<sup>+</sup> Transfer" Binder, J. F.; **Swidan, A.**; Macdonald, C. L. B., *Inorg. Chem.* **2018**, 57(18), 11717–11725.
8. "Tris(benzoimidazol)amine (L) complexes of pnictogen(III) and pnictogen(V) cations and assessment of the [LP]<sup>3+</sup>/[LPF<sub>2</sub>]<sup>3+</sup> redox couple" **Swidan, A.**; Suter, R.; Macdonald, C. L. B.; Burford, N., *Chem. Sci.*, **2018**, 9, 5837-5841.
9. "Oxidation of a germanium(II) dication to access cationic germanium(IV) fluorides" Suter, R.; **Swidan, A.**; Macdonald, C. L. B.; Burford, N., *Chem. Commun.*, **2018**, 54, 4140.

10. "Synthesis and structural characterization of new polyether complexes of germanium(II) and tin(II)" Secara, A. M.; Binder, J. F.; **Swidan, A.**, Macdonald, C. L. B., *Can. J. Chem.*, **2018**, 96(6): 570-577.
11. "Convenient Preparation and Detailed Analysis of a Series of NHC-Stabilized Phosphorus(I) Dyes and Their Derivatives" Macdonald, C. L. B., Binder, J. F.; **Swidan, A.**, Nguyen, J. H., Kosnik, S. C., Ellis, B. D., *Inorg. Chem.*, **2016**, 55 (14), 7152–7166.
12. "Polyether complexes of groups 13 and 14" **Swidan, A.**; Macdonald, C. L. B., *Chem. Soc. Rev.*, **2016**, 45, 3883-3915.
13. "Fe(IV) alkylidenes via protonation of Fe(II) vinyl chelates and a comparative Mössbauer spectroscopic study" Lindley, B. M.; **Swidan, A.**; Lobkovsky, E. B.; Wolczanski, P. T.; Adelhardt, M.; Jörg Sutter, J.; Meyer, K., *Chem. Sci.* **2015**, 6, 4730-4736.
14. "Remarkably stable chelating bis-N-heterocyclic carbene adducts of phosphorus(I) cations" Binder, J. F.; **Swidan, A.**; Tang, M.; Nguyen, J. H.; Macdonald, C. L. B., *Chem. Commun.*, **2015**, 51, 7741.
15. "Water and Ammonia Complexes of Germanium(II) Dications" Bandyopadhyay, R.; Nguyen, J. H.; **Swidan, A.**; Macdonald, C. L. B., *Angew. Chem. - Int. Ed.*, **2013**, 52, 3469-3472.
16. "Low-Oxidation-State Main Group Compounds" Macdonald, C. L. B.; Ellis, B. D.; **Swidan, A.** In the Encyclopedia of Inorganic and Bioinorganic Chemistry; John Wiley & Sons, Ltd: **2012**.

## CONFERENCE PRESENTATIONS

1. CSC2018 (101st Canadian Chemistry Conference and Exhibition), Oral Presentation, May 2018, Edmonton, AB, Swidan, A.; St. Ong, B. P., Macdonald, C. L. B. "Novel Pincer Complexes of Group 13-15 Main Group Elements"
2. CSC2017 (100th Canadian Chemistry Conference and Exhibition), poster presentation, May 2017, Toronto, ON. Swidan, A.; St. Ong, B. P., "Pincer Ligand Complexation to Various Main Group Metals"
3. CSC2016 (99th Canadian Chemistry Conference and Exhibition), poster presentation, June 2016; Halifax, NS. Swidan, A.; Schröder, J.; Macdonald, C. L. B.; "Towards The Synthesis of Anionic Carbodiphosphoranes"
4. IRIS-13 (13th International Symposium on Inorganic Ring Systems), poster presentation July 2012; Victoria, BC. Swidan, A.; Nguyen, J.; Ellis, B. D.; Macdonald, C. L. B.; "Synthesis and Characterization of N-heterocyclic carbene adducts of PI cations."
5. CERM2012 (43rd ACS Central Regional Meeting), poster presentation, June 2012; Dearborn, MI. Swidan, A.; Nguyen, J.; Ellis, B. D.; Macdonald, C. L. B.; "Synthesis and Characterization of N-heterocyclic carbene adducts of PI cations."
