Vertical Temperature Profiles with Light Breezes at Night in Urban and Rural Areas of Obuse, Nagano

Yasushi SAKAKIBARA * and Kiyotaka NAKAGAWA **

Abstract

This paper describes the vertical structure of the nocturnal heat island in a small town. Tethered balloon soundings were conducted 180 times in and around an urban area on nights with light winds from March 2003 to May 2005. Surface inversions developed not only in rural areas but also in urban areas. Surface inversions developed quickly after sunset at the rural site, whereas development was slower at the urban site. At six hours after sunset the vertical temperature profile in the urban area was the same as that in the rural area. Heat island formation in the small town was related to the delay in the development of surface inversion in the urban area. The crossover effect can be seen in only three of 23 surveys for which vertical soundings were performed in both urban and rural areas.

Key words : heat island, air temperature, Obuse, vertical profile, crossover

Fig. 8 Mean vertical profile in lapse rate of potential temperature.

①Case in which crossover phenomenon appeared,
②Case in which urban area was warmer than rural area only in a surface layer.

Fig. 9 Relation between heat island intensity and rural lapse rate.

●: Case in which crossover phenomenon appeared, □: Case in which urban area was warmer than rural area only in a surface layer, + : Others.
