## INTRODUCTION

**BACKGROUND**: The outbreak of nanotechnology in pharmaceutical and nanomedicine fields calls the need for developing strategies to guaranty the safety and effectiveness of nanostructured materials for treatment as well as for clinical trials progress.

Sterilization is a crucial step in the development of this type of materials<sup>[1]</sup>. Although often effective, the conventional sterilization methods may change the physico-chemical properties of the nanoparticles and their biocompatibility, compromising their functionality<sup>[1],[2]</sup>.

<u>AIM OF THE WORK:</u> to evaluate the effect and effectiveness of different sterilization methods on a model chitosan-based nanogel.

## RESULTS AUTOCLAVE **OZONE GAS** γ IRRADIATION VISUA Without protective sugars: aggregates and sediments Loss of color and formations of large sediments No visual alterations With protective sugars: no visual alterations 4000 500 100% size [15-50] nm 80% 0 kG 8 kGv ize 400 3000 Average s (nm) 60% [100-490] nm ■25 kGy 300 40% 2000 e parl [>1000] nm 20% **EFFECT ON SIZE** 200 0% 1000 Control 100 5 min 10 min Exposure time at 110 °C NP 2.5% Glucose NP 5% Glucos 5% Mannite NP 2.5% Mannito 2F 4P Figure 3 Number of O Figure 1 Figure 2 Sterilization by irradiation promotes aggregation resulting in · Degradation of the nanogel structure large particles agglomerates. · Very low particle count and several No significant changes (Fig 3) • In the presence of both protective sugars (mannitol and glucose) populations of different sizes (Fig 1). the degradation effects decrease considerably (Fig 2) PDI increases Without sugars: PDI increases 👚 ZP decreases 👢 No significant changes ZP increases 1 With sugars: No significant alterations Nanogel/Glucose 5%-25kG (P-O) SEM / FTIR gel Contro No significant changes in SEM analysis Not Tested No significant changes in FTIR analysis Figure 5 SEM did not reveal significant changes (Fig 4) FITR: chemical alterations were observed in the presence of protective sugars. The amides and PO groups seem to be the most affected (Fig 5). $\leq$ 4 ozonation pulses: bacterial growth STERILITY 8 ozonation pulses: low bioburden · No bacterial growth in all tested conditions Not Tested 10 ozonation pulses: no bacterial growth CONCLUSIONS ACKNOWLEDGMENTS

The nanogel severely degrades by autoclaving. Concerning gamma irradiation, the nanogel resistance increases considerably in the presence of protective sugars. Regarding ozone sterilization the nanogel seems to withstand the method without displaying significant physical adverse effects, although the method is not as effective as gamma irradiation.

To Dr. Pablo Vasquez for his valuable and unwearying collaboration.
