- HUANG 08 reexamined the b' mass lower bound of 268 GeV obtained in AALTONEN 07c that assumes $B(b' \rightarrow Zb) = 1$, which does not hold for $m_{b'} > 255$ GeV. The lower mass bound is given in the plane of $\sin^2(\theta_{tb'})$ and $m_{b'}$.
- AFFOLDER 00 looked for b' that decays in to $b+Z$. The signal searched for is bbZ events where one Z decays into e^+e^- or $\mu^+\mu^-$ and the other Z decays hadronically. The bound assumes $B(b' \rightarrow Zb) = 100\%$. Between 100 GeV and 199 GeV, the 95% CL upper bound on $\sigma(b' \rightarrow \bar{b}') \times B^2(b' \rightarrow Zb)$ is also given (see their Fig. 2).
- ABE 98N looked for $Z \rightarrow e^+e^-$ decays with displaced vertices. Quoted limit assumes $B(b' \rightarrow Zb) = 1$ and $c\tau_{b'} = 1$ cm. The limit is lower than m_{Z+m_b} (~ 96 GeV) if $c\tau > 22$ cm or $c\tau < 0.009$ cm. See their Fig. 4.
- ABACHI 97D searched for b' that decays mainly via FCNC. They obtained 95% CL upper bounds on $B(b'\bar{b}' \rightarrow \gamma + 3 \text{ jets})$ and $B(b'\bar{b}' \rightarrow 2\gamma + 2 \text{ jets})$, which can be interpreted as the lower mass bound $m_{b'} > m_{Z+m_b}$.
- ABACHI 95F bound on the top-quark also applies to b' and t' quarks that decay predominantly into W . See FROGGATT 97.
- MUKHOPADHYAYA 93 analyze CDF dilepton data of ABE 92G in terms of a new quark decaying via flavor-changing neutral current. The above limit assumes $B(b' \rightarrow b\ell^+\ell^-) = 1\%$. For an exotic quark decaying only via virtual $Z [B(b\ell^+\ell^-) = 3\%]$, the limit is 85 GeV.
- ABE 92 dilepton analysis limit of >85 GeV at CL=95% also applies to b' quarks, as discussed in ABE 90B.
- ABE 90B exclude the region 28-72 GeV.
- AKESSON 90 searched for events having an electron with $p_T > 12$ GeV, missing momentum > 15 GeV, and a jet with $E_T > 10$ GeV, $|\eta| < 2.2$, and excluded $m_{b'}$ between 30 and 69 GeV.
- For the reduction of the limit due to non-charged-current decay modes, see Fig. 19 of ALBAJAR 90B.
- ALBAJAR 88 study events at $E_{cm} = 546$ and 630 GeV with a muon or isolated electron, accompanied by one or more jets and find agreement with Monte Carlo predictions for the production of charm and bottom, without the need for a new quark. The lower mass limit is obtained by using a conservative estimate for the $b'\bar{b}'$ production cross section and by assuming that it cannot be produced in W decays. The value quoted here is revised using the full $O(\alpha_s^3)$ cross section of ALTARELLI 88.

$b'(-1/3)$ mass limits from single production in $p\bar{p}$ and pp collisions

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT

- Based on 19.7 fb^{-1} of data in pp collisions at 8 TeV. Limit on left-handed b' assuming 100% decay to tW and using all-hadronic, lepton + jets, and dilepton final states.
- Based on 19.7 fb^{-1} of data in pp collisions at 8 TeV. Limit on right-handed b' assuming 100% decay to tW and using all-hadronic, lepton + jets, and dilepton final states.
- Based on 19.7 fb^{-1} of data in pp collisions at 8 TeV. Limit on vector-like b' assuming 100% decay to tW and using all-hadronic, lepton+jets, and dilepton final states.
- Based on 5.4 fb^{-1} of data in pp collisions at 1.96 TeV. ABAZOV 11F looked for single production of b' via the W or Z coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes $p\bar{p} \rightarrow b'q \rightarrow Wuq$, and $p\bar{p} \rightarrow b'q \rightarrow Zdq$ are given in Figs. 3 and 4,

See key on page 601

Quark Particle Listings

 b' (Fourth Generation) Quark, t' (Fourth Generation) Quark

respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

REFERENCES FOR Searches for (Fourth Generation) b' QuarkMASS LIMITS for b' (4th Generation) Quark or Hadron in e^+e^- Collisions

Search for hadrons containing a fourth-generation $-1/3$ quark denoted b' .

The last column specifies the assumption for the decay mode (CC denotes the conventional charged-current decay) and the event signature which is looked for.

- DECAMP 90F looked for isolated charged particles, for isolated photons, and for four-jet final states. The modes $b' \rightarrow b\gamma$ for $B(b' \rightarrow b\gamma) > 65\%$ and $b' \rightarrow b\gamma$ for $B(b' \rightarrow b\gamma) > 5\%$ are excluded. Charged Higgs decay were not discussed.
- ABDALLAH 07 searched for b' pair production at $E_{\text{cm}} = 196\text{--}209$ GeV, with 420 pb^{-1} . No signal leads to the 95% CL upper limits on $B(b' \rightarrow bZ)$ and $B(b' \rightarrow cW)$ for $m_{b'} = 96$ to 103 GeV.
- ADRIANI 93G search for vector quarkonium states near Z and give limit on quarkonium- Z mixing parameter $\delta m^2 < (10\text{--}30) \text{ GeV}^2$ (95%CL) for the mass $88\text{--}94.5$ GeV. Using Richardson potential, a $1S$ ($b'\bar{b}'$) state is excluded for the mass range $87.7\text{--}94.7$ GeV. This range depends on the potential choice.
- ABREU 90D assumed $m_{H^-} < m_{b'} - 3$ GeV.
- Superseded by ABREU 91F.
- AKRAWY 90B search was restricted to data near the Z peak at $E_{\text{cm}} = 91.26$ GeV at LEP. The excluded region is between 23.6 and 41.4 GeV if no H^+ decays exist. For charged Higgs decays the excluded regions are between ($m_{H^+} + 1.5$ GeV) and 45.5 GeV.
- AKRAWY 90J search for isolated photons in hadronic Z decay and derive $B(Z \rightarrow b'\bar{b}')B(b' \rightarrow \gamma X)/B(Z \rightarrow \text{hadrons}) < 2.2 \times 10^{-3}$. Mass limit assumes $B(b' \rightarrow \gamma X) > 10\%$.
- ABE 89E search at $E_{\text{cm}} = 56\text{--}57$ GeV at TRISTAN for multihadron events with a spherical shape (using thrust and acoplanarity) or containing isolated leptons.
- ABE 89G search was at $E_{\text{cm}} = 55\text{--}60.8$ GeV at TRISTAN.
- If the photonic decay mode is large ($B(b' \rightarrow b\gamma) > 25\%$), the ABRAMS 89C limit is 45.4 GeV. The limit for Higgs decay ($b' \rightarrow cH^-, H^- \rightarrow \bar{\nu}_s$) is 45.2 GeV.
- ADACHI 89C search was at $E_{\text{cm}} = 56.5\text{--}60.8$ GeV at TRISTAN using multi-hadron events accompanying muons.
- ADACHI 89C also gives limits for any mixture of CC and bg decays.
- ENO 89 search at $E_{\text{cm}} = 50\text{--}60.8$ at TRISTAN.
- ENO 89 considers arbitrary mixture of the charged current, bg , and $b\gamma$ decays.
- IGARASHI 88 searches for leptons in low-thrust events and gives $\Delta R(b') < 0.26$ (95% CL) assuming charged current decay, which translates to $m_{b'} > 24.4$ GeV.
- SAGAWA 88 set limit $\sigma(\text{top}) < 6.1 \text{ pb}$ at $\text{CL} = 95\%$ for top-flavored hadron production from event shape analyses at $E_{\text{cm}} = 52$ GeV. By using the quark parton model cross-section formula near threshold, the above limit leads to lower mass bounds of 23.8 GeV for charge $-1/3$ quarks.
- ADEVA 86 give 95%CL upper bound on an excess of the normalized cross section, ΔR , as a function of the minimum c.m. energy (see their figure 3). Production of a pair of $1/3$ charge quarks is excluded up to $E_{\text{cm}} = 45.4$ GeV.
- ALTHOFF 84C narrow state search sets limit $\Gamma(e^+e^-)B(\text{hadrons}) < 2.4 \text{ keV}$ CL = 95% and heavy charge $1/3$ quark pair production $m > 21$ GeV, CL = 95%.
- ALTHOFF 84I exclude heavy quark pair production for $7 < m < 19$ GeV ($1/3$ charge) using aplanarity distributions (CL = 95%).

- AAD 15AR based on 20.3 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV. Used lepton-plus-jets final state. See Fig. 20 for mass limits in the plane of $B(t' \rightarrow Ht)$ vs. $B(t' \rightarrow Wb)$ from a combination of $t'\bar{t}' \rightarrow Wb + X$ and $t'\bar{t}' \rightarrow Ht + X$ searches. Any branching ratio scenario is excluded for mass below 715 GeV.
- AAD 15BY based on 20.3 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV. Limit on pair-produced vector-like t' assuming the branching fractions to W, Z , and h modes of the singlet lepton pair. Used events containing $\geq 2e + \cancel{E}_T + \geq 2j$ ($\geq 1b$) and including a same-sign lepton pair.
- KHACHATRYAN 15AI based on 19.7 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV. The search exploits all-hadronic final states by tagging boosted Higgs boson using jet substructure and b -tagging.

Quark Particle Listings

t' (Fourth Generation) Quark, Free Quark Searches

- ⁴ Based on 20.3 fb⁻¹ of pp data at $\sqrt{s} = 8$ TeV. No significant excess over SM expectation is found in the search for pair production or single production of t' in the events with dilepton from a high p_T Z and additional jets (≥ 1 b -tag). If instead of $B(b' \rightarrow Wt) = 1$ an electroweak singlet with $B(b' \rightarrow Wt) \sim 0.45$ is assumed, the limit reduces to 685 GeV.
- ⁵ Based on 19.5 fb⁻¹ of pp data at $\sqrt{s} = 8$ TeV. The t' quark is pair produced and is assumed to decay into three different final states of bW , tZ , and th . The search is carried out using events with at least one isolated lepton.
- ⁶ Based on 1.04 fb⁻¹ of pp data at $\sqrt{s} = 7$ TeV. No signal is found for the search of heavy quark pair production that decay into W and a quark in the events with dileptons, large E_T , and ≥ 2 jets.
- ⁷ Based on 1.04 fb⁻¹ of data in pp collisions at 7 TeV. AAD 12c looked for $t'\bar{t}'$ production followed by t' decaying into a top quark and X , an invisible particle, in a final state with an isolated high- p_T lepton, four or more jets, and a large missing transverse energy. No excess over the SM $t\bar{t}$ production gives the upper limit on $t'\bar{t}'$ production cross section as a function of $m_{t'}$ and m_X . The result is obtained for $B(t' \rightarrow Wt) = 1$.
- ⁸ Based on 5 fb⁻¹ of pp data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 12BH searched for QCD and EW production of single and pair of degenerate 4th generation quarks that decay to Wb or Wt . Absence of signal in events with one lepton, same-sign dileptons or tripletons gives the bound. With a mass difference of 25 GeV/ c^2 between $m_{t'}$ and $m_{b'}$, the corresponding limit shifts by about ± 20 GeV/ c^2 .
- ⁹ Based on 5.0 fb⁻¹ of pp data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 12P looked for $t'\bar{t}'$ production events with two isolated high p_T leptons, large E_T , and 2 high p_T jets with b -tag. The absence of signal above the SM background gives the limit for $B(t' \rightarrow Wb) = 1$.
- ¹⁰ Based on 4.7 fb⁻¹ of pp data at $\sqrt{s} = 7$ TeV. No signal is found for the search of heavy quark pair production that decay into W and a b quark in the events with a high p_T isolated lepton, large E_T and at least 3 jets (≥ 1 b -tag). Vector-like quark of charge 2/3 with $400 < m_{t'} < 550$ GeV and $B(t' \rightarrow Wb) > 0.63$ is excluded at 95% CL.
- ¹¹ Based on 5.0 fb⁻¹ of pp data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 13l looked for events with one isolated electron or muon, large E_T , and at least four jets with large transverse momenta, where one jet is likely to originate from the decay of a bottom quark.
- ¹² Based on 1.04 fb⁻¹ of pp data at $\sqrt{s} = 7$ TeV. No signal is found in the search for pair produced heavy quarks that decay into W boson and a b quark in the events with a high p_T isolated lepton, large E_T and at least 3 jets (≥ 1 b -tag).
- ¹³ Based on 5.0 fb⁻¹ of pp data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 12Bc looked for $t'\bar{t}'$ production events with a single isolated high p_T lepton, large E_T and at least 4 high p_T jets with a b -tag. The absence of signal above the SM background gives the limit for $B(t' \rightarrow Wb) = 1$.
- ¹⁴ Based on 5.7 fb⁻¹ of data in $p\bar{p}$ collisions at 1.96 TeV. AALTONEN 11AH looked for $t'\bar{t}'$ production followed by t' decaying into a top quark and X , an invisible particle, in the all hadronic decay mode of $t\bar{t}$. No excess over the SM $t\bar{t}$ production gives the upper limit on $t'\bar{t}'$ production cross section as a function of $m_{t'}$ and m_X . The result is obtained for $B(t' \rightarrow Xt) = 1$.
- ¹⁵ Based on 5.6 fb⁻¹ of data in $p\bar{p}$ collisions at 1.96 TeV. AALTONEN 11AL looked for $\ell + \geq 4j$ events and set upper limits on $\sigma(t'\bar{t}')$ as functions of $m_{t'}$.
- ¹⁶ Based on 4.8 fb⁻¹ of data in $p\bar{p}$ collisions at 1.96 TeV. AALTONEN 11o looked for $t'\bar{t}'$ production signal when t' decays into a top quark and X , an invisible particle, in $\ell + E_T + jets$ channel. No excess over the SM $t\bar{t}$ production gives the upper limit on $t'\bar{t}'$ production cross section as a function of $m_{t'}$ and m_X . The result is obtained for $B(t' \rightarrow Xt) = 1$.
- ¹⁷ Based on 5.3 fb⁻¹ of data in $p\bar{p}$ collisions at 1.96 TeV. ABAZOV 11Q looked for $\ell + E_T + \geq 4j$ events and set upper limits on $\sigma(t'\bar{t}')$ as functions of $m_{t'}$.
- ¹⁸ Searches for pair production of a new heavy top-like quark t' decaying to a W boson and another quark by fitting the observed spectrum of total transverse energy and reconstructed t' mass in the lepton + jets events.
- ¹⁹ HUANG 08 reexamined the t' mass lower bound of 256 GeV obtained in AALTONEN 08H that assumes $B(b' \rightarrow qZ) = 1$ for $q = u, c$ which does not hold when $m_{b'} < m_{t'} - m_W$ or the mixing $\sin^2(\theta_{bt'})$ is so tiny that the decay occurs outside of the vertex detector. Fig. 1 gives that lower bound on $m_{t'}$ in the plane of $\sin^2(\theta_{bt'})$ and $m_{b'}$.

$t'(5/3)$ -quark/hadron mass limits in $p\bar{p}$ and pp collisions

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
>750	95	¹ AAD	15BY ATLS	$t'(5/3) \rightarrow tW^+$
>840	95	² AAD	15Z ATLS	$t'(5/3) \rightarrow tW^+$
>800	95	³ CHATRCHYAN 14T	CMS	$t'(5/3) \rightarrow tW^+$

- ¹ AAD 15BY based on 20.3 fb⁻¹ of pp data at $\sqrt{s} = 8$ TeV. Limit on $t'(5/3)$ in pair and single production assuming its coupling to Wt is equal to one. Used events containing $\geq 2\ell + E_T + \geq 2j$ (≥ 1 b) and including a same-sign lepton pair.
- ² AAD 15Z based on 20.3 fb⁻¹ of pp data at $\sqrt{s} = 8$ TeV. Used events with $\ell + E_T + \geq 6j$ (≥ 1 b) and at least one pair of jets from weak boson decay, sensitive to the final state $b\bar{b}W^+W^-W^+W^-$.
- ³ Based on 19.5 fb⁻¹ of pp data at $\sqrt{s} = 8$ TeV. Non-observation of anomaly in H_T distribution in the same sign dilepton events leads to the limit when pair produced $t'(5/3)$ quark decays exclusively into t and W^+ , resulting in the final state with $b\bar{b}W^+W^-W^+W^-$.

$t'(2/3)$ mass limits from single production in $p\bar{p}$ and pp collisions

VALUE (GeV)	CL%	DOCUMENT ID	TECN	COMMENT
>403	95	¹ ABAZOV	11F D0	$q\bar{d} \rightarrow q't' \rightarrow q'(Wd)$ $\bar{\kappa}_{d't'}=1, B(t' \rightarrow Wd)=1$
>551	95	¹ ABAZOV	11F D0	$qu \rightarrow q't' \rightarrow q(Zu)$ $\bar{\kappa}_{ut'}=\sqrt{2}, B(t' \rightarrow Zu)=1$

- ¹ Based on 5.4 fb⁻¹ of data in $p\bar{p}$ collisions at 1.96 TeV. ABAZOV 11F looked for single production of t' via the Z or E coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes $p\bar{p} \rightarrow t'q \rightarrow (Wd)q$, and $p\bar{p} \rightarrow t'q \rightarrow (Zd)q$ are given in Figs. 3 and 4, respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

Free Quark Searches

FREE QUARK SEARCHES

The basis for much of the theory of particle scattering and hadron spectroscopy is the construction of the hadrons from a set of fractionally charged constituents (quarks). A central but unproven hypothesis of this theory, Quantum Chromodynamics, is that quarks cannot be observed as free particles but are confined to mesons and baryons.

Experiments show that it is at best difficult to “unglue” quarks. Accelerator searches at increasing energies have produced no evidence for free quarks, while only a few cosmic-ray and matter searches have produced uncorroborated events.

This compilation is only a guide to the literature, since the quoted experimental limits are often only indicative. Reviews can be found in Refs. 1–4.

Quark Flux — Accelerator Searches

The definition of FLUX depends on the experiment

- is the ratio of measured free quarks to predicted free quarks if there is no "confinement."
- is the probability of fractional charge on nuclear fragments. Energy is in GeV/nucleon.
- is the 90%CL upper limit on fractionally-charged particles produced per interaction.
- is quarks per collision.
- is inclusive quark-production cross-section ratio to $\sigma(e^+e^- \rightarrow \mu^+\mu^-)$.
- is quark flux per charged particle.
- is the flux per ν -event.
- is quark yield per π^- yield.
- is 2-body exclusive quark-production cross-section ratio to $\sigma(e^+e^- \rightarrow \mu^+\mu^-)$.

- ¹HUENTRUP 96 quote 95% CL limits for production of fragments with charge differing by as much as $\pm 1/3$ (in units of e) for charge $6 \leq Z \leq 10$.
- ²BUSKULIC 93c limits for inclusive quark production are more conservative if the ALEPH hadronic fragmentation function is assumed.
- ³CECCHINI 93 limit at 90%CL for $23/3 \leq Z \leq 40/3$, for 16A GeV O, 14.5A Si, and 200A S incident on Cu target. Other limits are 2.3×10^{-4} for $17/3 \leq Z \leq 20/3$ and 1.2×10^{-4} for $20/3 \leq Z \leq 23/3$.
- ⁴GHOSH 92 reports measurement of spallation fragment charge based on ionization in emulsion. Out of 650 measured tracks, 2 were consistent with charge $5e/3$, and 4 with $7e/3$.
- ⁵Hadronic quark.
- ⁶Leptonic quark.
- ⁷HE 91 limits are for charges of the form $N \pm 1/3$ from 23/3 to 38/3, and correspond to cross-section limits of $380\mu\text{b}$ (Pb) and $320\mu\text{b}$ (Cu).
- ⁸The limits apply to projectile fragment charges of 17, 19, 20, 22, 23 in units of e/3.
- ⁹The limits apply to projectile fragment charges of 16, 17, 19, 20, 22, 23 in units of e/3.
- ¹⁰Flux limits and mass range depend on charge.
- ¹¹Bound to nuclei.
- ¹²Quark lifetimes $> 1 \times 10^{-8}$ s.
- ¹³One candidate $m < 0.17$ GeV.

- See AGNESE 15 Fig.6 for limits on vertical density as function of charge extending to $|q|/e < 1/10$.
- AMBROSIO 00c limit is below 11×10^{-15} for $0.25 < q/e < 0.5$, and is changing rapidly near $q/e=2/3$, where it is 2×10^{-14} .
- Distribution in celestial sphere was described as anisotropic.
- With telescope axis at zenith angle 40° to the south.
- Lepton quarks.
- Lifetime $> 10^{-8}$ s; charge $\pm 0.70, 0.68, 0.42$; and mass $> 4.4, 4.8, \text{ and } 20$ GeV, respectively.
- Time delayed air shower search.
- Prompt air shower search.
- Also $e/4$ and $e/6$ charges.
- No events in subsequent experiments.

1 95% CL limit for fractional charge particles with $0.18e \leq |Q_{residual}| \leq 0.82e$ in total of 70.1 mg of silicone oil.

2 95% CL limit for particles with fractional charge $|Q_{residual}| > 0.16e$ in total of 17.4 mg of silicone oil.

3 Also set limits for $Q = \pm e/6$.

4 Note that in PHILLIPS 88 these authors report a subtle magnetic effect which could account for the apparent fractional charges.

5 Limit inferred by JONES 77B.

LIGHT UNFLAVORED MESONS
(S = C = B = 0)

For $l = 1$ (π, b, ρ, a): $u\bar{d}, (u\bar{u}-d\bar{d})/\sqrt{2}, d\bar{u}$;
for $l = 0$ ($\eta, \eta', h, h', \omega, \phi, f, f'$): $c_1(u\bar{u} + d\bar{d}) + c_2(s\bar{s})$

$$J^G(J^P) = 1^-(0^-)$$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** 1 (1988).

π^\pm MASS

The most accurate charged pion mass measurements are based upon x-ray wavelength measurements for transitions in π^- -mesonic atoms. The observed line is the blend of three components, corresponding to different K-shell occupancies. JECKELMANN 94 revisits the occupancy question, with the conclusion that two sets of occupancy ratios, resulting in two different pion masses (Solutions A and B), are equally probable. We choose the higher Solution B since only this solution is consistent with a positive mass-squared for the muon neutrino, given the precise muon momentum measurements now available (DAUM 91, ASSAMAGAN 94, and ASSAMAGAN 96) for the decay of pions at rest. Earlier mass determinations with π -mesonic atoms may have used incorrect K-shell screening corrections.

Measurements with an error of > 0.005 MeV have been omitted from this Listing.

¹ LENZ 98 result does not suffer K-electron configuration uncertainties as does JECKELMANN 94.
² JECKELMANN 94 Solution B (dominant 2-electron K-shell occupancy), chosen for consistency with positive $m_{\nu_\mu}^2$.
³ ASSAMAGAN 96 measures the μ^+ momentum p_μ in $\pi^+ \rightarrow \mu^+ \nu_\mu$ decay at rest to be 29.79200 ± 0.00011 MeV/c. Combined with the μ^+ mass and the assumption $m_{\nu_\mu} = 0$, this gives the π^+ mass above; if $m_{\nu_\mu} > 0$, m_{π^+} given above is a lower limit. Combined instead with m_μ and (assuming *CPT*) the π^- mass of JECKELMANN 94, p_μ gives an upper limit on m_{ν_μ} (see the ν_μ).
⁴ JECKELMANN 94 Solution A (small 2-electron K-shell occupancy) in combination with either the DAUM 91 or ASSAMAGAN 94 pion decay muon momentum measurement yields a significantly negative $m_{\nu_\mu}^2$. It is accordingly not used in our fits.
⁵ The DAUM 91 value includes the ABELA 84 result. The value is based on a measurement of the μ^+ momentum for π^+ decay at rest, $p_\mu = 29.79179 \pm 0.00053$ MeV, uses $m_\mu = 105.658389 \pm 0.000034$ MeV, and assumes that $m_{\nu_\mu} = 0$. The last assumption means that in fact the value is a lower limit.
⁶ JECKELMANN 86b gives $m_\pi/m_e = 273.12677(71)$. We use $m_e = 0.51099906(15)$ MeV from COHEN 87. The authors note that two solutions for the probability distribution of K-shell occupancy fit equally well, and use other data to choose the lower of the two possible π^\pm masses.
⁷ These values are scaled with a new wavelength-energy conversion factor $V\lambda = 1.23984244(37) \times 10^{-6}$ eV m from COHEN 87. The LU 80 screening correction relies upon a theoretical calculation of inner-shell refilling rates.
⁸ This MARUSHENKO 76 value used at the authors' request to use the accepted set of calibration γ energies. Error increased from 0.0017 MeV to include QED calculation error of 0.0017 MeV (12 ppm).

Γ_7 $e^+ \nu_e \nu \bar{\nu}$	< 5	× 10^{-6} 90%

Lepton Family number (LF) or Lepton number (L) violating modes

Γ_8 $\mu^+ \bar{\nu}_e$	L	[c] < 1.5	× 10^{-3} 90%
Γ_9 $\mu^+ \nu_e$	LF	[c] < 8.0	× 10^{-3} 90%
Γ_{10} $\mu^- e^+ e^+ \nu$	LF	< 1.6	× 10^{-6} 90%

[a] Measurements of $\Gamma(e^+ \nu_e)/\Gamma(\mu^+ \nu_\mu)$ always include decays with γ 's, and measurements of $\Gamma(e^+ \nu_e \gamma)$ and $\Gamma(\mu^+ \nu_\mu \gamma)$ never include low-energy γ 's. Therefore, since no clean separation is possible, we consider the modes with γ 's to be subreactions of the modes without them, and let $[\Gamma(e^+ \nu_e) + \Gamma(\mu^+ \nu_\mu)]/\Gamma_{\text{total}} = 100\%$.

[b] See the Particle Listings below for the energy limits used in this measurement; low-energy γ 's are not included.

[c] Derived from an analysis of neutrino-oscillation experiments.

FORM FACTORS FOR RADIATIVE PION AND KAON DECAYS

Updated August 2015 by M. Bychkov (University of Virginia) and G. D'Ambrosio (INFN Sezione di Napoli)

The radiative decays, $\pi^\pm \rightarrow l^\pm \nu \gamma$ and $K^\pm \rightarrow l^\pm \nu \gamma$, with l standing for an e or a μ , and γ for a real or virtual photon ($e^+ e^-$ pair), provide a powerful tool to investigate the hadronic structure of pions and kaons. The structure-dependent part SD_i of the amplitude describes the emission of photons from virtual hadronic states, and is parametrized in terms of form factors V, A , (vector, axial vector), in the standard description [1,2,3,4]. Note that in the Listings below and some literature, equivalent nomenclature F_V and F_A for the vector and axial form factors is often used. Exotic, non-standard contributions like $i = T, S$ (tensor, scalar) have also been considered. Apart from the SD terms, there is also the Inner Bremsstrahlung amplitude, IB, corresponding to photon radiation from external charged particles and described by Low theorem in terms of the physical decay $\pi^\pm (K^\pm) \rightarrow l^\pm \nu$. Experiments try to optimize their kinematics so as to minimize the IB part of the amplitude.

The SD amplitude in its standard form is given as

$$M(SD_V) = \frac{-eG_F U_{qq'}}{\sqrt{2}m_P} \epsilon^\mu l^\nu V^P \epsilon_{\mu\nu\sigma\tau} k^\sigma q^\tau \quad (1)$$

$$M(SD_A) = \frac{-ieG_F U_{qq'}}{\sqrt{2}m_P} \epsilon^\mu l^\nu \{A^P [(qk - k^2)g_{\mu\nu} - q_\mu k_\nu] + R^P k^2 g_{\mu\nu}\}, \quad (2)$$

which contains an additional axial form factor R^P which only can be accessed if the photon remains virtual. $U_{qq'}$ is the Cabibbo-Kobayashi-Maskawa mixing-matrix element; ϵ^μ is the polarization vector of the photon (or the effective vertex, $\epsilon^\mu = (e/k^2)\bar{u}(p_-)\gamma^\mu v(p_+)$, of the e^+e^- pair); $\ell^\nu = \bar{u}(p_\nu)\gamma^\nu(1 - \gamma_5)v(p_\ell)$ is the lepton-neutrino current; q and k are the meson and photon four-momenta ($k = p_+ + p_-$ for virtual photons); and P stands for π or K .

The pion vector form factor, V^π , is related via CVC (Conserved Vector Current) to the $\pi^0 \rightarrow \gamma\gamma$ decay width. The constant term is given by $|V^\pi(0)| = (1/\alpha)\sqrt{2\Gamma_{\pi^0 \rightarrow \gamma\gamma}/\pi m_{\pi^0}}$ [3]. The resulting value, $V^\pi(0) = 0.0259(9)$, has been confirmed by calculations based on chiral perturbation theory (χPT) [4], and by two experiments given in the Listings below. A recent experiment by the PIBETA collaboration [5] obtained a $V^\pi(0)$ that is in excellent agreement with the CVC hypothesis. It also measured the slope parameter a in $V^\pi(s) = V^\pi(0)(1 + a \cdot s)$, where $s = (1 - 2E_\gamma/m_\pi)$, and E_γ is the gamma energy in the pion rest frame: $a = 0.095 \pm 0.058$. A functional dependence on s is expected for all form factors. It becomes non-negligible in the case of $V^\pi(s)$ when a wide range of photon momenta is recorded; proper treatment in the analysis of K decays is mandatory.

The form factor, R^P , can be related to the electromagnetic radius, r_P , of the meson [2]: $R^P = \frac{1}{3}m_P f_P \langle r_P^2 \rangle$ using PCAC (Partial Conserved Axial vector Current; f_P is the meson decay constant). In lowest order χPT , the ratio A^π/V^π is related to the pion electric polarizability $\alpha_E = [\alpha/(8\pi^2 m_\pi f_\pi^2)] \times A^\pi/V^\pi$ [6]. The experimental and theoretical status of the pion polarizability is currently an area under discussion and will be addressed in a future edition of this article. The first non-trivial χPT contributions to A^K and V^K appear at $\mathcal{O}(p^4)$ [4], respectively from Gasser-Leutwyler coefficients, L_i 's, and the anomalous lagrangian:

$$A^K = \frac{4\sqrt{2}M_K}{F_\pi}(L_9^r + L_{10}^r) = 0.042, \quad V^K = \frac{\sqrt{2}M_K}{8\pi^2 F_\pi} = 0.096. \quad (3)$$

$\mathcal{O}(p^6)$ contributions to A^K can be predicted accurately: they are flat in the momentum dependence and shift the $\mathcal{O}(p^4)$ value to 0.034. $\mathcal{O}(p^6)$ contributions to V^K are model dependent and can be approximated by a form factor linearly dependent on momentum. For example, when looking at the spread of results obtained within two different models, the constant piece of this linear form factor is shifted to 0.078 ± 0.005 [1,2,4].

For decay processes where the photon is real, the partial decay width can be written in analytical form as a sum of IB, SD, and IB/SD interference terms INT [1,4]:

$$\begin{aligned} \frac{d^2\Gamma_{P \rightarrow \ell\nu\gamma}}{dx dy} &= \frac{d^2(\Gamma_{IB} + \Gamma_{SD} + \Gamma_{INT})}{dx dy} \\ &= \frac{\alpha}{2\pi}\Gamma_{P \rightarrow \ell\nu} \frac{1}{(1-r)^2} \left\{ \text{IB}(x, y) \right. \end{aligned}$$

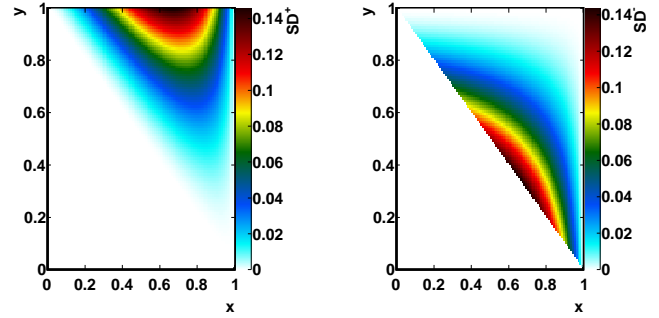

Figure 1: Components of the structure dependent terms of the decay width. Left: SD^+ , right: SD^-

$$\begin{aligned} &+ \frac{1}{r} \left(\frac{m_P}{2f_P} \right)^2 \left[(V+A)^2 \text{SD}^+(x, y) + (V-A)^2 \text{SD}^-(x, y) \right] \\ &+ \frac{m_P}{f_P} \left[(V+A) \text{S}_{\text{INT}}^+(x, y) + (V-A) \text{S}_{\text{INT}}^-(x, y) \right] \}. \quad (4) \end{aligned}$$

Here

$$\begin{aligned} \text{IB}(x, y) &= \left[\frac{1-y+r}{x^2(x+y-1-r)} \right] \\ &\quad \left[x^2 + 2(1-x)(1-r) - \frac{2xr(1-r)}{x+y-1-r} \right] \\ \text{SD}^+(x, y) &= (x+y-1-r) \left[(x+y-1)(1-x) - r \right] \\ \text{SD}^-(x, y) &= (1-y+r) \left[(1-x)(1-y) + r \right] \\ \text{S}_{\text{INT}}^+(x, y) &= \left[\frac{1-y+r}{x(x+y-1-r)} \right] \left[(1-x)(1-x-y) + r \right] \\ \text{S}_{\text{INT}}^-(x, y) &= \left[\frac{1-y+r}{x(x+y-1-r)} \right] \left[x^2 - (1-x)(1-x-y) - r \right] \end{aligned} \quad (5)$$

where $x = 2E_\gamma/m_P$, $y = 2E_\ell/m_P$, and $r = (m_\ell/m_P)^2$. The structure dependent terms SD^+ and SD^- are shown in Fig. 1. The SD^- term is maximized in the same kinematic region where overwhelming IB term dominates (along $x+y=1$ diagonal). Thus experimental yields with less background are dominated by SD^+ contribution and proportional to $A^P + V^P$ making simultaneous precise determination of the form factors difficult.

Recently, formulas (4) and (5) have been extended to describe polarized distributions in radiative meson and muon decays [7].

The ‘‘helicity’’ factor r is responsible for the enhancement of the SD over the IB amplitude in the decays $\pi^\pm \rightarrow e^\pm \nu \gamma$, while $\pi^\pm \rightarrow \mu^\pm \nu \gamma$ is dominated by IB. Interference terms are important for the decay $K^\pm \rightarrow \mu^\pm \nu \gamma$ [8], but contribute only a few percent correction to pion decays. However, they provide the basis for determining the signs of V and A . Radiative corrections to the decay $\pi^+ \rightarrow e^+ \nu \gamma$ have to be taken into account in the analysis of the precision experiments. They

Meson Particle Listings

 π^\pm

make up to 4% corrections in the total decay rate [9]. In $\pi^\pm \rightarrow e^\pm \nu e^+ e^-$ and $K^\pm \rightarrow \ell^\pm \nu e^+ e^-$ decays, all three form factors, V^P , A^P , and R^P , can be determined [10,11].

We give the experimental π^\pm form factors F_T^π , A^π , and R^π in the Listings below. In the K^\pm Listings, we give the extracted sum $A^K + V^K$ and difference $A^K - V^K$, as well as V^K , A^K and R^K . In particular KLOE has measured for the constant piece of the form factor $A^K + V^K = 0.125 \pm 0.007 \pm 0.001$ [13] while Istra+, $V^K - A^K = 0.21 \pm 0.04 \pm 0.04$ [14].

Several searches for the exotic form factors F_T^π , F_T^K (tensor), and F_S^K (scalar) have been pursued in the past. In particular, F_T^π has been brought into focus by experimental as well as theoretical work [12]. New high-statistics data from the PIBETA collaboration have been re-analyzed together with an additional data set optimized for low backgrounds in the radiative pion decay. In particular, lower beam rates have been used in order to reduce the accidental background, thereby making the treatment of systematic uncertainties easier and more reliable. The PIBETA analysis now restricts F_T^π to the range $-5.2 \times 10^{-4} < F_T^\pi < 4.0 \times 10^{-4}$ at a 90% confidence limit [5]. This result is in excellent agreement with the most recent theoretical work [4].

Precision measurements of radiative pion and kaon decays are effective tools to study QCD in the non-perturbative region and are of interest beyond the scope of radiative decays. Meanwhile other processes such as $\pi^+ \rightarrow e^+ \nu$ that seem to be better suited to search for new physics at the precision frontier are currently studied. The advantages of such process are the very accurate and reliable theoretical predictions and the more straightforward experimental analysis.

4.6056 ± 0.0055	CZIRR 63	CNTR	

 π^0 MEAN LIFE

Most experiments measure the π^0 width which we convert to a lifetime. AHERTON 85 is the only direct measurement of the π^0 lifetime. Our average based only on indirect measurement yields $(8.30 \pm 0.19) \times 10^{-17}$ s. The two Primakoff measurements from 1970 have been excluded from our average because they suffered model-related systematics unknown at the time. More information on the π^0 lifetime can be found in BERNSTEIN 13.

VALUE (10^{-17} s)	EVS	DOCUMENT ID	TECN	COMMENT
8.52±0.18 OUR AVERAGE				Error includes scale factor of 1.2.

9 ± 0.68		KRYSHKIN 70	CNTR	Primakoff effect
7.3 ± 1.1		BELLETTINI 65B	CNTR	Primakoff effect

- ¹LARIN 11 reported $\Gamma(\pi^0 \rightarrow \gamma\gamma) = 7.82 \pm 0.14 \pm 0.17$ eV which we converted to mean life $\tau = \hbar/\Gamma$ (total).
- ²BYCHKOV 09 obtains this using the conserved-vector-current relation between the vector form factor F_V and the π^0 lifetime.
- ³WILLIAMS 88 gives $\Gamma(\gamma\gamma) = 7.7 \pm 0.5 \pm 0.5$ eV. We give here $\tau = \hbar/\Gamma$ (total).
- ⁴BROWMAN 74 gives a π^0 width $\Gamma = 8.02 \pm 0.42$ eV. The mean life is \hbar/Γ .

 π^0 DECAY MODES

For decay limits to particles which are not established, see the appropriate Search sections (A^0 (axion) and Other Light Boson (X^0) Searches, etc.).

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Γ_1 2 γ	(98.823±0.034) %	S=1.5
Γ_2 $e^+ e^- \gamma$	(1.174±0.035) %	S=1.5
Γ_3 γ positronium	(1.82 ± 0.29) × 10 ⁻⁹	
Γ_4 $e^+ e^- e^- e^-$	(3.34 ± 0.16) × 10 ⁻⁵	
Γ_5 $e^+ e^-$	(6.46 ± 0.33) × 10 ⁻⁸

[a] Astrophysical and cosmological arguments give limits of order 10^{-13} ; see the Particle Listings below.

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 6 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 4.6$ for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

π^0 ELECTROMAGNETIC FORM FACTOR

The amplitude for the process $\pi^0 \rightarrow e^+ e^- \gamma$ contains a form factor $F(x)$ at the $\pi^0 \gamma \gamma$ vertex, where $x = [m_{e^+ e^-} / m_{\pi^0}]^2$. The parameter a in the linear expansion $F(x) = 1 + ax$ is listed below.

All the measurements except that of BEHREND 91 are in the time-like region of momentum transfer.

LINEAR COEFFICIENT OF π^0 ELECTROMAGNETIC FORM FACTOR

20 BEHREND 91 estimates that their systematic error is of the same order of magnitude as their statistical error, and so we have included a systematic error of this magnitude. The value of a is obtained by extrapolation from the region of large space-like momentum transfer assuming vector dominance.					
21 TUPPER 83 is a theoretical analysis of FISCHER 78 including 2-photon exchange in the corrections.					
22 The FISCHER 78 error is statistical only. The result without radiation corrections is +0.05 ± 0.03.

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** (1988).

η MASS

Recent measurements resolve the obvious inconsistency in previous η mass measurements in favor of the higher value first reported by NA48 (LA1 02). We use only precise measurements consistent with this higher mass value for our η mass average.

[a] C parity forbids this to occur as a single-photon process.

CONSTRAINED FIT INFORMATION

An overall fit to 2 decay rate and 19 branching ratios uses 50 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 43.8$ for 42 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

0.324 ± 0.046		BROWMAN	74B	CNTR Primakoff effect
1.00 ± 0.22		² BEMPORAD	67	CNTR Primakoff effect

¹ RODRIGUES 08 uses a more sophisticated calculation for the inelastic background due to incoherent photoproduction to reanalyze the η photoproduction data on Be and Cu at 9 GeV from BROWMAN 74B. This brings the value of $\Gamma(\eta \rightarrow 2\gamma)$ in line with direct measurements of the width. The error here is only statistical.

² BEMPORAD 67 gives $\Gamma(2\gamma) = 1.21 \pm 0.26$ keV assuming $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.314$. Bemporad private communication gives $\Gamma(2\gamma)^2/\Gamma(\text{total}) = 0.380 \pm 0.083$. We evaluate this using $\Gamma(2\gamma)/\Gamma(\text{total}) = 0.38 \pm 0.01$. Not included in average because the uncertainty resulting from the separation of the coulomb and nuclear amplitudes has apparently been underestimated.

••• We do not use the following data for averages, fits, limits, etc. •••			
0.12 ± 0.06		¹ THALER 72	ASPK

¹The authors don't believe this indicates D -wave because the dependence of β on the γ energy is inconsistent with the theoretical prediction. A $\cos^2\theta$ dependence can also come from P - and F -wave interference.

 η CP -NONCONSERVING DECAY PARAMETER $\pi^+\pi^-e^+e^-$ DECAY-PLANE ASYMMETRY PARAMETER A_ϕ

In the η rest frame, the total momentum of the e^+e^- pair is equal and opposite to that of the $\pi^+\pi^-$ pair. Let \hat{z} be the unit vector along the momentum of the e^+e^- pair; let \hat{n}_{ee} and $\hat{n}_{\pi\pi}$ be the unit vectors normal to the e^+e^- and $\pi^+\pi^-$ planes; and let ϕ be the angle between the two normals. Then

$$\sin\phi \cos\phi = [(\hat{n}_{ee} \times \hat{n}_{\pi\pi}) \cdot \hat{z}] (\hat{n}_{ee} \cdot \hat{n}_{\pi\pi}),$$

and

$$A_\phi \equiv \frac{N_{\sin\phi \cos\phi > 0} - N_{\sin\phi \cos\phi < 0}}{N_{\sin\phi \cos\phi > 0} + N_{\sin\phi \cos\phi < 0}}.$$

NOTE ON SCALAR MESONS BELOW 2 GEV

Revised November 2015 by C. Amsler (Univ. of Bern), S. Eidelman (Budker Institute of Nuclear Physics, Novosibirsk), T. Gutsche (University of Tübingen), C. Hanhart (Forschungszentrum Jülich), S. Spanier (University of Tennessee), and N.A. Törnqvist (University of Helsinki)

I. Introduction: In contrast to the vector and tensor mesons, the identification of the scalar mesons is a long-standing puzzle. Scalar resonances are difficult to resolve because some of them have large decay widths which cause a strong overlap between resonances and background. In addition, several decay channels sometimes open up within a short mass interval (*e.g.* at the $K\bar{K}$ and $\eta\eta$ thresholds), producing cusps in the line shapes of the near-by resonances. Furthermore, one expects non- $q\bar{q}$ scalar objects, such as glueballs and multiquark states in the mass range below 2 GeV (for reviews see, *e.g.*, Refs. [1–5] and the mini-review on *non- $q\bar{q}$ states* in this Review of Particle Physics (RPP)).

Light scalars are produced, for example, in πN scattering on polarized/unpolarized targets, $p\bar{p}$ annihilation, central hadronic production, J/Ψ , B^- , D^- and K -meson decays, $\gamma\gamma$ formation, and ϕ radiative decays. Especially for the lightest scalar mesons simple parameterizations fail and more advanced theory tools are necessary to extract the resonance parameters from data. In the analyses available in the literature fundamental properties of the amplitudes such as unitarity, analyticity, Lorentz invariance, chiral and flavor symmetry are implemented at different levels of rigor. Especially, chiral symmetry implies the appearance of zeros close to the threshold in elastic S -wave scattering amplitudes involving soft pions [6,7], which may be shifted or removed in associated production processes [8]. The methods employed are the K -matrix formalism, the N/D -method, the Dalitz–Tuan ansatz, unitarized quark models with coupled channels, effective chiral field theories and the linear sigma model, *etc.* Dynamics near the lowest two-body thresholds in some analyses are described by crossed channel (t , u) meson exchange or with an effective range parameterization instead of, or in addition to, resonant features in the s -channel. Dispersion theoretical approaches are applied to pin down the location of resonance poles for the low-lying states [9–12].

The mass and width of a resonance are found from the position of the nearest pole in the process amplitude (T -matrix or S -matrix) at an unphysical sheet of the complex energy plane, traditionally labeled as

$$\sqrt{s_{\text{Pole}}} = M - i\Gamma/2 .$$

It is important to note that the pole of a Breit-Wigner parameterization agrees with this pole position only for narrow

and well-separated resonances, far away from the opening of decay channels. For a detailed discussion of this issue we refer to the review on *Resonances* in this RPP.

In this note, we discuss the light scalars below 2 GeV organized in the listings under the entries ($I = 1/2$) $K_0^*(800)$ (or κ , currently omitted from the summary table), $K_0^*(1430)$, ($I = 1$) $a_0(980)$, $a_0(1450)$, and ($I = 0$) $f_0(500)$ (or σ), $f_0(980)$, $f_0(1370)$, $f_0(1500)$, and $f_0(1710)$. This list is minimal and does not necessarily exhaust the list of actual resonances. The ($I = 2$) $\pi\pi$ and ($I = 3/2$) $K\pi$ phase shifts do not exhibit any resonant behavior.

II. The $I = 1/2$ States: The $K_0^*(1430)$ [13] is perhaps the least controversial of the light scalar mesons. The $K\pi$ S -wave scattering has two possible isospin channels, $I = 1/2$ and $I = 3/2$. The $I = 3/2$ wave is elastic and repulsive up to 1.7 GeV [14] and contains no known resonances. The $I = 1/2$ $K\pi$ phase shift, measured from about 100 MeV above threshold in Kp production, rises smoothly, passes 90° at 1350 MeV, and continues to rise to about 170° at 1600 MeV. The first important inelastic threshold is $K\eta'(958)$. In the inelastic region the continuation of the amplitude is uncertain since the partial-wave decomposition has several solutions. The data are extrapolated towards the $K\pi$ threshold using effective range type formulas [13,15] or chiral perturbation predictions [16,17]. From analyses using unitarized amplitudes there is agreement on the presence of a resonance pole around 1410 MeV having a width of about 300 MeV. With reduced model dependence, Ref. [18] finds a larger width of 500 MeV.

Similar to the situation for the $f_0(500)$, discussed in the next section, the presence and properties of the light $K_0^*(800)$ (or κ) meson in the 700-900 MeV region are difficult to establish since it appears to have a very large width ($\Gamma \approx 500$ MeV) and resides close to the $K\pi$ threshold. Hadronic D - and B -meson decays provide additional data points in the vicinity of the $K\pi$ threshold and are discussed in detail in the *Review on Multibody Charm Analyses* in this RPP. Precision information from semileptonic D decays avoiding theoretically ambiguous three-body final state interactions is not available. BES II [19] (re-analyzed in [20]) finds a $K_0^*(800)$ -like structure in J/ψ decays to $\bar{K}^{*0}(892)K^+\pi^-$ where $K_0^*(800)$ recoils against the $K^*(892)$. Also clean with respect to final state interaction is the decay $\tau^- \rightarrow K_S^0\pi^-\nu_\tau$ studied by Belle [21], with $K_0^*(800)$ parameters fixed to those of Ref. [19].

Some authors find a $K_0^*(800)$ pole in their phenomenological analysis (see, *e.g.*, [22–33]), while others do not need to include it in their fits (see, *e.g.*, [17,34–37]). Similarly to the case of the $f_0(500)$ discussed below, all works including constraints from chiral symmetry at low energies naturally seem to find a light $K_0^*(800)$ below 800 MeV, see, *e.g.*, [38–42]. In these works the $K_0^*(800)$, $f_0(500)$, $f_0(980)$ and $a_0(980)$ appear to form a nonet [39,40]. Additional evidence for this assignment is presented in Ref. [12], where the couplings of the nine states to $q\bar{q}$ sources were compared. The same low-lying scalar nonet was

Meson Particle Listings

$f_0(500)$

also found earlier in the unitarized quark model of Ref. [41]. The analysis of Ref. [43] is based on the Roy-Steiner equations, which include analyticity and crossing symmetry. It establishes the existence of a light $K_0^*(800)$ pole in the $K\pi \rightarrow K\pi$ amplitude on the second sheet. In Ref. [44] a first lattice study for the $K\pi$ S-wave system is presented, however, with a pion mass of 400 MeV it can not be compared to data yet.

III. The $I = 1$ States: Two isovector scalar states are known below 2 GeV, the $a_0(980)$ and the $a_0(1450)$. Independent of any model, the $K\bar{K}$ component in the $a_0(980)$ wave function must be large: it lies just below the opening of the $K\bar{K}$ channel to which it strongly couples [15,45]. This generates an important cusp-like behavior in the resonant amplitude. Hence, its mass and width parameters are strongly distorted. To reveal its true coupling constants, a coupled-channel model with energy-dependent widths and mass shift contributions is necessary. All listed $a_0(980)$ measurements agree on a mass position value near 980 MeV, but the width takes values between 50 and 100 MeV, mostly due to the different models. For example, the analysis of the $p\bar{p}$ -annihilation data [15] using a unitary K -matrix description finds a width as determined from the T -matrix pole of 92 ± 8 MeV, while the observed width of the peak in the $\pi\eta$ mass spectrum is about 45 MeV.

The relative coupling $K\bar{K}/\pi\eta$ is determined indirectly from $f_1(1285)$ [46–48] or $\eta(1410)$ decays [49–51], from the line shape observed in the $\pi\eta$ decay mode [52–55], or from the coupled-channel analysis of the $\pi\pi\eta$ and $K\bar{K}\pi$ final states of $p\bar{p}$ annihilation at rest [15].

The $a_0(1450)$ is seen in $p\bar{p}$ annihilation experiments with stopped and higher momenta antiprotons, with a mass of about 1450 MeV or close to the $a_2(1320)$ meson which is typically a dominant feature. A contribution from $a_0(1450)$ is also found in the analysis of the $D^\pm \rightarrow K^+K^-\pi^\pm$ decay [56]. The broad structure at about 1300 MeV observed in $\pi N \rightarrow K\bar{K}N$ reactions [57] needs still further confirmation in its existence and isospin assignment.

IV. The $I = 0$ States: The $I = 0, J^{PC} = 0^{++}$ sector is the most complex one, both experimentally and theoretically. The data have been obtained from the $\pi\pi$, $K\bar{K}$, $\eta\eta$, 4π , and $\eta\eta'(958)$ systems produced in S -wave. Analyses based on several different production processes conclude that probably four poles are needed in the mass range from $\pi\pi$ threshold to about 1600 MeV. The claimed isoscalar resonances are found under separate entries $f_0(500)$ (or σ), $f_0(980)$, $f_0(1370)$, and $f_0(1500)$.

For discussions of the $\pi\pi$ S wave below the $K\bar{K}$ threshold and on the long history of the $f_0(500)$, which was suggested in linear sigma models more than 50 years ago, see our reviews in previous editions and the recent review [5].

Information on the $\pi\pi$ S -wave phase shift $\delta_J^I = \delta_0^0$ was already extracted many years ago from πN scattering [58–60],

and near threshold from the K_{e4} -decay [61]. The kaon decays were later revisited leading to consistent data, however, with very much improved statistics [62,63]. The reported $\pi\pi \rightarrow K\bar{K}$ cross sections [64–67] have large uncertainties. The πN data have been analyzed in combination with high-statistics data (see entries labeled as RVUE for re-analyses of the data). The $2\pi^0$ invariant mass spectra of the $p\bar{p}$ annihilation at rest [68–70] and the central collision [71] do not show a distinct resonance structure below 900 MeV, but these data are consistently described with the standard solution for πN data [59,72], which allows for the existence of the broad $f_0(500)$. An enhancement is observed in the $\pi^+\pi^-$ invariant mass near threshold in the decays $D^+ \rightarrow \pi^+\pi^-\pi^+$ [73–101] and $J/\psi \rightarrow \omega\pi^+\pi^-$ [76,98], and in $\psi(2S) \rightarrow J/\psi\pi^+\pi^-$ with very limited phase space [78,79].

The precise $f_0(500)$ (or σ) pole is difficult to establish because of its large width, and because it can certainly not be modeled by a naive Breit-Wigner resonance. For the same reason a splitting in background and resonance contributions is not possible in a model-independent way. The $\pi\pi$ scattering amplitude shows an unusual energy dependence due to the presence of a zero in the unphysical regime close to the threshold [6–7], required by chiral symmetry, and possibly due to crossed channel exchanges, the $f_0(1370)$, and other dynamical features. However, most of the analyses listed under $f_0(500)$ agree on a pole position near $(500 - i250)$ MeV. In particular, analyses of $\pi\pi$ data that include unitarity, $\pi\pi$ threshold behavior, strongly constrained by the K_{e4} data, and the chiral symmetry constraints from Adler zeroes and/or scattering lengths find a light $f_0(500)$, see, *e.g.*, [80,81].

Precise pole positions with an uncertainty of less than 20 MeV (see our table for the T -matrix pole) were extracted by use of Roy equations, which are twice subtracted dispersion relations derived from crossing symmetry and analyticity. In Ref. [10] the subtraction constants were fixed to the S -wave scattering lengths a_0^0 and a_0^2 derived from matching Roy equations and two-loop chiral perturbation theory [9]. The only additional relevant input to fix the $f_0(500)$ pole turned out to be the $\pi\pi$ -wave phase shifts at 800 MeV. The analysis was improved further in Ref. [12]. Alternatively, in Ref. [11] only data were used as input inside Roy equations. In that reference also once-subtracted Roy-like equations, called GKPY equations, were used, since the extrapolation into the complex plane based on the twice subtracted equations leads to larger uncertainties mainly due to the limited experimental information on the isospin-2 $\pi\pi$ scattering length. All these extractions find consistent results. Using analyticity and unitarity only to describe data from $K_{2\pi}$ and K_{e4} decays, Ref. [82] finds consistent values for the pole position and the scattering length a_0^0 . The importance of the $\pi\pi$ scattering data for fixing the $f_0(500)$ pole is nicely illustrated by comparing analyses of $p\bar{p} \rightarrow 3\pi^0$ omitting [68,83] or including [69,84] information on $\pi\pi$ scattering: while the former analyses find an extremely broad structure above 1 GeV, the latter find $f_0(500)$ masses of the order of 400 MeV.

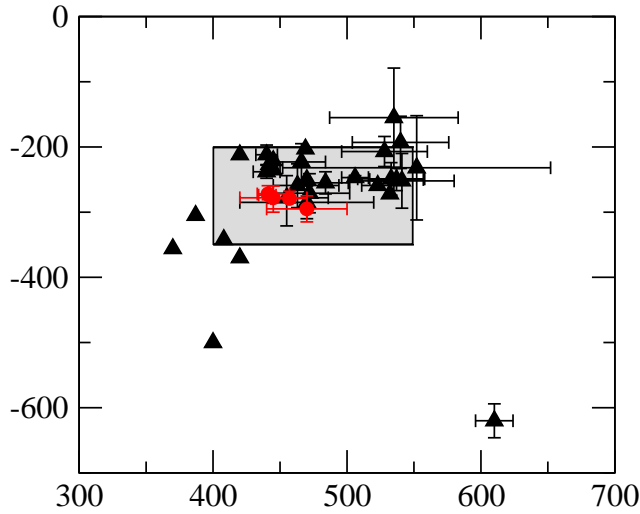

Figure 1: Location of the $f_0(500)$ (or σ) poles in the complex energy plane. Circles denote the recent analyses based on Roy(-like) dispersion relations [9–12], while all other analyses are denoted by triangles. The corresponding references are given in the listing.

As a result of the sensitivity of the extracted $f_0(500)$ pole position on the high accuracy low energy $\pi\pi$ scattering data [62,63], the currently quoted range of pole positions for the $f_0(500)$, namely

$$\sqrt{s_{\text{Pole}}^{\sigma}} = (400 - 550) - i(200 - 350) \text{ MeV} ,$$

in the listing was fixed including only those analyses consistent with these data, Refs. [26,29,39,41,42,54,69,78–82,85–101] as well as the advanced dispersion analyses [9–12]. The pole positions from those references are compared to the range of pole positions quoted above in Fig. 1. Note that this range is labeled as 'our estimate' — it is not an average over the quoted analyses but is chosen to include the bulk of the analyses consistent with the mentioned criteria. An averaging procedure is not justified, since the analyses use overlapping or identical data sets.

One might also take the more radical point of view and just average the most advanced dispersive analyses, Refs. [9–12], shown as solid dots in Fig. 1, for they provide a determination of the pole positions with minimal bias. This procedure leads to the much more restricted range of $f_0(500)$ parameters

$$\sqrt{s_{\text{Pole}}^{\sigma}} = (446 \pm 6) - i(276 \pm 5) \text{ MeV} .$$

Due to the large strong width of the $f_0(500)$ an extraction of its two-photon width directly from data is not possible. Thus, the values for $\Gamma(\gamma\gamma)$ quoted in the literature as well as the listing are based on the expression in the narrow width approximation [102] $\Gamma(\gamma\gamma) \simeq \alpha^2 |g_{\gamma}|^2 / (4\text{Re}(\sqrt{s_{\text{Pole}}^{\sigma}}))$ where g_{γ} is derived from the residue at the $f_0(500)$ pole to two photons and α denotes the electromagnetic fine structure constant.

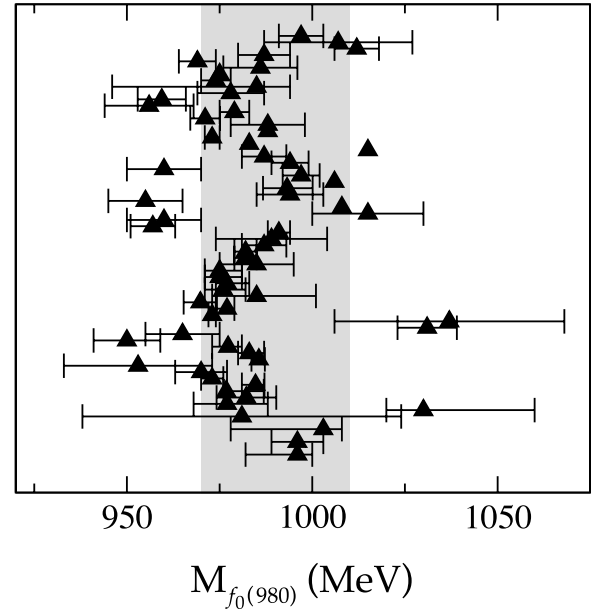

Figure 2: Values of the $f_0(980)$ masses as they appear in the listing compared to the currently quoted mass estimate. The newest references appear at the bottom, the oldest on the top. The corresponding references are given in the listing.

The explicit form of the expression may vary between different authors due to different definitions of the coupling constant, however, the expression given for $\Gamma(\gamma\gamma)$ is free of ambiguities. According to Refs. [103,104], the data for $f_0(500) \rightarrow \gamma\gamma$ are consistent with what is expected for a two-step process of $\gamma\gamma \rightarrow \pi^+\pi^-$ via pion exchange in the t - and u -channel, followed by a final state interaction $\pi^+\pi^- \rightarrow \pi^0\pi^0$. The same conclusion is drawn in Ref. [105] where the bulk part of the $f_0(500) \rightarrow \gamma\gamma$ decay width is dominated by re-scattering. Therefore, it might be difficult to learn anything new about the nature of the $f_0(500)$ from its $\gamma\gamma$ coupling. For the most recent work on $\gamma\gamma \rightarrow \pi\pi$, see [106–108]. There are theoretical indications (*e.g.*, [109–112]) that the $f_0(500)$ pole behaves differently from a $q\bar{q}$ -state – see next section and the mini-review on *non* $q\bar{q}$ -states in this RPP for details.

The **$f_0(980)$** overlaps strongly with the background represented mainly by the $f_0(500)$ and the $f_0(1370)$. This can lead to a dip in the $\pi\pi$ spectrum at the $K\bar{K}$ threshold. It changes from a dip into a peak structure in the $\pi^0\pi^0$ invariant mass spectrum of the reaction $\pi^-p \rightarrow \pi^0\pi^0n$ [113], with increasing four-momentum transfer to the $\pi^0\pi^0$ system, which means increasing the a_1 -exchange contribution in the amplitude, while the π -exchange decreases. The $f_0(500)$ and the $f_0(980)$ are also observed in data for radiative decays ($\phi \rightarrow f_0\gamma$) from SND [114,115], CMD2 [116], and KLOE [117,118]. A dispersive analysis was used to simultaneously pin down the pole parameters of both the $f_0(500)$ and the $f_0(980)$ [11]; the uncertainty in the pole position quoted for the latter state is

Meson Particle Listings

$f_0(500)$

of the order of 10 MeV, only (see the lowest point in Fig. 2). Compared to the 2010 issue of the *Review of Particle Physics*, in this issue we extended the allowed range of the $f_0(980)$ masses to include the mass value derived in Ref. [11]. We now quote for the mass

$$M_{f_0(980)} = 990 \pm 20 \text{ MeV} .$$

As in case of the $f_0(500)$ (or σ), this range is not an average, but is labeled as 'our estimate'. A comparison of the mass values in the listing and the allocated range is shown in Fig. 2.

Analyses of $\gamma\gamma \rightarrow \pi\pi$ data [119–121] underline the importance of the $K\bar{K}$ coupling of $f_0(980)$, while the resulting two-photon width of the $f_0(980)$ cannot be determined precisely [122]. The prominent appearance of the $f_0(980)$ in the semileptonic D_s decays and decays of B and B_s -mesons implies a dominant ($\bar{s}s$) component: those decays occur via weak transitions that alternatively result in $\phi(1020)$ production. Ratios of decay rates of B and/or B_s mesons into J/ψ plus $f_0(980)$ or $f_0(500)$ were proposed to allow for an extraction of the flavor mixing angle and to probe the tetraquark nature of those mesons within a certain model [123,124]. The phenomenological fits of the LHCb collaboration using the isobar model do neither allow for a contribution of the $f_0(980)$ in the $B \rightarrow J/\psi\pi\pi$ [125] nor for an $f_0(500)$ in $B_s \rightarrow J/\psi\pi\pi$ decays [126]. From the former analysis the authors conclude that their data is incompatible with a model where $f_0(500)$ and $f_0(980)$ are formed from two quarks and two antiquarks (tetraquarks) at the eight standard deviation level. In addition, they extract an upper limit for the mixing angle of 17° at 90% C.L. between the $f_0(980)$ and the $f_0(500)$ that would correspond to a substantial ($\bar{s}s$) content in $f_0(980)$ [125]. However, in a dispersive analysis of the same data that allows for a model-independent inclusion of the hadronic final state interactions in Ref. [127] a substantial $f_0(980)$ contribution is also found in the B -decays putting into question the conclusions of Ref. [125].

The f_0 's above 1 GeV. A meson resonance that is very well studied experimentally, is the $f_0(1500)$ seen by the Crystal Barrel experiment in five decay modes: $\pi\pi$, $K\bar{K}$, $\eta\eta$, $\eta\eta'(958)$, and 4π [15,69,70]. Due to its interference with the $f_0(1370)$ (and $f_0(1710)$), the peak attributed to the $f_0(1500)$ can appear shifted in invariant mass spectra. Therefore, the application of simple Breit-Wigner forms arrives at slightly different resonance masses for $f_0(1500)$. Analyses of central-production data of the likewise five decay modes Refs. [128,129] agree on the description of the S -wave with the one above. The $p\bar{p}$, $p\bar{n}/n\bar{p}$ measurements [70,130–132] show a single enhancement at 1400 MeV in the invariant 4π mass spectra, which is resolved into $f_0(1370)$ and $f_0(1500)$ [133,134]. The data on 4π from central production [135] require both resonances, too, but disagree on the relative content of $\rho\rho$ and $f_0(500)f_0(500)$ in 4π . All investigations agree that the 4π decay mode represents about half of the $f_0(1500)$ decay width and is dominant for $f_0(1370)$.

The determination of the $\pi\pi$ coupling of $f_0(1370)$ is aggravated by the strong overlap with the broad $f_0(500)$ and $f_0(1500)$. Since it does not show up prominently in the 2π spectra, its mass and width are difficult to determine. Multi-channel analyses of hadronically produced two- and three-body final states agree on a mass between 1300 MeV and 1400 MeV and a narrow $f_0(1500)$, but arrive at a somewhat smaller width for $f_0(1370)$.

V. Interpretation of the scalars below 1 GeV: In the literature, many suggestions are discussed, such as conventional $q\bar{q}$ mesons, $q\bar{q}q\bar{q}$ or meson-meson bound states. In addition, one expects a scalar glueball in this mass range. In reality, there can be superpositions of these components, and one often depends on models to determine the dominant one. Although we have seen progress in recent years, this question remains open. Here, we mention some of the present conclusions.

The $f_0(980)$ and $a_0(980)$ are often interpreted as multi-quark states [136–140] or $K\bar{K}$ bound states [141]. The insight into their internal structure using two-photon widths [115,142–148] is not conclusive. The $f_0(980)$ appears as a peak structure in $J/\psi \rightarrow \phi\pi^+\pi^-$ and in D_s decays without $f_0(500)$ background, while being nearly invisible in $J/\psi \rightarrow \omega\pi^+\pi^-$. Based on that observation it is suggested that $f_0(980)$ has a large $s\bar{s}$ component, which according to Ref. [149] is surrounded by a virtual $K\bar{K}$ cloud (see also Ref. [150]). Data on radiative decays ($\phi \rightarrow f_0\gamma$ and $\phi \rightarrow a_0\gamma$) from SND, CMD2, and KLOE (see above) are consistent with a prominent role of kaon loops. This observation is interpreted as evidence for a compact four-quark [151] or a molecular [152,153] nature of these states. Details of this controversy are given in the comments [154,155]; see also Ref. [156]. It remains quite possible that the states $f_0(980)$ and $a_0(980)$, together with the $f_0(500)$ and the $K_0^*(800)$, form a new low-mass state nonet of predominantly four-quark states, where at larger distances the quarks recombine into a pair of pseudoscalar mesons creating a meson cloud (see, *e.g.*, Ref. [157]). Different QCD sum rule studies [158–162] do not agree on a tetraquark configuration for the same particle group.

Models that start directly from chiral Lagrangians, either in non-linear [42,25,80,152] or in linear [163–169] realization, predict the existence of the $f_0(500)$ meson near 500 MeV. Here the $f_0(500)$, $a_0(980)$, $f_0(980)$, and $K_0^*(800)$ (in some models the $K_0^*(1430)$) would form a nonet (not necessarily $q\bar{q}$). In the linear sigma models the lightest pseudoscalars appear as their chiral partners. In these models the light $f_0(500)$ is often referred to as the "Higgs boson of strong interactions", since here the $f_0(500)$ plays a role similar to the Higgs particle in electro-weak symmetry breaking: within the linear sigma models it is important for the mechanism of chiral symmetry breaking, which generates most of the proton mass, and what is referred to as the constituent quark mass.

In the non-linear approaches of [25,80] the above resonances together with the low lying vector states are generated starting from chiral perturbation theory predictions near the first open

channel, and then by extending the predictions to the resonance regions using unitarity and analyticity.

Ref. [163] uses a framework with explicit resonances that are unitarized and coupled to the light pseudoscalars in a chirally invariant way. Evidence for a non- $\bar{q}q$ nature of the lightest scalar resonances is derived from their mixing scheme. In Ref. [164] the scheme is extended and applied to the decay $\eta' \rightarrow \eta\pi\pi$, which lead to the same conclusions. To identify the nature of the resonances generated from scattering equations, in Ref. [170] the large N_c behavior of the poles was studied, with the conclusion that, while the light vector states behave consistent with what is predicted for $\bar{q}q$ states, the light scalars behave very differently. This finding provides strong support for a non- $\bar{q}q$ nature of the light scalar resonances. Note, the more refined study of Ref. [109] found, in case of the $f_0(500)$, in addition to a dominant non- $\bar{q}q$ nature, indications for a subdominant $\bar{q}q$ component located around 1 GeV. Additional support for the non- $\bar{q}q$ nature of the $f_0(500)$ is given in Ref. [171], where the connection between the pole of resonances and their Regge trajectories is analyzed.

A model-independent method to identify hadronic molecules goes back to a proposal by Weinberg [172], shown to be equivalent to the pole counting arguments of [173–175] in Ref. [176]. The formalism allows one to extract the amount of molecular component in the wave function from the effective coupling constant of a physical state to a nearby continuum channel. It can be applied to near threshold states only and provided strong evidence that the $f_0(980)$ is a $\bar{K}K$ molecule, while the situation turned out to be less clear for the $a_0(980)$ (see also Refs. [148,146]). Further insights into $a_0(980)$ and $f_0(980)$ are expected from their mixing [177]. The corresponding signal predicted in Refs. [178,179] was recently observed at BES III [180]. It turned out that in order to get a quantitative understanding of those data in addition to the mixing mechanism itself, some detailed understanding of the production mechanism seems necessary [181].

In the unitarized quark model with coupled $q\bar{q}$ and meson-meson channels, the light scalars can be understood as additional manifestations of bare $q\bar{q}$ confinement states, strongly mass shifted from the 1.3 - 1.5 GeV region and very distorted due to the strong 3P_0 coupling to S -wave two-meson decay channels [182] vanbeveren01b. Thus, in these models the light scalar nonet comprising the $f_0(500)$, $f_0(980)$, $K_0^*(800)$, and $a_0(980)$, as well as the nonet consisting of the $f_0(1370)$, $f_0(1500)$ (or $f_0(1710)$), $K_0^*(1430)$, and $a_0(1450)$, respectively, are two manifestations of the same bare input states (see also Ref. [184]).

Other models with different groupings of the observed resonances exist and may, *e.g.*, be found in earlier versions of this review.

VI. Interpretation of the f_0 's above 1 GeV: The $f_0(1370)$ and $f_0(1500)$ decay mostly into pions (2π and 4π) while the $f_0(1710)$ decays mainly into the $K\bar{K}$ final states. The $K\bar{K}$ decay branching ratio of the $f_0(1500)$ is small [128,185].

If one uses the naive quark model, it is natural to assume that the $f_0(1370)$, $a_0(1450)$, and the $K_0^*(1430)$ are in the same SU(3) flavor nonet, being the $(u\bar{u} + d\bar{d})$, $u\bar{d}$ and $u\bar{s}$ states, probably mixing with the light scalars [186], while the $f_0(1710)$ is the $s\bar{s}$ state. Indeed, the production of $f_0(1710)$ (and $f_2'(1525)$) is observed in $p\bar{p}$ annihilation [187] but the rate is suppressed compared to $f_0(1500)$ (respectively, $f_2(1270)$), as would be expected from the OZI rule for $s\bar{s}$ states. The $f_0(1500)$ would also qualify as a $(u\bar{u} + d\bar{d})$ state, although it is very narrow compared to the other states and too light to be the first radial excitation.

However, in $\gamma\gamma$ collisions leading to $K_S^0 K_S^0$ [188] a spin-0 signal is observed at the $f_0(1710)$ mass (together with a dominant spin-2 component), while the $f_0(1500)$ is not observed in $\gamma\gamma \rightarrow K\bar{K}$ nor $\pi^+\pi^-$ [189]. In $\gamma\gamma$ collisions leading to $\pi^0\pi^0$ Ref. [190] reports the observation of a scalar around 1470 MeV albeit with large uncertainties on the mass and $\gamma\gamma$ couplings. This state could be the $f_0(1370)$ or the $f_0(1500)$. The upper limit from $\pi^+\pi^-$ [189] excludes a large $n\bar{n}$ (here n stands for the two lightest quarks) content for the $f_0(1500)$ and hence points to a mainly $s\bar{s}$ state [191]. This appears to contradict the small $K\bar{K}$ decay branching ratio of the $f_0(1500)$ and makes a $q\bar{q}$ assignment difficult for this state. Hence the $f_0(1500)$ could be mainly glue due the absence of a 2γ -coupling, while the $f_0(1710)$ coupling to 2γ would be compatible with an $s\bar{s}$ state. This is in accord with the recent high-statistics Belle data in $\gamma\gamma \rightarrow K_S^0 K_S^0$ [192] in which the $f_0(1500)$ is absent, while a prominent peak at 1710 MeV is observed with quantum numbers 0^{++} , compatible with the formation of an $s\bar{s}$ state. However, the 2γ -couplings are sensitive to glue mixing with $q\bar{q}$ [193].

Note that an isovector scalar, possibly the $a_0(1450)$ (albeit at a lower mass of 1317 MeV) is observed in $\gamma\gamma$ collisions leading to $\eta\pi^0$ [194]. The state interferes destructively with the non-resonant background, but its $\gamma\gamma$ coupling is comparable to that of the $a_2(1320)$, in accord with simple predictions (see, *e.g.*, Ref. [191]).

The small width of $f_0(1500)$, and its enhanced production at low transverse momentum transfer in central collisions [195–197] also favor $f_0(1500)$ to be non- $q\bar{q}$. In the mixing scheme of Ref. [193], which uses central production data from WA102 and the recent hadronic J/ψ decay data from BES [198,199], glue is shared between $f_0(1370)$, $f_0(1500)$ and $f_0(1710)$. The $f_0(1370)$ is mainly $n\bar{n}$, the $f_0(1500)$ mainly glue and the $f_0(1710)$ dominantly $s\bar{s}$. This agrees with previous analyses [200,201]. In Ref. [202] $f_0(1710)$ qualifies as a glueball candidate based on an analysis of decay data in an extended linear sigma model with a dilaton field.

However, alternative schemes have been proposed (*e.g.*, in [203–204]; for a review see, *e.g.*, Ref. [1]). In particular, for a scalar glueball, the two-gluon coupling to $n\bar{n}$ appears to be suppressed by chiral symmetry [205] and therefore the $K\bar{K}$ decay could be enhanced. This mechanism would imply that the $f_0(1710)$ can possibly be interpreted as an unmixed

Meson Particle Listings

 $f_0(500)$

glueball [206]. In Ref. [207], a large K^+K^- scalar signal reported by Belle in B decays into $KK\bar{K}$ [208], compatible with the $f_0(1500)$, is explained as due to constructive interference with a broad glueball background. However, the Belle data are inconsistent with the BaBar measurements which show instead a broad scalar at this mass for B decays into both $K^\pm K^\pm K^\mp$ [209] and $K^+K^-\pi^0$ [210].

Whether the $f_0(1500)$ is observed in 'gluon rich' radiative J/ψ decays is debatable [211] because of the limited amount of data - more data for this and the $\gamma\gamma$ mode are needed.

In Ref. [212], further refined in Ref. [213], $f_0(1370)$ and $f_0(1710)$ (together with $f_2(1270)$ and $f_2'(1525)$) were interpreted as bound systems of two vector mesons. This picture could be tested in radiative J/ψ decays [214] as well as radiative decays of the states themselves [215]. The vector-vector component of the $f_0(1710)$ might also be the origin of the enhancement seen in $J/\psi \rightarrow \gamma\phi\omega$ near threshold [216] observed at BES [217].

¹ Applying the chiral unitary approach at NLO to the K_{e4} data of BATLEY 10 and $\pi N \rightarrow \pi N$ data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.

² Uses the K_{e4} data of BATLEY 10c and the $\pi N \rightarrow \pi N$ data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.

³ Analytic continuation using Roy equations.

⁴ Analytic continuation using GKPY equations.

⁵ Using Roy equations.

⁶ Average of three variants of the analytic K-matrix model. Uses the K_{e4} data of BATLEY 08A and the $\pi N \rightarrow \pi N$ data of HYAMS 73 and GRAYER 74.

⁷ Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08A, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82B.

⁸ From the K_{e4} data of BATLEY 08A and $\pi N \rightarrow \pi N$ data of HYAMS 73.

⁹ From the K_{e4} data of BATLEY 08A and $\pi N \rightarrow \pi N$ data of PROTOPODESCU 73, GRAYER 74, and ESTABROOKS 74.

¹⁰ From a mean of three different $f_0(500)$ parametrizations. Uses 40k events.

¹¹ From an isobar model using 2.6k events.

¹² Reanalysis of ABLIKIM 04A, PISLAK 01, and HYAMS 73 data.

¹³ Using the N/D method.

¹⁴ From the solution of the Roy equation (ROY 71) for the isoscalar S-wave and using a phase-shift analysis of HYAMS 73 and PROTOPODESCU 73 data.

- 15 Reanalysis of the data from PROTOPOESCU 73, ESTABROOKS 74, GRAYER 74, ROSSELET 77, PISLAK 03, and AKHMETSHIN 04.
 16 From a mean of six different analyses and $f_0(500)$ parameterizations.
 17 Using data on $\psi(2S) \rightarrow J/\psi \pi \pi$ from BAI 00e and on $\Upsilon(nS) \rightarrow \Upsilon(mS) \pi \pi$ from BUTLER 94b and ALEXANDER 98.
 18 Reanalysis of data from PROTOPOESCU 73, ESTABROOKS 74, GRAYER 74, and COHEN 80 in the unitarized ChPT model.
 19 From a combined analysis of HYAMS 73, AUGUSTIN 89, AITALA 01b, and PISLAK 01.
 20 A similar analysis (KOMADA 01) finds $(580^{+79}_{-30}) - i(190^{+107}_{-49})$ MeV.
 21 Coupled channel reanalysis of BATON 70, BENSINGER 71, BAILLON 72, HYAMS 73, HYAMS 75, ROSSELET 77, COHEN 80, and ETKIN 82b using the uniformizing variable.
 22 Using the inverse amplitude method and data of ESTABROOKS 73, GRAYER 74, and PROTOPOESCU 73.
 23 Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
 24 Average and spread of 4 variants ("up" and "down") of KAMINSKI 97B 3-channel model.
 25 Uses data from BEIER 72b, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91b. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
 26 Demonstrates explicitly that $f_0(500)$ and $f_0(1370)$ are two different poles.
 27 Analysis of data from FALVARD 88.
 28 Analysis of data from OCHS 73, ESTABROOKS 75, ROSSELET 77, and MUKHIN 80.
 29 Analysis of data from OCHS 73, GRAYER 74, and ROSSELET 77.
 30 Coupled-channel analysis using data from PROTOPOESCU 73, HYAMS 73, HYAMS 75, GRAYER 74, ESTABROOKS 74, ESTABROOKS 75, FROGGATT 77, CORDEEN 79, BISWAS 81.
 31 Analysis of data from APEL 73, GRAYER 74, CASON 76, PAWLICKI 77. Includes spread and errors of 4 solutions.
 32 Analysis of data from BATON 70, BENSINGER 71, COLTON 71, BAILLON 72, PROTOPOESCU 73, and WALKER 67.

35 ± 12	47 TROYAN	98	$5.2 n p \rightarrow n p \pi^+ \pi^-$
780 ± 60	ALDE	97	$450 p p \rightarrow p p \pi^0 \pi^0$
385 ± 70	48 ISHIDA	97	$\pi \pi \rightarrow \pi \pi$
290 ± 54	49 SVEC	96	$6-17 \pi N \text{ polar} \rightarrow \pi^+ \pi^- N$
~ 880	50,51 TORNQVIST	96	$\pi \pi \rightarrow \pi \pi, K \bar{K}, K \pi, \eta \pi$
460 ± 40	52,53 ANISOVICH	95	$\pi^- p \rightarrow \pi^0 \pi^0 n,$ $\bar{p} p \rightarrow \pi^0 \pi^0 \pi^0, \pi^0 \pi^0 \eta,$ $\pi^0 \eta \eta$
~ 3200	54 ACHASOV	94	$\pi \pi \rightarrow \pi \pi$
494 ± 58	49 AUGUSTIN	89	DM2

- 44 Statistical uncertainty only.
 45 A similar analysis (KOMADA 01) finds 301^{+145}_{-100} MeV.
 46 From the best fit of the Dalitz plot.
 47 6σ effect, no PWA.
 48 Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
 49 Breit-Wigner fit to S-wave intensity measured in $\pi N \rightarrow \pi^- \pi^+ N$ on polarized targets. The fit does not include $f_0(980)$.
 50 Uses data from ASTON 88, OCHS 73, HYAMS 73, ARMSTRONG 91b, GRAYER 74, CASON 83, ROSSELET 77, and BEIER 72b. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
 51 Also observed by ASNER 00 in $\tau^- \rightarrow \pi^- \pi^0 \pi^0 \nu_\tau$ decays.
 52 Uses $\pi^0 \pi^0$ data from ANISOVICH 94, AMSLER 94D, and ALDE 95b, $\pi^+ \pi^-$ data from OCHS 73, GRAYER 74 and ROSSELET 77, and $\eta \eta$ data from ANISOVICH 94.
 53 The pole is on Sheet III. Demonstrates explicitly that $f_0(500)$ and $f_0(1370)$ are two different poles.
 54 Analysis of data from OCHS 73, ESTABROOKS 75, ROSSELET 77, and MUKHIN 80.

- 33 Statistical uncertainty only.
 34 A similar analysis (KOMADA 01) finds 526^{+48}_{-37} MeV.
 35 From the best fit of the Dalitz plot.
 36 6σ effect, no PWA.
 37 Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
 38 Breit-Wigner fit to S-wave intensity measured in $\pi N \rightarrow \pi^- \pi^+ N$ on polarized targets. The fit does not include $f_0(980)$.
 39 Uses data from ASTON 88, OCHS 73, HYAMS 73, ARMSTRONG 91b, GRAYER 74, CASON 83, ROSSELET 77, and BEIER 72b. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
 40 Also observed by ASNER 00 in $\tau^- \rightarrow \pi^- \pi^0 \pi^0 \nu_\tau$ decays.
 41 Uses $\pi^0 \pi^0$ data from ANISOVICH 94, AMSLER 94D, and ALDE 95b, $\pi^+ \pi^-$ data from OCHS 73, GRAYER 74 and ROSSELET 77, and $\eta \eta$ data from ANISOVICH 94.
 42 The pole is on Sheet III. Demonstrates explicitly that $f_0(500)$ and $f_0(1370)$ are two different poles.
 43 Analysis of data from OCHS 73, ESTABROOKS 75, ROSSELET 77, and MUKHIN 80.

- 55 Using dispersive analysis with phases from GARCIA-MARTIN 11A and BUETTIGER 04 as input.
 56 Using Roy-Steiner equations with $\pi \pi$ phase shifts from an update of COLANGELO 01 and from GARCIA-MARTIN 11A.
 57 Using an analytic K-matrix model.
 58 Using dispersion integral with phase input from Roy equations and data from MARSISKE 90, BOYER 90, BEHREND 92, UEHARA 08A, and MORI 07.
 59 Used dispersion theory. The value quoted used the $f_0(500)$ pole position of $457 - i276$ MeV.
 60 Using p, n polarizabilities from PDG 06 and fitting to $\pi \pi$ phase motion from GARCIA-MARTIN 07 and σ -poles from GARCIA-MARTIN 07 and CAPRINI 06.
 61 Using twice-subtracted dispersion integrals.
 62 Supersedes OLLER 08.
 63 Solution A (preferred solution based on χ^2 -analysis).
 64 Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.
 65 Solution B (worse than solution A; still acceptable when systematic uncertainties are included).
 66 Using unitarity and the σ pole position from CAPRINI 06.
 67 This width could equally well be assigned to the $f_0(1370)$. The authors analyse data from BOYER 90 and MARSISKE 90 and report strong correlation with $\gamma \gamma$ width of $f_2(1270)$.
 68 Supersedes MORGAN 90.

THE $\rho(770)$

Updated May 2012 by S. Eidelman (Novosibirsk) and G. Venanzoni (Frascati).

The determination of the parameters of the $\rho(770)$ is beset with many difficulties because of its large width. In physical region fits, the line shape does not correspond to a relativistic Breit-Wigner function with a P -wave width, but requires some additional shape parameter. This dependence on parameterization was demonstrated long ago [1]. Bose-Einstein correlations are another source of shifts in the $\rho(770)$ line shape, particularly in multiparticle final state systems [2].

The same model-dependence afflicts any other source of resonance parameters, such as the energy-dependence of the phase shift δ_1^+ , or the pole position. It is, therefore, not surprising that a study of $\rho(770)$ dominance in the decays of the η and η' reveals the need for specific dynamical effects, in addition to the $\rho(770)$ pole [3,4].

The cleanest determination of the $\rho(770)$ mass and width comes from e^+e^- annihilation and τ -lepton decays. Analysis of ALEPH [5] showed that the charged $\rho(770)$ parameters measured from τ -lepton decays are consistent with those of the neutral one determined from e^+e^- data [6]. This conclusion is qualitatively supported by the later studies of CLEO [7] and Belle [8]. However, model-independent comparison of the two-pion mass spectrum in τ decays, and the $e^+e^- \rightarrow \pi^+\pi^-$ cross section, gave indications of discrepancies between the overall normalization: τ data are about 3% higher than e^+e^- data [7,9]. A detailed analysis using such two-pion mass spectra from τ decays measured by OPAL [10], CLEO [7], and ALEPH [11,12], as well as recent pion form factor measurements in e^+e^- annihilation by CMD-2 [13,14], showed that the discrepancy can be as high as 10% above the ρ meson [15,16]. This discrepancy remains after recent measurements of the two-pion cross section in e^+e^- annihilation at KLOE [17,18] and SND [19,20]. This effect is not accounted for by isospin breaking [21–24], but the accuracy of its calculation may be overestimated [25,26].

This problem seems to be solved after a recent analysis in [27] which showed that after correcting the τ data for the missing $\rho - \gamma$ mixing contribution, besides the other known isospin symmetry violating corrections, the $\pi\pi$ I=1 part of the hadronic vacuum polarization contribution to the muon $g - 2$ is fully compatible between τ based and e^+e^- based evaluations including more recent BaBar [28] and KLOE [29] data. Further proof of the consistency of the data on τ decays to two pions and e^+e^- annihilation is given by the global fit of the whole set of the ρ , ω , and ϕ decays, taking into account mixing effects in the hidden local symmetry model [30].

Meson Particle Listings

$\rho(770)$

WEIGHTED AVERAGE
769.0±0.9 (Error scaled by 1.4)

- 1 Using the GOUNARIS 68 parametrization with the complex phase of the ρ - ω interference and leaving the masses and widths of the $\rho(1450)$, $\rho(1700)$, and $\rho(2150)$ resonances as free parameters of the fit.
- 2 A combined fit of AKHMETSHIN 07, AULCHENKO 06, and AULCHENKO 05.
- 3 Supersedes ACHASOV 05A.
- 4 A fit of the SND data from 400 to 1000 MeV using parameters of the $\rho(1450)$ and $\rho(1700)$ from a fit of the data of BARKOV 85, BISELLO 89 and ANDERSON 00A.
- 5 Using the GOUNARIS 68 parametrization with the complex phase of the ρ - ω interference.
- 6 Update of A KHMETSHIN 02.
- 7 Assuming $m_{\rho^+} = m_{\rho^-}$, $\Gamma_{\rho^+} = \Gamma_{\rho^-}$.
- 8 From the GOUNARIS 68 parametrization of the pion form factor.
- 9 Assuming $m_{\rho^+} = m_{\rho^-} = m_{\rho^0}$, $\Gamma_{\rho^+} = \Gamma_{\rho^-} = \Gamma_{\rho^0}$.
- 10 Without limitations on masses and widths.
- 11 Assuming $m_{\rho^0} = m_{\rho^\pm}$, $g_{\rho^0\pi\pi} = g_{\rho^\pm\pi\pi}$.
- 12 Using the data of BARKOV 85 in the hidden local symmetry model.
- 13 From the fit to $e^+e^- \rightarrow \pi^+\pi^-$ data from the compilations of HEYN 81 and BARKOV 85, including the GOUNARIS 68 parametrization of the pion form factor.
- 14 A fit of BARKOV 85 data assuming the direct $\omega\pi\pi$ coupling.
- 15 Applying the S-matrix formalism to the BARKOV 85 data.
- 16 Includes BARKOV 85 data. Model-dependent width definition.
- 17 $|F_\pi(0)|^2$ fixed to 1.
- 18 From the GOUNARIS 68 parametrization of the pion form factor.
- 19 The error combines statistical and systematic uncertainties. Supersedes BARATE 97M.
- 20 $\rho(1700)$ mass and width fixed at 1700 MeV and 235 MeV respectively.
- 21 From the GOUNARIS 68 parametrization of the pion form factor. The second error is a model error taking into account different parametrizations of the pion form factor.
- 22 Using the data of BARATE 97M and the effective chiral Lagrangian.
- 23 From a fit of the model-independent parametrization of the pion form factor to the data of BARATE 97M.
- 24 Assuming the equality of ρ^+ and ρ^- masses and widths.
- 25 Mass errors enlarged by us to Γ/\sqrt{N} ; see the note with the $K^*(892)$ mass.
- 26 Phase shift analysis. Systematic errors added corresponding to spread of different fits.
- 27 From fit of 3-parameter relativistic P-wave Breit-Wigner to total mass distribution. Includes BATON 68, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, BLIEDEN 65 and CARMONY 64.
- 28 Using the KUHN 90 parametrization of the pion form factor, neglecting ρ - ω interference.
- 29 From the parametrization according to SOEDING 66.
- 30 From the parametrization according to ROSS 66.
- 31 HEYN 81 includes all spacelike and timelike F_π values until 1978.
- 32 From pole extrapolation.
- 33 From phase shift analysis of GRAYER 74 data.
- 34 Includes MALAMUD 69, ARMENISE 68, BACON 67, HUWE 67, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, GOLDBERGER 64, ABOLINS 63.
- 35 Breit-Wigner mass from a phase-shift analysis of HYAMS 73 and PROTOPOESCU 73 data.
- 36 Using relativistic Breit-Wigner and taking into account ρ - ω interference.
- 37 Systematic errors not evaluated.
- 38 Systematic effects not studied.
- 39 From fit of 3-parameter relativistic Breit-Wigner to helicity-zero part of P-wave intensity. CHABAUD 83 includes data of GRAYER 74.

$\rho(770)$ RANGE PARAMETER

The range parameter R enters an energy-dependent correction to the width, of the form $(1 + q^2 R^2) / (1 + q^2 R^2)$, where q is the momentum of one of the pions in the $\pi\pi$ rest system. At resonance, $q = q_r$.

45 Using the GOUNARIS 68 parametrization with the complex phase of the ρ - ω interference and leaving the masses and widths of the $\rho(1450)$, $\rho(1700)$, and $\rho(2150)$ resonances as free parameters of the fit.

46 A combined fit of AKHMETSHIN 07, AULCHENKO 06, and AULCHENKO 05.

47 Supersedes ACHASOV 05A.

48 A fit of the SND data from 400 to 1000 MeV using parameters of the $\rho(1450)$ and $\rho(1700)$ from a fit of the data of BARKOV 85, BISELLO 89 and ANDERSON 00A.

49 Using the GOUNARIS 68 parametrization with the complex phase of the ρ - ω interference.

50 From a fit in the energy range 0.61 to 0.96 GeV. Update of AKHMETSHIN 02.

51 Assuming $m_{\rho^+} = m_{\rho^-}$, $\Gamma_{\rho^+} = \Gamma_{\rho^-}$.

52 From the GOUNARIS 68 parametrization of the pion form factor.

53 Assuming $m_{\rho^+} = m_{\rho^-} = m_{\rho^0}$, $\Gamma_{\rho^+} = \Gamma_{\rho^-} = \Gamma_{\rho^0}$.

54 Without limitations on masses and widths.

55 Assuming $m_{\rho^0} = m_{\rho^\pm}$, $g_{\rho^0 \pi \pi} = g_{\rho^\pm \pi \pi}$.

56 Using the data of BARKOV 85 in the hidden local symmetry model.

57 From the fit to $e^+ e^- \rightarrow \pi^+ \pi^-$ data from the compilations of HEYN 81 and BARKOV 85, including the GOUNARIS 68 parametrization of the pion form factor.

58 A fit of BARKOV 85 data assuming the direct $\omega \pi \pi$ coupling.

59 Applying the S-matrix formalism to the BARKOV 85 data.

60 Includes BARKOV 85 data. Model-dependent width definition.

61 $|F_\pi(0)|^2$ fixed to 1.

62 From the GOUNARIS 68 parametrization of the pion form factor.

63 The error combines statistical and systematic uncertainties. Supersedes BARATE 97M.

64 $\rho(1700)$ mass and width fixed at 1700 MeV and 235 MeV respectively.

65 From the GOUNARIS 68 parametrization of the pion form factor. The second error is a model error taking into account different parametrizations of the pion form factor.

66 Using the data of BARATE 97M and the effective chiral Lagrangian.

67 Assuming the equality of ρ^+ and ρ^- masses and widths.

68 Width errors enlarged by us to $4\Gamma/\sqrt{N}$; see the note with the $K^*(892)$ mass.

69 Phase shift analysis. Systematic errors added corresponding to spread of different fits.

70 From fit of 3-parameter relativistic P-wave Breit-Wigner to total mass distribution. Includes BATON 68, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, BLIEDEN 65 and CARMONY 64.

71 Using the KUHN 90 parametrization of the pion form factor, neglecting ρ - ω interference.

72 From the parametrization according to SOEDING 66.

73 From the parametrization according to ROSS 66.

74 From pole extrapolation.

75 From phase shift analysis of GRAYER 74 data.

76 Using relativistic Breit-Wigner and taking into account ρ - ω interference.

77 Systematic errors not evaluated.

78 From fit of 3-parameter relativistic Breit-Wigner to helicity-zero part of P-wave intensity. CHABAUD 83 includes data of GRAYER 74.

79 HEYN 81 includes all spacelike and timelike F_π values until 1978.

80 Includes MALAMUD 69, ARMENISE 68, BACON 67, HUWE 67, MILLER 67B, ALFF-STEINBERGER 66, HAGOPIAN 66, HAGOPIAN 66B, JACOBS 66B, JAMES 66, WEST 66, GOLDBERGER 64, ABOLINS 63.

[a] The $\omega\rho$ interference is then due to $\omega\rho$ mixing only, and is expected to be small. If $e\mu$ universality holds, $\Gamma(\rho^0 \rightarrow \mu^+ \mu^-) = \Gamma(\rho^0 \rightarrow e^+ e^-) \times 0.99785$.

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 10 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 10.7$ for 8 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

105 Possibly large ρ - ω interference leads us to increase the minus error.

¹⁰⁶ Result contains 11 ± 11% correction using SU(3) for central value. The error on the correction takes account of possible ρ - ω interference and the upper limit agrees with the upper limit of $\omega \rightarrow \mu^+\mu^-$ from this experiment.

¹⁰⁷ HYAMS 67's mass resolution is 20 MeV. The ω region was excluded.

¹⁰⁸ The ρ' contribution is not taken into account.

¹⁰⁹ ACHASOV 07B reports $[\Gamma(\rho(770) \rightarrow \eta\gamma)/\Gamma_{\text{total}}] \times [B(\rho(770) \rightarrow e^+e^-)] = (1.32 \pm 0.14 \pm 0.08) \times 10^{-8}$ which we divide by our best value $B(\rho(770) \rightarrow e^+e^-) = (4.72 \pm 0.05) \times 10^{-5}$. Our first error is their experiment's error and our second

Meson Particle Listings

 $\rho(770)$, $\omega(782)$

- error is the systematic error from using our best value. Supersedes ACHASOV 00d and ACHASOV 06A.
- 110 Solution corresponding to constructive ω - ρ interference.
- 111 Using $B(\rho \rightarrow e^+e^-) = (4.67 \pm 0.09) \times 10^{-5}$ and $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$.
- 112 Not independent of the corresponding $\Gamma(e^+e^-) \times \Gamma(\eta\gamma)/\Gamma_{\text{total}}^2$.
- 113 The combined fit from 600 to 1380 MeV taking into account $\rho(770)$, $\omega(782)$, $\phi(1020)$, and $\rho(1450)$ (mass and width fixed at 1450 MeV and 310 MeV respectively).
- 114 Using $B(\rho \rightarrow e^+e^-) = (4.75 \pm 0.10) \times 10^{-5}$ from AKHMETSHIN 02 and $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$.
- 115 Reanalysis of DRUZHININ 84, DOLINSKY 89, and DOLINSKY 91 taking into account a triangle anomaly contribution. Constructive ρ - ω interference solution.
- 116 Statistical significance is less than 3 σ .
- 117 Model dependent, assumes $l = 1, 2, \text{ or } 3$ for the 3π system.
- 118 Assuming no interference between the ρ and ω contributions.
- 119 Bremsstrahlung from a decay pion and for photon energy above 50 MeV.
- 120 Superseded by DOLINSKY 91.
- 121 Structure radiation due to quark rearrangement in the decay.
- 122 Using $B(\rho \rightarrow e^+e^-) = (4.67 \pm 0.09) \times 10^{-5}$.
- 123 Not independent of the corresponding $\Gamma(e^+e^-) \times \Gamma(\pi^0\gamma)/\Gamma_{\text{total}}^2$.
- 124 Using $B(\rho \rightarrow e^+e^-) = (4.54 \pm 0.10) \times 10^{-5}$.
- 125 Reanalysis of DRUZHININ 84, DOLINSKY 89, and DOLINSKY 91 taking into account a triangle anomaly contribution.
- 126 This branching ratio includes the conventional VMD mechanism $\rho \rightarrow \omega\pi^0$, $\omega \rightarrow \pi^0\gamma$, and the new decay mode $\rho \rightarrow f_0(500)\gamma$, $f_0(500) \rightarrow \pi^0\pi^0$ with a branching ratio $(2.0_{-0.9}^{+1.1} \pm 0.3) \times 10^{-5}$ differing from zero by 2.0 standard deviations.
- 127 This branching ratio includes the conventional VMD mechanism $\rho \rightarrow \omega\pi^0$, $\omega \rightarrow \pi^0\gamma$ and the new decay mode $\rho \rightarrow f_0(500)\gamma$, $f_0(500) \rightarrow \pi^0\pi^0$ with a branching ratio $(1.9_{-0.9}^{+0.8} \pm 0.4) \times 10^{-5}$ differing from zero by 2.4 standard deviations. Supersedes ACHASOV 00g.
- 128 Superseded by ACHASOV 02f.

CONSTRAINED FIT INFORMATION

An overall fit to 15 branching ratios uses 51 measurements and one constraint to determine 10 parameters. The overall fit has a $\chi^2 = 51.8$ for 42 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

7.3 ± 2.9		2,4 DOLINSKY	89 ND	$e^+e^- \rightarrow \eta\gamma$

¹ No flat $\eta\eta\gamma$ background assumed.

² Solution corresponding to constructive $\omega\rho$ interference.

³ ACHASOV 07B reports $[\Gamma(\omega(782) \rightarrow \eta\gamma)/\Gamma_{\text{total}}] \times [B(\omega(782) \rightarrow e^+e^-)] = (3.10 \pm 0.31 \pm 0.11) \times 10^{-8}$ which we divide by our best value $B(\omega(782) \rightarrow e^+e^-) = (7.28 \pm 0.14) \times 10^{-5}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Supersedes ACHASOV 00B and ACHASOV 06A.

⁴ Not independent of the corresponding $\Gamma(e^+e^-) \times \Gamma(\eta\gamma)/\Gamma_{\text{total}}^2$.

⁵ Using $B(\omega \rightarrow e^+e^-) = (7.14 \pm 0.13) \times 10^{-5}$ and $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$.

⁶ Using $B(\omega \rightarrow e^+e^-) = (7.07 \pm 0.19) \times 10^{-5}$ and using $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$. Solution corresponding to constructive $\omega\rho$ interference. The combined

fit from 600 to 1380 MeV taking into account $\rho(770)$, $\omega(782)$, $\phi(1020)$, and $\rho(1450)$ (mass and width fixed at 1450 MeV and 310 MeV respectively). Not independent of the corresponding $\Gamma(e^+e^-) \times \Gamma(\eta\gamma)/\Gamma_{\text{total}}^2$.

⁷ Depending on the degree of coherence with the flat $\eta\eta\gamma$ background and using $B(\omega \rightarrow \pi^0\gamma) = (8.5 \pm 0.5) \times 10^{-2}$.

⁸ Reanalysis of DRUZHININ 84, DOLINSKY 89, DOLINSKY 91 taking into account the triangle anomaly contributions.

PARAMETER Λ IN $\omega \rightarrow \pi^0 \mu^+ \mu^-$ DECAY

In the pole approximation the electromagnetic transition form factor for a resonance of mass M is given by the expression:

$$|F|^2 = (1 - M^2/\Lambda^2)^{-2},$$

where for the parameter Λ vector dominance predicts $\Lambda = M_p \approx 0.770$ GeV. The ARNALDI 09 measurement is in obvious conflict with this expectation. Note that for $\eta \rightarrow \mu^+ \mu^- \gamma$ decay ARNALDI 09 and DZHELYADIN 80 obtain the value of Λ consistent with vector dominance.

[a] C parity forbids this to occur as a single-photon process.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, 2 combinations of partial widths obtained from integrated cross section, and 16 branching ratios uses 46 measurements and one constraint to determine 9 parameters. The overall fit has a $\chi^2 = 52.8$ for 38 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 $\eta'(958) \rightarrow \eta\pi\pi$ DECAY PARAMETERS

$$|\text{MATRIX ELEMENT}|^2 = |1 + \alpha Y|^2 + CX + DX^2$$

X and Y are Dalitz variables; α is complex and C , and D are real-valued. Parameters C and D are not necessarily equal to c and d , respectively, in the generalized parameterization following this one. May be different for $\eta'(958) \rightarrow \eta\pi^+\pi^-$ and $\eta'(958) \rightarrow \eta\pi^0\pi^0$ decays. Because of different initial assumptions and strong correlations of the parameters we do not average the parameters in the section below.

 $\eta'(958)$ C-NONCONSERVING DECAY PARAMETER

See the note on η decay parameters in the Stable Particle Particle Listings for definition of this parameter.

DECAY ASYMMETRY PARAMETER FOR $\pi^+\pi^-\gamma$

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
-0.03 ± 0.04	OUR AVERAGE			
-0.019 ± 0.056		AIHARA 87	TPC	$2\gamma \rightarrow \pi^+\pi^-\gamma$
-0.069 ± 0.078	295	GRIGORIAN 75	STRC	$2.1 \pi^- p$
0.00 ± 0.10	103	KALBFLEISCH 75	HBC	$2.18 K^- p \rightarrow \Lambda\pi^+\pi^-\gamma$
0.07 ± 0.08	152	RITTENBERG 65	HBC	$2.1-2.7 K^- p$

 $\eta'(958) \rightarrow \gamma\ell^+\ell^-$ TRANSITION FORM FACTOR SLOPE

Related to the effective virtual meson mass Λ , via slope $\approx \Lambda^{-2}$. See e.g. LANDSBERG 85, eq. (3.8), for a detailed definition.

VALUE (GeV ⁻²)	EVTS	DOCUMENT ID	TECN	COMMENT
1.62 ± 0.17	OUR AVERAGE			
$1.60 \pm 0.17 \pm 0.08$	864	¹ ABLIKIM 15g	BES3	$J/\psi \rightarrow \gamma e^+e^-$
1.7 ± 0.4	33	¹ VIKTOROV 80		$25,33 \pi^- p \rightarrow 2\mu\gamma$

¹ In the single-pole Ansatz where slope = $1/(\Lambda^2 + \gamma^2)$ with Λ, γ being a Breit-Wigner mass, width for the effective contributing vector meson.

1 Analytic continuation using Roy equations. Uses the K_{e4} data of BATLEY 10C and the $\pi N \rightarrow \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.
 2 Quoted number refers to twice imaginary part of pole position.
 3 Analytic continuation using GKPY equations. Uses the K_{e4} data of BATLEY 10C and the $\pi N \rightarrow \pi\pi N$ data of HYAMS 73, GRAYER 74, and PROTOPODESCU 73.
 4 Pole position. Used Roy equations.
 5 Average of the analyses of three data sets in the K-matrix model. Uses the data of BATLEY 08A, HYAMS 73, and GRAYER 74, partially of COHEN 80 or ETKIN 82B.
 6 On sheet II in a 2-pole solution. The other pole is found on sheet III at (850-100i) MeV
 7 Using a relativistic Breit-Wigner function and taking into account the finite D_s mass.
 8 Breit-Wigner $\pi\pi$ width. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0} K \bar{K} / g_{f_0} \pi\pi = 0$.
 9 Systematic errors not estimated.
 10 Breit-Wigner $\pi\pi$ width. Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0} K \bar{K} / g_{f_0} \pi\pi = 4.21 \pm 0.25 \pm 0.21$ from ABLIKIM 05.
 11 Breit-Wigner, solution 1, PWA ambiguous.
 12 K-matrix pole from combined analysis of $\pi^-p \rightarrow \pi^0\pi^0n, \pi^-p \rightarrow K\bar{K}n, \pi^+\pi^- \rightarrow \pi^+\pi^-, \bar{p}p \rightarrow \pi^0\pi^0\pi^0, \pi^0\eta\eta, \pi^0\pi^0\eta, \pi^+\pi^-\pi^0, K^+K^-\pi^0, K_S^0 K_S^0 \pi^0, K^+K_S^0 \pi^-,$ at rest, $\bar{p}n \rightarrow \pi^-\pi^-\pi^+, K_S^0 K^- \pi^0, K_S^0 K_S^0 \pi^-$ at rest.

13 Using the data of AKHMETSHIN 99C, ACHASOV 00H, and ALOISIO 02D.
 14 Breit-Wigner width.
 15 Supersedes ACHASOV 98i. Using the model of ACHASOV 89.
 16 Supersedes ACHASOV 98i.
 17 In the "narrow resonance" approximation.
 18 From the combined fit of the photon spectra in the reactions $e^+e^- \rightarrow \pi^+\pi^-\gamma, \pi^0\pi^0\gamma$.
 19 Supersedes BARBERIS 99 and BARBERIS 99B
 20 T-matrix pole.
 21 On sheet II in a 2 pole solution. The other pole is found on sheet III at (1039-93i) MeV.
 22 From invariant mass fit.
 23 On sheet II in a 2 pole solution. The other pole is found on sheet III at (963-29i) MeV.
 24 Reanalysis of data from HYAMS 73, GRAYER 74, SRINIVASAN 75, and ROSSELET 77 using the interfering amplitude method.
 25 At high $|t|$.
 26 At low $|t|$.
 27 On sheet II in a 4-pole solution, the other poles are found on sheet III at (953-55i) MeV and on sheet IV at (938-35i) MeV.
 28 Combined fit of ALDE 95B, ANISOVICH 94,
 29 On sheet II in a 2 pole solution. The other pole is found on sheet III at (996-103i) MeV.
 30 From sheet II pole position.
 31 On sheet II in a 2 pole solution. The other pole is found on sheet III at (797-185i) MeV and can be interpreted as a shadow pole.
 32 On sheet II in a 2 pole solution. The other pole is found on sheet III at (978-28i) MeV.
 33 From coupled channel analysis.
 34 Coupled channel analysis with finite width corrections.
 35 From coupled channel fit to the HYAMS 73 and PROTOPODESCU 73 data. With a simultaneous fit to the $\pi\pi$ phase-shifts, inelasticity and to the $K_S^0 K_S^0$ invariant mass.
 36 Included in AGUILAR-BENITEZ 78 fit.

 3 Using finite width corrections according to FLATTE 76 and ACHASOV 05, and the ratio $g_{f_0} K \bar{K} / g_{f_0} \pi\pi = 4.21 \pm 0.25 \pm 0.21$ from ABLIKIM 05.
 4 OEST 90 quote systematic errors ± 0.08 / ± 0.18 . We use ± 0.18 . Observed 60 events.
 5 Uses an analytic K-matrix model. Compilation.
 6 Using dispersion integral with phase input from Roy equations and data from MARSISKE 90, BOYER 90, BEHREND 92, UEHARA 08A, and MORI 07.
 7 Solution A (preferred solution based on χ^2 -analysis).
 8 Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.
 9 Solution B (worse than solution A; still acceptable when systematic uncertainties are included).
 10 Supersedes MORGAN 90.
 11 From analysis allowing arbitrary background unconstrained by unitarity.
 12 Data included in MORGAN 90, BOGLIONE 99 analyses.
 13 From amplitude analysis of BOYER 90 and MARSISKE 90, data corresponds to resonance parameters $m = 989$ MeV, $\Gamma = 61$ MeV.

¹ Using the model of ACHASOV 89 and ACHASOV 03b.

² From a fit with the S-wave amplitude including two interfering Breit-Wigners plus a background term.

³ Parameterizes couplings to $\bar{K}K, \pi\eta,$ and $\pi\eta'$.

⁴ Using AMSLER 94D and ABELE 98.

⁵ From the T-matrix pole on sheet II.

⁶ Using the model of ACHASOV 89. Supersedes ACHASOV 98b.

⁷ Using the model of JAFFE 77. Supersedes ACHASOV 98b.

⁸ T-matrix pole.

⁹ Breit-Wigner fit, average between a_0^\pm and a_0^0 . The fit favors a slightly heavier a_0^\pm .

¹⁰ From a single Breit-Wigner fit.

¹¹ From $f_1(1285)$ decay.

1.2 ± 0.8 OUR FIT				
1.17 ± 0.52 ± 0.64	3285	9 AKHMETSHIN 00e	CMD2	$e^+e^- \rightarrow \pi^+\pi^-\pi^+\pi^-$

1 From the combined fit assuming that the total $\phi(1020)$ production cross section is saturated by those of K^+K^- , $K_S^0K_L^0$, $\pi^+\pi^-\pi^0$, and $\eta\gamma$ decays modes and using ACHASOV 00b for the $\eta\gamma$ decay mode.

2 Update of AKHMETSHIN 99d

3 Recalculated by us from the cross section in the peak.

4 From a combined fit of $\sigma(e^+e^- \rightarrow \eta\gamma)$ with $\eta \rightarrow 3\pi^0$ and $\eta \rightarrow \pi^+\pi^-\pi^0$, and fixing $B(\eta \rightarrow 3\pi^0) / B(\eta \rightarrow \pi^+\pi^-\pi^0) = 1.44 \pm 0.04$. Recalculated by us from the cross section at the peak. Supersedes ACHASOV 00d and ACHASOV 06a.

5 From the $\eta \rightarrow 2\gamma$ decay and using $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$.

6 From the $\eta \rightarrow 3\pi^0$ decay and using $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$.

7 The combined fit from 600 to 1380 MeV taking into account $\rho(770)$, $\omega(782)$, $\phi(1020)$, and $\rho(1450)$ (mass and width fixed at 1450 MeV and 310 MeV respectively).

8 From the $\eta \rightarrow 2\gamma$ decay and using $B(\eta \rightarrow 2\gamma) = (39.21 \pm 0.34) \times 10^{-2}$.

9 Recalculated by the authors from the cross section in the peak.

10 From the $\eta \rightarrow \pi^+\pi^-\pi^0$ decay and using $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (23.1 \pm 0.5) \times 10^{-2}$.

11 A simultaneous fit of $e^+e^- \rightarrow \pi^+\pi^-, \pi^+\pi^-\pi^0, \pi^0\gamma, \eta\gamma$ data.

12 From the $\pi^0 \rightarrow 2\gamma$ decay and using $B(\pi^0 \rightarrow 2\gamma) = (98.798 \pm 0.032) \times 10^{-2}$.

13 A simultaneous fit to $e^+e^- \rightarrow \pi^+\pi^-, \pi^+\pi^-\pi^0, \pi^0\gamma, \eta\gamma, K\bar{K}$, and $\tau^- \rightarrow \pi^-\pi^0\nu_\tau$ data.

14 Recalculated by the authors from the cross section at the peak.

15 AMBROSINO 08g reports $[\Gamma(\phi(1020) \rightarrow \omega\pi^0)/\Gamma_{\text{total}} \times \Gamma(\phi(1020) \rightarrow e^+e^-)/\Gamma_{\text{total}}] \times [B(\omega(782) \rightarrow \pi^+\pi^-\pi^0)] = (1.22 \pm 0.13 \pm 0.08) \times 10^{-8}$ which we divide by our best value $B(\omega(782) \rightarrow \pi^+\pi^-\pi^0) = (89.2 \pm 0.7) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

16 Calculated by the authors from the cross section at the peak.

<1 $\times 10^{-6}$	90	78 BABUSCI	13B KLOE	$1.02 e^+e^- \rightarrow \eta e^+e^-$

- 1 Combined analysis of the CMD-2 data on $\phi \rightarrow K^+K^-, K_S^0 K_L^0, \pi^+\pi^-\pi^0, \eta\gamma$ assuming that the sum of their branching fractions is 0.99741 \pm 0.00007.
- 2 Using $B(\phi \rightarrow e^+e^-) = (2.93 \pm 0.14) \times 10^{-4}$.
- 3 Theoretical analysis of BRAMON 00 taking into account phase-space difference, electromagnetic radiative corrections, as well as isospin breaking, predicts 0.62. FLOREZ-BAEZ 08 predicts 0.63 considering also structure-dependent radiative corrections. FISCHBACH 02 calculates additional corrections caused by the close threshold and predicts 0.68. See also BENAYOUN 01 and DUBYNSKIY 07. BENAYOUN 12 obtains 0.71 \pm 0.01 in the HLS model.
- 4 Using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.
- 5 Using $\Gamma(\phi) = 4.1$ MeV. If interference between the $\rho\pi$ and 3π modes is neglected, the fraction of the $\rho\pi$ is more than 80% at the 90% confidence level.
- 6 From a fit without limitations on charged and neutral ρ masses and widths.
- 7 Adding the direct and $\omega\pi$ contributions and considering the interference between the $\rho\pi$ and $\pi^+\pi^-\pi^0$.
- 8 Neglecting the interference between the $\rho\pi$ and $\pi^+\pi^-\pi^0$.
- 9 Using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ and $B(\eta \rightarrow 3\pi^0) = (32.2 \pm 0.4) \times 10^{-2}$.
- 10 From $\pi^+\pi^-\pi^0$ decay mode of η .
- 11 From 2γ decay mode of η .
- 12 From $3\pi^0$ decay mode of η .
- 13 ACHASOV 07b reports $[\Gamma(\phi(1020) \rightarrow \eta\gamma)/\Gamma_{\text{total}}] \times [B(\phi(1020) \rightarrow e^+e^-)] = (4.050 \pm 0.067 \pm 0.118) \times 10^{-6}$ which we divide by our best value $B(\phi(1020) \rightarrow e^+e^-) = (2.954 \pm 0.030) \times 10^{-4}$. Our first error is their experiment's error and our second error is the systematic error from using our best value. Supersedes ACHASOV 00b and ACHASOV 06a.
- 14 Using $B(\phi \rightarrow e^+e^-) = (2.98 \pm 0.04) \times 10^{-4}$ and $B(\eta \rightarrow \gamma\gamma) = 39.43 \pm 0.26\%$.
- 15 Not independent of the corresponding $\Gamma(e^+e^-) \times \Gamma(\eta\gamma)/\Gamma_{\text{total}}^2$.
- 16 Using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$ and $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$.
- 17 The combined fit from 600 to 1380 MeV taking into account $\rho(770), \omega(782), \phi(1020)$, and $\rho(1450)$ (mass and width fixed at 1450 MeV and 310 MeV respectively).
- 18 From the $\eta \rightarrow 2\gamma$ decay and using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.
- 19 From $\pi^+\pi^-\pi^0$ decay mode of η and using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.
- 20 Reanalysis of DRUZHININ 84, DOLINSKY 89, and DOLINSKY 91 taking into account a triangle anomaly contribution.
- 21 Using $B(\phi \rightarrow e^+e^-) = (2.98 \pm 0.04) \times 10^{-4}$.
- 22 Not independent of the corresponding $\Gamma(e^+e^-) \times \Gamma(\pi^0\gamma)/\Gamma_{\text{total}}^2$.
- 23 From the $\pi^0 \rightarrow 2\gamma$ decay and using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.
- 24 From the combined fit assuming that the total $\phi(1020)$ production cross section is saturated by those of $K^+K^-, K_S^0 K_L^0, \pi^+\pi^-\pi^0$, and $\eta\gamma$ decays modes and using ACHASOV 00b for the $\eta\gamma$ decay mode.
- 25 Using total width 4.2 MeV. They detect 3π mode and observe significant interference with ω tail. This is accounted for in the result quoted above.
- 26 Neglecting interference between resonance and continuum.
- 27 Using $B(\phi \rightarrow e^+e^-) = (2.91 \pm 0.07) \times 10^{-4}$.
- 28 Recalculated by us using $B(\phi \rightarrow e^+e^-) = (2.99 \pm 0.08) \times 10^{-4}$.
- 29 Using $B(\eta \rightarrow 3\pi^0) = (32.57 \pm 0.23)\%$ from PDG 12.
- 30 Using $B(\eta \rightarrow \gamma\gamma) = (39.25 \pm 0.32)\%$, $B(\phi \rightarrow \eta\gamma) = (1.26 \pm 0.06)\%$, and $B(\phi \rightarrow e^+e^-) = (3.00 \pm 0.06) \times 10^{-4}$.
- 31 The average of the branching ratios separately obtained from the $\eta \rightarrow \gamma\gamma, 3\pi^0, \pi^+\pi^-\pi^0$ decays.
- 32 From $\eta \rightarrow \gamma\gamma$ decays and using $B(\eta \rightarrow \gamma\gamma) = (39.33 \pm 0.25) \times 10^{-2}$, $B(\eta \rightarrow \pi^+\pi^-\gamma) = (4.75 \pm 11) \times 10^{-2}$, and $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$.
- 33 From $\eta \rightarrow 3\pi^0$ decays and using $B(\pi^0 \rightarrow \gamma\gamma) = (98.798 \pm 0.033) \times 10^{-2}$, $B(\eta \rightarrow 3\pi^0) = (32.24 \pm 0.29) \times 10^{-2}$, $B(\eta \rightarrow \pi^+\pi^-\gamma) = (4.75 \pm 0.11) \times 10^{-2}$, and $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$.
- 34 From $\eta \rightarrow \pi^+\pi^-\pi^0$ decays and using $B(\pi^0 \rightarrow \gamma\gamma) = (98.798 \pm 0.033) \times 10^{-2}$, $B(\pi^0 \rightarrow e^+e^-\gamma) = (1.198 \pm 0.032) \times 10^{-2}$, $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (23.0 \pm 0.4) \times 10^{-2}$, $B(\phi \rightarrow \pi^+\pi^-\pi^0) = (15.5 \pm 0.6) \times 10^{-2}$, and $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$.
- 35 Using the 1996 and 1998 data.
- 36 (2.3 \pm 0.3)% correction for other decay modes of the $\omega(782)$ applied.
- 37 Not independent of the corresponding $\Gamma(\omega\pi^0) \times \Gamma(e^+e^-) / \Gamma^2(\text{total})$.
- 38 Using the 1996 data.
- 39 Using the 1998 data.
- 40 Supersedes AKHMETSHIN 97c.
- 41 For $E_\gamma > 20$ MeV and assuming that $B(\phi(1020) \rightarrow f_0(980)\gamma)$ is negligible. Supersedes AKHMETSHIN 97c.
- 42 For $E_\gamma > 20$ MeV and assuming that $B(\phi(1020) \rightarrow f_0(980)\gamma)$ is negligible.
- 43 Obtained by the authors taking into account the $\pi^+\pi^-$ decay mode. Includes a component due to $\pi\pi$ production via the $f_0(500)$ meson. Supersedes ALOISIO 02D.
- 44 From the combined fit of the photon spectra in the reactions $e^+e^- \rightarrow \pi^+\pi^-\gamma, \pi^0\pi^0\gamma$.
- 45 From the negative interference with the $f_0(500)$ meson of AITALA 01b using the ACHASOV 89 parameterization for the $f_0(980)$, a Breit-Wigner for the $f_0(500)$, and ACHASOV 01f for the $\rho\pi$ contribution. Superseded by AMBROSINO 07.
- 46 Assuming that the $\pi^0\pi^0\gamma$ final state is completely determined by the $f_0\gamma$ mechanism, neglecting the decay $B(\phi \rightarrow K\bar{K}\gamma)$ and using $B(f_0 \rightarrow \pi^+\pi^-) = 2B(f_0 \rightarrow \pi^0\pi^0)$.
- 47 Using the value $B(\phi \rightarrow \eta\gamma) = (1.338 \pm 0.053) \times 10^{-2}$.
- 48 For $E_\gamma > 20$ MeV. Supersedes AKHMETSHIN 97c.
- 49 Neglecting other intermediate mechanisms ($\rho\pi, \sigma\gamma$).

- 50 A narrow pole fit taking into account $f_0(980)$ and $f_0(1200)$ intermediate mechanisms.
- 51 For destructive interference with the Bremsstrahlung process
- 52 For constructive interference with the Bremsstrahlung process
- 53 Supersedes ALOISIO 02D.
- 54 Supersedes ACHASOV 98b. Excluding $\omega\pi^0$.
- 55 Using various branching ratios from the 2000 Edition of this Review (PDG 00).
- 56 Using $B(\pi^0 \rightarrow \gamma\gamma) = 0.98798 \pm 0.00032$, $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033) \times 10^{-2}$, and $B(\eta \rightarrow \pi^+\pi^-\gamma) = (4.75 \pm 0.11) \times 10^{-2}$.
- 57 Combined results of $\eta \rightarrow \gamma\gamma$ and $\eta \rightarrow \pi^+\pi^-\pi^0$ decay modes measurements.
- 58 From the decay mode $\eta \rightarrow \gamma\gamma$.
- 59 From the decay mode $\eta \rightarrow \pi^+\pi^-\pi^0$.
- 60 Supersedes ACHASOV 98b.
- 61 Using $B(\phi \rightarrow \eta\gamma) = (1.304 \pm 0.025)\%$, $B(\eta \rightarrow 3\pi^0) = (32.56 \pm 0.23)\%$, and $B(\eta \rightarrow \gamma\gamma) = (39.31 \pm 0.20)\%$.
- 62 Using $B(\phi \rightarrow \eta\gamma) = (1.304 \pm 0.025)\%$, $B(\eta \rightarrow 3\pi^0) = (32.56 \pm 0.23)\%$, and $B(\eta \rightarrow \pi^+\pi^-\pi^0) = (22.73 \pm 0.28)\%$.
- 63 Using $M_{a_0(980)} = 984.8$ MeV and assuming $a_0(980)\gamma$ dominance.
- 64 Assuming $a_0(980)\gamma$ dominance in the $\eta\pi^0\gamma$ final state.
- 65 Using data of ACHASOV 00f.
- 66 Using results of ALOISIO 02D and assuming that $f_0(980)$ decays into $\pi\pi$ only and $a_0(980)$ into $\eta\pi$ only.
- 67 AMBROSINO 07a reports $[\Gamma(\phi(1020) \rightarrow \eta'(958)\gamma)/\Gamma_{\text{total}}] / [B(\phi(1020) \rightarrow \eta\gamma)] = (4.77 \pm 0.09 \pm 0.19) \times 10^{-3}$ which we multiply by our best value $B(\phi(1020) \rightarrow \eta\gamma) = (1.309 \pm 0.024) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.
- 68 Averaging AULCHENKO 03b with AULCHENKO 99.
- 69 Using $B(\phi \rightarrow \eta\gamma) = (1.297 \pm 0.033)\%$.
- 70 Using the value $B(\phi \rightarrow \eta\gamma) = (1.26 \pm 0.06) \times 10^{-2}$.
- 71 Using $B(\phi \rightarrow K_S^0 K_L^0) = (33.8 \pm 0.6)\%$.
- 72 Averaging AKHMETSHIN 00b with AKHMETSHIN 00f.
- 73 Using the value $B(\eta' \rightarrow \eta\pi^+\pi^-) = (43.7 \pm 1.5) \times 10^{-2}$ and $B(\eta \rightarrow \gamma\gamma) = (39.25 \pm 0.31) \times 10^{-2}$.
- 74 Using various branching ratios of $K_S^0, K_L^0, \eta, \eta'$ from the 2000 edition (The European Physical Journal **C15** (2000)) of this Review.
- 75 From the decay mode $\eta' \rightarrow \eta\pi^+\pi^-, \eta \rightarrow \gamma\gamma$.
- 76 Superseded by AKHMETSHIN 00b.
- 77 For $E_\gamma > 20$ MeV.
- 78 For a narrow vector U with mass between 5 and 470 MeV, from the combined analysis of $\eta \rightarrow \pi^+\pi^-\pi^0$ and $\eta \rightarrow \pi^0\pi^0\pi^0$ from ARCHILLI 12. Measured 90% CL limits as a function of m_U range from 2.2×10^{-8} to 10^{-6} .

- We do not use the following data for averages, fits, limits, etc. •••
- 1 Dalitz plot analysis taking into account interference between the contact and $\rho\pi$ amplitudes.
- 2 From a fit without limitations on charged and neutral ρ masses and widths.
- 3 Recalculated by us to match the notations of AKHMETSHIN 98.
- 4 Assuming zero phase for the contact term.

PARAMETER β IN $\phi \rightarrow \eta e^+e^-$ DECAY

In the one-pole approximation the electromagnetic transition form factor for $\phi \rightarrow \eta e^+e^-$ is given as a function of the e^+e^- invariant mass squared, q^2 , by the expression:

$$|F(q^2)|^2 = (1 - q^2/\Lambda^2)^{-2},$$

where vector meson dominance predicts parameter $\Lambda \approx 0.770$ GeV ($\Lambda^{-2} \approx 1.687$ GeV $^{-2}$). The slope of this form factor, $\beta = dF/dq^2(q^2=0)$, equals Λ^{-2} in this approximation.

The measurements below obtain β in the one-pole approximation.

VALUE (GeV $^{-2}$)	CL%	EVTS	DOCUMENT ID	TECN	COMMENT
1.29 \pm 0.13 OUR AVERAGE					
1.28 \pm 0.10 $^{+0.09}_{-0.08}$		30k	BABUSCI	15 KLOE	$1.02 e^+e^- \rightarrow \eta e^+e^-$
3.8 \pm 1.8		213	1 ACHASOV	01B SND	$1.02 e^+e^- \rightarrow \eta e^+e^-$

- 1 The uncertainty is statistical only. The systematic one is negligible, in comparison.

- 41 From a fit to the Dalitz plot.
- 42 Assuming for $\rho(1450)$ mass and width of 1370 and 386 MeV respectively.
- 43 Assuming for σ mass and width of 860 and 880 MeV respectively.
- 44 Assuming for $f_0(1370)$ mass and width of 1186 and 350 MeV respectively.
- 45 Assuming for $f_2(1270)$ mass and width of 1275 and 185 MeV respectively.
- 46 Using structure functions from KUHN 92 and DECKER 93A and $B(\tau^- \rightarrow K^- \pi^- K^+ \nu_\tau) = (0.155 \pm 0.006 \pm 0.009)\%$ from BRIERE 03.
- 47 From a comparison to ALAM 94 assuming purely resonant production of the $K^- K^* 0$ system.
- 48 From a fit to the 3π mass spectrum including the $K\bar{K}^*(892)$ threshold.
- 49 Assuming $a_1(1260)$ dominance and taking $B(\tau \rightarrow a_1(1260)\nu_\tau)$ from BUSKULIC 96.
- 50 Uses multichannel Aitchison-Bowler model (BOWLER 75). Uses data from GAVILLET 77, DAUM 80, and DANKOWYCH 81.
- 51 Inconsistent with observations of $\sigma\pi$, $f_0(1370)\pi$, and $f_2(1270)\pi$ decay modes.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 4 partial widths, a combination of partial widths obtained from integrated cross sections, and 6 branching ratios uses 45 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 83.0$ for 38 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 $\Gamma(\gamma\gamma)$ Γ_7

The value of this width depends on the theoretical model used. Unitary approaches with scalars typically (with exception of PENNINGTON 08) give values clustering around 2.6 keV; without an S-wave contribution, values are systematically higher (typically around 3 keV).

<1.7	90	VOROBYEV 88	ND	$e^+e^- \rightarrow \pi^0\pi^0$

- From a partial-wave analysis of data using a K-matrix formalism with 5 poles.
- From analysis of L3 data at 91 and 183–209 GeV and using SU(3) relations.
- Based on a K-matrix analysis of BELLE data from MORI 07, UEHARA 08A, UEHARA 09 and UEHARA 13. The width is derived from the pole on the third sheet which is closest to the physical axis. Supersedes PENNINGTON 08.
- Solution A (preferred solution based on χ^2 -analysis).
- Dispersion theory based amplitude analysis of BOYER 90, MARSISKE 90, BEHREND 92, and MORI 07.
- Solution B (worse than solution A; still acceptable when systematic uncertainties are included).
- With a narrow scalar state around 1220 MeV.
- Using a unitarized model with a 300–500 keV wide scalar at 1100 MeV.
- Using the unitarized model of LYTH 85.
- Error includes spread of different solutions. Data of MARK2 and CRYSTAL BALL used in the analysis. Authors report strong correlations with $\gamma\gamma$ width of $f_0(1370)$: $\Gamma(f_2) + 1/4 \Gamma(f_0) = 3.6 \pm 0.3$ KeV.
- Radiative corrections modify the partial widths; for instance the COURAU 84 value becomes 2.66 ± 0.21 in the calculation of LANDRO 86.
- Using the MENNESSIER 83 model.
- Superseded by BOYER 90.
- If helicity = 2 assumption is not made.
- Using mass, width and $B(f_2(1270) \rightarrow 2\pi)$ from PDG 78.

 $f_2(1270)$ $\Gamma(i)\Gamma(\gamma\gamma)/\Gamma(\text{total})$ $\Gamma(K\bar{K}) \times \Gamma(\gamma\gamma)/\Gamma_{\text{total}}$ $\Gamma_3\Gamma_7/\Gamma$

CONSTRAINED FIT INFORMATION

An overall fit to 7 branching ratios uses 16 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 24.7$ for 12 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATIONAn overall fit to 5 branching ratios uses 18 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 9.3$ for 15 degrees of freedom.The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

¹ KARSHON 74 suggest an additional $l = 0$ state strongly coupled to $\omega\pi\pi$ which could explain discrepancies in branching ratios and masses. We use a central value and a systematic spread.

² Decays to $b_1(1040)\pi$, $b_1 \rightarrow \omega\pi$. Error increased to account for possible systematic errors of complicated analysis.

1 Another pole is found at (1510 ± 130) - i(800 +100
-150) MeV.
2 Coupled channel analysis of $\pi^+ \pi^- \pi^0, K^+ K^- \pi^0$, and $K^\pm K_S^0 \pi^\mp$.
3 Average between $\pi^+ \pi^- 2\pi^0$ and $2(\pi^+ \pi^-)$.
4 T-matrix pole on sheet ---.
5 Supersedes ANISOVICH 94.
6 Coupled-channel analysis of $\bar{p}p \rightarrow 3\pi^0, \pi^0 \eta \eta$, and $\pi^0 \pi^0 \eta$ on sheet IV. Demonstrates explicitly that $f_0(500)$ and $f_0(1370)$ are two different poles.

Meson Particle Listings

 $f_0(1370)$

- ⁷ Analysis of data from FALVARD 88.
⁸ The pole is on Sheet III. Demonstrates explicitly that $f_0(500)$ and $f_0(1370)$ are two different poles.
⁹ Uses data from BEIER 72b, OCHS 73, HYAMS 73, GRAYER 74, ROSSELET 77, CASON 83, ASTON 88, and ARMSTRONG 91b. Coupled channel analysis with flavor symmetry and all light two-pseudoscalars systems.
¹⁰ Reanalysis of ANISOVICH 94 data.
¹¹ T-matrix pole on sheet III.
¹² Analysis of data from OCHS 73, GRAYER 74, BECKER 79, and CASON 83.

THE PSEUDOSCALAR AND PSEUDOVECTOR MESONS IN THE 1400 MEV REGION

Revised July 2015 by C. Amsler (University of Bern) and A. Masoni (INFN Cagliari).

This minireview deals with some of the 0^{-+} and 1^{++} mesons reported in the 1200–1500 MeV region, namely the $\eta(1405)$, $\eta(1475)$, $f_1(1285)$, $f_1(1420)$, $a_1(1420)$ and $f_1(1510)$. The first observation of a pseudoscalar resonance around 1400 MeV – the $\eta(1440)$ – was made in $p\bar{p}$ annihilation at rest into $\eta(1440)\pi^+\pi^-$, $\eta(1440) \rightarrow K\bar{K}\pi$ [1]. This state was reported to decay into $a_0(980)\pi$ and $K^*(892)\bar{K}$ with roughly equal contributions. The $\eta(1440)$ was also observed in radiative $J/\psi(1S)$ decay into $K\bar{K}\pi$ [2–4] and $\gamma\rho$ [5]. However, two pseudoscalars are now reported in this mass region, the $\eta(1405)$ and $\eta(1475)$. The former decays mainly through $a_0(980)\pi$ (or direct $K\bar{K}\pi$) and the latter mainly to $K^*(892)\bar{K}$.

The simultaneous observation of two pseudoscalars is reported in three production mechanisms: π^-p [6,7]; radiative $J/\psi(1S)$ decay [8,9]; and $p\bar{p}$ annihilation at rest [10–13]. All of them give values for the masses, widths, and decay modes that are in reasonable agreement. However, Ref. [9] favors a state decaying into $K^*(892)\bar{K}$ at a lower mass than the state decaying into $a_0(980)\pi$. In $J/\psi(1S)$ radiative decay, the $\eta(1405)$ decays into $K\bar{K}\pi$ through $a_0(980)\pi$, and hence a signal is also expected in the $\eta\pi\pi$ mass spectrum. This was indeed observed by MARK III in $\eta\pi^+\pi^-$ [14], which reported a mass of 1400 MeV, in line with the existence of the $\eta(1405)$ decaying into $a_0(980)\pi$.

BESII [15] observes an enhancement in $K^+K^-\pi^0$ around 1.44 GeV in $J/\psi(1S)$ decay, recoiling against an ω (but not a ϕ) without resolving the presence of two states nor performing a spin-parity analysis, due to low statistics. This state could also be the $f_1(1420)$ (see below). On the other hand, BESII observes $\eta(1405) \rightarrow \eta\pi\pi$ in $J/\psi(1S)$ decay, recoiling against an ω [16]. A single unresolved broad peak is also observed by

BESIII in the decay $\psi(2S) \rightarrow \omega K^* K$ which could be due to $\eta(1405)$, $\eta(1475)$ and $f_1(1420)$ [17].

The $\eta(1405)$ is also observed in $p\bar{p}$ annihilation at rest into $\eta\pi^+\pi^-\pi^0\pi^0$, where it decays into $\eta\pi\pi$ [18]. The intermediate $a_0(980)\pi$ accounts for roughly half of the $\eta\pi\pi$ signal, in agreement with MARK III [14] and DM2 [4].

However, the issue remains controversial as to whether two pseudoscalar mesons really exist. According to Ref. [19] the splitting of a single state could be due to nodes in the decay amplitudes which differ in $\eta\pi\pi$ and $K^*(892)\bar{K}$. Based on the isospin violating decay $J/\psi(1S) \rightarrow \gamma 3\pi$ observed by BESIII [20] the splitting could also be due to a triangular singularity mixing $\eta\pi\pi$ and $K^*(892)\bar{K}$ [21–22]. However, in a further paper [23], using the approach of [21], the authors concluded that the BESIII results can be reproduced either with the $\eta(1405)$ or the $\eta(1475)$, or by a mixture of these two states.

The $\eta(1295)$ has been observed by four π^-p experiments [7,24–26], and evidence is reported in $p\bar{p}$ annihilation [27–29]. In $J/\psi(1S)$ radiative decay, the $\eta(1295)$ signal is evident in the 0^{-+} $\eta\pi\pi$ wave of the DM2 data [9]. Also BaBar [30] reports evidence for a signal around 1295 MeV in B decays into $\eta\pi\pi K$. Nonetheless, the existence of the $\eta(1295)$ is questioned in Refs. [19] and [31] in which the authors claim the existence of a single pseudoscalar meson at 1440 MeV, the first radial excitation of the η . This conclusion is mainly based on the analysis of the annihilation $p\bar{p} \rightarrow 4\pi\eta$ with Crystal Barrel data [32].

Considering that the $\eta(1295)$ has been reported by several experiments, using different production mechanisms, we shall assume that this state is established. The $\eta(1475)$ could then be the first radial excitation of the η' , with the $\eta(1295)$ being the first radial excitation of the η . Ideal mixing, suggested by the $\eta(1295)$ and $\pi(1300)$ mass degeneracy, would then imply that the second isoscalar in the nonet is mainly $s\bar{s}$, and hence couples to $K^*\bar{K}$, in agreement with properties of the $\eta(1475)$. Also, its width matches the expected width for the radially excited $s\bar{s}$ state [33,34]. A study of radial excitations of pseudoscalar mesons [35] favors the $s\bar{s}$ interpretation of the $\eta(1475)$. However, due to the strong kinematical suppression the data are not sufficient to exclude a sizeable $s\bar{s}$ admixture also in the $\eta(1405)$.

The $K\bar{K}\pi$ and $\eta\pi\pi$ channels were studied in $\gamma\gamma$ collisions by L3 [36]. The analysis led to a clear $\eta(1475)$ signal in $K\bar{K}\pi$, decaying into $K^*\bar{K}$, very well identified in the untagged data sample, where contamination from spin 1 resonances is not allowed. At the same time, L3 [36] did not observe the $\eta(1405)$, neither in $K\bar{K}\pi$ nor in $\eta\pi\pi$. The observation of the $\eta(1475)$, combined with the absence of an $\eta(1405)$ signal, strengthens the two-resonances hypothesis. Since gluonium production is presumably suppressed in $\gamma\gamma$ collisions, the L3 results [36] suggest that $\eta(1405)$ has a large gluonic content (see also Refs. [37] and [38]).

The L3 result is somewhat in disagreement with that of CLEO-II, which did not observe any pseudoscalar signal in $\gamma\gamma \rightarrow \eta(1475) \rightarrow K_S^0 K^\pm \pi^\mp$ [39]. However, more data are

Meson Particle Listings

$\eta(1405)$

required. Moreover, after the CLEO-II result, L3 performed a further analysis with full statistics [40], confirming their previous evidence for the $\eta(1475)$. The CLEO upper limit [39] for $\Gamma_{\gamma\gamma}(\eta(1475))$, and the L3 results [40], are consistent with the world average for the $\eta(1475)$ width.

BaBar [30] also reports the $\eta(1475)$ in B decays into $K\bar{K}^*$ recoiling against a K , but upper limits only are given for the $\eta(1405)$. As mentioned above, in B decays into $\eta\pi\pi K$ the $\eta(1295) \rightarrow \eta\pi\pi$ is observed while only upper limits are given for the $\eta(1405)$. The $f_1(1420)$ (and $f_1(1285)$) are not seen.

The gluonium interpretation for the $\eta(1405)$ is not favored by lattice gauge theories which predict the 0^{-+} state above 2 GeV [41,42] (see also the article on the “Quark model” in this issue of the Review). However, the $\eta(1405)$ is an excellent candidate for the 0^{-+} glueball in the fluxtube model [43]. In this model, the 0^{++} $f_0(1500)$ glueball is also naturally related to a 0^{-+} glueball with mass degeneracy broken in QCD. Also, Ref. [44] shows that the pseudoscalar glueball could lie at a lower mass than predicted from lattice calculation. In this model the $\eta(1405)$ appears as the natural glueball candidate, see also Refs. [45–47]. A detailed review of the experimental situation is available in Ref. [48].

Let us now deal with the 1^{++} mesons. The pseudovector nonet is believed to consist of the isovector $a_1(1260)$, the isoscalars $f_1(1285)$ and $f_1(1420)$, and the K_{1A} , which is a mixture of about 50% $K_1(1270)$ and 50% $K_1(1400)$. (This last property prevents a straightforward calculation of the nonet mixing angle via the mass formulae.) The $f_1(1285)$ could also be a $K^*\bar{K}$ molecule [49] or as a tetraquark state [50] and the $f_1(1420)$ a $K^*\bar{K}$ molecule, due to the proximity of the $K^*\bar{K}$ threshold [51]. LHCb has analyzed the decays \bar{B}^0 and $\bar{B}_s^0 \rightarrow J/\psi(1S)f_1(1285)$ and determined the nonet mixing angle to be consistent with a mostly $u\bar{u} + d\bar{d}$ structure [52] without specifying the identity of its isoscalar partner. This is consistent with earlier determinations assuming the $f_1(1420)$ as the isoscalar partner [53] and the ratio of \bar{B}^0/\bar{B}_s^0 decay rates excludes the tetraquark interpretation of this state [52].

The $f_1(1420)$, decaying into $K^*\bar{K}$, was first reported in π^-p reactions at 4 GeV/c [54]. However, later analyses found that the 1400–1500 MeV region was far more complex [55–57]. A reanalysis of the MARK III data in radiative $J/\psi(1S)$ decay into $K\bar{K}\pi$ [8] shows the $f_1(1420)$ decaying into $K^*\bar{K}$. A $C=+1$ state is also seen in tagged $\gamma\gamma$ collisions (*e.g.*, Ref. [58]).

In $\pi^-p \rightarrow \eta\pi\pi n$ charge-exchange reactions at 8–9 GeV/c the $\eta\pi\pi$ mass spectrum is dominated by the $\eta(1440)$ and $\eta(1295)$ [24,59], and at 100 GeV/c Ref. [25] reports the $\eta(1295)$ and $\eta(1440)$ decaying into $\eta\pi^0\pi^0$ with a weak $f_1(1285)$ signal, and no evidence for the $f_1(1420)$.

Axial (1^{++}) mesons are not observed in $\bar{p}p$ annihilation at rest in liquid hydrogen, which proceeds dominantly through S -wave annihilation. However, in gaseous hydrogen, P -wave annihilation is enhanced and, indeed, Ref. [11] reports $f_1(1420)$ decaying into $K^*\bar{K}$. The $f_1(1420)$, decaying into $K\bar{K}\pi$, is also seen in pp central production, together with the $f_1(1285)$. The

latter decays via $a_0(980)\pi$, and the former only via $K^*\bar{K}$, while the $\eta(1440)$ is absent [60,61]. The $K_S^0 K_S^0 \pi^0$ decay mode of the $f_1(1420)$ establishes unambiguously $C=+1$. On the other hand, there is no evidence for any state decaying into $\eta\pi\pi$ around 1400 MeV, and hence the $\eta\pi\pi$ mode of the $f_1(1420)$ must be suppressed [62].

The COMPASS Collaboration has recently reported an isovector state at 1414 MeV, the $a_1(1420)$ [63]. This relatively narrow state ($\simeq 150$ MeV) is produced by diffractive dissociation with 190 GeV pions in $\pi N \rightarrow 3\pi N$, decays into $f_0(980)\pi \rightarrow 3\pi$ (P-wave) and has therefore the quantum numbers $(I^G)J^{PC} = (1^-)1^{++}$. The pseudovector nonet already contains the established $a_1(1260)$ as the $I = 1$ state. As mentioned above, the $f_1(1420)$ has been interpreted as a $K^*\bar{K}$ molecule [51]. The new $a_1(1420)$ could be its isovector partner. Arguments favoring the $f_1(1420)$ being a hybrid $q\bar{q}g$ meson [64] or a four-quark state [65] were also put forward. The $q\bar{q}$ state would then remain to be identified, with the $f_1(1510)$ (see below) as a candidate. However, an alternative explanation is suggested in Ref. [66] in which the authors claim a single 1^{++} isovector around 1400 MeV, leading to two peaks in the 3π mass spectrum, depending on the production mechanism, $\rho\pi$ for the $a_1(1260)$ and $f_0(980)\pi$ for the $a_1(1420)$.

We now turn to the experimental evidence for the $f_1(1510)$. The $f_1(1510)$ was seen in $K^-p \rightarrow \Lambda K\bar{K}\pi$ at 4 GeV/c [67], and at 11 GeV/c [68]. Evidence is also reported in π^-p at 8 GeV/c, based on the phase motion of the 1^{++} $K^*\bar{K}$ wave [57]. A somewhat broader 1^{++} signal is also observed in $J/\psi(1S) \rightarrow \gamma\eta\pi^+\pi^-$ [69] as well as a small signal in $J/\psi(1S) \rightarrow \gamma\eta'\pi^+\pi^-$, attributed to the $f_1(1510)$ [70].

The absence of $f_1(1420)$ in K^-p [68] argues against the $f_1(1420)$ being the $s\bar{s}$ member of the 1^{++} nonet. However, the $f_1(1420)$ was reported in K^-p but not in π^-p [71], while two experiments do not observe the $f_1(1510)$ in K^-p [71,72]. The latter is also not seen in central collisions [61], nor $\gamma\gamma$ collisions [73], although, surprisingly for an $s\bar{s}$ state, a signal is reported in 4π decays [74]. These facts led to the conclusion that $f_1(1510)$ was not well established [75].

Summarizing, there is evidence for two isovector 1^{++} states in the 1400 MeV region, the $a_1(1260)$ and $a_1(1420)$, which cannot be both $q\bar{q}$ states. These two states could stem from the same pole, or the latter be exotic (tetraquark or hybrid) or a molecular state. The $f_1(1285)$ and the $f_1(1420)$ are well known but their nature ($q\bar{q}$, tetraquark or molecular) remains to be established. In the 0^{-+} sector there is evidence for two pseudoscalars in the 1400 MeV region, the $\eta(1405)$ and $\eta(1475)$, decaying into $a_0(980)\pi$ and $K^*\bar{K}$, respectively. Alternatively, these two structures could originate from a single pole. Doubts have been expressed on the existence of the $\eta(1295)$. The $f_1(1510)$ remains to be firmly established.

80 ± 10	800	22,24 BAILLON 67	HBC	$0.0 \bar{p} p \rightarrow K\bar{K}\pi\pi\pi$

14 The selected process is $J/\psi \rightarrow \omega a_0(980)\pi$.15 From fit to the $a_0(980)\pi 0^-$ partial wave.16 From $\eta\pi^+\pi^-$ mass distribution - mainly $a_0(980)\pi$ - no spin-parity determination available.17 Decaying dominantly directly to $K^+ K^- \pi^0$.18 Decaying into $(K\bar{K})_S \pi$, $(K\pi)_S \bar{K}$, and $a_0(980)\pi$.19 From fit to the $a_0(980)\pi 0^-$ partial wave, but $a_0(980)\pi 1^+$ cannot be excluded.20 This peak in the $\gamma\rho$ channel may not be related to the $\eta(1405)$.

21 Estimated by us from various fits.

22 These experiments identify only one pseudoscalar in the 1400–1500 range. Data could also refer to $\eta(1475)$.

23 Systematic uncertainty not evaluated.

24 From best fit to 0^- partial wave, 50% $K^*(892)K$, 50% $a_0(980)\pi$. **$\eta(1405)$ DECAY MODES**

• • • We do not use the following data for averages, fits, limits, etc. • • •

⁹From a fit with a width fixed at 55 MeV.
¹⁰The form factor parameter from the fit is 926 ± 78 MeV.
¹¹Assume a ρ -pole form factor.
¹²A ϕ -pole form factor gives considerably smaller widths.
¹³Published value divided by 2.

- $\omega\pi$ not included.
- Using ABELE 97.
- Using Breit-Wigner parameterization of the $\rho(1450)$ and assuming equal probabilities of the $\rho(1450) \rightarrow \pi\pi$ and $\rho(1450) \rightarrow \omega\pi$ decays.
- From a phenomenological model based on vector meson dominance with $\rho(1450)$ and $\phi(1680)$ masses and widths from the PDG 12.
- From a fit to the $e^+e^- \rightarrow \eta\pi^+\pi^-$ cross section with vector meson dominance model including $\rho(770)$, $\rho(1450)$, and $\rho(1700)$ decaying exclusively via $\eta\rho(770)$. Masses and widths of vector states are fixed to PDG 14. Coupling constants are assumed to be real.
- Reports the inverse of the quoted value as 12.3 ± 3.1 .
- Using data from BISELLO 91B, DOLINSKY 86 and ALBRECHT 87L.

¹ From partial wave analysis including all possible combinations of $0^{++}, 2^{++}$, and 4^{++} resonances.

² T-matrix pole.

³ Average between $\pi^+\pi^-2\pi^0$ and $2(\pi^+\pi^-)$.

⁴ T-matrix pole, supersedes ANISOVICH 94.

⁵ T-matrix pole, supersedes ANISOVICH 94 and AMSLER 92.

⁶ Using CLEO-c data but not authored by the CLEO Collaboration.

⁷ From a fit to a Breit-Wigner line shape with fixed $\Gamma = 109$ MeV.

⁸ Reanalysis of AITALA 01A data. This state could also be $f_0(1370)$.

⁹ Breit-Wigner mass. May also be the $f_0(1370)$.

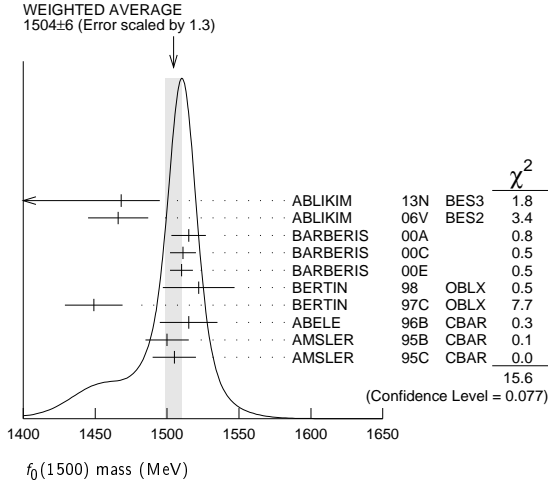

¹⁰ Breit-Wigner mass.

¹¹ Statistical error only.

Meson Particle Listings

$f_0(1500)$

- 12 Breit-Wigner, solution 1, PWA ambiguous.
- 13 K-matrix pole from combined analysis of $\pi^- p \rightarrow \pi^0 \pi^0 n$, $\pi^- p \rightarrow K \bar{K} n$, $\pi^+ \pi^- \rightarrow \pi^+ \pi^-$, $\bar{p} p \rightarrow \pi^0 \pi^0 \pi^0$, $\pi^0 \eta \eta$, $\pi^0 \pi^0 \eta$, $\pi^+ \pi^- \pi^0$, $K^+ K^- \pi^0$, $K_S^0 K_S^0 \pi^0$, $K^+ K_S^0 \pi^-$ at rest, $\bar{p} n \rightarrow \pi^- \pi^- \pi^+$, $K_S^0 K^- \pi^0$, $K_S^0 K_S^0 \pi^-$ at rest.
- 14 Supersedes BARBERIS 99 and BARBERIS 99b.
- 15 T-matrix pole on sheet $--+$.
- 16 T-matrix pole. Coupled-channel analysis of AMSLER 95B, AMSLER 95c, and AMSLER 94d.
- 17 Supersedes ABATZIS 94, ARMSTRONG 89E. Breit-Wigner mass.
- 18 From a simultaneous analysis of the annihilations $\bar{p} p \rightarrow 3\pi^0, \pi^0 \eta \eta$.
- 19 Reanalysis of ANISOVICH 94 data.
- 20 From central value and spread of two solutions. Breit-Wigner mass.

- 21 From partial wave analysis including all possible combinations of 0^{++} , 2^{++} , and 4^{++} resonances.
- 22 T-matrix pole.
- 23 Average between $\pi^+ \pi^- 2\pi^0$ and $2(\pi^+ \pi^-)$.
- 24 T-matrix pole, supersedes ANISOVICH 94.
- 25 T-matrix pole, supersedes ANISOVICH 94 and AMSLER 92.
- 26 Breit-Wigner width. May also be the $f_0(1370)$.
- 27 Breit-Wigner width.
- 28 Statistical error only.
- 29 Breit-Wigner, solution 1, PWA ambiguous.
- 30 K-matrix pole from combined analysis of $\pi^- p \rightarrow \pi^0 \pi^0 n$, $\pi^- p \rightarrow K \bar{K} n$, $\pi^+ \pi^- \rightarrow \pi^+ \pi^-$, $\bar{p} p \rightarrow \pi^0 \pi^0 \pi^0$, $\pi^0 \eta \eta$, $\pi^0 \pi^0 \eta$, $\pi^+ \pi^- \pi^0$, $K^+ K^- \pi^0$, $K_S^0 K_S^0 \pi^0$, $K^+ K_S^0 \pi^-$ at rest, $\bar{p} n \rightarrow \pi^- \pi^- \pi^+$, $K_S^0 K^- \pi^0$, $K_S^0 K_S^0 \pi^-$ at rest.
- 31 Supersedes BARBERIS 99 and BARBERIS 99b.
- 32 T-matrix pole on sheet $--+$.
- 33 T-matrix pole. Coupled-channel analysis of AMSLER 95B, AMSLER 95c, and AMSLER 94d.
- 34 Supersedes ABATZIS 94, ARMSTRONG 89E. Breit-Wigner mass.
- 35 From a simultaneous analysis of the annihilations $\bar{p} p \rightarrow 3\pi^0, \pi^0 \eta \eta$.
- 36 Reanalysis of ANISOVICH 94 data.
- 37 From central value and spread of two solutions. Breit-Wigner mass.

CONSTRAINED FIT INFORMATION

An overall fit to 6 branching ratios uses 10 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 11.4$ for 6 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

39 Excluding $\rho\rho$ contribution to 4π .
 40 From a combined K-matrix analysis of Crystal Barrel (0. $\bar{p}p \rightarrow \pi^0 \pi^0 \pi^0, \pi^0 \eta\eta, \pi^0 \pi^0 \eta$), GAMS ($\pi p \rightarrow \pi^0 \pi^0 n, \eta\eta n$), and BNL ($\pi p \rightarrow K\bar{K}n$) data.
 41 From the combined data of ABELE 96 and ABELE 96C.
 42 Using AMSLER 95B (3 π^0).

Meson Particle Listings

$f_0(1500)$, $f_1(1510)$

- 43 2π width determined to be 60 ± 12 MeV.
- 44 Coupled-channel analysis of AMSLER 95B, AMSLER 95C, and AMSLER 94D.
- 45 Using AMSLER 94E ($\eta\eta'\pi^0$).
- 46 Coupled channel analysis of $\pi^+\pi^-\pi^0$, $K^+K^-\pi^0$, and $K^\pm K_S^0 \pi^\mp$.
- 47 Using $\pi^0\pi^0$ from AMSLER 95B.
- 48 Using AMSLER 95B ($3\pi^0$), AMSLER 94C ($2\pi^0\eta$) and SU(3).
- 49 Combining results of GAM4 with those of WA76 on $K\bar{K}$ central production.
- 50 Using ETKIN 82B and COHEN 80.

- 16 From a partial-wave analysis of data using a K-matrix formalism with 5 poles.
- 17 CHABAUD 81 is a reanalysis of PAWLICKI 77 data.
- 18 From an amplitude analysis where the $f'_2(1525)$ width and elasticity are in complete disagreement with the values obtained from $K\bar{K}$ channel, making the solution dubious.
- 19 From a fit to the D with $f_2(1270)$ - $f'_2(1525)$ interference. Mass fixed at 1516 MeV.
- 20 Systematic errors not estimated.
- 21 From partial wave analysis including all possible combinations of $0^{++}, 2^{++},$ and 4^{++} resonances.
- 22 Supersedes ACCIARRI 95J.
- 23 From an analysis ignoring interference with $f_0(1710)$.
- 24 From analysis of L3 data at 91 and 183-209 GeV.
- 25 From an analysis including interference with $f_0(1710)$.
- 26 T-matrix pole.
- 27 4-poles, 5-channel K matrix fit.
- 28 In the SU(3) based model with a specific interference pattern of the $f_2(1270), a_2^0(1320),$ and $f'_2(1525)$ mesons incoherently added to the $f_0(1710)$ and non-resonant background.
- 29 Systematic errors not estimated.

$f'_2(1525)$ DECAY MODES

Mode	Fraction (Γ_i/Γ)
$\Gamma_1 K\bar{K}$	(88.7 ± 2.2) %
$\Gamma_2 \eta\eta$	(10.4 ± 2.2) %
$\Gamma_3 \pi\pi$	(8.2 ± 1.5) × 10 ⁻³
$\Gamma_4 K\bar{K}^*(892) + c.c.$	
$\Gamma_5 \pi K\bar{K}$	
$\Gamma_6 \pi\pi\eta$	
$\Gamma_7 \pi^+\pi^+\pi^-\pi^-$	
$\Gamma_8 \gamma\gamma$	(1.10 ± 0.14) × 10 ⁻⁶

CONSTRAINED FIT INFORMATION

An overall fit to the total width, 2 partial widths, a combination of partial widths obtained from integrated cross sections, and 3 branching ratios uses 17 measurements and one constraint to determine 5 parameters. The overall fit has a $\chi^2 = 14.3$ for 13 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 6 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 1.9$ for 3 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{total}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\rho_3(1690)$

CONSTRAINED FIT INFORMATION

An overall fit to 5 branching ratios uses 10 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 14.7$ for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

 $\rho(1700)$

$$J^G(J^{PC}) = 1^+(1^{--})$$

THE $\rho(1450)$ AND THE $\rho(1700)$

Updated November 2015 by S. Eidelman (Novosibirsk), C. Hanhart (Juelich) and G. Venanzoni (Frascati).

In our 1988 edition, we replaced the $\rho(1600)$ entry with two new ones, the $\rho(1450)$ and the $\rho(1700)$, because there was emerging evidence that the 1600-MeV region actually contains two ρ -like resonances. Erkal [1] had pointed out this possibility with a theoretical analysis on the consistency of 2π and 4π electromagnetic form factors and the $\pi\pi$ scattering length. Donnachie [2], with a full analysis of data on the 2π and 4π final states in e^+e^- annihilation and photoproduction reactions, had also argued that in order to obtain a consistent picture, two resonances were necessary. The existence of $\rho(1450)$ was supported by the analysis of $\eta\rho^0$ mass spectra obtained in photoproduction and e^+e^- annihilation [3], as well as that of $e^+e^- \rightarrow \omega\pi$ [4].

The analysis of [2] was further extended by [5,6] to include new data on 4π -systems produced in e^+e^- annihilation, and in τ -decays (τ decays to 4π , and e^+e^- annihilation to 4π can be related by the Conserved Vector Current assumption). These systems were successfully analyzed using interfering contributions from two ρ -like states, and from the tail of the $\rho(770)$ decaying into two-body states. While specific conclusions on $\rho(1450) \rightarrow 4\pi$ were obtained, little could be said about the $\rho(1700)$.

Independent evidence for two 1^- states is provided by [7] in 4π electroproduction at $\langle Q^2 \rangle = 1$ (GeV/c) 2 , and by [8] in a high-statistics sample of the $\eta\pi\pi$ system in π^-p charge exchange.

This scenario with two overlapping resonances is supported by other data. Bisello [9] measured the pion form factor in the interval 1.35–2.4 GeV, and observed a deep minimum around 1.6 GeV. The best fit was obtained with the hypothesis of ρ -like resonances at 1420 and 1770 MeV, with widths of about 250 MeV. Antonelli [10] found that the $e^+e^- \rightarrow \eta\pi^+\pi^-$ cross section is better fitted with two fully interfering Breit-Wigners, with parameters in fair agreement with those of [2] and [9]. These results can be considered as a confirmation of the $\rho(1450)$.

Decisive evidence for the $\pi\pi$ decay mode of both $\rho(1450)$ and $\rho(1700)$ comes from $\bar{p}p$ annihilation at rest [11]. It has been shown that these resonances also possess a $K\bar{K}$ decay mode [12–14]. High-statistics studies of the decays $\tau \rightarrow \pi\pi\nu_\tau$ [15,16], and $\tau \rightarrow 4\pi\nu_\tau$ [17] also require the $\rho(1450)$, but are not sensitive to the $\rho(1700)$, because it is too close to the τ mass. A recent very-high-statistics study of the $\tau \rightarrow \pi\pi\nu_\tau$ decay performed at Belle [18] reports the first observation of both $\rho(1450)$ and $\rho(1700)$ in τ decays. A clear picture of the two $\pi^+\pi^-$ resonances interfering with the $\rho(770)$ was also reported by BaBar using the ISR method [19].

The structure of these ρ states is not yet completely clear. Barnes [20] and Close [21] claim that $\rho(1450)$ has a mass consistent with radial $2S$, but its decays show characteristics of hybrids, and suggest that this state may be a $2S$ -hybrid mixture. Donnachie [22] argues that hybrid states could have a 4π decay mode dominated by the $a_1\pi$. Such behavior has been observed by [23] in $e^+e^- \rightarrow 4\pi$ in the energy range 1.05–1.38 GeV, and by [17] in $\tau \rightarrow 4\pi$ decays. CLEO [24] and Belle [25] observe the $\rho(1450) \rightarrow \omega\pi$ decay mode in B -meson decays, however, do not find $\rho(1700) \rightarrow \omega\pi^0$. A similar conclusion is made by [26], who studied the process $e^+e^- \rightarrow \omega\pi^0$. Various decay modes of the $\rho(1450)$ and $\rho(1700)$ are observed in $\bar{p}n$ and $\bar{p}p$ annihilation [27,28], but no definite conclusions can be drawn. More data should be collected to clarify the nature of the ρ states, particularly in the energy range above 1.6 GeV.

We now list under a separate entry the $\rho(1570)$, the $\phi\pi$ state with $J^{PC} = 1^{--}$ earlier observed by [29] (referred to as $C(1480)$) and recently confirmed by [30]. While [31] shows that it may be a threshold effect, [5] and [32] suggest two independent vector states with this decay mode. The $C(1480)$ has not been seen in the $\bar{p}p$ [33] and e^+e^- [34,35] experiments. However, the sensitivity of the two latter is an order of magnitude lower than that of [30]. Note that [30] can not exclude that their observation is due to an OZI-suppressed decay mode of the $\rho(1700)$.

Several observations on the $\omega\pi$ system in the 1200-MeV region [36–42] may be interpreted in terms of either $J^P = 1^- \rho(770) \rightarrow \omega\pi$ production [43], or $J^P = 1^+ b_1(1235)$ production [41,42]. We argue that no special entry for a $\rho(1250)$ is needed. The LASS amplitude analysis [44] showing

Meson Particle Listings

 $\rho(1700)$

evidence for $\rho(1270)$ is preliminary and needs confirmation. For completeness, the relevant observations are listed under the $\rho(1450)$.

Recently [45] reported a very broad 1^{--} resonance-like K^+K^- state in $J/\psi \rightarrow K^+K^-\pi^0$ decays. Its pole position corresponds to mass of 1576 MeV and width of 818 MeV. [46–48] suggest its exotic structure (molecular or multiquark), while [49] and [50] explain it by the interference between the $\rho(1450)$ and $\rho(1700)$. We quote [45] as $X(1575)$ in the section “Further States.”

Evidence for ρ -like mesons decaying into 6π states was first noted by [51] in the analysis of 6π mass spectra from e^+e^- annihilation [52,53] and diffractive photoproduction [54]. Clegg [51] argued that two states at about 2.1 and 1.8 GeV exist: while the former is a candidate for the $\rho(2150)$, the latter could be a manifestation of the $\rho(1700)$ distorted by threshold effects. BaBar reported observations of the new decay modes of the $\rho(2150)$ in the channels $\eta'(958)\pi^+\pi^-$ and $f_1(1285)\pi^+\pi^-$ [55]. The relativistic quark model [56] predicts the 2^3D_1 state with $J^{PC} = 1^{--}$ at 2.15 GeV which can be identified with the $\rho(2150)$.

We no longer list under a separate particle $\rho(1900)$ various observations of irregular behavior of the cross sections near the $N\bar{N}$ threshold. Dips of various width around 1.9 GeV were reported by the E687 Collaboration (a narrow one in the $3\pi^+3\pi^-$ diffractive photoproduction [57,58]), by the FENICE experiment (a narrow structure in the R value [59]), by BaBar in ISR (a narrow structure in $e^+e^- \rightarrow \phi\pi$ final state [60], but much broader in $e^+e^- \rightarrow 3\pi^+3\pi^-$ and $e^+e^- \rightarrow 2(\pi^+\pi^-\pi^0)$ [61]), by CMD-3 (also a rather broad dip in $e^+e^- \rightarrow 3\pi^+3\pi^-$ [62]). Most probably, these structures emerge as a threshold effect due to the opening of the $N\bar{N}$ channel [63,64].

180 ± 50			30	HYAMS	73	ASPK 17 $\pi^- p \rightarrow \pi^+\pi^- n$

²² Using the KUHN 90 parametrization of the pion form factor, neglecting $\rho-\omega$ interference.

²³ Using the GOUNARIS 68 parametrization of the pion form factor leaving the masses and widths of the $\rho(1450)$, $\rho(1700)$, and $\rho(2150)$ resonances as free parameters of the fit.

²⁴ $|F_\pi(0)|^2$ fixed to 1.

²⁵ From the GOUNARIS 68 parametrization of the pion form factor.

²⁶ T-matrix pole.

²⁷ From phase shift analysis of HYAMS 73 data.

²⁸ Simple relativistic Breit-Wigner fit with constant width.

²⁹ An additional 40 MeV uncertainty in both the mass and width is present due to the choice of the background shape.

³⁰ Included in BECKER 79 analysis.

- 1 From partial wave analysis including all possible combinations of 0^{++} , 2^{++} , and 4^{++} resonances.
- 2 In the SU(3) based model with a specific interference pattern of the $f_2(1270)$, $a_2^0(1320)$, and $f_2^0(1525)$ mesons incoherently added to the $f_0(1710)$ and non-resonant background.
- 3 This state may be different from $f_0(1710)$, see CLOSE 05.
- 4 $J^P = 0^+$.
- 5 T-matrix pole.
- 6 Supersedes BARBERIS 99 and BARBERIS 99B.
- 7 $J^P = 0^+$, supersedes by ARMSTRONG 89D.
- 8 $N_B J^{PC}$ determination.
- 9 $J^P = 2^+$.
- 10 Using CLEO-c data but not authored by the CLEO Collaboration.
- 11 From a fit to a Breit-Wigner line shape with fixed $\Gamma = 135$ MeV.
- 12 Breit-Wigner mass.
- 13 Systematic errors not estimated.
- 14 K-matrix pole, assuming $J^P = 0^+$, from combined analysis of $\pi^- p \rightarrow \pi^0\pi^0 n, \pi^- p \rightarrow K^+ K^- n, \pi^+ \pi^- \rightarrow \pi^+ \pi^-, \bar{p}p \rightarrow \pi^0\pi^0\pi^0, \pi^0\eta\eta, \pi^0\pi^0\eta, \pi^+\pi^-\pi^0, K^+K^-\pi^0, K_S^0 K_S^0\pi^0, K^+K_S^0\pi^-$ at rest, $\bar{p}n \rightarrow \pi^-\pi^-\pi^+, K_S^0 K^- \pi^0, K_S^0 K_S^0\pi^-$ at rest.
- 15 Decaying to $f_0(1370)\pi\pi$.
- 16 $J^P = 0^+$.
- 17 Not seen by AMSLER 02.
- 18 T-matrix pole, assuming $J^P = 0^+$.
- 19 No J^{PC} determination.
- 20 No J^{PC} determination, width not determined.
- 21 From a fit to the 0^+ partial wave.
- 22 ALDE 92D combines all the GAMS-2000 data.
- 23 $J^P = 2^+$, superseded by FRENCH 99.
- 24 From an analysis ignoring interference with $f_2^0(1525)$.
- 25 From an analysis including interference with $f_2^0(1525)$.
- 26 Superseded by ALDE 92D.
- 27 Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.
- 28 $J^P = 2^+$ preferred.
- 29 From fit neglecting nearby $f_2^0(1525)$. Replaced by BLOOM 83.
- 30 Superseded by LONGACRE 86.

200 ± 156		29		ETKIN 82B MPS $23 \pi^- p \rightarrow n2K_S^0$

- 1 From partial wave analysis including all possible combinations of 0^{++} , 2^{++} , and 4^{++} resonances.
- 2 In the SU(3) based model with a specific interference pattern of the $f_2(1270)$, $a_2^0(1320)$, and $f_2^0(1525)$ mesons incoherently added to the $f_0(1710)$ and non-resonant background.
- 3 Breit-Wigner width.
- 4 $J^P = 0^+$.
- 5 T-matrix pole.
- 6 Supersedes BARBERIS 99 and BARBERIS 99B.
- 7 $J^P = 0^+$, supersedes by ARMSTRONG 89D.
- 8 $N_B J^{PC}$ determination.
- 9 $J^P = 2^+$.
- 10 No J^{PC} determination.
- 11 Systematic errors not estimated.
- 12 This state may be different from $f_0(1710)$, see CLOSE 05.
- 13 (Solution 1)
- 14 K-matrix pole, assuming $J^P = 0^+$, from combined analysis of $\pi^- p \rightarrow \pi^0\pi^0 n, \pi^- p \rightarrow K^+ K^- n, \pi^+ \pi^- \rightarrow \pi^+ \pi^-, \bar{p}p \rightarrow \pi^0\pi^0\pi^0, \pi^0\eta\eta, \pi^0\pi^0\eta, \pi^+\pi^-\pi^0, K^+K^-\pi^0, K_S^0 K_S^0\pi^0, K^+K_S^0\pi^-$ at rest, $\bar{p}n \rightarrow \pi^-\pi^-\pi^+, K_S^0 K^- \pi^0, K_S^0 K_S^0\pi^-$ at rest.

Meson Particle Listings

 $f_0(1710)$

- ¹⁵ (Solution I)
¹⁶ Decaying to $f_0(1370)\pi\pi$.
¹⁷ $J^P = 0^+$.
¹⁸ Not seen by AMSLER 02.
¹⁹ T-matrix pole, assuming $J^P = 0^+$
²⁰ No J^{PC} determination.
²¹ From a fit to the 0^+ partial wave.
²² ALDE 92d combines all the GAMS-2000 data.
²³ $J^P = 2^+$, (0^+ excluded).
²⁴ From an analysis ignoring interference with $f_2'(1525)$.
²⁵ From an analysis including interference with $f_2'(1525)$.
²⁶ Uses MRK3 data. From a partial-wave analysis of data using a K-matrix formalism with 5 poles, but assuming spin 2. Fit with constrained inelasticity.
²⁷ $J^P = 2^+$ preferred.
²⁸ From fit neglecting nearby $f_2'(1525)$. Replaced by BLOOM 83.
²⁹ From an amplitude analysis of the $K_S^0 K_S^0$ system, superseded by LONGACRE 86.

⁵ OAKDEN 94 makes an amplitude analysis of LEAR data on $\bar{p}p \rightarrow \pi\pi$ using a method based on Barrelet zeros. This is solution A. The amplitude analysis of HASAN 94 includes earlier data as well, and assume that the data can be parametrized in terms of towers of nearly degenerate resonances on the leading Regge trajectory. See also KLOET 96 and MARTIN 97 who make related analyses.

⁶ From solution B of amplitude analysis of data on $\bar{p}p \rightarrow \pi\pi$.

⁷ $I(J^P) = 0(2^+)$ from simultaneous analysis of $p\bar{p} \rightarrow \pi^- \pi^+ \pi^0$ and $\pi^0 \pi^0$.

⁸ $I^G(J^P) = 0^+(2^+)$ from partial-wave amplitude analysis.

~ 300	ALDE 92c	GAM4	100 $\pi^- \rho \rightarrow \omega \pi^0 n$

- Using the GOUNARIS 68 parametrization of the pion form factor leaving the masses and widths of the $\rho(1450)$, $\rho(1700)$, and $\rho(2150)$ resonances as free parameters of the fit.
- Includes ATKINSON 85.
- See however KLOET 96 who fit $\pi^+ \pi^-$ only and find waves only up to $J = 3$ to be important but not significantly resonant.
- $I(J^P) = 1(1^-)$ from simultaneous analysis of $p\bar{p} \rightarrow \pi^- \pi^+$ and $\pi^0 \pi^0$.
- From the combined analysis of ANISOVICH 00J, ANISOVICH 01D, ANISOVICH 01E, and ANISOVICH 02.
- From a fit to the total elastic cross section.
- Isospins 0 and 1 not separated.
- Seen as bump in $I = 1$ state. See also COOPER 68. PEASLEE 75 confirm $\bar{p}p$ results of ABRAMS 70, no narrow structure.

STRANGE MESONS ($S = \pm 1, C = B = 0$)

$$K^+ = u\bar{s}, K^0 = d\bar{s}, \bar{K}^0 = \bar{d}s, K^- = \bar{u}s, \text{ similarly for } K^{*s}$$

 K^\pm

$$I(J^P) = \frac{1}{2}(0^-)$$

THE CHARGED KAON MASS

Revised 1994 by T.G. Trippe (LBNL).

The average of the six charged kaon mass measurements which we use in the Particle Listings is

$$m_{K^\pm} = 493.677 \pm 0.013 \text{ MeV } (S = 2.4), \quad (1)$$

where the error has been increased by the scale factor S . The large scale factor indicates a serious disagreement between different input data. The average before scaling the error is

$$m_{K^\pm} = 493.677 \pm 0.005 \text{ MeV}, \quad \chi^2 = 22.9 \text{ for } 5 \text{ D.F.}, \text{ Prob.} = 0.04\%, \quad (2)$$

where the high χ^2 and correspondingly low χ^2 probability further quantify the disagreement.

The main disagreement is between the two most recent and precise results,

$$m_{K^\pm} = 493.696 \pm 0.007 \text{ MeV} \quad \text{DENISOV 91}$$

$$m_{K^\pm} = 493.636 \pm 0.011 \text{ MeV } (S = 1.5) \quad \text{GALL 88}$$

$$\text{Average} = 493.679 \pm 0.006 \text{ MeV}$$

$$\chi^2 = 21.2 \text{ for } 1 \text{ D.F.}, \text{ Prob.} = 0.0004\%, \quad (3)$$

both of which are measurements of x-ray energies from kaonic atoms. Comparing the average in Eq. (3) with the overall average in Eq. (2), it is clear that DENISOV 91 and GALL 88 dominate the overall average, and that their disagreement is responsible for most of the high χ^2 .

The GALL 88 measurement was made using four different kaonic atom transitions, $K^- \text{ Pb } (9 \rightarrow 8)$, $K^- \text{ Pb } (11 \rightarrow 10)$, $K^- \text{ W } (9 \rightarrow 8)$, and $K^- \text{ W } (11 \rightarrow 10)$. The m_{K^\pm} values they obtain from each of these transitions is shown in the Particle Listings and in Fig. 1. Their $K^- \text{ Pb } (9 \rightarrow 8)$ m_{K^\pm} is below and somewhat inconsistent with their other three transitions. The average of their four measurements is

$$m_{K^\pm} = 493.636 \pm 0.007, \quad \chi^2 = 7.0 \text{ for } 3 \text{ D.F.}, \text{ Prob.} = 7.2\%. \quad (4)$$

This is a low but acceptable χ^2 probability so, to be conservative, GALL 88 scaled up the error on their average by $S=1.5$ to obtain their published error ± 0.011 shown in Eq. (3) above and used in the Particle Listings average.

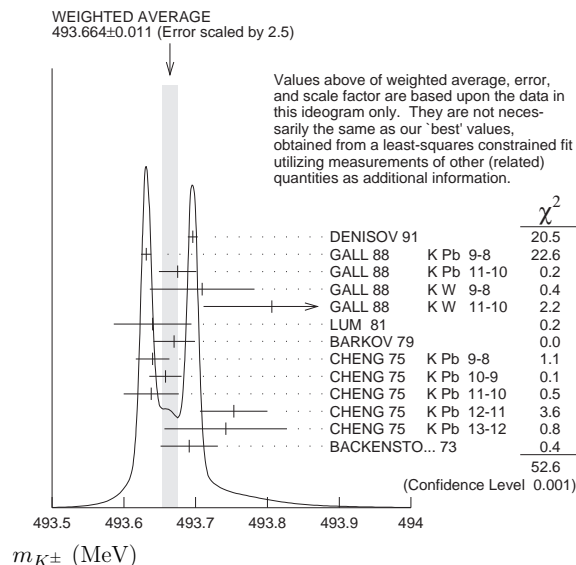

Figure 1: Ideogram of m_{K^\pm} mass measurements. GALL 88 and CHENG 75 measurements are shown separately for each transition they measured.

The ideogram in Fig. 1 shows that the DENISOV 91 measurement and the GALL 88 $K^- \text{ Pb } (9 \rightarrow 8)$ measurement yield two well-separated peaks. One might suspect the GALL 88 $K^- \text{ Pb } (9 \rightarrow 8)$ measurement since it is responsible both for the internal inconsistency in the GALL 88 measurements and the disagreement with DENISOV 91.

Table 1: m_{K^\pm} averages for some combinations of Fig. 1 data.

m_{K^\pm} (MeV)	χ^2	D.F.	Prob. (%)	Measurements used
493.664 ± 0.004	52.6	12	0.00005	all 13 measurements
493.690 ± 0.006	10.1	10	43	no $K^- \text{ Pb } (9 \rightarrow 8)$
493.687 ± 0.006	14.6	11	20	no GALL 88 $K^- \text{ Pb } (9 \rightarrow 8)$
493.642 ± 0.006	17.8	11	8.6	no DENISOV 91

To see if the disagreement could result from a systematic problem with the $K^- \text{ Pb } (9 \rightarrow 8)$ transition, we have separated the CHENG 75 data, which also used $K^- \text{ Pb}$, into its separate transitions. Figure 1 shows that the CHENG 75 and GALL 88 $K^- \text{ Pb } (9 \rightarrow 8)$ values are consistent, suggesting the possibility of a common effect such as contaminant nuclear γ rays near the $K^- \text{ Pb } (9 \rightarrow 8)$ transition energy, although the CHENG 75 errors are too large to make a strong conclusion. The average of all 13 measurements has a χ^2 of 52.6 as shown in Fig. 1 and the first line of Table 1, yielding an unacceptable χ^2 probability of 0.00005%. The second line of Table 1 excludes both the GALL 88 and CHENG 75 measurements of the $K^- \text{ Pb } (9 \rightarrow 8)$ transition and yields a χ^2 probability of 43%. The third [fourth] line of Table 1 excludes only the GALL 88 $K^- \text{ Pb } (9 \rightarrow 8)$ [DENISOV 91] measurement and yields a

Meson Particle Listings

K^\pm

χ^2 probability of 20% [8.6%]. Table 1 shows that removing both measurements of the K^- Pb (9 \rightarrow 8) transition produces the most consistent set of data, but that excluding only the GALL 88 K^- Pb (9 \rightarrow 8) transition or DENISOV 91 also produces acceptable probabilities.

Yu.M. Ivanov, representing DENISOV 91, has estimated corrections needed for the older experiments because of improved ^{192}Ir and ^{198}Au calibration γ -ray energies. He estimates that CHENG 75 and BACKENSTOSS 73 m_{K^\pm} values could be raised by about 15 keV and 22 keV, respectively. With these estimated corrections, Table 1 becomes Table 2. The last line of Table 2 shows that if such corrections are assumed, then GALL 88 K^- Pb (9 \rightarrow 8) is inconsistent with the rest of the data even when DENISOV 91 is excluded. Yu.M. Ivanov warns that these are rough estimates. Accordingly, we do not use Table 2 to reject the GALL 88 K^- Pb (9 \rightarrow 8) transition, but we note that a future reanalysis of the CHENG 75 data could be useful because it might provide supporting evidence for such a rejection.

Table 2: m_{K^\pm} averages for some combinations of Fig. 1 data after raising CHENG 75 and BACKENSTOSS 73 values by 0.015 and 0.022 MeV respectively.

m_{K^\pm} (MeV)	χ^2	D.F.	Prob. (%)	Measurements used
493.666 ± 0.004	53.9	12	0.00003	all 13 measurements
493.693 ± 0.006	9.0	10	53	no K^- Pb(9 \rightarrow 8)
493.690 ± 0.006	11.5	11	40	no GALL 88 K^- Pb(9 \rightarrow 8)
493.645 ± 0.006	23.0	11	1.8	no DENISOV 91

The GALL 88 measurement uses a Ge semiconductor spectrometer which has a resolution of about 1 keV, so they run the risk of some contaminant nuclear γ rays. Studies of γ rays following stopped π^- and Σ^- absorption in nuclei (unpublished) do not show any evidence for contaminants according to GALL 88 spokesperson, B.L. Roberts. The DENISOV 91 measurement uses a crystal diffraction spectrometer with a resolution of 6.3 eV for radiation at 22.1 keV to measure the 4f-3d transition in K^- ^{12}C . The high resolution and the light nucleus reduce the probability for overlap by contaminant γ rays, compared with the measurement of GALL 88. The DENISOV 91 measurement is supported by their high-precision measurement of the 4d-2p transition energy in π^- ^{12}C , which is good agreement with the calculated energy.

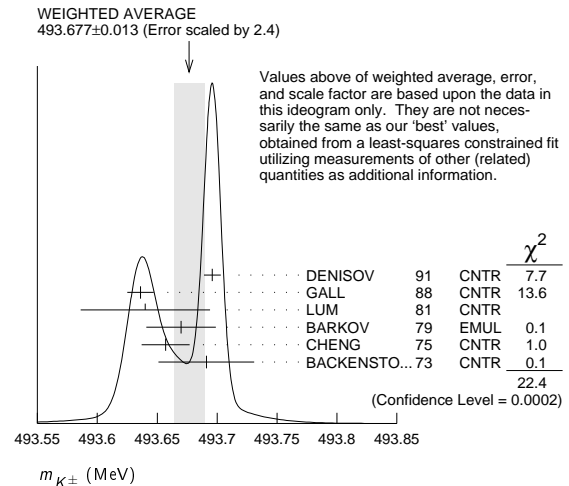

While we suspect that the GALL 88 K^- Pb (9 \rightarrow 8) measurements could be the problem, we are unable to find clear grounds for rejecting it. Therefore, we retain their measurement in the average and accept the large scale factor until further information can be obtained from new measurements and/or from reanalysis of GALL 88 and CHENG 75 data.

We thank B.L. Roberts (Boston Univ.) and Yu.M. Ivanov (Petersburg Nuclear Physics Inst.) for their extensive help in understanding this problem.

RARE KAON DECAYS

Revised September 2015 by L. Littenberg (BNL) and G. Valencia (Monash University).

A. Introduction: There are several useful reviews on rare kaon decays and related topics [1–17]. Activity in rare kaon decays can be divided roughly into four categories:

1. Searches for explicit violations of the Standard Model
2. Measurements of Standard Model parameters
3. Searches for direct CP violation
4. Studies of strong interactions at low energy.

The paradigm of Category 1 is the lepton flavor violating decay $K_L \rightarrow \mu e$. Category 2 includes processes such as $K^+ \rightarrow \pi^+ \nu \bar{\nu}$, which is sensitive to CKM parameters. Much of the interest in Category 3 is focused on the decays $K_L \rightarrow \pi^0 \ell \bar{\ell}$, where $\ell \equiv e, \mu, \nu$. Category 4 includes reactions like $K^+ \rightarrow \pi^+ \ell^+ \ell^-$ which constitute a testing ground for the ideas of chiral perturbation theory. Category 4 also includes $K_L \rightarrow \pi^0 \gamma \gamma$ and $K_L \rightarrow \ell^+ \ell^- \gamma$. The former is important in understanding a CP -conserving contribution to $K_L \rightarrow \pi^0 \ell^+ \ell^-$, whereas the latter could shed light on long distance contributions to $K_L \rightarrow \mu^+ \mu^-$.

The interplay between Categories 2–4 can be illustrated in Fig. 1. The modes $K \rightarrow \pi \nu \bar{\nu}$ are the cleanest ones theoretically. They can provide accurate determinations of certain CKM parameters (shown in the figure). In combination with alternate determinations of these parameters, they also constrain new interactions. The modes $K_L \rightarrow \pi^0 e^+ e^-$, $K_L \rightarrow \pi^0 \mu^+ \mu^-$ and $K_L \rightarrow \mu^+ \mu^-$ are also sensitive to CKM parameters. However, they suffer from a number of hadronic uncertainties that can be addressed, at least in part, through a systematic study of the additional modes indicated in the figure.

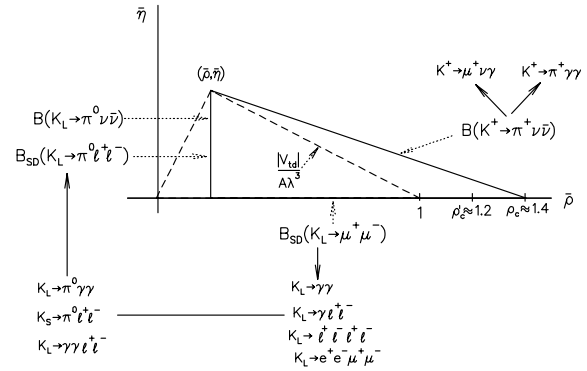

Figure 1: Role of rare kaon decays in determining the unitarity triangle. The solid arrows point to auxiliary modes needed to interpret the main results, or potential backgrounds to them.

B. Explicit violations of the Standard Model: Much activity has focussed on searches for lepton flavor violation (LFV). This is motivated by the fact that many extensions of the minimal Standard Model violate lepton flavor and by the potential to access very high energy scales. For example, the tree-level exchange of a LFV vector boson of mass M_X that couples to left-handed fermions with electroweak strength and without mixing angles yields $B(K_L \rightarrow \mu e) = 4.7 \times 10^{-12} (148 \text{ TeV}/M_X)^4$ [4]. This simple dimensional analysis may be used to read from Table 1 that the reaction $K_L \rightarrow \mu e$ is already probing scales of over 100 TeV. Table 1 summarizes the present experimental situation vis-à-vis LFV. The decays $K_L \rightarrow \mu^\pm e^\mp$ and $K^+ \rightarrow \pi^+ e^\mp \mu^\pm$ (or $K_L \rightarrow \pi^0 e^\mp \mu^\pm$) provide complementary information on potential family number violating interactions, since the former is sensitive to parity-odd couplings and the latter is sensitive to parity-even couplings. Limits on certain lepton-number violating kaon decays also exist, some recent ones being those of Refs. [18,19,20]. Related searches in μ and τ processes are discussed in our section “Tests of Conservation Laws.”

Table 1: Searches for lepton flavor violation in K decay

Mode	90% CL		
	upper limit	Exp't	Yr./Ref.
$K^+ \rightarrow \pi^+ e^- \mu^+$	1.2×10^{-11}	BNL-865	2005/Ref. 21
$K^+ \rightarrow \pi^+ e^+ \mu^-$	5.2×10^{-10}	BNL-865	2000/Ref. 18
$K_L \rightarrow \mu e$	4.7×10^{-12}	BNL-871	1998/Ref. 22
$K_L \rightarrow \pi^0 e \mu$	7.6×10^{-11}	KTeV	2008/Ref. 23
$K_L \rightarrow \pi^0 \pi^0 e \mu$	1.7×10^{-10}	KTeV	2008/Ref. 23

Physics beyond the SM is also pursued through the search for $K^+ \rightarrow \pi^+ X^0$, where X^0 is a new light particle. The searches cover both long-lived particles (*e.g.*, hyperphoton, axion, familon, *etc.*), and short lived ones that decay to muon, electron or photon pairs. The 90% CL upper limit on $K^+ \rightarrow \pi^+ X^0$ is 7.3×10^{-11} [24] for the case of massless X^0 ; additional results as a function of the X^0 mass can be found in [37].

Meson Particle Listings

K^\pm

Recently these limits have been reinterpreted in connection with a dark photon [25] or dark Z [26]. Such vectors have also been sought in their e^+e^- decay mode by NA48 [27]. Additional bounds for a short lived pseudoscalar X^0 decaying to muons or photons are $B(K_L \rightarrow \pi^0\pi^0\mu^+\mu^-) < 1 \times 10^{-10}$ [28] and $B(K_L \rightarrow \pi^0\pi^0\gamma\gamma) < 2.4 \times 10^{-7}$ [29].

C. Measurements of Standard Model parameters:

In the SM, the decay $K^+ \rightarrow \pi^+\nu\bar{\nu}$ is dominated by one-loop diagrams with top-quark intermediate states and long-distance contributions are known to be quite small [2,30]. This permits a precise calculation of this rate in terms of SM parameters. Studies of this process are thus motivated by the possibility of detecting non-SM physics when comparing with the results of global fits [31,32].

BNL-787 observed two candidate events [33,34] in the clean high π^+ momentum and one event [35] in the low-momentum region. The successor experiment BNL-949 observed one more in the high-momentum region [24] and three more in the low-momentum region [36] yielding a branching ratio of $(1.73_{-1.05}^{+1.15}) \times 10^{-10}$ [37]. A subsequent experiment, NA62, with a sensitivity goal of $\sim 10^{-12}$ /event was proposed [38] at CERN in 2005. It was approved and ran with a partial detector in autumn 2012, followed by a successful commissioning run in the fall of 2014. The first physics run started in the summer of 2015. The NA62 experiment will be the first one performed with kaon decays in flight. In the future, this mode may provide grounds for precision tests of flavor dynamics [40].

The branching ratio can be written in a compact form that exhibits the different ingredients that go into the calculation [41],

$$B(K^+ \rightarrow \pi^+\nu\bar{\nu}(\gamma)) = \kappa_+(1 + \Delta_{\text{EM}}) \left[\left(\frac{\text{Im}(V_{ts}^*V_{td})}{\lambda^5} X_t \right)^2 + \left(\frac{\text{Re}(V_{cs}^*V_{cd})}{\lambda} (P_c + \delta P_{c,u}) + \frac{\text{Re}(V_{ts}^*V_{td})}{\lambda^5} X_t \right)^2 \right]. \quad (1)$$

The parameters in Eq. (1) incorporate the *a priori* unknown hadronic matrix element in terms of the very well-measured $K_{\ell 3}$ rate [2] in κ_+ ; long distance QED corrections in Δ_{EM} [43]; the Inami-Lim function for the short distance top-quark contribution [44] including NLO QCD corrections [45] and the two-loop electroweak correction [41], all in X_t ; and the charm-quark contributions due to short distance effects including NNLO QCD corrections [46] and NLO electroweak corrections via P_c [47], as well as certain long distance effects via $\delta P_{c,u}$ [48]. An interesting approximate way to cast this result in terms of the CKM parameters λ , V_{cb} , $\bar{\rho}$ and $\bar{\eta}$ (see our Section on “The Cabibbo-Kobayashi-Maskawa mixing matrix”) [11] is:

$$B(K^+ \rightarrow \pi^+\nu\bar{\nu}) \approx 1.6 \times 10^{-5} |V_{cb}|^4 [\sigma \bar{\eta}^2 + (\rho_c - \bar{\rho})^2], \quad (2)$$

where $\rho_c \approx 1.45$ and $\sigma \equiv 1/(1 - \frac{1}{2}\lambda^2)^2$. Thus, $B(K^+ \rightarrow \pi^+\nu\bar{\nu})$ determines an ellipse in the $\bar{\rho}, \bar{\eta}$ plane with center $(\rho_c, 0)$ and semiaxes $\approx \frac{1}{|V_{cb}|^2} \sqrt{\frac{B(K^+ \rightarrow \pi^+\nu\bar{\nu})}{1.6 \times 10^{-5}}}$ and $\frac{1}{\sigma |V_{cb}|^2} \sqrt{\frac{B(K^+ \rightarrow \pi^+\nu\bar{\nu})}{1.6 \times 10^{-5}}}$. A recent numerical study leads to a predicted branching ratio

$(7.81_{-0.71}^{+0.80} \pm 0.29) \times 10^{-11}$ [41], near the lower end of the measurement of BNL-787 and 949. However, parametric uncertainty in the CKM angles can result in numbers that differ from this one by up to 10% [42].

Modes with an extra pion, $K \rightarrow \pi\pi\nu\bar{\nu}$, could also be used in the extraction of CKM parameters as they are also dominated by short distance contributions [49]. However, they occur at much lower rates with branching ratios of order 10^{-13} , and the current best bound from KEK-391a is $B(K_L \rightarrow \pi^0\pi^0\nu\bar{\nu}) < 8.1 \times 10^{-7}$ at 90% CL [50]. There is also an older bound of $B(K^+ \rightarrow \pi^+\pi^0\nu\bar{\nu}) < 4.3 \times 10^{-5}$ at 90% CL [51] from BNL-787.

The decay $K_L \rightarrow \mu^+\mu^-$ also has a short distance contribution sensitive to the CKM parameter $\bar{\rho}$, given by [11]:

$$B_{\text{SD}}(K_L \rightarrow \mu^+\mu^-) \approx 2.7 \times 10^{-4} |V_{cb}|^4 (\rho'_c - \bar{\rho})^2 \quad (3)$$

where ρ'_c depends on the charm quark mass and is approximately 1.2. This decay, however, is dominated by a long-distance contribution from a two-photon intermediate state. The absorptive (imaginary) part of the long-distance component is determined by the measured rate for $K_L \rightarrow \gamma\gamma$ to be $B_{\text{abs}}(K_L \rightarrow \mu^+\mu^-) = (6.64 \pm 0.07) \times 10^{-9}$; and it almost completely saturates the observed rate $B(K_L \rightarrow \mu^+\mu^-) = (6.84 \pm 0.11) \times 10^{-9}$ [52]. The difference between the observed rate and the absorptive component can be attributed to the (coherent) sum of the short-distance amplitude and the real part of the long-distance amplitude. The latter cannot be derived directly from experiment [53], but can be estimated with certain assumptions [54,55].

The decay $K_L \rightarrow e^+e^-$ is completely dominated by long distance physics and is easier to estimate. The result, $B(K_L \rightarrow e^+e^-) \sim 9 \times 10^{-12}$ [53,56], is in good agreement with the BNL-871 measurement, $(8.7_{-4.1}^{+5.7}) \times 10^{-12}$ [57].

The mode $K_S \rightarrow \mu^+\mu^-$ also has a short distance contribution proportional to the square of the CKM parameter $\bar{\eta}$ entering at the 10^{-13} level [15] as well as long distance contributions which arise in this case from a two photon intermediate state and result in a rate $B(K_S \rightarrow \mu^+\mu^-)_{\text{LD}} = 5.1 \times 10^{-12}$ [15]. A 95% (90%) c.l. limit $B(K_S \rightarrow \mu^+\mu^-) < 11(9) \times 10^{-9}$ was obtained by LHCb [58].

D. Searches for direct CP violation: The mode $K_L \rightarrow \pi^0\nu\bar{\nu}$ is dominantly *CP*-violating and free of hadronic uncertainties [2,59,60]. In the Standard Model, this mode is dominated by an intermediate top-quark state and does not suffer from the small uncertainty associated with the charm-quark intermediate state that affects the mode $K^+ \rightarrow \pi^+\nu\bar{\nu}$. The branching ratio is given by Ref. 11:

$$B(K_L \rightarrow \pi^0\nu\bar{\nu}) = \kappa_L \left(\frac{\text{Im}(V_{ts}^*V_{td})}{\lambda^5} X_t \right)^2 \approx 7.6 \times 10^{-5} |V_{cb}|^4 \bar{\eta}^2. \quad (4)$$

The hadronic matrix element can be related to that measured in $K_{\ell 3}$ decay and is parameterized in κ_L . A recent numerical evaluation leads to a predicted branching ratio $(2.43_{-0.37}^{+0.40} \pm$

$0.06) \times 10^{-11}$ [41]. As noted for the charged kaon mode, parametric uncertainty in the CKM angles can result in a central value that differs from this one by up to almost 20% [42]. The 90% CL bound on $K^+ \rightarrow \pi^+ \nu \bar{\nu}$ provides a nearly model-independent bound $B(K_L \rightarrow \pi^0 \nu \bar{\nu}) < 1.46 \times 10^{-9}$ [61]. KEK-391a, which took data in 2004 and 2005, has published a 90% CL upper bound of $B(K_L \rightarrow \pi^0 \nu \bar{\nu}) \leq 2.6 \times 10^{-8}$ [62]. The KOTO experiment at J-PARC [63], whose initial goal is to observe it, had a short physics run in the spring of 2013, reaching a single event sensitivity of 1.29×10^{-8} [65], and resuming the data taking in May 2015. It was pointed out in a recent paper that the above Grossman-Nir bound [61] on the three body decay $K_L \rightarrow \pi^0 \nu \bar{\nu}$ doesn't necessarily apply to two body decays such as $K_L \rightarrow \pi^0 X^0$, so that KOTO may be interesting for new physics searches at the current sensitivity level [64].

There has been much theoretical work on possible contributions to rare K decays beyond the SM. A comprehensive discussion of these can be found in Refs. [14] and [66].

The decay $K_L \rightarrow \pi^0 e^+ e^-$ also has sensitivity to the CKM parameter η through its CP -violating component. There are both direct and indirect CP -violating amplitudes that can interfere. The direct CP -violating amplitude is short distance dominated and has been calculated in detail within the SM [8]. The indirect CP -violating amplitude can be inferred from a measurement of $K_S \rightarrow \pi^0 e^+ e^-$. The complete CP -violating contribution to the rate can be written as [67,68]:

$$B_{\text{CPV}} \approx 10^{-12} \left[15.7 |a_S|^2 \pm 1.4 \left(\frac{|V_{cb}|^2 \bar{\eta}}{10^{-4}} \right) |a_S| + 0.12 \left(\frac{|V_{cb}|^2 \bar{\eta}}{10^{-4}} \right)^2 \right] \quad (5)$$

where the three terms correspond to the indirect CP violation, the interference, and the direct CP violation respectively. The parameter a_S has been extracted by NA48 from a measurement of the decay $K_S \rightarrow \pi^0 e^+ e^-$ with the result $|a_S| = 1.06_{-0.21}^{+0.26} \pm 0.07$ [69], as well as from a measurement of the decay $K_S \rightarrow \pi^0 \mu^+ \mu^-$ with the result $|a_S| = 1.54_{-0.32}^{+0.40} \pm 0.06$ [70]. With current constraints on the CKM parameters, and assuming a positive sign for the interference term [68,71], this implies that $B_{\text{CPV}}(K_L \rightarrow \pi^0 e^+ e^-) \approx (3.1 \pm 0.9) \times 10^{-11}$, and that the indirect CP violation is larger than the direct CP violation. The complete CP violating amplitude for the related mode $K_L \rightarrow \pi^0 \mu^+ \mu^-$ is predicted to be $B_{\text{CPV}}(K_L \rightarrow \pi^0 \mu^+ \mu^-) \approx (1.4 \pm 0.5) \times 10^{-11}$ [72,15].

$K_L \rightarrow \pi^0 e^+ e^-$ also has a CP -conserving component dominated by a two-photon intermediate state. This component can be decomposed into an absorptive and a dispersive part. The absorptive part can be extracted from the measurement of the low $m_{\gamma\gamma}$ region of the $K_L \rightarrow \pi^0 \gamma \gamma$ spectrum. The rate and the shape of the distribution $d\Gamma/dm_{\gamma\gamma}$ in $K_L \rightarrow \pi^0 \gamma \gamma$ are well described in chiral perturbation theory in terms of three (*a priori*) unknown parameters [73,74].

Both KTeV and NA48 have studied the mode $K_L \rightarrow \pi^0 \gamma \gamma$, reporting similar results. KTeV finds $B(K_L \rightarrow \pi^0 \gamma \gamma) = (1.29 \pm 0.03_{\text{stat}} \pm 0.05_{\text{sys}}) \times 10^{-6}$ [75], while NA48 finds $B(K_L \rightarrow \pi^0 \gamma \gamma) = (1.36 \pm 0.03_{\text{stat}} \pm 0.03_{\text{sys}} \pm 0.03_{\text{norm}}) \times 10^{-6}$ [76]. Both experiments are consistent with a negligible rate in the low $m_{\gamma\gamma}$ region, suggesting a very small CP -conserving component $B_{\text{CP}}(K_L \rightarrow \pi^0 e^+ e^-) \sim \mathcal{O}(10^{-13})$ [68,74,76]. There remains some model dependence in the estimate of the dispersive part of the CP -conserving $K_L \rightarrow \pi^0 e^+ e^-$ [68].

The related process, $K_L \rightarrow \pi^0 \gamma e^+ e^-$, is potentially an additional background in some region of phase space [77]. This process has been observed with a branching ratio of $(1.62 \pm 0.14_{\text{stat}} \pm 0.09_{\text{sys}}) \times 10^{-8}$ [78].

The decay $K_L \rightarrow \gamma \gamma e^+ e^-$ constitutes the dominant background to $K_L \rightarrow \pi^0 e^+ e^-$. It was first observed by BNL-845 [79], and subsequently confirmed with a much larger sample by KTeV [80]. It has been estimated that this background will enter at about the 10^{-10} level [81,82], comparable to or larger than the signal level. Because of this, the observation of $K_L \rightarrow \pi^0 e^+ e^-$ at the SM level will depend on background subtraction with good statistics. Possible alternative strategies are discussed in Ref. 68 and references cited therein.

The 90% CL upper bound for the process $K_L \rightarrow \pi^0 e^+ e^-$ is 2.8×10^{-10} [82]. For the closely related muonic process, the published upper bound is $B(K_L \rightarrow \pi^0 \mu^+ \mu^-) \leq 3.8 \times 10^{-10}$ [83], compared with the SM prediction of $(1.5 \pm 0.3) \times 10^{-11}$ [72] (assuming positive interference between the direct- and indirect- CP violating components).

A study of $K_L \rightarrow \pi^0 \mu^+ \mu^-$ has indicated that it might be possible to extract the direct CP -violating contribution by a joint study of the Dalitz plot variables and the components of the μ^+ polarization [84]. The latter tends to be quite substantial so that large statistics may not be necessary.

Combined information from the two $K_L \rightarrow \pi^0 \ell^+ \ell^-$ modes complements the $K \rightarrow \pi \nu \bar{\nu}$ measurements in constraining physics beyond the SM [85].

E. Other long distance dominated modes:

The decays $K^+ \rightarrow \pi^+ \ell^+ \ell^-$ ($\ell = e$ or μ) have received considerable attention. The rate and spectrum have been measured for both the electron and muon modes [86,87,20].

The measurements have been used to exclude new physics such as a dark photon [25]. Ref. 67 has proposed a parametrization inspired by chiral perturbation theory, which provides a successful description of data but indicates the presence of large corrections beyond leading order. More work is needed to fully understand the origin of these large corrections. NA62 has now also observed the mode $K^+ \rightarrow \pi^+ \pi^0 e^+ e^-$ [88] studied in [89].

The decay $K^+ \rightarrow \pi^+ \gamma \gamma$ can be predicted in terms of one unknown parameter to leading order in χ PT resulting in a correlation between the rate and the diphoton mass spectrum [90]. Certain important corrections at the next order are also known [91]. The rate was first measured by E787 [92], more recently NA48/2 [93] has obtained a more precise result with 6% error along with the corresponding spectrum fits. The most recent, and precise, result is from NA62 based on a sample

Meson Particle Listings

 K^\pm

of 232 events [94] and is still insufficient to distinguish between the leading order and next order χ PT parametrizations.

Much information has been recorded by KTeV and NA48 on the rates and spectrum for the Dalitz pair conversion modes $K_L \rightarrow \ell^+ \ell^- \gamma$ [95,96], and $K_L \rightarrow \ell^+ \ell^- \ell'^+ \ell'^-$ for $\ell, \ell' = e$ or μ [19,97–99]. All these results are used to test hadronic models and could further our understanding of the long distance component in $K_L \rightarrow \mu^+ \mu^-$.

- [g] Violates angular-momentum conservation.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life, a decay rate, and 15 branching ratios uses 35 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 53.4$ for 28 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

Hadronic modes with photons

$\Gamma(\pi^+ \pi^0 \gamma(\text{INT}))/\Gamma_{\text{total}}$

Γ_{21}/Γ

The $K^+ \rightarrow \pi^+ \pi^0 \gamma$ differential decay rate can be described in terms of T_{π^+} , the charged pion kinetic energy, and $W^2 = (P_K \cdot P_\gamma)(P_{\pi^+} \cdot P_\gamma)/(m_K m_{\pi^+})^2$; then we can write $d^2\Gamma(K^+ \rightarrow \pi^+ \pi^0 \gamma)/(dT_{\pi^+} dW^2) = d^2\Gamma(K^+ \rightarrow \pi^+ \pi^0 \gamma)_{IB}/(dT_{\pi^+} dW^2) [1 + 2 \cos(\pm\phi + \delta_1^2 - \delta_0^2) m_\pi^2 m_K^2 W^2 X_E + m_\pi^4 m_K^4 (X_E^2 + X_M^2) W^4]$. The IB differential and total branching ratios are expressed in terms of the non-radiative experimental width $\Gamma(K^+ \rightarrow \pi^+ \pi^0)$ by Low's theorem. Using PDG 10 $B(K^+ \rightarrow \pi^+ \pi^0) = 0.2066 \pm 0.0008$, one obtains respectively $B(K^+ \rightarrow \pi^+ \pi^0 \gamma)_{IB}$ (55 < T_{π^+} < 90 MeV) = 2.55×10^{-4} and $B(K^+ \rightarrow \pi^+ \pi^0 \gamma)_{IB}$ (0 < T_{π^+} < 80 MeV) = 1.80×10^{-4} . Fitting respectively the piece proportional to W^2 and the piece proportional to W^4 , the interference contribution (INT), proportional to X_E , and the direct contribution (DE) proportional to $X_E^2 + X_M^2$ are extracted.

VALUE (units 10^{-6})	EVTS	DOCUMENT ID	TECN	CHG	COMMENT
-4.24 ± 0.63 ± 0.70	600k	¹ BATLEY	10A	NA48 ±	T_{π^+} 0-80 MeV

¹ The cut on the photon energy implies $W^2 > 0.2$. BATLEY 10A obtains the INT and DE fractional branchings with respect to IB from a simultaneous kinematical fit of INT and DE and then we use the PDG 10 value for $B(K^+ \rightarrow \pi^+ \pi^0) = 0.2066 \pm 0.08$ to determine the IB. The INT and DE correlation coefficients -0.83. Assuming a constant electric amplitude, X_E , this INT value implies $X_E = -24 \pm 6 \text{ GeV}^{-4}$.

-100 ± 600			CHEN	68	OSPK +	T_π 60-90 MeV

¹ LAZZERONI 14 combines NA62 and NA48/2 results. The result for the full kinematic range is extrapolated from the model-independent branching fraction $(9.65 \pm 0.61 \pm 0.14) \times 10^{-7}$ for $(m_{\gamma\gamma}/m_K)^2 > 0.2$. The measured ChPT parameter $\tilde{c} = 1.86 \pm 0.25$.

² KITCHING 97 is extrapolated from their model-independent branching fraction $(6.0 \pm 1.5 \pm 0.7) \times 10^{-7}$ for 100 MeV/c < P_π < 180 MeV/c using Chiral Perturbation Theory.

³ BATLEY 14 uses data collected in 2003 and 2004. Branching ratio is obtained by determining the parameter $\tilde{c} = 1.41 \pm 0.38 \pm 0.11$ and integrating the $\mathcal{O}(p^6)$ chiral spectrum. A model independent value for the branching ratio is also obtained $(8.77 \pm 0.87 \pm 0.17) \times 10^{-7}$ for kinematic range $(m_{\gamma\gamma}/m_K)^2 > 0.2$.

⁴ ARTAMONOV 05 limit assumes ChPT with $\tilde{c} = 1.8$ with unitarity corrections. With $\tilde{c} = 1.6$ and no unitarity corrections they obtain $< 2.3 \times 10^{-8}$ at 90% CL. This partial branching ratio is predicted to be 6.10×10^{-9} and 0.49×10^{-9} for the cases with and without unitarity correction.

 K^\pm DALITZ PLOT PARAMETERS FOR
 $K \rightarrow 3\pi$ DECAYS

Revised 1999 by T.G. Trippe (LBNL).

The Dalitz plot distribution for $K^\pm \rightarrow \pi^\pm \pi^\pm \pi^\mp$, $K^\pm \rightarrow \pi^0 \pi^0 \pi^\pm$, and $K_L^0 \rightarrow \pi^+ \pi^- \pi^0$ can be parameterized by a series expansion such as that introduced by Weinberg [1]. We use the form

$$\begin{aligned} |M|^2 \propto & 1 + g \frac{(s_3 - s_0)}{m_{\pi^+}^2} + h \left[\frac{s_3 - s_0}{m_{\pi^+}^2} \right]^2 \\ & + j \frac{(s_2 - s_1)}{m_{\pi^+}^2} + k \left[\frac{s_2 - s_1}{m_{\pi^+}^2} \right]^2 \\ & + f \frac{(s_2 - s_1)(s_3 - s_0)}{m_{\pi^+}^2 m_{\pi^+}^2} + \dots, \end{aligned} \quad (1)$$

where $m_{\pi^+}^2$ has been introduced to make the coefficients g , h , j , and k dimensionless, and

$$s_i = (P_K - P_i)^2 = (m_K - m_i)^2 - 2m_K T_i, \quad i = 1, 2, 3,$$

$$s_0 = \frac{1}{3} \sum_i s_i = \frac{1}{3} (m_K^2 + m_1^2 + m_2^2 + m_3^2).$$

Here the P_i are four-vectors, m_i and T_i are the mass and kinetic energy of the i^{th} pion, and the index 3 is used for the odd pion.

The coefficient g is a measure of the slope in the variable s_3 (or T_3) of the Dalitz plot, while h and k measure the quadratic dependence on s_3 and $(s_2 - s_1)$, respectively. The coefficient j is related to the asymmetry of the plot and must be zero if CP invariance holds. Note also that if CP is good, g , h , and k must be the same for $K^+ \rightarrow \pi^+ \pi^+ \pi^-$ as for $K^- \rightarrow \pi^- \pi^- \pi^+$.

Since different experiments use different forms for $|M|^2$, in order to compare the experiments we have converted to g , h , j , and k whatever coefficients have been measured. Where such conversions have been done, the measured coefficient a_y , a_t , a_u , or a_v is given in the comment at the right. For definitions of these coefficients, details of this conversion, and discussion of the data, see the April 1982 version of this note [2].

ENERGY DEPENDENCE OF K^\pm DALITZ PLOT

$$\begin{aligned} |\text{matrix element}|^2 &= 1 + gu + hu^2 + kv^2 \\ \text{where } u &= (s_3 - s_0) / m_{\pi^+}^2 \text{ and } v = (s_2 - s_1) / m_{\pi^+}^2 \end{aligned}$$

LINEAR COEFFICIENT g FOR $K^\pm \rightarrow \pi^\pm \pi^+ \pi^-$

Some experiments use Dalitz variables x and y . In the comments we give $a_y =$ coefficient of y term. See note above on "Dalitz Plot Parameters for $K \rightarrow 3\pi$ Decays." For discussion of the conversion of a_y to g , see the earlier version of the same note in the Review published in Physics Letters **111B** 70 (1982).

¹ BATLEY 07E includes data from BATLEY 06A. Uses quadratic parametrization and PDG 06 value $g = 0.626 \pm 0.007$ to obtain $g_+ - g_- = (2.2 \pm 2.1 \pm 0.7) \times 10^{-4}$. Neglects any possible charge asymmetries in higher order slope parameters h or k .

² Asymmetry obtained assuming that $g_+ + g_- = 2 \times 0.652$ (PDG 02) and that asymmetries in h and k are zero.

³ Linear and quadratic slopes from PDG 04 are used. Any possible charge asymmetries in higher order slope parameters h or k are neglected.

ALTERNATIVE PARAMETRIZATIONS OF $K^\pm \rightarrow \pi^\pm \pi^0 \pi^0$ DALITZ PLOT

The following functional form for the matrix element suggested by $\pi\pi$ rescattering in $K^+ \rightarrow \pi^+ \pi^+ \pi^- \rightarrow \pi^+ \pi^0 \pi^0$ is used for this fit (CABIBBO 04A, CABIBBO 05): Matrix element = $M_0 + M_1$ where $M_0 = 1 + (1/2)g_0 u + (1/2)h' u^2 + (1/2)k_0 v^2$ with $u = (s_3 - s_0)/(m_{\pi^+})^2$, $v = (s_2 - s_1)/(m_{\pi^+})^2$ and where M_1 takes into account the non-analytic piece due to $\pi\pi$ rescattering amplitudes a_0 and a_2 ; The parameters g_0 and h' are related to the parameters g and h of the matrix element squared given in the previous section by the approximations $g_0 \sim g^{PDG}$ and $h' \sim h^{PDG} - (g/2)^2$ and $k_0 \sim k^{PDG}$.

In addition, we also consider the effective field theory framework of COLANGELO 06A and BISSEGGER 09 to extract g_{BB} and h'_{BB} .

 $K_{\ell 3}^\pm$ AND $K_{\ell 3}^0$ FORM FACTORS

Updated September 2013 by T.G. Trippe (LBNL) and C.-J. Lin (LBNL).

Assuming that only the vector current contributes to $K \rightarrow \pi \ell \nu$ decays, we write the matrix element as

$$M \propto f_+(t) [(P_K + P_\pi)_\mu \bar{\ell} \gamma_\mu (1 + \gamma_5) \nu] + f_-(t) [m_\ell \bar{\ell} (1 + \gamma_5) \nu], \quad (1)$$

where P_K and P_π are the four-momenta of the K and π mesons, m_ℓ is the lepton mass, and f_+ and f_- are dimensionless form factors which can depend only on $t = (P_K - P_\pi)^2$, the square of the four-momentum transfer to the leptons. If time-reversal invariance holds, f_+ and f_- are relatively real. $K_{\mu 3}$ experiments, discussed immediately below, measure f_+ and f_- , while $K_{e 3}$ experiments, discussed further below, are sensitive only to f_+ because the small electron mass makes the f_- term negligible.

$K_{\mu 3}$ Experiments. Analyses of $K_{\mu 3}$ data frequently assume a linear dependence of f_+ and f_- on t , *i.e.*,

$$f_\pm(t) = f_\pm(0) [1 + \lambda_\pm(t/m_{\pi^+}^2)]. \quad (2)$$

Most $K_{\mu 3}$ data are adequately described by Eq. (2) for f_+ and a constant f_- (*i.e.*, $\lambda_- = 0$).

There are two equivalent parametrizations commonly used in these analyses:

(1) λ_+ , $\xi(0)$ parametrization. Older analyses of $K_{\mu 3}$ data often introduce the ratio of the two form factors

$$\xi(t) = f_-(t)/f_+(t). \quad (3)$$

The $K_{\mu 3}$ decay distribution is then described by the two parameters λ_+ and $\xi(0)$ (assuming time reversal invariance and $\lambda_- = 0$).

(2) λ_+ , λ_0 parametrization. More recent $K_{\mu 3}$ analyses have parametrized in terms of the form factors f_+ and f_0 , which are associated with vector and scalar exchange, respectively, to the lepton pair. f_0 is related to f_+ and f_- by

$$f_0(t) = f_+(t) + [t/(m_K^2 - m_\pi^2)] f_-(t). \quad (4)$$

Meson Particle Listings

K^\pm

Here $f_0(0)$ must equal $f_+(0)$ unless $f_-(t)$ diverges at $t = 0$. The earlier assumption that f_+ is linear in t and f_- is constant leads to f_0 linear in t :

$$f_0(t) = f_0(0) [1 + \lambda_0(t/m_{\pi^+}^2)] . \quad (5)$$

With the assumption that $f_0(0) = f_+(0)$, the two parametrizations, $(\lambda_+, \xi(0))$ and (λ_+, λ_0) are equivalent as long as correlation information is retained. (λ_+, λ_0) correlations tend to be less strong than $(\lambda_+, \xi(0))$ correlations.

Since the 2006 edition of the *Review* [4], we no longer quote results in the $(\lambda_+, \xi(0))$ parametrization. We have removed many older low statistics results from the Listings. See the 2004 version of this note [5] for these older results, and the 1982 version [6] for additional discussion of the $K_{\mu 3}^0$ parameters, correlations, and conversion between parametrizations.

Quadratic Parametrization. More recent high-statistics experiments have included a quadratic term in the expansion of $f_+(t)$,

$$f_+(t) = f_+(0) \left[1 + \lambda'_+(t/m_{\pi^+}^2) + \frac{\lambda''_+}{2}(t/m_{\pi^+}^2)^2 \right] . \quad (6)$$

If there is a non-vanishing quadratic term, then λ_+ of Eq. (2) represents the average slope, which is then different from λ'_+ . Our convention is to include the factor $\frac{1}{2}$ in the quadratic term, and to use m_{π^+} even for K_{e3}^+ and $K_{\mu 3}^+$ decays. We have converted other's parametrizations to match our conventions, as noted in the beginning of the “ K_{e3}^\pm and $K_{\mu 3}^0$ Form Factors” sections of the Listings.

Pole Parametrization: The pole model describes the t -dependence of $f_+(t)$ and $f_0(t)$ in terms of the exchange of the lightest vector and scalar K^* mesons with masses M_v and M_s , respectively:

$$f_+(t) = f_+(0) \left[\frac{M_v^2}{M_v^2 - t} \right] , \quad f_0(t) = f_0(0) \left[\frac{M_s^2}{M_s^2 - t} \right] . \quad (7)$$

Dispersive Parametrization [7,8]. This approach uses dispersive techniques and the known low-energy K - π phases to parametrize the vector and scalar form factors:

$$f_+(t) = f_+(0) \exp \left[\frac{t}{m_\pi^2} (\Lambda_+ + H(t)) \right] ; \quad (8)$$

$$f_0(t) = f_+(0) \exp \left[\frac{t}{(m_K^2 - m_\pi^2)} (\ln[C] - G(t)) \right] , \quad (9)$$

where Λ_+ is the slope of the vector form factor, and $\ln[C] = \ln[f_0(m_K^2 - m_\pi^2)]$ is the logarithm of the scalar form factor at the Callan-Treiman point. The functions $H(t)$ and $G(t)$ are dispersive integrals.

K_{e3} Experiments: Analysis of K_{e3} data is simpler than that of $K_{\mu 3}$ because the second term of the matrix element assuming a pure vector current [Eq. (1) above] can be neglected. Here f_+ can be assumed to be linear in t , in which case the linear coefficient λ_+ of Eq. (2) is determined, or quadratic, in which case the linear coefficient λ'_+ and quadratic coefficient λ''_+ of Eq. (6) are determined.

If we remove the assumption of a pure vector current, then the matrix element for the decay, in addition to the terms in Eq. (1), would contain

$$+2m_K f_S \bar{\ell}(1 + \gamma_5)\nu \\ + (2f_T/m_K)(P_K)_\lambda (P_\pi)_\mu \bar{\ell} \sigma_{\lambda\mu} (1 + \gamma_5)\nu , \quad (10)$$

where f_S is the scalar form factor, and f_T is the tensor form factor. In the case of the K_{e3} decays where the f_- term can be neglected, experiments have yielded limits on $|f_S/f_+|$ and $|f_T/f_+|$.

Fits for K_{e3} Form Factors. For K_{e3} data, we determine best values for the three parametrizations: linear (λ_+) , quadratic $(\lambda'_+, \lambda''_+)$ and pole (M_v) . For $K_{\mu 3}$ data, we determine best values for the three parametrizations: linear (λ_+, λ_0) , quadratic $(\lambda'_+, \lambda''_+, \lambda_0)$ and pole (M_v, M_s) . We then assume $\mu - e$ universality so that we can combine K_{e3} and $K_{\mu 3}$ data, and again determine best values for the three parametrizations: linear (λ_+, λ_0) , quadratic $(\lambda'_+, \lambda''_+, \lambda_0)$, and pole (M_v, M_s) . When there is more than one parameter, fits are done including input correlations. Simple averages suffice in the two K_{e3} cases where there is only one parameter: linear (λ_+) and pole (M_v) .

Both KTeV and KLOE see an improvement in the quality of their fits relative to linear fits when a quadratic term is introduced, as well as when the pole parametrization is used. The quadratic parametrization has the disadvantage that the quadratic parameter λ''_+ is highly correlated with the linear parameter λ'_+ , in the neighborhood of 95%, and that neither parameter is very well determined. The pole fit has the same number of parameters as the linear fit, but yields slightly better fit probabilities, so that it would be advisable for all experiments to include the pole parametrization as one of their choices [9].

The “Kaon Particle Listings” show the results with and without assuming $\mu - e$ universality. The “Meson Summary Tables” show all of the results assuming $\mu - e$ universality, but most results not assuming $\mu - e$ universality are given only in the Listings.

K_{e3}^\pm FORM FACTORS

In the form factor comments, the following symbols are used.

f_+ and f_- are form factors for the vector matrix element.

f_S and f_T refer to the scalar and tensor term.

$$f_0 = f_+ + f_- t / (m_{K^+}^2 - m_{\pi^0}^2).$$

$t =$ momentum transfer to the π .

λ_+ and λ_0 are the linear expansion coefficients of f_+ and f_0 :

$$f_+(t) = f_+(0) (1 + \lambda_+ t / m_{\pi^+}^2)$$

For quadratic expansion

$$f_+(t) = f_+(0) (1 + \lambda'_+ t / m_{\pi^+}^2 + \frac{\lambda''_+}{2} t^2 / m_{\pi^+}^4)$$

as used by KTeV. If there is a non-vanishing quadratic term, then λ_+ represents an average slope, which is then different from λ'_+ .

NA48 and ISTRA quadratic expansion coefficients are converted with $\lambda_+^{PDG} = \lambda_+^{NA48}$ and $\lambda''_+^{PDG} = 2 \lambda''_+^{NA48}$

$$\lambda_+^{PDG} = \left(\frac{m_{\pi^+}}{m_{\pi^0}}\right)^2 \lambda_+ \text{ ISTRA and}$$

$$\lambda''_+^{PDG} = 2 \left(\frac{m_{\pi^+}}{m_{\pi^0}}\right)^4 \lambda''_+ \text{ ISTRA}$$

ISTRA linear expansion coefficients are converted with

$$\lambda_+^{PDG} = \left(\frac{m_{\pi^+}}{m_{\pi^0}}\right)^2 \lambda_+ \text{ ISTRA and } \lambda_0^{PDG} = \left(\frac{m_{\pi^+}}{m_{\pi^0}}\right)^2 \lambda_0 \text{ ISTRA}$$

The pole parametrization is

$$f_+(t) = f_+(0) \left(\frac{M_V^2}{M_V^2 - t}\right)$$

$$f_0(t) = f_0(0) \left(\frac{M_S^2}{M_S^2 - t}\right)$$

where M_V and M_S are the vector and scalar pole masses.

The following abbreviations are used:

DP = Dalitz plot analysis.

PI = π spectrum analysis.

MU = μ spectrum analysis.

POL = μ polarization analysis.

BR = $K_{\mu 3}^\pm / K_{e 3}^\pm$ branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

 λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN K_{e3}^\pm DECAY)

These results are for a linear expansion only. See the next section for fits including a quadratic term. Given in BOLOTOV 86b, BARMIN 88b, and SHIMIZU 04.

 $K^\pm \rightarrow \ell^\pm \nu \gamma$ FORM FACTORSFor definitions of the axial-vector F_A and vector F_V form factor, see the "Note on $\pi^\pm \rightarrow \ell^\pm \nu \gamma$ and $K^\pm \rightarrow \ell^\pm \nu \gamma$ Form Factors" in the π^\pm section. In the kaon literature, often different definitions $a_K = F_A/m_K$ and $v_K = F_V/m_K$ are used. $F_A + F_V$, SUM OF AXIAL-VECTOR AND VECTOR FORM FACTOR FOR $K \rightarrow e \nu \gamma$

VALUE	EVTS	DOCUMENT ID	TECN	COMMENT
0.133 ± 0.008 OUR AVERAGE				Error includes scale factor of 1.3. See the ideogram below.

¹ AOKI 94 measures $\xi P_\mu = -0.9996 \pm 0.0030 \pm 0.0048$. The above limit is obtained by summing the statistical and systematic errors in quadrature, normalizing to the physically significant region ($|\xi P_\mu| < 1$) and assuming that $\xi=1$, its maximum value.

² Assumes $\xi=1$.

FORWARD-BACKWARD ASYMMETRY IN K^\pm DECAYS

$A_{FB}(K^\pm_{\pi\mu\mu}) = \frac{\Gamma(\cos\theta_{K\mu} > 0) - \Gamma(\cos\theta_{K\mu} < 0)}{\Gamma(\cos\theta_{K\mu} > 0) + \Gamma(\cos\theta_{K\mu} < 0)}$

VALUE	CL%	DOCUMENT ID	TECN
< 2.3×10^{-2}	90	¹ BATLEY 11A	NA48
¹ BATLEY 11A gives a corresponding value of the asymmetry $A_{FB} = (-2.4 \pm 1.8) \times 10^{-2}$.

T-VIOLATION PARAMETER IN K^0 - \bar{K}^0 MIXING

The asymmetry $A_T = \frac{\Gamma(\bar{K}^0 \rightarrow K^0) - \Gamma(K^0 \rightarrow \bar{K}^0)}{\Gamma(\bar{K}^0 \rightarrow K^0) + \Gamma(K^0 \rightarrow \bar{K}^0)}$ must vanish if T invariance holds.

ASYMMETRY A_T IN K^0 - \bar{K}^0 MIXING

VALUE (units 10^{-3})	EVTS	DOCUMENT ID	TECN
$6.6 \pm 1.3 \pm 1.0$	640k	¹ ANGELOPO...	98E CPLR

¹ANGELOPOULOS 98E measures the asymmetry $A_T = [\Gamma(\bar{K}^0_{t=0} \rightarrow e^+ \pi^- \nu_{t=\tau}) - \Gamma(K^0_{t=0} \rightarrow e^- \pi^+ \bar{\nu}_{t=\tau})] / [\Gamma(\bar{K}^0_{t=0} \rightarrow e^+ \pi^- \nu_{t=\tau}) + \Gamma(K^0_{t=0} \rightarrow e^- \pi^+ \bar{\nu}_{t=\tau})]$ as a function of the neutral-kaon eigentime τ . The initial strangeness of the neutral kaon is tagged by the charge of the accompanying charged kaon in the reactions $p\bar{p} \rightarrow K^- \pi^+ K^0$ and $p\bar{p} \rightarrow K^+ \pi^- \bar{K}^0$. The strangeness at the time of the decay is tagged by the lepton charge. The reported result is the average value of A_T over the interval $1\tau_S < \tau < 20\tau_S$. From this value of A_T ANGELOPOULOS 01B, assuming CPT invariance in the $e\pi\nu$ decay amplitude, determine the T -violating as $\Delta S = \Delta S$ conserving parameter (for its definition, see Review below) $4\text{Re}(\epsilon) = (6.2 \pm 1.4 \pm 1.0) \times 10^{-3}$.

 CPT INVARIANCE TESTS IN NEUTRAL KAON DECAY

Updated October 2013 by M. Antonelli (LNF-INFN, Frascati) and G. D'Ambrosio (INFN Sezione di Napoli).

CPT theorem is based on three assumptions: quantum field theory, locality, and Lorentz invariance, and thus it is a fundamental probe of our basic understanding of particle physics. Strangeness oscillation in $K^0 - \bar{K}^0$ system, described by the equation

$$i \frac{d}{dt} \begin{bmatrix} K^0 \\ \bar{K}^0 \end{bmatrix} = [M - i\Gamma/2] \begin{bmatrix} K^0 \\ \bar{K}^0 \end{bmatrix},$$

where M and Γ are hermitian matrices (see PDG review [1], references [2,3], and KLOE paper [5] for notations and previous literature), allows a very accurate test of CPT symmetry; indeed since CPT requires $M_{11} = M_{22}$ and $\Gamma_{11} = \Gamma_{22}$, the mass and width eigenstates, $K_{S,L}$, have a CPT -violating piece, δ , in addition to the usual CPT -conserving parameter ϵ :

$$K_{S,L} = \frac{1}{\sqrt{2(1 + |\epsilon_{S,L}|^2)}} \left[(1 + \epsilon_{S,L}) K^0 \pm (1 - \epsilon_{S,L}) \bar{K}^0 \right]$$

$$\epsilon_{S,L} = \frac{-i\Im(M_{12}) - \frac{1}{2}\Im(\Gamma_{12}) \mp \frac{1}{2} \left[M_{11} - M_{22} - \frac{i}{2}(\Gamma_{11} - \Gamma_{22}) \right]}{m_L - m_S + i(\Gamma_S - \Gamma_L)/2}$$

$$\equiv \epsilon \pm \delta. \quad (1)$$

Using the phase convention $\Im(\Gamma_{12}) = 0$, we determine the phase of ϵ to be $\varphi_{SW} \equiv \arctan \frac{2(m_L - m_S)}{\Gamma_S - \Gamma_L}$. Imposing unitarity to an arbitrary combination of K^0 and \bar{K}^0 wave functions, we obtain the Bell-Steinberger relation [4] connecting CP and CPT violation in the mass matrix to CP and CPT violation in the decay; in fact, neglecting $\mathcal{O}(\epsilon)$ corrections to the coefficient of the CPT -violating parameter, δ , we can write [5]

$$\left[\frac{\Gamma_S + \Gamma_L}{\Gamma_S - \Gamma_L} + i \tan \phi_{SW} \right] \left[\frac{\Re(\epsilon)}{1 + |\epsilon|^2} - i\Im(\delta) \right] = \frac{1}{\Gamma_S - \Gamma_L} \sum_f A_L(f) A_S^*(f), \quad (2)$$

Table 1: Values, errors, and correlation coefficients for $\Re(\delta)$, $\Im(\delta)$, $\Re(x_-)$, $\Im(x_+)$, and $A_S + A_L$ obtained from a combined fit, including KLOE [5] and CPLEAR [14].

	value	Correlations coefficients			
$\Re(\delta)$	$(3.0 \pm 2.3) \times 10^{-4}$	1			
$\Im(\delta)$	$(-0.66 \pm 0.65) \times 10^{-2}$	-0.21	1		
$\Re(x_-)$	$(-0.30 \pm 0.21) \times 10^{-2}$	-0.21	-0.60	1	
$\Im(x_+)$	$(0.02 \pm 0.22) \times 10^{-2}$	-0.38	-0.14	0.47	1
$A_S + A_L$	$(-0.40 \pm 0.83) \times 10^{-2}$	-0.10	-0.63	0.99	0.43 1

where $A_{L,S}(f) \equiv A(K_{L,S} \rightarrow f)$. We stress that this relation is phase-convention-independent. The advantage of the neutral kaon system is that only a few decay modes give significant contributions to the r.h.s. in Eq. (2); in fact, defining for the hadronic modes

$$\alpha_i \equiv \frac{1}{\Gamma_S} \langle \mathcal{A}_L(i) \mathcal{A}_S^*(i) \rangle = \eta_i \mathcal{B}(K_S \rightarrow i),$$

$$i = \pi^0 \pi^0, \pi^+ \pi^- (\gamma), 3\pi^0, \pi^0 \pi^+ \pi^- (\gamma), \quad (3)$$

the recent data from CPLEAR, KLOE, KTeV, and NA48 have led to the following determinations (the analysis described in Ref. 5 has been updated by using the recent measurements of K_L branching ratios from KTeV [6,7], NA48 [8,9], and the results described in the CP violation in K_L decays minireview, and the recent KLOE result [10])

$$\alpha_{\pi^+ \pi^-} = ((1.112 \pm 0.010) + i(1.061 \pm 0.010)) \times 10^{-3},$$

$$\alpha_{\pi^0 \pi^0} = ((0.493 \pm 0.005) + i(0.471 \pm 0.005)) \times 10^{-3},$$

$$\alpha_{\pi^+ \pi^- \pi^0} = ((0 \pm 2) + i(0 \pm 2)) \times 10^{-6},$$

$$|\alpha_{\pi^0 \pi^0 \pi^0}| < 1.5 \times 10^{-6} \quad \text{at } 95\% \text{ CL}. \quad (4)$$

The semileptonic contribution to the right-handed side of Eq. (2) requires the determination of several observables: we define [2,3]

$$\mathcal{A}(K^0 \rightarrow \pi^- l^+ \nu) = \mathcal{A}_0(1 - y),$$

$$\mathcal{A}(K^0 \rightarrow \pi^+ l^- \nu) = \mathcal{A}_0^*(1 + y^*)(x_+ - x_-)^*,$$

$$\mathcal{A}(\bar{K}^0 \rightarrow \pi^+ l^- \nu) = \mathcal{A}_0^*(1 + y^*),$$

$$\mathcal{A}(\bar{K}^0 \rightarrow \pi^- l^+ \nu) = \mathcal{A}_0(1 - y)(x_+ + x_-), \quad (5)$$

where x_+ (x_-) describes the violation of the $\Delta S = \Delta Q$ rule in CPT -conserving (violating) decay amplitudes, and y parametrizes CPT violation for $\Delta S = \Delta Q$ transitions. Taking advantage of their tagged $K^0(\bar{K}^0)$ beams, CPLEAR has measured $\Im(x_+)$, $\Re(x_-)$, $\Im(\delta)$, and $\Re(\delta)$ [11]. These determinations have been improved in Ref. 5 by including the information $A_S - A_L = 4[\Re(\delta) + \Re(x_-)]$, where $A_{L,S}$ are the K_L and K_S semileptonic charge asymmetries, respectively, from the PDG [12] and KLOE [13]. Here we are also including the T -violating asymmetry measurement from CPLEAR [14].

Meson Particle Listings

K^0

The value $A_S + A_L$ in Table 1 can be directly included in the semileptonic contributions to the Bell Steinberger relations in Eq. (2)

$$\begin{aligned} & \sum_{\pi\ell\nu} \langle \mathcal{A}_L(\pi\ell\nu) \mathcal{A}_S^*(\pi\ell\nu) \rangle \\ &= 2\Gamma(K_L \rightarrow \pi\ell\nu) (\Re(\epsilon) - \Re(y) - i(\Im(x_+) + \Im(\delta))) \\ &= 2\Gamma(K_L \rightarrow \pi\ell\nu) ((A_S + A_L)/4 - i(\Im(x_+) + \Im(\delta))) . \end{aligned} \quad (6)$$

Defining

$$\alpha_{\pi\ell\nu} \equiv \frac{1}{\Gamma_S} \sum_{\pi\ell\nu} \langle \mathcal{A}_L(\pi\ell\nu) \mathcal{A}_S^*(\pi\ell\nu) \rangle + 2i \frac{\tau_{K_S}}{\tau_{K_L}} \mathcal{B}(K_L \rightarrow \pi\ell\nu) \Im(\delta) , \quad (7)$$

we find:

$$\alpha_{\pi\ell\nu} = ((-0.2 \pm 0.5) + i(0.1 \pm 0.5)) \times 10^{-5} .$$

Inserting the values of the α parameters into Eq. (2), we find

$$\begin{aligned} \Re(\epsilon) &= (161.1 \pm 0.5) \times 10^{-5} , \\ \Im(\delta) &= (-0.7 \pm 1.4) \times 10^{-5} . \end{aligned} \quad (8)$$

The complete information on Eq. (8) is given in Table 2.

Table 2: Summary of results: values, errors, and correlation coefficients for $\Re(\epsilon)$, $\Im(\delta)$, $\Re(\delta)$, and $\Re(x_-)$.

	value	Correlations coefficients		
$\Re(\epsilon)$	$(161.1 \pm 0.5) \times 10^{-5}$	+1		
$\Im(\delta)$	$(-0.7 \pm 1.4) \times 10^{-5}$	+0.09	1	
$\Re(\delta)$	$(2.4 \pm 2.3) \times 10^{-4}$	+0.08	-0.12	1
$\Re(x_-)$	$(-4.1 \pm 1.7) \times 10^{-3}$	+0.14	0.22	-0.43 1

Now the agreement with CPT conservation, $\Im(\delta) = \Re(\delta) = \Re(x_-) = 0$, is at 18% C.L.

The allowed region in the $\Re(\epsilon) - \Im(\delta)$ plane at 68% CL and 95% C.L. is shown in the top panel of Fig. 1.

The process giving the largest contribution to the size of the allowed region is $K_L \rightarrow \pi^+\pi^-$, through the uncertainty on ϕ_{+-} .

The limits on $\Im(\delta)$ and $\Re(\delta)$ can be used to constrain the $K^0 - \bar{K}^0$ mass and width difference

$$\delta = \frac{i(m_{K^0} - m_{\bar{K}^0}) + \frac{1}{2}(\Gamma_{K^0} - \Gamma_{\bar{K}^0})}{\Gamma_S - \Gamma_L} \cos \phi_{SW} e^{i\phi_{SW}} [1 + \mathcal{O}(\epsilon)] .$$

The allowed region in the $\Delta M = (m_{K^0} - m_{\bar{K}^0})$, $\Delta\Gamma = (\Gamma_{K^0} - \Gamma_{\bar{K}^0})$ plane is shown in the bottom panel of Fig. 1. As a result, we improve on the previous limits (see for instance, P. Bloch in Ref. 12) and in the limit $\Gamma_{K^0} - \Gamma_{\bar{K}^0} = 0$ we obtain

$$\begin{aligned} -4.0 \times 10^{-19} \text{ GeV} &< m_{K^0} - m_{\bar{K}^0} \\ &< 4.0 \times 10^{-19} \text{ GeV} \quad \text{at } 95\% \text{ C.L.} \end{aligned}$$

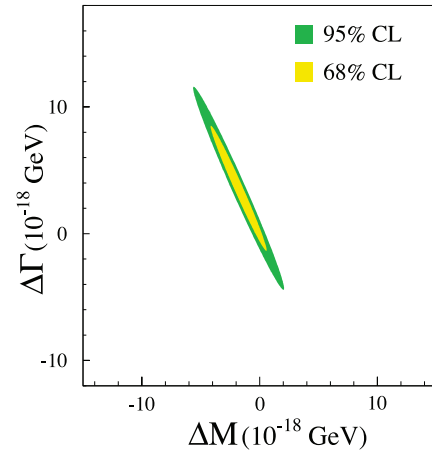

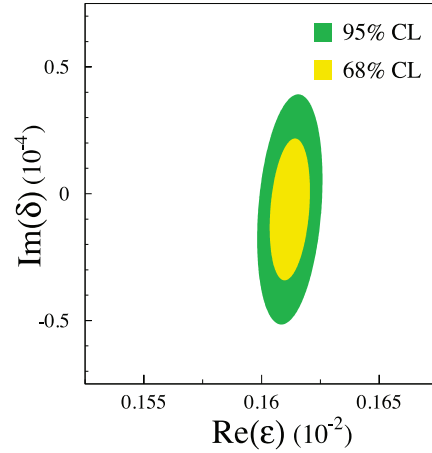

Figure 1: Top: allowed region at 68% and 95% C.L. in the $\Re(\epsilon)$, $\Im(\delta)$ plane. Bottom: allowed region at 68% and 95% C.L. in the ΔM , $\Delta\Gamma$ plane.

1.664 ± 0.010	² LAI	05A NA48

¹ AMBROSINO 06H uses Bell-Steinberger relations with the following measurements: $B(K_L^0 \rightarrow \pi^+ \pi^-)$ in AMBROSINO 06F, $B(K_S^0 \rightarrow \pi^0 \pi^0 \pi^0)$ in AMBROSINO 05B, the K_S^0 -semileptonic charge asymmetry in AMBROSINO 06E, and K^0 -semileptonic results in ANGELOPOULOS 98F.
² LAI 05A values are obtained through unitarity (Bell-Steinberger relations), improving determination of η_{000} and combining other data from PDG 04 and APOSTOLAKIS 99B.

CPT-VIOLATION PARAMETERS

In K^0 - \bar{K}^0 mixing, if CP-violating interactions include a T conserving part then

$$|K_S\rangle = [|K_1\rangle + (\epsilon + \delta)|K_2\rangle] / \sqrt{1 + |\epsilon + \delta|^2}$$

$$|K_L\rangle = [|K_2\rangle + (\epsilon - \delta)|K_1\rangle] / \sqrt{1 + |\epsilon - \delta|^2}$$

where

$$|K_1\rangle = [|K^0\rangle + |\bar{K}^0\rangle] / \sqrt{2}$$

$$|K_2\rangle = [|K^0\rangle - |\bar{K}^0\rangle] / \sqrt{2}$$

and

$$|\bar{K}^0\rangle = CP|K^0\rangle.$$

The parameter δ specifies the CPT-violating part.

Estimates of δ are given below assuming the validity of the $\Delta S = \Delta Q$ rule. See also THOMSON 95 for a test of CPT-symmetry conservation in K^0 decays using the Bell-Steinberger relation.

¹ The two ABOUZAID 11 values use the same full KTeV dataset from 1996, 1997, and 1999. The first enters the "assuming CPT " fit and the second enters the "not assuming CPT " fit.
² ABOUZAID 11 fit has Δm , τ_S , ϕ_c , $\text{Re}(e'/\epsilon)$, and $\text{Im}(e'/\epsilon)$ as free parameters. See $\text{Im}(e'/\epsilon)$ in the " K_L^0 CP violation" section for correlation information.
³ ABOUZAID 11 fit has Δm and τ_S free but constrains ϕ_c to the Superweak value, i.e. assumes CPT . This τ_S value is correlated with their $\Delta m = m_{K_L^0} - m_{K_S^0}$ measurement in the K_L^0 listings. The correlation coefficient $\rho(\tau_S, \Delta m) = -0.670$.
⁴ Fit to the proper time distribution.
⁵ This ALAVI-HARATI 03 fit has Δm and τ_S free but constrains ϕ_{+-} to the Superweak value, i.e. assumes CPT . This τ_S value is correlated with their $\Delta m = m_{K_L^0} - m_{K_S^0}$ measurement in the K_L^0 listings. The correlation coefficient $\rho(\tau_S, \Delta m) = -0.396$. Superseded by ABOUZAID 11.
⁶ This ALAVI-HARATI 03 fit has Δm , ϕ_{+-} , and τ_{K_S} free. See ϕ_{+-} in the " K_L CP violation" section for correlation information. Superseded by ABOUZAID 11.

⁷ ARONSON 82 find that K_S^0 mean life may depend on the kaon energy.

⁸ CARITHERS 75 measures the Δm dependence of the total decay rate (inverse mean life) to be $\Gamma(K_S^0) = [(1.122 \pm 0.004) + 0.16(\Delta m - 0.5348)/\Delta m] 10^{10}/s$, or, in terms of mean life, CARITHERS 75 measures $\tau_S = (0.8913 \pm 0.0032) - 0.238 [\Delta m - 0.5348] (10^{-10} \text{ s})$. We have adjusted the measurement to use our best values of ($\Delta m = 0.5293 \pm 0.0009$) (10^{10} h s^{-1}). Our first error is their experiment's error and our second error is the systematic error from using our best values.

⁹ HILL 68 has been changed by the authors from the published value (0.865 ± 0.009) because of a correction in the shift due to η_{+-} . SKJEGGESTAD 72 and HILL 68 give detailed discussions of systematics encountered in this type of experiment.

¹⁰ Pre-1971 experiments are excluded from the average because of disagreement with later more precise experiments.

[a] See the Particle Listings below for the energy limits used in this measurement.

[b] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.

[c] The value is for the sum of the charge states or particle/antiparticle states indicated.

[d] Not a measurement. Calculated as $0.666 \cdot B(\pi^\pm e^\mp \nu_e)$.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 5 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 0.1$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

7.2 ± 1.4 75 AKHMETSHIN 99 CMD2 Tagged K_S^0 using $\phi \rightarrow K_L^0 K_S^0$

Meson Particle Listings

 K_S^0

¹ Reconstructed from $K^0(\bar{K}^0)(t) \rightarrow \pi e \nu$ distributions using PDG values of $B(K_L^0 \rightarrow \pi e \nu) = 0.4053 \pm 0.0015$, $\tau_L = (5.114 \pm 0.021) \times 10^{-8}$ s and $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$ s.

² Uses the PDG 00 value for $B(K_S^0 \rightarrow \pi^+ \pi^-)$.

³ Obtained by imposing $\sum_i B(K_S^0 \rightarrow i) = 1$, where i runs over all the four branching ratios $\pi^+ \pi^-$, $\pi^0 \pi^0$, $\pi e \nu$, and $\pi \mu \nu$. Input value of $B(K_S^0 \rightarrow \pi^+ \pi^-) / B(K_S^0 \rightarrow \pi^0 \pi^0)$ from AMBROSINO 06c is used. To derive $\Gamma(K_S^0 \rightarrow \pi^+ \mu \nu) / \Gamma(K_S^0 \rightarrow \pi^+ e \nu)$, lepton universality is assumed, radiative corrections from ANDRE 07 are used, and phase space integrals are taken from KTeV, ALEXOPOULOS 04A. This branching fraction enters our fit via their $\Gamma(\pi^\pm e^\mp \nu_e) / \Gamma(\pi^+ \pi^-)$ branching ratio measurement.

 $\Gamma(\pi^\pm \mu^\mp \nu_\mu) / \Gamma_{\text{total}}$ Γ_9 / Γ

The PDG 06 value below has not been measured but is computed to be 0.666 times the $K_S \rightarrow \pi^\pm e^\mp \nu_e$ branching fraction. It is included in the fit that constrains the four branching ratios $\pi^+ \pi^-$, $\pi^0 \pi^0$, $\pi e \nu$, and $\pi \mu \nu$ to sum to 1. This treatment, used by AMBROSINO 06E, is preferable to our previous practice of constraining the $\pi^+ \pi^-$ and $\pi^0 \pi^0$ modes to sum to 1. The 0.666 factor is obtained from AMBROSINO 06E and assumes lepton universality, radiative corrections from ANDRE 07, and phase space integrals from KTeV, ALEXOPOULOS 04A.

¹ BABUSCI 13c uses 1.7 fb^{-1} of data of $\phi \rightarrow K_L^0 K_S^0$ decays with K_L^0 interaction in the calorimeter, collected from 2004 to 2005. No candidate events were found in the data with an expected background of $0.04^{+0.15}_{-0.03}$ events. Upper limit is obtained by normalizing to $K_S^0 \rightarrow 2\pi^0$ decays.

² LAI 05A value is obtained from their bound on $|\eta_{000}|$ (not assuming CPT) and $B(K_L^0 \rightarrow 3\pi^0) = 0.211 \pm 0.003$, and PDG 04 values for K_L^0 and K_S^0 lifetimes. If CPT is assumed then $B(K_S^0 \rightarrow 3\pi^0)_{CPT} < 2.3 \times 10^{-7}$ at 90% CL

³ ANGELOPOULOS 98B is from $\text{Im}(\eta_{000}) = -0.05 \pm 0.12 \pm 0.05$, assuming $\text{Re}(\eta_{000}) = \text{Re}(\epsilon) = 1.635 \times 10^{-3}$ and using the value $B(K_L^0 \rightarrow \pi^0 \pi^0 \pi^0) = 0.2112 \pm 0.0027$.

 $\Gamma(\mu^+ \mu^-) / \Gamma_{\text{total}}$ Γ_{11} / Γ

Test for $\Delta S = 1$ weak neutral current. Allowed by first-order weak interaction combined with electromagnetic interaction.

 K_S^0 FORM FACTORS

For discussion, see note on K_{e3} form factors in the K^\pm section of the Particle Listings above. Because the semileptonic branching fraction is smaller in K_S^0 than K_L^0 by the ratio of the mean lives, the K_S^0 semileptonic form factor has so far been measured only in the K_{e3} mode using the linear expansion $f_+(t) = f_+(0) (1 + \lambda_+ t / m_{\pi^+}^2)$, which gives the vector form factor $f_+(t)$ relative to its value at $t = 0$.

CP VIOLATION IN $K_S \rightarrow 3\pi$

Written 1996 by T. Nakada (Paul Scherrer Institute) and L. Wolfenstein (Carnegie-Mellon University).

The possible final states for the decay $K^0 \rightarrow \pi^+ \pi^- \pi^0$ have isospin $I = 0, 1, 2$, and 3 . The $I = 0$ and $I = 2$ states have $CP = +1$ and K_S can decay into them without violating CP symmetry, but they are expected to be strongly suppressed by centrifugal barrier effects. The $I = 1$ and $I = 3$ states, which have no centrifugal barrier, have $CP = -1$ so that the K_S decay to these requires CP violation.

In order to see CP violation in $K_S \rightarrow \pi^+ \pi^- \pi^0$, it is necessary to observe the interference between K_S and K_L decay, which determines the amplitude ratio

$$\eta_{+-0} = \frac{A(K_S \rightarrow \pi^+ \pi^- \pi^0)}{A(K_L \rightarrow \pi^+ \pi^- \pi^0)}. \quad (1)$$

If η_{+-0} is obtained from an integration over the whole Dalitz plot, there is no contribution from the $I = 0$ and $I = 2$ final states and a nonzero value of η_{+-0} is entirely due to CP violation.

Only $I = 1$ and $I = 3$ states, which are $CP = -1$, are allowed for $K^0 \rightarrow \pi^0 \pi^0 \pi^0$ decays and the decay of K_S into $3\pi^0$ is an unambiguous sign of CP violation. Similarly to η_{+-0} , η_{000} is defined as

$$\eta_{000} = \frac{A(K_S \rightarrow \pi^0 \pi^0 \pi^0)}{A(K_L \rightarrow \pi^0 \pi^0 \pi^0)}. \quad (2)$$

If one assumes that CPT invariance holds and that there are no transitions to $I = 3$ (or to nonsymmetric $I = 1$ states), it can be shown that

$$\eta_{+-0} = \eta_{000} = \epsilon + i \frac{\text{Im } a_1}{\text{Re } a_1}. \quad (3)$$

With the Wu-Yang phase convention, a_1 is the weak decay amplitude for K^0 into $I = 1$ final states; ϵ is determined from CP violation in $K_L \rightarrow 2\pi$ decays. The real parts of η_{+-0} and η_{000} are equal to $\text{Re}(\epsilon)$. Since currently-known upper limits on $|\eta_{+-0}|$ and $|\eta_{000}|$ are much larger than $|\epsilon|$, they can be interpreted as upper limits on $\text{Im}(\eta_{+-0})$ and $\text{Im}(\eta_{000})$ and so as limits on the CP -violating phase of the decay amplitude a_1 .

CP-VIOLATION PARAMETERS IN K_S^0 DECAY

$A_S = [\Gamma(K_S^0 \rightarrow \pi^- e^+ \nu_e) - \Gamma(K_S^0 \rightarrow \pi^+ e^- \bar{\nu}_e)] / \text{SUM}$

Such asymmetry violates CP . If CPT is assumed then $A_S = 2 \text{Re}(\epsilon)$.

$-0.015 \pm 0.017 \pm 0.025$	272k	³ ZOU 94	94	SPEC	

¹ADLER 97B also find $\text{Re}(\eta_{+-0}) = -0.002 \pm 0.007 \pm 0.004$. See also ANGELOPOULOS 98c.

²The ADLER 96D fit also yields $\text{Re}(\eta_{+-0}) = 0.006 \pm 0.013 \pm 0.001$ with a correlation +0.66 between real and imaginary parts. Their results correspond to $|\eta_{+-0}| < 0.037$ with 90% CL.

³ZOU 94 use theoretical constraint $\text{Re}(\eta_{+-0}) = \text{Re}(\epsilon) = 0.0016$. Without this constraint they find $\text{Im}(\eta_{+-0}) = 0.019 \pm 0.061$ and $\text{Re}(\eta_{+-0}) = 0.019 \pm 0.027$.

$\text{Im}(\eta_{000})^2 = \Gamma(K_S^0 \rightarrow 3\pi^0) / \Gamma(K_L^0 \rightarrow 3\pi^0)$

CPT assumed valid (i.e. $\text{Re}(\eta_{000}) \simeq 0$). This limit determines branching ratio $\Gamma(3\pi^0) / \Gamma_{\text{total}}$ above.

VALUE	CL%	EVTS	DOCUMENT ID	TECN	COMMENT
<0.1	90	632	¹ BARMIN 83	HLBC	
<0.28	90		² GJESDAL 74B	SPEC	Indirect meas.

¹BARMIN 83 find $\text{Re}(\eta_{000}) = (-0.08 \pm 0.18)$ and $\text{Im}(\eta_{000}) = (-0.05 \pm 0.27)$. Assuming CP invariance they obtain the limit quoted above.

²GJESDAL 74B uses $K_{2\pi}$, $K_{\mu 3}$, and K_{e3} decay results, unitarity, and CPT . Calculates $|\eta_{000}| = 0.26 \pm 0.20$. We convert to upper limit.

$\text{Im}(\eta_{000}) = \text{Im}(A(K_S^0 \rightarrow \pi^0 \pi^0 \pi^0) / A(K_L^0 \rightarrow \pi^0 \pi^0 \pi^0))$

$K_S^0 \rightarrow \pi^0 \pi^0 \pi^0$ violates CP conservation, in contrast to $K_S^0 \rightarrow \pi^+ \pi^- \pi^0$ which has a CP -conserving part.

$$I(J^P) = \frac{1}{2}(0^-)$$

$$m_{K_L^0} - m_{K_S^0}$$

For earlier measurements, beginning with GOOD 61 and FITCH 61, see our 1986 edition, Physics Letters **170B** 132 (1986).

OUR FIT is described in the note on "CP violation in K_L decays" in the K_L^0 Particle Listings. The result labeled "OUR FIT Assuming $CP T$ " ["OUR FIT Not assuming $CP T$ "] includes all measurements except those with the comment "Not assuming $CP T$ " ["Assuming $CP T$ "]. Measurements with neither comment do not assume CPT and enter both fits.

1 The two ABOUZAIID 11 values use the same data. The first enters the "assuming CPT " fit and the second enters the "not assuming CPT " fit.
 2 ABOUZAIID 11 fit has Δm , τ_S , ϕ_e , $\text{Re}(\epsilon'/\epsilon)$, and $\text{Im}(\epsilon'/\epsilon)$ as free parameters. See $\text{Im}(\epsilon'/\epsilon)$ in the " K_L^0 CP violation" section for correlation information.
 3 ABOUZAIID 11 fit has Δm and τ_S free but constrains ϕ_e to the Superweak value, i.e. assumes CPT . See " K_S^0 Mean Life" section for correlation information.
 4 Fits Δm and ϕ_{+-} simultaneously. GIBBONS 93c systematic error is from B. Winstein via private communication. 20-160 GeV K beams.
 5 GIBBONS 93 value assume $\phi_{+-} = \phi_{00} = \phi_{SW} = (43.7 \pm 0.2)^\circ$, i.e. assumes CPT . 20-160 GeV K beams.
 6 These two experiments have a common systematic error due to the uncertainty in the momentum scale, as pointed out in WAHL 89.
 7 GJESDAL 74 uses charge asymmetry in $K_{S,L}^0$ decays.
 8 ALAVI-HARATI 03 fit Δm and $\tau_{K_S^0}$ simultaneously. ϕ_{+-} is constrained to the Superweak value, i.e. CPT is assumed. See " K_S^0 Mean Life" section for correlation information. Superseded by ABOUZAIID 11.
 9 ALAVI-HARATI 03 fit Δm , ϕ_{+-} , and $\tau_{K_S^0}$ simultaneously. See ϕ_{+-} in the " K_L CP violation" section for correlation information. Superseded by ABOUZAIID 11.
 10 ANGELOPOULOS 01 uses strong interactions strangeness tagging at two different times.
 11 Uses \bar{K}_{e3}^0 and K_{e3}^0 strangeness tagging at production and decay. Assumes CPT conservation on $\Delta S = -\Delta Q$ transitions.

12 ADLER 96c is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value above.
 13 ARONSON 82 find that Δm may depend on the kaon energy.
 14 ARONSON 70 and CARNEGIE 71 use K_S^0 mean life = $(0.862 \pm 0.006) \times 10^{-10}$ s. We have not attempted to adjust these values for the subsequent change in the K_S^0 mean life or in η_{+-} .

K_L^0 MEAN LIFE

VALUE (10^{-8} s)	EVTS	DOCUMENT ID	TECN	COMMENT
5.116 ± 0.021 OUR FIT	Error includes scale factor of 1.1.			
5.099 ± 0.021 OUR AVERAGE

5.092 ± 0.017 ± 0.025	15M	AMBROSINO 05c	KLOE	
5.154 ± 0.044	0.4M	VOSBURGH 72	CNTR	

• • • We do not use the following data for averages, fits, limits, etc. • • •

5.15 ± 0.14 DEVLIN 67 CNTR
 1 AMBROSINO 06 uses $\phi \rightarrow K_L K_S$ with K_L tagged by $K_S \rightarrow \pi^+ \pi^-$. The four major K_L BR's are measured, the small remainder ($\pi^+ \pi^-, \pi^0 \pi^0, \gamma \gamma$) is taken from PDG 04. This KLOE K_L lifetime is obtained by imposing $\sum_i B_i = 1$. The correlation matrix among the four measured K_L BR's and this K_L lifetime is

	K_{e3}	$K_{\mu 3}$	$3\pi^0$	$\pi^+ \pi^- \pi^0$	τ_{K_L}
K_{e3}	1	-0.25	-0.56	-0.07	0.25
$K_{\mu 3}$		1	-0.43	-0.20	0.33
$3\pi^0$			1	-0.39	-0.21
$\pi^+ \pi^- \pi^0$				1	-0.39
τ_{K_L}					1

These correlations are taken into account in our fit. The average of this KLOE mean life measurement and the independent KLOE measurement in AMBROSINO 05c is $(5.084 \pm 0.023) \times 10^{-8}$ s.

K_L^0 DECAY MODES

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Semileptonic modes

Γ_{36}	$\pi^0 \mu^\pm e^\mp$	LF	[a] < 7.6	$\times 10^{-11}$	CL=90%
Γ_{37}	$\pi^0 \pi^0 \mu^\pm e^\mp$	LF	< 1.7	$\times 10^{-10}$	CL=90%

- [a] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [b] This mode includes gammas from inner bremsstrahlung but not the direct emission mode $K_L^0 \rightarrow \pi^+ \pi^- \gamma$ (DE).
- [c] See the Particle Listings below for the energy limits used in this measurement.
- [d] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.
- [e] Allowed by higher-order electroweak interactions.
- [f] Violates CP in leading order. Test of direct CP violation since the indirect CP-violating and CP-conserving contributions are expected to be suppressed.

CONSTRAINED FIT INFORMATION

An overall fit to the mean life and 15 branching ratios uses 27 measurements and one constraint to determine 11 parameters. The overall fit has a $\chi^2 = 37.4$ for 17 degrees of freedom.

The following off-diagonal array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

¹ E_{ee}^* is the energy of the $e^+ e^-$ pair in the kaon rest frame. ABOUZAID 07c reports $[\Gamma(K_L^0 \rightarrow \pi^\pm e^\mp \nu_e e^\pm)/\Gamma(K_L^0 \rightarrow \pi^+ \pi^- \pi^0)] / [B(\pi^0 \rightarrow e^+ e^- \gamma)] = (8.54 \pm 0.07 \pm 0.13) \times 10^{-3}$ which we multiply by our best value $B(\pi^0 \rightarrow e^+ e^- \gamma) = (1.174 \pm 0.035) \times 10^{-2}$. Our first error is their experiment's error and our second error is the systematic error from using our best value.

 V_{ud}, V_{us} , THE CABIBBO ANGLE, AND CKM UNITARITY

Updated May 2016 by E. Blucher (Univ. of Chicago) and W.J. Marciano (BNL)

The Cabibbo-Kobayashi-Maskawa (CKM) [1,2] three-generation quark mixing matrix written in terms of the Wolfenstein parameters (λ, A, ρ, η) [3] nicely illustrates the orthonormality constraint of unitarity and central role played by λ .

$$V_{\text{CKM}} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} = \begin{pmatrix} 1 - \lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1 - \lambda^2/2 & A\lambda^2 \\ A\lambda^3(1 - \rho - i\eta) & -A\lambda^2 & 1 \end{pmatrix} + \mathcal{O}(\lambda^4). \quad (1)$$

That cornerstone is a carryover from the two-generation Cabibbo angle, $\lambda = \sin(\theta_{\text{Cabibbo}}) = V_{us}$. Its value is a critical ingredient in determinations of the other parameters and in tests of CKM unitarity.Until about 11 years ago, the precise value of λ was somewhat controversial, with kaon decays suggesting [4] $\lambda \simeq 0.220$, while indirect determinations via nuclear β -decays implied a somewhat larger $\lambda \simeq 0.225 - 0.230$. This difference resulted in a 2 - 2.5 sigma deviation from the unitarity requirement

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1, \quad (2)$$

a potential signal [5] for new physics effects. Below, we discuss the current status of V_{ud}, V_{us} , and their associated unitarity test in Eq. (2). (Since $|V_{ub}|^2 \simeq 1 \times 10^{-5}$ is negligibly small,

Meson Particle Listings

 K_L^0

it is ignored in this discussion.) Eq. (2) is currently the most stringent test of unitarity in the CKM matrix.

 V_{ud}

The value of V_{ud} has been obtained from superallowed nuclear, neutron, and pion decays. Currently, the most precise determination of V_{ud} comes from a set of superallowed nuclear beta-decays [5] ($0^+ \rightarrow 0^+$ transitions). Measuring their half-lives, t , and Q values that give the decay rate factor, f , leads to a precise determination of V_{ud} via the master formula [6–10]

$$|V_{ud}|^2 = \frac{2984.48(5) \text{ sec}}{ft(1 + \Delta)}, \quad (3)$$

where Δ denotes the entire effect of electroweak radiative corrections (RC), nuclear structure, and isospin violating nuclear effects. Δ is nucleus-dependent, ranging from about +3.0% to +3.6% for the best measured superallowed decays.

The most recent analysis of 14 precisely measured superallowed transitions by Hardy and Towner [11] gives a weighted average of

$$V_{ud} = 0.97417(5)_{\text{exp.}}(9)_{\text{nucl.dep.}}(18)_{\text{RC}} \text{ (superallowed)}, \quad (4)$$

which, assuming unitarity, corresponds to $\lambda = 0.2258(9)$. This recent determination of V_{ud} has shifted downward compared to the 2014 value of 0.97425(22) primarily from improvements in the nuclear isospin breaking corrections [11]. It is now closer to the central value quoted in 2007.

Combined measurements of the neutron lifetime, τ_n , and the ratio of axial-vector/vector couplings, $g_A \equiv G_A/G_V$, via neutron decay asymmetries can also be used to determine V_{ud} :

$$|V_{ud}|^2 = \frac{4908.7(1.9) \text{ sec}}{\tau_n(1 + 3g_A^2)}, \quad (5)$$

where the error stems from uncertainties in the electroweak radiative corrections [7] due to hadronic loop effects. Those effects were updated and their error was reduced by about a factor of 2 [8], leading to a ± 0.0002 theoretical uncertainty in V_{ud} (common to all V_{ud} extractions). Using the world averages from this *Review*

$$\begin{aligned} \tau_n^{\text{ave}} &= 880.3(1.1) \text{ sec} \quad (\times 1.9 \text{ PDG scale factor}) \\ g_A^{\text{ave}} &= 1.2723(23) \quad (\times 2.2 \text{ PDG scale factor}) \end{aligned} \quad (6)$$

leads to

$$V_{ud} = 0.9758(6)_{\tau_n}(15)_{g_A}(2)_{\text{RC}}, \quad (7)$$

with the error dominated by g_A uncertainties. We note that the larger g_A now adopted in Eq. (6) leads to a value of V_{ud} that is still somewhat high, but in accord with the superallowed nuclear beta decay result in Eq. (4). Future neutron studies [12] are expected to resolve any current inconsistencies and significantly

reduce the uncertainties in g_A and τ_n , potentially making them a competitive way to determine V_{ud} without nuclear physics uncertainties.

The PIBETA experiment at PSI measured the very small ($\mathcal{O}(10^{-8})$) branching ratio for $\pi^+ \rightarrow \pi^0 e^+ \nu_e$ with about $\pm 1/2\%$ precision. Their result gives [13]

$$V_{ud} = 0.9749(26) \left[\frac{BR(\pi^+ \rightarrow e^+ \nu_e(\gamma))}{1.2352 \times 10^{-4}} \right]^{\frac{1}{2}} \quad (8)$$

which is normalized using the very precisely determined theoretical prediction for $BR(\pi^+ \rightarrow e^+ \nu_e(\gamma)) = 1.2352(5) \times 10^{-4}$ [6], rather than the experimental branching ratio from this *Review* of $1.230(4) \times 10^{-4}$ which would lower the value to $V_{ud} = 0.9728(30)$. Theoretical uncertainties in the pion β -decay determination are very small; however, much higher statistics would be required to make this approach competitive with others.

 V_{us}

$|V_{us}|$ may be determined from kaon decays, hyperon decays, and tau decays. Previous determinations have most often used $K\ell 3$ decays:

$$\Gamma_{K\ell 3} = \frac{G_F^2 M_K^5}{192\pi^3} S_{EW}(1 + \delta_K^\ell + \delta_{SU2}) C^2 |V_{us}|^2 f_+^2(0) I_K^\ell. \quad (9)$$

Here, ℓ refers to either e or μ , G_F is the Fermi constant, M_K is the kaon mass, S_{EW} is the short-distance radiative correction, δ_K^ℓ is the mode-dependent long-distance radiative correction, $f_+(0)$ is the calculated form factor at zero momentum transfer for the $\ell\nu$ system, and I_K^ℓ is the phase-space integral, which depends on measured semileptonic form factors. For charged kaon decays, δ_{SU2} is the deviation from one of the ratio of $f_+(0)$ for the charged to neutral kaon decay; it is zero for the neutral kaon. C^2 is 1 (1/2) for neutral (charged) kaon decays. Most early determinations of $|V_{us}|$ were based solely on $K \rightarrow \pi e \nu$ decays; $K \rightarrow \pi \mu \nu$ decays were not used because of large uncertainties in I_K^ℓ . The experimental measurements are the semileptonic decay widths (based on the semileptonic branching fractions and lifetime) and form factors (allowing calculation of the phase space integrals). Theory is needed for S_{EW} , δ_K^ℓ , δ_{SU2} , and $f_+(0)$.

Many measurements during the last decade have resulted in a significant shift in V_{us} . Most importantly, recent measurements of the $K \rightarrow \pi e \nu$ branching fractions are significantly different than earlier PDG averages, probably as a result of inadequate treatment of radiation in older experiments. This effect was first observed by BNL E865 [14] in the charged kaon system and then by KTeV [15,16] in the neutral kaon system; subsequent measurements were made by KLOE [17–20], NA48 [21–23], and ISTRA+ [24]. Current averages (*e.g.*, by the PDG [25] or Flavianet [26]) of the semileptonic branching fractions are based only on recent, high-statistics experiments

where the treatment of radiation is clear. In addition to measurements of branching fractions, new measurements of lifetimes [27] and form factors [28–32], have resulted in improved precision for all of the experimental inputs to V_{us} . Precise measurements of form factors for $K_{\mu 3}$ decay make it possible to use both semileptonic decay modes to extract V_{us} .

Following the analysis of Moulson [33] and the Flavianet group [26], one finds, after including the isospin violating up-down mass difference effect, the values of $|V_{us}|f_+(0)$ in Table 1. The average of these measurements gives

$$f_+(0)|V_{us}| = 0.2165(4). \quad (10)$$

Figure 1 shows a comparison of these results with the PDG evaluation from 2002 [34], as well as $f_+(0)(1-|V_{ud}|^2-|V_{ub}|^2)^{1/2}$, the expectation for $f_+(0)|V_{us}|$ assuming unitarity, based on $|V_{ud}| = 0.97417 \pm 0.00021$, and $|V_{ub}| = (4.1 \pm 0.4) \times 10^{-3}$ [35].

Lattice calculations of $f_+(0)$ have been carried out for 2, 2+1, and 2+1+1 quark flavors and range from about 0.96 to 0.97. Here, we use $f_+(0) = 0.9677(37)$, the 2015 preliminary (2+1)-flavor FLAG average reported by Rosner, Stone, and Van de Water in footnote 10 of their PDG review of pseudoscalar decay constants [35], in Eq. (10), and find

$$|V_{us}| = \lambda = 0.2237(4)_{\text{exp+RC}}(9)_{\text{lattice}} (K_{\ell 3} \text{ Decays}). \quad (11)$$

Table 1: $|V_{us}|f_+(0)$ from $K_{\ell 3}$.

Average	0.2165 ± 0.0004

A value of V_{us} can also be obtained from a comparison of the radiative inclusive decay rates for $K \rightarrow \mu\nu(\gamma)$ and $\pi \rightarrow \mu\nu(\gamma)$ combined with a lattice gauge theory calculation of f_{K^+}/f_{π^+} via [42]

$$\frac{|V_{us}|f_{K^+}}{|V_{ud}|f_{\pi^+}} = 0.23871(20) \left[\frac{\Gamma(K \rightarrow \mu\nu(\gamma))}{\Gamma(\pi \rightarrow \mu\nu(\gamma))} \right]^{\frac{1}{2}} \quad (12)$$

with the small error coming from electroweak radiative corrections and isospin breaking effects. Employing

$$\frac{\Gamma(K \rightarrow \mu\nu(\gamma))}{\Gamma(\pi \rightarrow \mu\nu(\gamma))} = 1.3367(29), \quad (13)$$

which includes the recent update $\Gamma(K \rightarrow \mu\nu(\gamma)) = 5.134(11) \times 10^7 \text{s}^{-1}$ [33,43] and [35]

$$f_{K^+}/f_{\pi^+} = 1.1928(26) \quad (14)$$

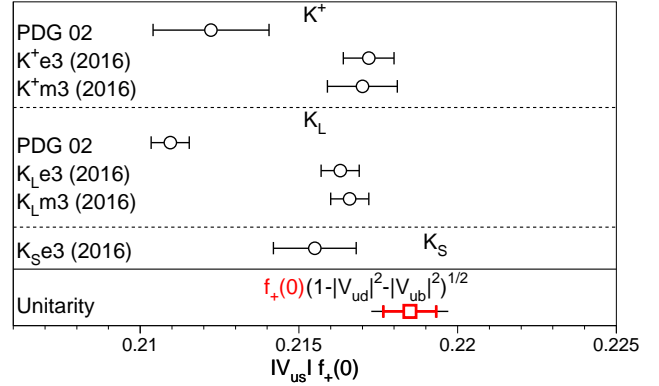

Figure 1: Comparison of determinations of $|V_{us}|f_+(0)$ from this review (labeled 2016), from the PDG 2002, and with the prediction from unitarity using $|V_{ud}|$ and the lattice calculation of $f_+(0) = 0.9677(37)$ [35]. For $f_+(0)(1-|V_{ud}|^2-|V_{ub}|^2)^{1/2}$, the inner error bars are from the quoted uncertainty in $f_+(0)$; the total uncertainties include the $|V_{ud}|$ and $|V_{ub}|$ errors.

along with the value of V_{ud} in Eq. (4) leads to

$$|V_{us}| = 0.22540(53)_{\text{exp}}(19)_{\text{RC}}(49)_{\text{lattice}} (K_{\mu 2} \text{ Decays}). \quad (15)$$

Together, a weighted average of the $K_{\ell 3}$ (Eq. (11)) and $K_{\mu 2}$ (Eq. (15)) results gives

$$|V_{us}| = 0.2248(6). \quad (16)$$

It should be mentioned that hyperon decay fits suggest [45]

$$|V_{us}| = 0.2250(27) \text{ (Hyperon Decays)} \quad (17)$$

modulo SU(3) breaking effects that could shift that value up or down. We note that a representative effort [46] that incorporates SU(3) breaking found $V_{us} = 0.226(5)$. Strangeness changing tau decays, averaging both inclusive and exclusive measurements, currently give [47]

$$|V_{us}| = 0.2202(15) \text{ (Tau Decays)}, \quad (18)$$

which differs by about 3 sigma from the kaon determination discussed above, and would, if combined with V_{ud} from super-allowed beta decays, lead to a 2.6 sigma deviation from unitarity. This discrepancy results mainly from the inclusive tau decay results that rely on Finite Energy Sum Rule techniques and assumptions. Further investigation of that approach seems to be warranted.

Employing the values of V_{ud} and V_{us} from Eq. (4) and Eq. (16), respectively, leads to the unitarity consistency check

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9995(4)(3). \quad (19)$$

where the first error is the uncertainty from $|V_{ud}|^2$ and the second error is the uncertainty from $|V_{us}|^2$.

 K_L^0

CKM Unitarity Constraints

The current good experimental agreement with unitarity, $|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 0.9995(5)$, provides strong confirmation of Standard Model radiative corrections (which range between 3-4% depending on the nucleus used) at better than the 50 sigma level [48]. In addition, it implies constraints on “New Physics” effects at both the tree and quantum loop levels. Those effects could be in the form of contributions to nuclear beta decays, K decays and/or muon decays, with the last of these providing normalization via the muon lifetime [49], which is used to obtain the Fermi constant, $G_\mu = 1.1663787(6) \times 10^{-5} \text{GeV}^{-2}$.

In the following sections, we illustrate the implications of CKM unitarity for (1) exotic muon decays [50] (beyond ordinary muon decay $\mu^+ \rightarrow e^+ \nu_e \bar{\nu}_\mu$) and (2) new heavy quark mixing V_{uD} [51]. Other examples in the literature [52,53] include Z_χ boson quantum loop effects, supersymmetry, leptoquarks, compositeness etc.

Exotic Muon Decays

If additional lepton flavor violating decays such as $\mu^+ \rightarrow e^+ \bar{\nu}_e \nu_\mu$ (wrong neutrinos) occur, they would cause confusion in searches for neutrino oscillations at, for example, muon storage rings/neutrino factories or other neutrino sources from muon decays. Calling the rate for all such decays $\Gamma(\text{exotic } \mu \text{ decays})$, they should be subtracted before the extraction of G_μ and normalization of the CKM matrix. Since that is not done and unitarity works, one has (at one-sided 95% CL)

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 - BR(\text{exotic } \mu \text{ decays}) \geq 0.9987 \quad (20)$$

or

$$BR(\text{exotic } \mu \text{ decays}) \leq 0.0013. \quad (21)$$

This bound is a factor of 10 better than the direct experimental bound on $\mu^+ \rightarrow e^+ \bar{\nu}_e \nu_\mu$.

New Heavy Quark Mixing

Heavy D quarks naturally occur in fourth quark generation models and some heavy quark “new physics” scenarios such as E_6 grand unification. Their mixing with ordinary quarks gives rise to V_{uD} which is constrained by unitarity (one sided 95% CL)

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1 - |V_{uD}|^2 \geq 0.9987 \quad (22)$$

$$|V_{uD}| \leq 0.04.$$

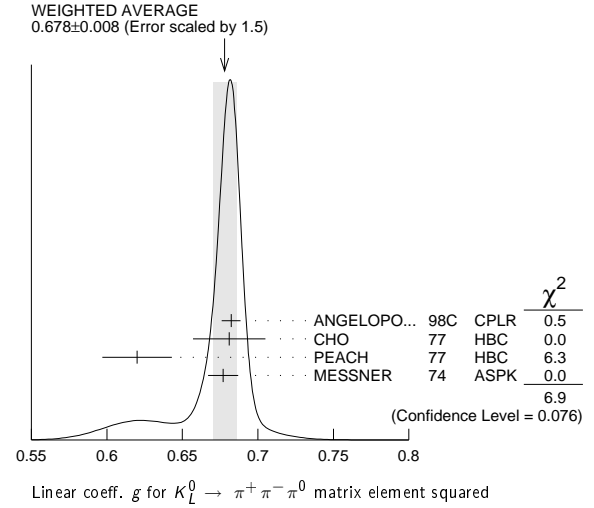

A similar constraint applies to heavy neutrino mixing and the couplings $V_{\mu N}$ and V_{eN} .

- ¹ Result obtained using Cl3pl model of CABIBBO 05 to include $\pi\pi$ rescattering effects. The systematic error includes an external error of 1.06×10^{-3} from the parametrization input of $(a_0 - a_2) m_{\pi^+} = 0.268 \pm 0.017$ from BATLEY 06B.
- ² LAI 01B and SOMALWAR 92 results do not include $\pi\pi$ final state rescattering effects.
- ³ SOMALWAR 92 chose m_{π^+} as normalization to make it compatible with the Particle Data Group $K_L^0 \rightarrow \pi^+ \pi^- \pi^0$ definitions.

Meson Particle Listings

 K_L^0 K_L^0 FORM FACTORS

For discussion, see note on form factors in the K^\pm section of the Particle Listings above.

In the form factor comments, the following symbols are used.

f_+ and f_- are form factors for the vector matrix element.

f_S and f_T refer to the scalar and tensor term.

$f_0(t) = f_+(t) + f_-(t) t / (m_{K^0}^2 - m_{\pi^+}^2)$.

$t =$ momentum transfer to the π .

λ_+ and λ_0 are the linear expansion coefficients of f_+ and f_0 :

$f_+(t) = f_+(0) (1 + \lambda_+ t / m_{\pi^+}^2)$

For quadratic expansion

$f_+(t) = f_+(0) (1 + \lambda_+ t / m_{\pi^+}^2 + \frac{\lambda''_+}{2} t^2 / m_{\pi^+}^4)$

as used by KTeV. If there is a non-vanishing quadratic term, then λ_+

represents an average slope, which is then different from λ'_+ .

NA48 (K_{e3}) and ISTRA quadratic expansion coefficients are converted with

$\lambda'_+{}^{PDG} = \lambda_+{}^{NA48}$ and $\lambda''_+{}^{PDG} = 2 \lambda_+{}^{NA48}$

$\lambda'_+{}^{PDG} = (\frac{m_{\pi^+}}{m_{K^0}})^2 \lambda_+{}^{ISTRA}$ and

$\lambda''_+{}^{PDG} = 2 (\frac{m_{\pi^+}}{m_{K^0}})^4 \lambda_+{}^{ISTRA}$

ISTRA linear expansion coefficients are converted with

$\lambda_+{}^{PDG} = (\frac{m_{\pi^+}}{m_{K^0}})^2 \lambda_+{}^{ISTRA}$ and $\lambda_0{}^{PDG} = (\frac{m_{\pi^+}}{m_{K^0}})^2 \lambda_0{}^{ISTRA}$

The pole parametrization is

$f_+(t) = f_+(0) (\frac{M_V^2}{M_V^2 - t})$

$f_0(t) = f_0(0) (\frac{M_S^2}{M_S^2 - t})$

where M_V and M_S are the vector and scalar pole masses.

The dispersive parametrization is

$f_+(t) = f_+(0) \exp[\frac{t}{m_{\pi^+}^2} (\Lambda_+ + H(t))];$

$f_0(t) = f_0(0) \exp[\frac{t}{m_K^2 - m_{\pi^+}^2} (\ln[C] - G(t))];$

where Λ_+ is the slope parameter and $\ln[C] = \ln[f_0(m_K^2 - m_{\pi^+}^2)]$

is the logarithm of the scalar form factor at the Callan-Treiman point.

$H(t)$ and $G(t)$ are dispersive integrals.

The following abbreviations are used:

DP = Dalitz plot analysis.

PI = π spectrum analysis.

MU = μ spectrum analysis.

POL = μ polarization analysis.

BR = $K_{\mu 3}^0 / K_{e 3}^0$ branching ratio analysis.

E = positron or electron spectrum analysis.

RC = radiative corrections.

 λ_+ (LINEAR ENERGY DEPENDENCE OF f_+ IN $K_{e 3}^0$ DECAY)

4.27 ± 0.44 150k BIRULEV 81 SPEC DP

¹ LAI 07A gives a correlation -0.40 between their λ_0 and λ_+ measurements.

 λ_0 (LINEAR ENERGY DEPENDENCE OF f_0 IN $K_{\mu 3}^0$ DECAY)

Wherever possible, we have converted the above values of $\xi(0)$ into values of λ_0 using the associated λ'_+ and $d\xi(0)/d\lambda_+$. Results labeled OUR FIT are discussed in the

review " $K_{\mu 3}^\pm$ and $K_{e 3}^0$ Form Factors" in the K^\pm Listings. For earlier, lower statistics results, see the 2004 edition of this review, Physics Letters **B592** 1 (2004).

$\alpha_{K^*}^{\text{eff}}$ DECAY FORM FACTOR FOR $K_L \rightarrow e^+ e^- e^+ e^-$

$\alpha_{K^*}^{\text{eff}}$ is the parameter describing the relative strength of an intermediate pseudoscalar decay amplitude and a vector meson decay amplitude in the model of BERGSTROM 83. It takes into account both the radiative effects and the form factor. Since there are two $e^+ e^-$ pairs here compared with one in $e^+ e^- \gamma$ decays, a factorized expression is used for the $e^+ e^- e^+ e^-$ decay form factor.

VALUE	EVTS	DOCUMENT ID	TECN
The data in this block is included in the average printed for a previous datablock.

CP VIOLATION IN K_L DECAYS

Updated April 2016 by L. Wolfenstein (Carnegie-Mellon University), C.-J. Lin (LBNL), and T.G. Trippe (LBNL).

The symmetries C (particle-antiparticle interchange) and P (space inversion) hold for strong and electromagnetic interactions. After the discovery of large C and P violation in the weak interactions, it appeared that the product CP was a good symmetry. In 1964 CP violation was observed in K^0 decays at a level given by the parameter $\epsilon \approx 2.3 \times 10^{-3}$.

A unified treatment of CP violation in K , D , B , and B_s mesons is given in “ CP Violation in Meson Decays” by D. Kirkby and Y. Nir in this *Review*. A more detailed review including a thorough discussion of the experimental techniques used to determine CP violation parameters is given in a book

by K. Kleinknecht [1]. Here we give a concise summary of the formalism needed to define the parameters of CP violation in K_L decays, and a description of our fits for the best values of these parameters.

1. Formalism for CP violation in Kaon decay:

CP violation has been observed in the semi-leptonic decays $K_L^0 \rightarrow \pi^\mp \ell^\pm \nu$, and in the nonleptonic decay $K_L^0 \rightarrow 2\pi$. The experimental numbers that have been measured are

$$A_L = \frac{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) - \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)}{\Gamma(K_L^0 \rightarrow \pi^- \ell^+ \nu) + \Gamma(K_L^0 \rightarrow \pi^+ \ell^- \nu)} \quad (1a)$$

$$\eta_{+-} = A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-) = |\eta_{+-}| e^{i\phi_{+-}} \quad (1b)$$

$$\eta_{00} = A(K_L^0 \rightarrow \pi^0 \pi^0) / A(K_S^0 \rightarrow \pi^0 \pi^0) = |\eta_{00}| e^{i\phi_{00}} \quad (1c)$$

CP violation can occur either in the $K^0 - \bar{K}^0$ mixing or in the decay amplitudes. Assuming CPT invariance, the mass eigenstates of the $K^0 - \bar{K}^0$ system can be written

$$|K_S\rangle = p|K^0\rangle + q|\bar{K}^0\rangle, \quad |K_L\rangle = p|K^0\rangle - q|\bar{K}^0\rangle. \quad (2)$$

If CP invariance held, we would have $q = p$ so that K_S would be CP -even and K_L CP -odd. (We define $|\bar{K}^0\rangle$ as $CP|K^0\rangle$). CP violation in $K^0 - \bar{K}^0$ mixing is then given by the parameter $\tilde{\epsilon}$ where

$$\frac{p}{q} = \frac{(1 + \tilde{\epsilon})}{(1 - \tilde{\epsilon})}. \quad (3)$$

CP violation can also occur in the decay amplitudes

$$A(K^0 \rightarrow \pi\pi(I)) = A_I e^{i\delta_I}, \quad A(\bar{K}^0 \rightarrow \pi\pi(I)) = A_I^* e^{i\delta_I}, \quad (4)$$

where I is the isospin of $\pi\pi$, δ_I is the final-state phase shift, and A_I would be real if CP invariance held. The CP -violating observables are usually expressed in terms of ϵ and ϵ' defined by

$$\eta_{+-} = \epsilon + \epsilon', \quad \eta_{00} = \epsilon - 2\epsilon'. \quad (5a)$$

One can then show [2]

$$\epsilon = \tilde{\epsilon} + i (\text{Im } A_0 / \text{Re } A_0), \quad (5b)$$

$$\sqrt{2}\epsilon' = ie^{i(\delta_2 - \delta_0)} (\text{Re } A_2 / \text{Re } A_0) (\text{Im } A_2 / \text{Re } A_2 - \text{Im } A_0 / \text{Re } A_0), \quad (5c)$$

$$A_L = 2\text{Re } \epsilon / (1 + |\epsilon|^2) \approx 2\text{Re } \epsilon. \quad (5d)$$

In Eqs. (5a), small corrections [3] of order $\epsilon' \times \text{Re}(A_2/A_0)$ are neglected, and Eq. (5d) assumes the $\Delta S = \Delta Q$ rule.

The quantities $\text{Im } A_0$, $\text{Im } A_2$, and $\text{Im } \tilde{\epsilon}$ depend on the choice of phase convention, since one can change the phases of K^0 and \bar{K}^0 by a transformation of the strange quark state $|s\rangle \rightarrow |s\rangle e^{i\alpha}$; of course, observables are unchanged. It is possible by a choice of phase convention to set $\text{Im } A_0$ or $\text{Im } A_2$ or $\text{Im } \tilde{\epsilon}$ to zero, but none of these is zero with the usual phase conventions in the Standard Model. The choice $\text{Im } A_0 = 0$ is called the Wu-Yang phase convention [4], in which case $\epsilon = \tilde{\epsilon}$. The value of ϵ' is independent of phase convention, and a nonzero value demonstrates CP violation in the decay amplitudes, referred to

Meson Particle Listings

K_L^0

as direct CP violation. The possibility that direct CP violation is essentially zero, and that CP violation occurs only in the mixing matrix, was referred to as the superweak theory [5].

By applying CPT invariance and unitarity the phase of ϵ is given approximately by

$$\phi_\epsilon \approx \tan^{-1} \frac{2(m_{K_L} - m_{K_S})}{\Gamma_{K_S} - \Gamma_{K_L}} \approx 43.52 \pm 0.05^\circ, \quad (6a)$$

while Eq. (5c) gives the phase of ϵ' to be

$$\phi_{\epsilon'} = \delta_2 - \delta_0 + \frac{\pi}{2} \approx 42.3 \pm 1.5^\circ, \quad (6b)$$

where the numerical value is based on an analysis of $\pi\text{-}\pi$ scattering using chiral perturbation theory [6]. The approximation in Eq. (6a) depends on the assumption that direct CP violation is very small in all K^0 decays. This is expected to be good to a few tenths of a degree, as indicated by the small value of ϵ' and of η_{+-0} and η_{000} , the CP -violation parameters in the decays $K_S \rightarrow \pi^+\pi^-\pi^0$ [7], and $K_S \rightarrow \pi^0\pi^0\pi^0$ [8]. The relation in Eq. (6a) is exact in the superweak theory, so this is sometimes called the superweak-phase ϕ_{SW} . An important point for the analysis is that $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$. The consequence is that only two real quantities need be measured, the magnitude of ϵ and the value of (ϵ'/ϵ) , including its sign. The measured quantity $|\eta_{00}/\eta_{+-}|^2$ is very close to unity so that we can write

$$|\eta_{00}/\eta_{+-}|^2 \approx 1 - 6\text{Re}(\epsilon'/\epsilon) \approx 1 - 6\epsilon'/\epsilon, \quad (7a)$$

$$\text{Re}(\epsilon'/\epsilon) \approx \frac{1}{3}(1 - |\eta_{00}/\eta_{+-}|). \quad (7b)$$

From the experimental measurements in this edition of the *Review*, and the fits discussed in the next section, one finds

$$|\epsilon| = (2.228 \pm 0.011) \times 10^{-3}, \quad (8a)$$

$$\phi_\epsilon = (43.5 \pm 0.5)^\circ, \quad (8b)$$

$$\text{Re}(\epsilon'/\epsilon) \approx \epsilon'/\epsilon = (1.66 \pm 0.23) \times 10^{-3}, \quad (8c)$$

$$\phi_{+-} = (43.4 \pm 0.5)^\circ, \quad (8d)$$

$$\phi_{00} - \phi_{+-} = (0.34 \pm 0.32)^\circ, \quad (8e)$$

$$A_L = (3.32 \pm 0.06) \times 10^{-3}. \quad (8f)$$

Direct CP violation, as indicated by ϵ'/ϵ , is expected in the Standard Model. However, the numerical value cannot be reliably predicted because of theoretical uncertainties [9]. The value of A_L agrees with Eq. (5d). The values of ϕ_{+-} and $\phi_{00} - \phi_{+-}$ are used to set limits on CPT violation [see “Tests of Conservation Laws”].

2. Fits for K_L^0 CP -violation parameters:

In recent years, K_L^0 CP -violation experiments have improved our knowledge of CP -violation parameters, and their consistency with the expectations of CPT invariance and unitarity. To determine the best values of the CP -violation parameters in $K_L^0 \rightarrow \pi^+\pi^-$ and $\pi^0\pi^0$ decay, we make two types of fits, one for the phases ϕ_{+-} and ϕ_{00} jointly with Δm and τ_S , and the other for the amplitudes $|\eta_{+-}|$ and $|\eta_{00}|$ jointly with the $K_L^0 \rightarrow \pi\pi$ branching fractions.

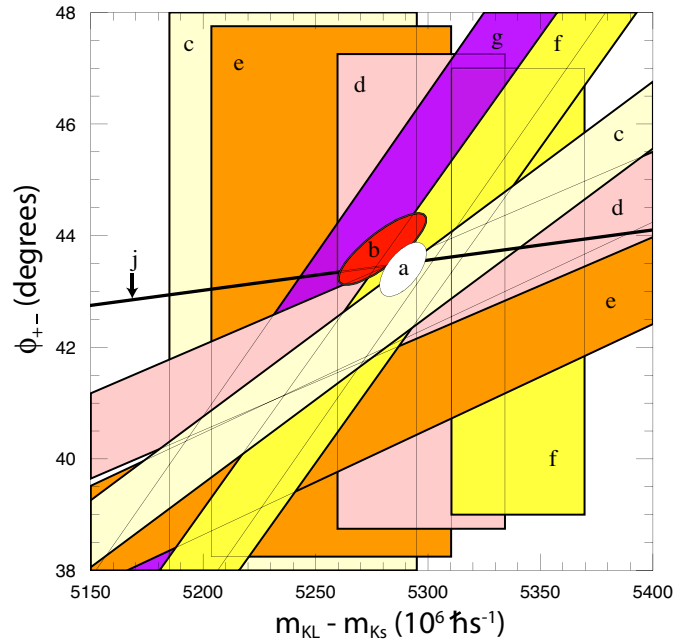

Figure 1: ϕ_{+-} vs Δm for experiments which do not assume CPT invariance. Δm measurements appear as vertical bands spanning $\Delta m \pm 1\sigma$, cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, and are cited in Table 1. The narrow band “j” shows ϕ_{SW} . The ellipse “a” shows the $\chi^2 = 1$ contour of the fit result.

Table 1: References, Document ID’s, and sources corresponding to the letter labels in the figures. The data are given in the ϕ_{+-} and Δm sections of the K_L Listings, and the τ_S section of the K_S Listings.

Fits to ϕ_{+-} , ϕ_{00} , $\Delta\phi$, Δm , and τ_S data: These are joint fits to the data on ϕ_{+-} , ϕ_{00} , the phase difference $\Delta\phi = \phi_{00} - \phi_{+-}$, the $K_L^0 - K_S^0$ mass difference Δm , and the K_S^0 mean life τ_S , including the effects of correlations.

Measurements of ϕ_{+-} and ϕ_{00} are highly correlated with Δm and τ_S . Some measurements of τ_S are correlated with Δm . The correlations are given in the footnotes of the ϕ_{+-} and ϕ_{00} sections of the K_L^0 Listings, and the τ_S section of the K_S^0 Listings.

In most cases, the correlations are quoted as 100%, *i.e.*, with the value and error of ϕ_{+-} or ϕ_{00} given at a fixed value of Δm and τ_S , with additional terms specifying the dependence of the value on Δm and τ_S . These cases lead to diagonal bands in Figs. 1 and 2. The KTeV experiment [10] quotes its results as values of Δm , τ_S , ϕ_ϵ , $\text{Re}(\epsilon'/\epsilon)$, and $\text{Im}(\epsilon'/\epsilon)$ with correlations, leading to the ellipses labeled “b.” The correlations for the KTeV measurements are given in the $\text{Im}(\epsilon'/\epsilon)$ section of the K_L^0 Listings. For small $|\epsilon'/\epsilon|$, $\phi_{+-} \approx \phi_\epsilon + \text{Im}(\epsilon'/\epsilon)$.

The data on τ_S , Δm , and ϕ_{+-} shown in Figs. 1 and 2 are combined with data on ϕ_{00} and $\phi_{00} - \phi_{+-}$ in two fits, one without assuming *CPT*, and the other with this assumption. The results without assuming *CPT* are shown as ellipses labeled “a.” These ellipses are seen to be in good agreement with the superweak phase

$$\phi_{\text{SW}} = \tan^{-1} \left(\frac{2\Delta m}{\Delta \Gamma} \right) = \tan^{-1} \left(\frac{2\Delta m \tau_S \tau_L}{\hbar(\tau_L - \tau_S)} \right). \quad (9)$$

In Figs. 1 and 2, ϕ_{SW} is shown as narrow bands labeled “j.”

Table 2 column 2, “Fit w/o *CPT*,” gives the resulting fitted parameters, while Table 3 gives the correlation matrix for this fit. The white ellipses labeled “a” in Fig. 1 and Fig. 2 are the $\chi^2 = 1$ contours for this fit.

For experiments which have dependencies on unseen fit parameters, that is, parameters other than those shown on the x or y axis of the figure, their band positions are evaluated using the fit results and their band widths include the fitted uncertainty in the unseen parameters. This is also true for the ϕ_{SW} bands.

If *CPT* invariance and unitarity are assumed, then by Eq. (6a), the phase of ϵ is constrained to be approximately equal to

$$\begin{aligned} \phi_{\text{SW}} = & (43.50258 \pm 0.00021)^\circ + 54.1(\Delta m - 0.5289)^\circ \\ & + 32.0(\tau_S - 0.89564) \end{aligned} \quad (10)$$

where we have linearized the Δm and τ_S dependence of Eq. (9). The error ± 0.00021 is due to the uncertainty in τ_L . Here Δm has units $10^{10} \hbar \text{s}^{-1}$ and τ_S has units 10^{-10}s .

If in addition we use the observation that $\text{Re}(\epsilon'/\epsilon) \ll 1$ and $\cos(\phi_{\epsilon'} - \phi_\epsilon) \simeq 1$, as well as the numerical value of $\phi_{\epsilon'}$ given in Eq. (6b), then Eqs. (5a), which are sketched in Fig. 3, lead to the constraint

$$\begin{aligned} \phi_{00} - \phi_{+-} & \approx -3 \text{Im} \left(\frac{\epsilon'}{\epsilon} \right) \\ & \approx -3 \text{Re} \left(\frac{\epsilon'}{\epsilon} \right) \tan(\phi_{\epsilon'} - \phi_\epsilon) \\ & \approx 0.006^\circ \pm 0.008^\circ, \end{aligned} \quad (11)$$

so that $\phi_{+-} \approx \phi_{00} \approx \phi_\epsilon \approx \phi_{\text{SW}}$.

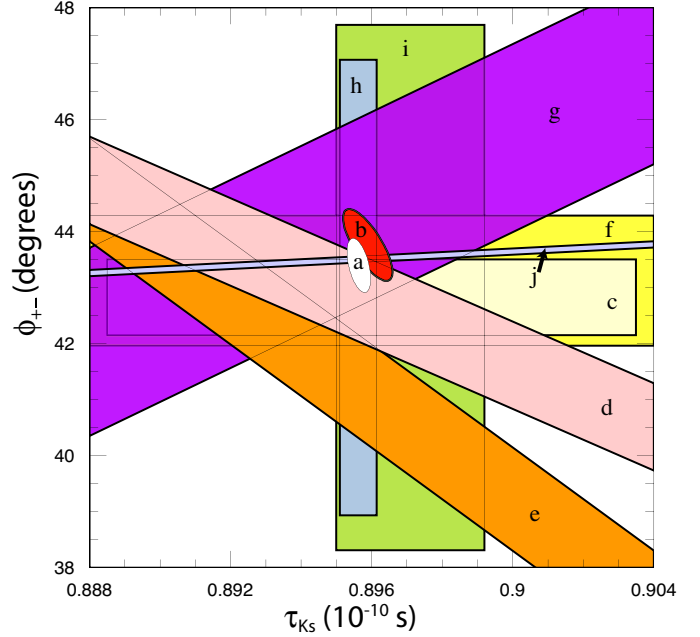

Figure 2: ϕ_{+-} vs τ_S . τ_S measurements appear as vertical bands spanning $\tau_S \pm 1\sigma$, some of which are cut near the top and bottom to aid the eye. Most ϕ_{+-} measurements appear as diagonal or horizontal bands spanning $\phi_{+-} \pm \sigma_\phi$. Data are labeled by letters: “b”–FNAL KTeV, “c”–CERN CPLEAR, “d”–FNAL E773, “e”–FNAL E731, “f”–CERN, “g”–CERN NA31, “h”–CERN NA48, “i”–CERN NA31, and are cited in Table 1. The narrow band “j” shows ϕ_{SW} . The ellipse “a” shows the fit result’s $\chi^2 = 1$ contour.

Table 2: Fit results for ϕ_{+-} , Δm , τ_S , ϕ_{00} , $\Delta\phi = \phi_{00} - \phi_{+-}$, and ϕ_ϵ without and with the *CPT* assumption.

Quantity(units)	Fit w/o <i>CPT</i>	Fit w/ <i>CPT</i>

In the fit assuming *CPT*, we constrain $\phi_\epsilon = \phi_{\text{SW}}$ using the linear expression in Eq. (10), and constrain $\phi_{00} - \phi_{+-}$ using Eq. (11). These constraints are inserted into the Listings with the Document ID of SUPERWEAK 16. Some additional data for which the authors assumed *CPT* are added to this fit or substitute for other less precise data for which the authors did not make this assumption. See the Listings for details.

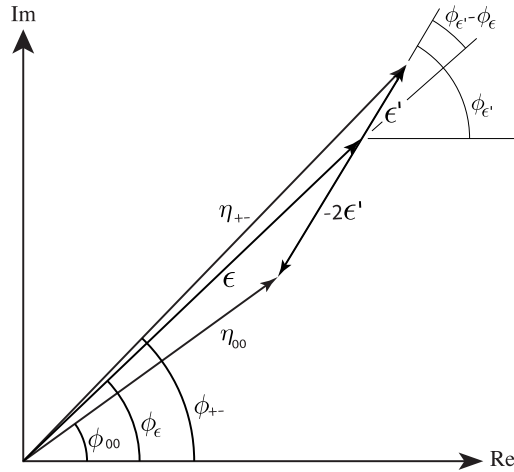

Figure 3: Sketch of Eqs. (5a). Not to scale.

The results of this fit are shown in Table 2, column 3, “Fit w/*CPT*,” and the correlation matrix is shown in Table 4. The Δm precision is improved by the *CPT* assumption.

Table 3: Correlation matrix for the results of the fit without the *CPT* assumption

Fits for ϵ'/ϵ , $|\eta_{+-}|$, $|\eta_{00}|$, and $B(K_L \rightarrow \pi\pi)$

We list measurements of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ . Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from measurements of the K_L^0 and K_S^0 lifetimes (τ_L , τ_S), and branching ratios (B) to $\pi\pi$, using the relations

$$|\eta_{+-}| = \left[\frac{B(K_L^0 \rightarrow \pi^+\pi^-)}{\tau_L} \frac{\tau_S}{B(K_S^0 \rightarrow \pi^+\pi^-)} \right]^{1/2}, \quad (12a)$$

$$|\eta_{00}| = \left[\frac{B(K_L^0 \rightarrow \pi^0\pi^0)}{\tau_L} \frac{\tau_S}{B(K_S^0 \rightarrow \pi^0\pi^0)} \right]^{1/2}. \quad (12b)$$

For historical reasons, the branching ratio fits and the *CP*-violation fits are done separately, but we want to include the influence of $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and ϵ'/ϵ measurements on $B(K_L^0 \rightarrow \pi^+\pi^-)$ and $B(K_L^0 \rightarrow \pi^0\pi^0)$ and vice versa. We approximate a global fit to all of these measurements by first performing two independent fits: 1) BRFIT, a fit to the K_L^0 branching ratios, rates, and mean life, and 2) ETAFIT, a fit to the $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{+-}/\eta_{00}|$, and ϵ'/ϵ measurements. The results from fit 1, along with the K_S^0 values from this edition, are used to compute values of $|\eta_{+-}|$ and $|\eta_{00}|$, which are included as measurements in the $|\eta_{00}|$ and $|\eta_{+-}|$ sections with a document ID of BRFIT 16. Thus, the fit values of $|\eta_{+-}|$ and $|\eta_{00}|$ given in this edition include both the direct measurements and the results from the branching ratio fit.

The process is reversed in order to include the direct $|\eta|$ measurements in the branching ratio fit. The results from fit 2 above (before including BRFIT 16 values) are used along with the K_L^0 and K_S^0 mean lives and the $K_S^0 \rightarrow \pi\pi$ branching fractions to compute the K_L^0 branching ratio $\Gamma(K_L^0 \rightarrow \pi^0\pi^0)/\Gamma(K_L^0 \rightarrow \pi^+\pi^-)$. This branching ratio value is included as a measurement in the branching ratio section with a document ID of ETAFIT 16. Thus, the K_L^0 branching ratio fit values in this edition include the results of the direct measurement of $|\eta_{00}/\eta_{+-}|$ and ϵ'/ϵ . Most individual measurements of $|\eta_{+-}|$ and $|\eta_{00}|$ enter our fits directly via the corresponding measurements of $\Gamma(K_L^0 \rightarrow \pi^+\pi^-)/\Gamma(\text{total})$ and $\Gamma(K_L^0 \rightarrow \pi^0\pi^0)/\Gamma(\text{total})$, and those that do not have too large errors to have any influence on the fitted values of these branching ratios. A more detailed discussion of these fits is given in the 1990 edition of this *Review* [20].

CP-VIOLATION PARAMETERS IN K_L^0 DECAYS

CHARGE ASYMMETRY IN K_S^0 DECAYS

Such asymmetry violates CP. It is related to $\text{Re}(\epsilon)$.

$A_L =$ weighted average of $A_L(\mu)$ and $A_L(e)$

In previous editions and in the literature the symbol used for this asymmetry was δ_L^{\pm} or δ . We use A_L for consistency with B^0 asymmetry notation and with recent K_S^0 notation.

PARAMETERS FOR $K_L^0 \rightarrow 2\pi$ DECAY

$$\eta_{+-} = A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-)$$

$$\eta_{00} = A(K_L^0 \rightarrow \pi^0 \pi^0) / A(K_S^0 \rightarrow \pi^0 \pi^0)$$

The fitted values of $|\eta_{+-}|$ and $|\eta_{00}|$ given below are the results of a fit to $|\eta_{+-}|$, $|\eta_{00}|$, $|\eta_{00}/\eta_{+-}|$, and $\text{Re}(\epsilon'/\epsilon)$. Independent information on $|\eta_{+-}|$ and $|\eta_{00}|$ can be obtained from the fitted values of the $K_L^0 \rightarrow \pi\pi$ and $K_S^0 \rightarrow \pi\pi$ branching ratios and the K_L^0 and K_S^0 lifetimes. This information is included as data in the $|\eta_{+-}|$ and $|\eta_{00}|$ sections with a Document ID "BRFIT." See the note "CP violation in K_L decays" above for details.

$$|\eta_{00}| = |A(K_L^0 \rightarrow 2\pi^0) / A(K_S^0 \rightarrow 2\pi^0)|$$

2.71 ±0.37	² WOLFF	71 OSPK	Cu reg., 4γ's
2.95 ±0.63	² CHOLLET	70 OSPK	Cu reg., 4γ's

¹ Error is statistical only.

² CHOLLET 70 gives $|\eta_{00}| = (1.23 \pm 0.24) \times (\text{regeneration amplitude, 2 GeV/c Cu})/10000\text{mb}$. WOLFF 71 gives $|\eta_{00}| = (1.13 \pm 0.12) \times (\text{regeneration amplitude, 2 GeV/c Cu})/10000\text{mb}$. We compute both $|\eta_{00}|$ values for (regeneration amplitude, 2 GeV/c Cu) = $24 \pm 2\text{mb}$. This regeneration amplitude results from averaging over FAISSNER 69, extrapolated using optical-model calculations of Bohm *et al.*, Physics Letters **27B** 594 (1968) and the data of BALATS 71. (From H. Faissner, private communication).

$$|\eta_{+-}| = |A(K_L^0 \rightarrow \pi^+ \pi^-) / A(K_S^0 \rightarrow \pi^+ \pi^-)|$$

¹ Value obtained from the NA48 measurements of $\Gamma(K_L^0 \rightarrow \pi^+ \pi^-) / \Gamma(K_L^0 \rightarrow \pi e \nu_e)$ and $\tau_{K_S^0}$ and KLOE measurements of $B(K_S^0 \rightarrow \pi^+ \pi^-)$ and $\tau_{K_L^0}$. $\Gamma(K_L^0 \rightarrow \pi^+ \pi^-)$ is defined to include the inner bremsstrahlung component $\Gamma(K_L^0 \rightarrow \pi^+ \pi^- \gamma(\text{IB}))$ but exclude the direct emission component $B(K_S^0 \rightarrow \pi^+ \pi^- (\text{DE}))$. Their $|\eta_{+-}|$ value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

² AMBROSINO 06F uses KLOE branching ratios and τ_L together with τ_S from PDG 04. Their $|\eta_{+-}|$ value is not directly used in our fit, but enters the fit via their branching ratio and lifetime measurements.

³ ALEXOPOULOS 04 $|\eta_{+-}|$ uses their $K_L^0 \rightarrow \pi\pi$ branching fractions, $\tau_S = (0.8963 \pm 0.0005) \times 10^{-10}$ s from the average of KTeV and NA48 τ_S measurements, and assumes that $\Gamma(K_S^0 \rightarrow \pi e \nu_e) = \Gamma(K_L^0 \rightarrow \pi e \nu_e)$ giving $B(K_S^0 \rightarrow \pi e \nu_e) = 0.118\%$. Their η_{+-} is not directly used in our fit, but enters our fit via their branching ratio measurements.

⁴ APOSTOLAKIS 99C report $(2.264 \pm 0.023 \pm 0.026 + 9.1[\tau_S - 0.8934]) \times 10^{-3}$. We evaluate for our 2006 best value $\tau_S = (0.8958 \pm 0.0005) \times 10^{-10}$ s.

⁵ ADLER 95B report $(2.312 \pm 0.043 \pm 0.030 - 1[\Delta m - 0.5274] + 9.1[\tau_S - 0.8926]) \times 10^{-3}$. We evaluate for our 1996 best values $\Delta m = (0.5304 \pm 0.0014) \times 10^{-10} \text{fs}^{-1}$ and $\tau_S = (0.8927 \pm 0.0009) \times 10^{-10}$ s. Superseded by APOSTOLAKIS 99C.

$$|\epsilon| = (2|\eta_{+-}| + |\eta_{00}|)/3$$

This expression is a very good approximation, good to about one part in 10^{-4} because of the small measured value of $\phi_{00} - \phi_{+-}$ and small theoretical ambiguities.

VALUE (units 10^{-3})	DOCUMENT ID
2.228±0.011 OUR FIT	Error includes scale factor of 1.8.

3.2 ± 2.8 ± 1.2	2	WOODS	88	E731	

1 The two ABOUZAID 11 values use the same data. The fits are performed with and without *CPT* invariance requirement.

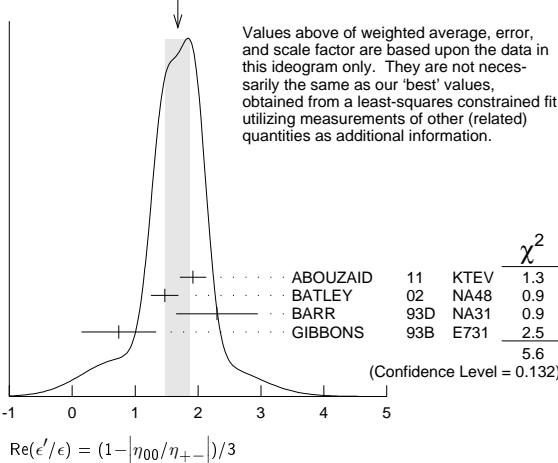

2 These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements. They enter the average in this section but enter the fit via the $|\eta_{00}/\eta_{+-}|$ only.

3 This is the combined results from BARR 93D and BURKHARDT 88, taking into account their common systematic uncertainty.

4 We use ABOUZAID 11 $\text{Re}(e'/\epsilon)$ value with *CPT* assumption in our fits for $|\eta_{+-}|$, $|\eta_{00}|$, and $\text{Re}(e'/\epsilon)$.

5 These values are derived from $|\eta_{00}/\eta_{+-}|$ measurements.

WEIGHTED AVERAGE
1.68 ± 0.20 (Error scaled by 1.4)

Values above of weighted average, error, and scale factor are based upon the data in this ideogram only. They are not necessarily the same as our 'best' values, obtained from a least-squares constrained fit utilizing measurements of other (related) quantities as additional information.

ϕ_{+-} , PHASE of η_{+-}

The dependence of the phase on Δm and τ_S is given for each experiment in the comments below, where Δm is the $K_L^0 - K_S^0$ mass difference in units 10^{10} h s^{-1} and τ_S is the K_S mean life in units 10^{-10} s . We also give the regeneration phase ϕ_f in the comments below.

OUR FIT is described in the note on "*CP* violation in K_L decays" in the K_L^0 Particle Listings. Most experiments in this section are included in both the "Not Assuming *CPT*" and "Assuming *CPT*" fits. In the latter fit, they have little direct influence on ϕ_{+-} because their errors are large compared to that assuming *CPT*, but they influence Δm and τ_S through their dependencies on these parameters, which are given in the footnotes.

1 APOSTOLAKIS 99C measures $\phi_{+-} = (43.19 \pm 0.53 \pm 0.28) + 300 [\Delta m - 0.5301] (\circ)$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$. Our first error is their experiment's error and our second error is the systematic error from using our best values.

2 SCHWINGENHEUER 95 measures $\phi_{+-} = (43.53 \pm 0.76) + 173 [\Delta m - 0.5282] - 275 [\tau_S - 0.8926] (\circ)$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$, $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$. Our first error is their experiment's error and our second error is the systematic error from using our best values.

3 These experiments measure $\phi_{+-} - \phi_f$ and calculate the regeneration phase from the power law momentum dependence of the regeneration amplitude using analyticity and dispersion relations. SCHWINGENHEUER 95 [GIBBONS 93] includes a systematic error of $0.35^\circ [0.5^\circ]$ for uncertainties in their modeling of the regeneration amplitude.

4 GIBBONS 93 measures $\phi_{+-} = (42.21 \pm 0.9) + 189 [\Delta m - 0.5257] - 460 [\tau_S - 0.8922] (\circ)$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$, $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$. Our first error is their experiment's error and our second error is the systematic error from using our best values. This is actually reported in SCHWINGENHEUER 95, footnote 8. GIBBONS 93 reports $\phi_{+-} (42.2 \pm 1.4)^\circ$. They measure $\phi_{+-} - \phi_f$ and calculate the regeneration phase ϕ_f from the power law momentum dependence of the regeneration amplitude using analyticity. An error of 0.6° is included for possible uncertainties in the regeneration phase.

5 CAROSI 90 measures $\phi_{+-} = (46.9 \pm 1.4 \pm 0.7) + 579 [\Delta m - 0.5351] + 303 [\tau_S - 0.8922] (\circ)$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$, $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$. Our first error is their experiment's error and our second error is the systematic error from using our best values.

6 GEWENIGER 74B measures $\phi_{+-} = (49.4 \pm 1.0) + 565 [\Delta m - 0.540] (\circ)$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$. Our first error is their experiment's error and our second error is the systematic error from using our best values.

7 Not independent of other phase parameters reported in ABOUZAID 11.

8 ALAVI-HARATI 03 ϕ_{+-} is correlated with their $\Delta m = m_{K_L^0} - m_{K_S^0}$ and τ_{K_S} measurements in the K_L^0 and K_S^0 sections respectively. The correlation coefficients are $\rho(\phi_{+-}, \Delta m) = +0.955$, $\rho(\phi_{+-}, \tau_S) = -0.871$, and $\rho(\tau_S, \Delta m) = -0.840$. *CPT* is not assumed. Uses scintillator Pb regenerator. Superseded by ABOUZAID 11.

9 ADLER 96C measures $\phi_{+-} = (43.82 \pm 0.41) + 339 [\Delta m - 0.5307] - 252 [\tau_S - 0.8922] (\circ)$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$, $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$. Our first error is their experiment's error and our second error is the systematic error from using our best values.

10 ADLER 96C is the result of a fit which includes nearly the same data as entered into the "OUR FIT" value in the 1996 edition of this Review (Physical Review **D54** 1 (1996)).

11 ADLER 95B measures $\phi_{+-} = (42.7 \pm 0.9 \pm 0.6) + 316 [\Delta m - 0.5274] + 30 [\tau_S - 0.8926] (\circ)$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$, $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$. Our first error is their experiment's error and our second error is the systematic error from using our best values.

12 ADLER 92B quote separately two systematic errors: ± 0.4 from their experiment and ± 1.0 degrees due to the uncertainty in the value of Δm .

13 KARLSSON 90 systematic error does not include regeneration phase uncertainty.

14 CARITHERS 75 measures $\phi_{+-} = (45.5 \pm 2.8) + 224 [\Delta m - 0.5348] (\circ)$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$. Our first error is their experiment's error and our second error is the systematic error from using our best values. $\phi_f = -40.9 \pm 2.6^\circ$.

ϕ_{00} , PHASE of η_{00}

See comment in ϕ_{+-} header above for treatment of Δm and τ_S dependence, as well as for the inclusion of data in both the "Assuming *CPT*" and "Not Assuming *CPT*" fits.

OUR FIT is described in the note on "*CP* violation in K_L decays" in the K_L^0 Particle Listings.

VALUE (°)	DOCUMENT ID	TECN	COMMENT
43.52 ± 0.05 OUR FIT	Error includes scale factor of 1.3. Assuming <i>CPT</i>		
43.7 ± 0.6 OUR FIT	Error includes scale factor of 1.2. Not assuming <i>CPT</i>		
44.5 ± 2.3 ± 0.5	1 CAROSI 90	NA31	
• • • We do not use the following data for averages, fits, limits, etc. • • •			
44.06 ± 0.68	2 ABOUZAID 11	KTEV	Not assuming <i>CPT</i>
41.7 ± 5.9 ± 0.2	3 ANGELOPO... 98	CPLR	
50.8 ± 7.1 ± 1.7	4 ADLER 96B	CPLR	Sup. by ANGELOPOULOS 98
47.4 ± 1.4 ± 0.9	5 KARLSSON 90	E731	

1 CAROSI 90 measures $\phi_{00} = (47.1 \pm 2.1 \pm 1.0) + 579 [\Delta m - 0.5351] + 252 [\tau_S - 0.8922] (\circ)$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$, $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$. Our first error is their experiment's error and our second error is the systematic error from using our best values.

2 Not independent of other phase parameters reported in ABOUZAID 11.

3 ANGELOPOULOS 98 measures $\phi_{00} = (42.0 \pm 5.6 \pm 1.9) + 240 [\Delta m - 0.5307] (\circ)$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$. Our first error is their experiment's error and our second error is the systematic error from using our best values. The τ_S dependence is negligible.

4 ADLER 96B identified initial neutral kaon individually as being a K^0 or a \bar{K}^0 . The systematic uncertainty is $\pm 1.5^\circ$ combined in quadrature with $\pm 0.8^\circ$ due to Δm .

5 KARLSSON 90 systematic error does not include regeneration phase uncertainty.

$\phi_\epsilon = (2\phi_{+-} + \phi_{00})/3$

This expression is a very good approximation, good to about 10^{-3} degrees because of the small measured values of $\phi_{00} - \phi_{+-}$ and $\text{Re } e'/\epsilon$, and small theoretical ambiguities.

VALUE (°)	DOCUMENT ID	TECN	COMMENT
43.52 ± 0.05 OUR FIT	Error includes scale factor of 1.2. Assuming <i>CPT</i>		
43.5 ± 0.5 OUR FIT	Error includes scale factor of 1.3. Not assuming <i>CPT</i>		
43.5164 ± 0.0002 ± 0.0518	1 SUPERWEAK 16		Assuming <i>CPT</i>
43.86 ± 0.63	2 ABOUZAID 11	KTEV	Not assuming <i>CPT</i>

1 SUPERWEAK 16 is a fake measurement used to impose the *CPT* or Superweak constraint $\phi_{+-} = \phi_{SW} = \tan^{-1} [2 \frac{\Delta m}{\hbar} (\frac{\tau_S \tau_L}{\tau_L - \tau_S})]$. This "measurement" is linearized using values near the PDG 04 edition values of Δm , τ_S and τ_L , and then adjusted to our current values as described in the following "measurement". SUPERWEAK 16 measures $\phi_\epsilon = (43.50258 \pm 0.00021) + 54.1 [\Delta m - 0.5289] + 32.0 [\tau_S - 0.89564] (\circ)$. We have adjusted the measurement to use our best values of $(\Delta m = 0.5293 \pm 0.0009) (10^{10} \text{ h s}^{-1})$, $(\tau_S = 0.8954 \pm 0.0004) (10^{-10} \text{ s})$. Our first error is their experiment's error and our second error is the systematic error from using our best values.

2 ABOUZAID 11 uses the full KTeV dataset collected in 1996, 1997, and 1999. See $\text{Im}(e'/\epsilon)$ section for correlation information.

See key on page 601

Meson Particle Listings

K_L^0

$\text{Im}(e'/\epsilon) = -(\phi_{00} - \phi_{+-})/3$

For small $|e'/\epsilon|$, $\text{Im}(e'/\epsilon)$ is related to the phases of η_{00} and η_{+-} by the above expression.

VALUE (°)	DOCUMENT ID	TECN	COMMENT

-0.11 ± 0.11 OUR FIT			Not assuming <i>CPT</i>
-0.0985 ± 0.1157	¹ ABOUZAID 11	KTEV	Not assuming <i>CPT</i>

¹ ABOUZAID 11 uses the full KTeV dataset collected in 1996, 1997, and 1999. The fit has Δm , τ_S , ϕ_e , $\text{Re}(e'/\epsilon)$, and $\text{Im}(e'/\epsilon)$ as free parameters. The reported value of $\text{Im}(e'/\epsilon) = (-17.20 \pm 20.20) \times 10^{-4}$ rad. The correlation coefficients are $\rho(\phi_e, \Delta m) = 0.828$, $\rho(\phi_e, \tau_S) = -0.765$, $\rho(\Delta m, \tau_S) = -0.858$, $\rho(\text{Im}(e'/\epsilon), \phi_e) = -0.041$, $\rho(\text{Im}(e'/\epsilon), \Delta m) = 0.026$, $\rho(\text{Im}(e'/\epsilon), \tau_S) = -0.010$.

DECAY-PLANE ASYMMETRY IN $\pi^+ \pi^- e^+ e^-$ DECAYS

This is the *CP*-violating asymmetry

$$A = \frac{N_{\sin\phi\cos\phi>0.0} - N_{\sin\phi\cos\phi<0.0}}{N_{\sin\phi\cos\phi>0.0} + N_{\sin\phi\cos\phi<0.0}}$$

where ϕ is the angle between the $e^+ e^-$ and $\pi^+ \pi^-$ planes in the K_L^0 rest frame.

CP ASYMMETRY A in $K_L^0 \rightarrow \pi^+ \pi^- e^+ e^-$

VALUE (%)	DOCUMENT ID	TECN

CPT-INVARIANCE TESTS IN K_L^0 DECAYS

PHASE DIFFERENCE $\phi_{00} - \phi_{+-}$

Test of *CPT*.

OUR FIT is described in the note on "*CP* violation in K_L decays" in the K_L^0 Particle Listings.

VALUE (°)	DOCUMENT ID	TECN	COMMENT
0.006 ± 0.014 OUR FIT			Error includes scale factor of 1.7. Assuming <i>CPT</i>
0.34 ± 0.32 OUR FIT			Not assuming <i>CPT</i>
0.006 ± 0.008	¹ SUPERWEAK 16		Assuming <i>CPT</i>
-0.30 ± 0.88	² SCHWINGEN... 95		Combined E731, E773
0.30 ± 0.35	³ ABOUZAID 11	KTEV	Not assuming <i>CPT</i>
0.39 ± 0.22 ± 0.45	⁴ ALAVI-HARATI03	KTEV	
0.62 ± 0.71 ± 0.75	SCHWINGEN... 95	E773	
-1.6 ± 1.2	⁵ GIBBONS 93	E731	
0.2 ± 2.6 ± 1.2	⁶ CAROSI 90	NA31	
-0.3 ± 2.4 ± 1.2	KARLSSON 90	E731	

¹ SUPERWEAK 16 is a fake experiment to constrain $\phi_{00} - \phi_{+-}$ to a small value as described in the note "*CP* violation in K_L decays."

² This SCHWINGENHEUER 95 values is the combined result of SCHWINGENHEUER 95 and GIBBONS 93, accounting for correlated systematic errors.

³ Not independent of other phase parameters reported in ABOUZAID 11.

⁴ ALAVI-HARATI 03 fit $\text{Re}(e'/\epsilon)$, $\text{Im}(e'/\epsilon)$, Δm , τ_S , and ϕ_{+-} simultaneously, not assuming *CPT*. Phase difference is obtained from $\phi_{00} - \phi_{+-} \approx -3\text{Im}(e'/\epsilon)$ for small $|e'/\epsilon|$. Superseded by ABOUZAID 11.

⁵ GIBBONS 93 give detailed dependence of systematic error on lifetime (see the section on the K_S^0 mean life) and mass difference (see the section on $m_{K_L^0} - m_{K_S^0}$).

⁶ CAROSI 90 is excluded from the fit because it is not independent of ϕ_{+-} and ϕ_{00} values.

PHASE DIFFERENCE $\phi_{+-} - \phi_{SW}$

Test of *CPT*. The Superweak phase $\phi_{SW} \equiv \tan^{-1}(2\Delta m/\Delta\Gamma)$ where $\Delta m = m_{K_L^0} - m_{K_S^0}$ and $\Delta\Gamma = \hbar(\tau_L - \tau_S)/(\tau_L \tau_S)$.

VALUE (°)	DOCUMENT ID	TECN
0.61 ± 0.62 ± 1.01	¹ ALAVI-HARATI03	KTEV

¹ ALAVI-HARATI 03 fit is the same as their ϕ_{+-} , τ_{K_S} , Δm fit, except that the parameter $\phi_{+-} - \phi_{SW}$ is used in place of ϕ .

$\text{Re}(\frac{2}{3}\eta_{+-} + \frac{1}{3}\eta_{00}) - \frac{A_\gamma}{A}$

Test of *CPT*

VALUE (units 10^{-6})	DOCUMENT ID	TECN	COMMENT
-3 ± 35	¹ ALAVI-HARATI02	E799	Uses A_L from K_{e3} decays

¹ ALAVI-HARATI 02 uses PDG 00 values of η_{+-} and η_{00} .

WEIGHTED AVERAGE
895.81 ± 0.19 (Error scaled by 1.4)

- Inclusive reaction. Complicated background and phase-space effects.
- Mass errors enlarged by us to Γ/\sqrt{N} . See note.
- Number of events in peak reevaluated by us.
- K-matrix pole.
- From a partial wave amplitude analysis.
- From a fit in the $K_0^*(800) + K^*(892) + K^*(1410)$ model.
- From the pole position of the $K\pi$ vector form factor using EPIFANOV 07 and constraints from K_{J3} decays in ANTONELLI 10.
- Systematic uncertainties not estimated.
- From the pole position of the $K\pi$ vector form factor in the complex s-plane and using EPIFANOV 07 data.
- Reanalysis of EPIFANOV 07 using resonance chiral theory.
- Calculated by us from the shift by 4.7 ± 0.9 MeV (statistical uncertainty only) reported in BONVICINI 02 with respect to the world average value from PDG 00.
- With mass and width of the $K^*(1410)$ fixed at 1412 MeV and 227 MeV, respectively.
- Taking into account the $K^*(892)^0, S$ -wave and P -wave ($K^*(1410)^0$).
- From the isobar model with a complex pole for the κ .
- Fit to $K\pi$ mass spectrum includes a non-resonant scalar component.
- From pole extrapolation.
- This value comes from a fit with χ^2 of 178/117.

$K^*(892)$ MASSES AND MASS DIFFERENCES

Unrealistically small errors have been reported by some experiments. We use simple "realistic" tests for the minimum errors on the determination of a mass and width from a sample of N events:

$$\delta_{\min}(m) = \frac{\Gamma}{\sqrt{N}}, \quad \delta_{\min}(\Gamma) = 4 \frac{\Gamma}{\sqrt{N}}. \quad (1)$$

Meson Particle Listings

$K^*(892)$

We consistently increase unrealistic errors before averaging. For a detailed discussion, see the 1971 edition of this Note.

CONSTRAINED FIT INFORMATION

An overall fit to the total width and a partial width uses 13 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 7.8$ for 11 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

~ 1450.0		MARTIN	78	SPEC	$10 K^\pm p \rightarrow K_S^0 \pi p$

¹ Using both $\eta \rightarrow \gamma\gamma$ and $\eta \rightarrow \pi^+ \pi^- \pi^0$. From a likelihood scan in the presence of several interfering scalar-meson resonances with fixed width $\Gamma(K_0^*(1430)) = 210$ MeV.

² S-matrix pole. Supersedes BUGG 06. Combined analysis of ASTON 88, ABLIKIM 06c, AITALA 06, and LINK 09 using an s -dependent width with couplings to $K\pi$ and $K\eta'$, and the Adler zero near thresholds.

³ From the isobar model with a complex pole for the κ .

⁴ From a non-parametric analysis.

⁵ A Breit-Wigner mass and width.

⁶ S-matrix pole. Reanalysis of ASTON 88, AITALA 02, and ABLIKIM 06c including the κ with an s -dependent width and an Adler zero near threshold.

⁷ S-matrix pole. Using ASTON 88 and assuming $K_0^*(800)$, $K_0^*(1950)$.

⁸ Using ASTON 88 and assuming $K_0^*(800)$.

⁹ T-matrix pole. Reanalysis of ASTON 88 data.

¹⁰ Breit-Wigner fit. Using ASTON 88.

¹¹ Assuming a low-mass scalar $K\pi$ resonance, $\kappa(800)$.

¹² T-matrix pole. Using data from ESTABROOKS 78 and ASTON 88.

¹³ J^P not determined, could be $K_2^*(1430)$.

¹⁴ T-matrix pole.

¹⁵ Uses a model for the background, without this background they get a mass 1340 MeV, where the phase shift passes 90° .

¹⁶ Mass defined by pole position. From elastic $K\pi$ partial-wave analysis.

CONSTRAINED FIT INFORMATION

An overall fit to the total width, a partial width, and 10 branching ratios uses 31 measurements and one constraint to determine 8 parameters. The overall fit has a $\chi^2 = 20.2$ for 24 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta p_i \delta p_j \rangle / (\delta p_i \delta p_j)$, in percent, from the fit to parameters p_i , including the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

CONSTRAINED FIT INFORMATION

An overall fit to 4 branching ratios uses 4 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 2.9$ for 2 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$\begin{array}{cc|c} x_2 & & -36 \\ x_3 & & -39 \quad -72 \\ & x_1 & x_2 \end{array}$$

1876 ± 15	50	PERUZZI	76	MRK1 $K^\mp \pi^\pm \pi^\pm$

¹PERUZZI 77 and SCHINDLER 81 errors do not include the 0.13% uncertainty in the absolute SPEAR energy calibration. TRILLING 81 uses the high precision $J/\psi(1S)$ and $\psi(2S)$ measurements of ZHOLENTZ 80 to determine this uncertainty and combines the PERUZZI 77 and SCHINDLER 81 results to obtain the value quoted.

 D^\pm MEAN LIFE

Measurements with an error $> 10 \times 10^{-15}$ s have been omitted from the Listings.

¹BARLAG 90c estimates the systematic error to be negligible.

 D^+ DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S^0 modes, not as \bar{K}^0 modes. Nearly always it is a K_S^0 that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$.

Mode	Fraction (Γ_i/Γ)	Scale factor/ Confidence level
Inclusive modes		
Γ_1 e^+ semileptonic	(16.07 ± 0.30) %

Γ_{141} Unaccounted decay modes $(50.2 \pm 0.9) \%$ S=1.1

[a] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[b] These subfractions of the $K^- 2\pi^+$ mode are uncertain: see the Particle Listings.

[c] Submodes of the $D^+ \rightarrow K^- 2\pi^+ \pi^0$ and $K_S^0 2\pi^+ \pi^-$ modes were studied by ANJOS 92C and COFFMAN 92B, but with at most 142 events for the first mode and 229 for the second – not enough for precise results. With nothing new for 18 years, we refer to our 2008 edition, Physics Letters **B667** 1 (2008), for those results.

[d] The unseen decay modes of the resonances are included.

[e] This is *not* a test for the $\Delta C=1$ weak neutral current, but leads to the $\pi^+ \ell^+ \ell^-$ final state.

[f] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

CONSTRAINED FIT INFORMATION

An overall fit to 23 branching ratios uses 31 measurements and one constraint to determine 15 parameters. The overall fit has a $\chi^2 = 33.4$ for 17 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

REVIEW OF MULTIBODY CHARM ANALYSES

Revised 2015 by D. M. Asner (Pacific Northwest National Laboratory) and J. Rademacker (University of Bristol)

Kinematics & Models The differential decay rate to a point $s = (s_1, \dots, s_n)$ in n dimensional phase space can be expressed as

$$d\Gamma = |\mathcal{M}(s)|^2 \left| \frac{\partial^n \phi}{\partial(s_1 \dots s_n)} \right| d^n s \quad (1)$$

where $|\frac{\partial^n \phi}{\partial(s_1 \dots s_n)}|$ represents the density of states at s , and \mathcal{M} the matrix element for the decay at that point in phase space.For two-body decays, $|\frac{\partial^n \phi}{\partial(s_1 \dots s_n)}|$ is a δ function, while for D^0 decays to 3, 4, 5, ... pseudoscalars, phase space is 2, 5, 8, ... dimensional, leading to a rich phenomenology. Additional parameters are required to fully describe decays with vector particles in the initial or final state.For the important case of a pseudoscalar decaying to 3 pseudoscalars, the decay kinematics can be described in a two dimensional Dalitz plot [1]. The Dalitz plot of $D \rightarrow abc$ is usually parametrized in terms of invariant-mass-squared variables $s_1 = (p_a + p_b)^2$ and $s_2 = (p_b + p_c)^2$, where p_a, p_b, p_c are the four-momenta of particles a, b, c . In terms of these variables, phase-space density is constant across the kinematically allowed region, so that any structure seen in the Dalitz plot is a direct consequence of the dynamics encoded in $|\mathcal{M}|^2$.

An important difference between decays to two or three pseudoscalars compared to decays to four or more particles is the behavior under parity. In the former case, the operation of parity can also be expressed as a rotation, so no parity violating observables can be defined (unless they also violate rotational invariance). This is not the case for decays to four or more particles. This leads to the interesting possibility of using parity-odd observables in four body decays for CP violation searches, as discussed below. Another consequence of these considerations is that four-body-decay kinematics cannot be described unambiguously in terms of invariant-mass-squared variables, as these are all parity even.

The matrix element \mathcal{M} is usually modeled as a sum of interfering decay amplitudes, each proceeding through resonant two-body decays [2]. See Refs [2–4] for a review of resonance phenomenology. In most analyses, each resonance is described by a Breit–Wigner or Flatté lineshape, and the model includes a non-resonant term with a constant phase and magnitude across the Dalitz plot. This approach has well-known theoretical limitations, such as the violation of unitarity and analyticity, which tend to be particularly problematic for broad, overlapping resonances. This motivates the use of more sophisticated descriptions, especially for the broad, overlapping resonances that occur typically in the S-wave components. In charm analyses, these have included the K-matrix approach [5,6,7] which respects unitarity; the use of LASS scattering data [8]; dispersive methods [9,10]; methods based on chiral symmetry [11,12]; and quasi model-independent parametrizations [13,14]. An important example first analyzed by CLEO [15,16,17] is $D^0 \rightarrow K_S \pi^+ \pi^-$, which is a key channel in CP violation and charm mixing analyses. Belle models this final state as a superposition of 18 resonances (including 4 significant doubly Cabibbo suppressed amplitudes) described by Breit–Wigner or Flatté lineshapes, plus a non-resonant component [18]. CDF’s analysis follows a similar approach [19]. BaBar’s model for the same decay replaces the broad $\pi\pi$ and $K\pi$ S-wave resonances and the non-resonant component with a K-matrix description [20]. Belle’s and BaBar’s data have been re-analyzed by [21] in a QCD factorization framework, using line-shape parametrizations for the S [11,12] and P wave [10] contributions (with input from $\tau^- \rightarrow K_S \pi^- \nu_\tau$ data [22] for the latter) that preserve 2-body unitarity and analyticity. The measurements give compatible results for the components they share. All three approaches remain within the confines of the “isobar” framework which treats the decay as a series of independent two-body processes, ignoring long-range hadronic effects. Dispersive techniques that account for these hadronic effects and respect full 3 body unitarity and analyticity have been applied to regions of the $D^- \rightarrow K^- \pi^+ \pi^+$ Dalitz plot below the η'/K threshold [23].

Limitations in the theoretical description of interfering resonances are the leading source of systematic uncertainty in many analyses. This is set to become increasingly problematic given the statistical precision achievable with the vast charm samples

available at the B factories, LHCb, and their upgrades. Already now, clean data samples with millions of charm events are available even in suppressed decay modes, e.g. 2.4M $D^0 \rightarrow \pi^- \pi^+ \pi^0$ events at LHCb [24]. In some cases, the model uncertainty can be removed through model-independent amplitude methods, often relying on input from the charm threshold, as discussed below. At the same time, increasingly sophisticated models are being developed, and applied to data.

Applications of multibody charm analyses The interference between the decay paths via which multibody decays proceed provides sensitivity to both relative magnitudes and phases of the contributing decay amplitudes. It is especially this sensitivity to phases that makes amplitude analyses such a uniquely powerful tool for studying a wide range of phenomena. Here we concentrate on their use for CP violation measurements and mixing in charm, and charm inputs to CP violation analyses in B meson decays. The properties of light-meson resonances determined in D -meson amplitude analyses are reported in the light-unflavored-meson section of this *Review*.

Time-integrated searches for CP violation in charm

Comparing the results of amplitude fits for CP -conjugate decay modes provides a measure of CP violation. The advantage of this approach over the model-independent searches discussed in the next paragraph is the physical interpretation of any CP violation observation that such a fit result would allow. The disadvantage lies in the theoretical uncertainty intrinsic to such analyses due to the amplitude-model dependence. Recent CP violation searches using this method include CLEO’s amplitude analysis of $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$ [25] and CDF’s analysis of $\sim 350,000$ $D^0 \rightarrow K_S \pi^+ \pi^-$ events [19].

The most common model-independent approach for searching for local CP violation across a Dalitz plot is based on performing a χ^2 comparison of the number of events in the bins of CP -conjugate Dalitz plots. This method was pioneered by BaBar [26] and developed further in [27,28], with recent results in $D^\pm \rightarrow K^+ K^- \pi^\pm$ [29,30,31], $D^0 \rightarrow K_S \pi^+ \pi^-$ [19], and $D^+ \rightarrow \pi^- \pi^+ \pi^+$ [32]. These techniques have been generalized to four-body decays, and applied to $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$ and $D^0 \rightarrow \pi^+ \pi^- \pi^+ \pi^-$ [33]. Un-binned methods can increase the sensitivity [34]; two different unbinned methods have been applied by LHCb to $D^+ \rightarrow \pi^- \pi^+ \pi^+$ [32] and $D^0 \rightarrow \pi^+ \pi^- \pi^0$ [24]. None of these analyses have shown evidence of CP violation.

Another model-independent approach, providing complementary information, is based on constructing observables in four body decays that are odd under motion reversal (“naïve T ”) [35–43], which is equivalent to P for scalar particles [43]. One such observable is $C_T = \vec{p}_{K^+} \cdot (\vec{p}_{\pi^+} \times \vec{p}_{\pi^-})$ in $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$. The rate asymmetry of positive and negative C_T , $A_T \equiv \frac{\Gamma(C_T > 0) - \Gamma(C_T < 0)}{\Gamma(C_T > 0) + \Gamma(C_T < 0)}$, is a P violating parameter. Comparing A_T with the C -conjugate asymmetry in \overline{D}^0 decays, \overline{A}_T , provides sensitivity to CP violation. Searches for CP violation in this manner have been carried out by FOCUS in $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$ [44], BaBar in $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$,

Meson Particle Listings

D^\pm

$D^+ \rightarrow K^+ K_S \pi^+ \pi^-$, and $D_s^+ \rightarrow K^+ K_S \pi^+ \pi^-$ [45,46], and LHCb in $D^0 \rightarrow K^+ K^- \pi^+ \pi^-$ [47]. In addition to a phase-space integrated result, LHCb's analysis is also carried out locally in sub-regions of phase space to enhance the sensitivity of the method. All results so far have been consistent with CP conservation.

D mixing and CP violation Time-dependent amplitude analyses in decays to final states that are accessible to both D^0 and \bar{D}^0 have unique sensitivity to mixing parameters. A Dalitz plot analysis of a self-conjugate final state, such as $K_S \pi^+ \pi^-$ and $K_S K^+ K^-$, allows the measurement of the phase difference between the relevant D^0 and \bar{D}^0 decay amplitudes, and thus a direct measurement of the mixing parameters x, y (rather than the decay-specific parameters x^2, y' measured for example in $D^0 \rightarrow K\pi$) [17]. These analyses are also sensitive to CP violation in mixing and in the interference between mixing and decay. These results are summarized in Ref. [48]. The important role from charm threshold data as input to such measurements is discussed below.

Charm amplitude analyses for measuring γ/ϕ_3 Neutral D mesons originating from $B^- \rightarrow DK^-$ (which we denote with D_{B^-}) are a superposition of D^0 and \bar{D}^0 with a relative phase that depends on γ/ϕ_3 :

$$D_{B^-} \propto D^0 + r_B e^{i(\delta_B - \gamma)} \bar{D}^0,$$

where δ_B is a CP conserving strong phase, and $r_B \sim 0.1$. In the corresponding CP -conjugate expression, γ/ϕ_3 changes sign. An amplitude analysis of the subsequent decay of the D_{B^\pm} allows an extraction of γ/ϕ_3 [49–54]. The method generalizes to similar B hadron decays, such as $B^0 \rightarrow DK^{*0}$. Measurements based on this technique have been reported by BaBar, Belle and LHCb using both model-dependent approaches and model-independent ones based on CLEO-c input [18,55–61,65–67]. The most precise individual results come from the study of the $D_{B^-} \rightarrow K_S \pi^+ \pi^-$ and $D_{B^-} \rightarrow K_S K^+ K^-$ with an uncertainty of approximately 15° [18,55,59,67].

Model independent methods for γ/ϕ_3 and charm mixing

The theoretical uncertainty on amplitude models of multibody D^0 decays potentially limits the precision of measurements of γ/ϕ_3 in $B^\pm \rightarrow DK^\pm$ and related decay modes. Model-independent methods to measure γ/ϕ_3 require input related to the relative phases of the D^0 and \bar{D}^0 decay amplitudes across the phase-space distribution. The same considerations apply to measurements of D^0 mixing and CP violation parameters in time-dependent Dalitz plot analyses. The required phase information is accessible at the charm threshold, where CLEO-c and BES III operate [48,52,68–74]. There, D mesons originate from the decay $\psi(3770) \rightarrow D\bar{D}$. The two D mesons are quantum-correlated which can be used to identify decays of well-defined $D^0 - \bar{D}^0$ superpositions to the final state of interest. The resulting interference of D^0 and \bar{D}^0 amplitudes provides the desired model-independent phase information. For decays to non-self-conjugate decays such as $D^0 \rightarrow K^+ \pi^- \pi^+ \pi^-$, analysing $D^0 - \bar{D}^0$

superpositions provides the only way of measuring the relative phase between the D^0 and \bar{D}^0 amplitudes.

These analyses can be performed in sub-regions/bins of phase space, or integrated across phase space. The relevant result can be expressed in terms of one complex parameter $\mathcal{Z} = R e^{-i\delta}$ per pair of CP -conjugate phase space bins, with magnitude $R \leq 1$. The larger R , the higher the sensitivity to interference effects, and thus to γ/ϕ_3 . The sensitivity of the binned analyses can be optimized by using amplitude model-dependent information to maximize R in each bin, without introducing a model-dependent bias in the result. CLEO-c data have been analyzed in this way to provide binned results for the self-conjugate decays $D^0 \rightarrow K_S \pi\pi$ and $D^0 \rightarrow K_S K K$ [75,76]. The phase-space integrated analyses for $D^0, \bar{D}^0 \rightarrow K_S K^+ \pi^-$, $K^- \pi^+ \pi^0$, and $K^- \pi^+ \pi^- \pi^+$ have yielded $\mathcal{Z}^{K_S K \pi} = (0.73 \pm 0.8) e^{-i(8.3^\circ \pm 15.2^\circ)}$, $\mathcal{Z}^{K \pi \pi^0} = (0.82 \pm 0.07) e^{-i(164^\circ \pm 14^\circ)}$, $\mathcal{Z}^{K 3\pi} = (0.32_{-0.28}^{+0.20}) e^{-i(225^\circ \pm 21^\circ_{-78^\circ})}$, respectively [77,78,79]. These results follow the usual convention for γ/ϕ_3 -related studies where $CP|D^0\rangle = +|\bar{D}^0\rangle$, while in charm mixing measurements, one usually takes $CP|D^0\rangle = -|\bar{D}^0\rangle$, leading to a phase-shift in δ of π . Restricting the analysis to a bin around the $K^* K$ resonance in the $K_S K \pi$ Dalitz plot, [77] find $R = 1.00 \pm 0.16$, illustrating the benefit in dividing phase space into bins.

The corresponding phase space-integrated input for self-conjugate decays such as $D^0 \rightarrow \pi^+ \pi^- \pi^0$ takes the form of a single real parameter, the CP -even fraction F_+ , defined such that a CP even eigenstate has $F_+ = 1$, while a CP -odd eigenstate has $F_+ = 0$ [72]. A recent analysis of CLEO-c data revealed that $D^0 \rightarrow \pi^+ \pi^- \pi^0$ is compatible with being completely CP -even with $F_+ = 1.014 \pm 0.045 \pm 0.022$, while $D^0 \rightarrow K^+ K^- \pi^0$ has $F_+ = 0.734 \pm 0.106 \pm 0.054$ and $D^0 \rightarrow \pi^+ \pi^- \pi^+ \pi^-$ has $F_+ = 0.737 \pm 0.028$ [73].

The charm system itself provides, through mixing, a well-defined, time-dependent superposition of D^0 and \bar{D}^0 . Using mixing parameters measured independently as input, this can be used to obtain the relevant information for γ/ϕ_3 measurements. This method is expected to be particularly powerful in doubly Cabibbo-suppressed decays such as $D^0 \rightarrow K^+ \pi^- \pi^+ \pi^-$, and when used in conjunction with information from charm threshold [80,81].

Summary Multibody charm decays offer a rich phenomenology, including unique sensitivity to CP violation and charm mixing. This is a highly dynamic field with many new results (some of which we presented here) and rapidly increasing, high quality datasets. These datasets constitute a huge opportunity, but also a challenge to improve the theoretical descriptions of soft hadronic effects in multibody decays. For some measurements, model-independent methods, many relying on input from the charm threshold, provide a way of removing model-induced uncertainties. At the same time, work is ongoing to improve the theoretical description of multibody decays.

 $\Gamma((K-\pi^+)S\text{-wave}\pi^+)/\Gamma(K-2\pi^+)$ Γ_{41}/Γ_{40}

This is the "fit fraction" from the Dalitz-plot analysis. The $K-\pi^+$ S-wave includes a broad scalar κ ($\bar{K}_0^*(800)$), the $\bar{K}_0^*(1430)^0$, and non-resonant background.

VALUE	DOCUMENT ID	TECN	COMMENT
0.801 ± 0.012 OUR AVERAGE			
0.8024 ± 0.0138 ± 0.0043	¹ LINK	09	FOCS MIPWA fit, 53k evts
0.838 ± 0.038	² BONVICINI	08A	CLEO QMIPWA fit, 141k evts
0.786 ± 0.014 ± 0.018	AITALA	06	E791 Dalitz fit, 15.1k events
0.8323 ± 0.0150 ± 0.0008	³ LINK	07B	FOCS See LINK 09

- ¹ This LINK 09 model-independent partial-wave analysis of the $K-\pi^+$ S-wave slices the $K-\pi^+$ mass range into 39 bins.
² The BONVICINI 08A QMIPWA (quasi-model-independent partial-wave analysis) of the $K-\pi^+$ S-wave amplitude slices the $K-\pi^+$ mass range into 26 bins but keeps the Breit-Wigner $\bar{K}_0^*(1430)^0$.
³ This LINK 07B fit uses a K matrix. The $K-\pi^+$ S-wave fit fraction given above breaks down into (207.3 ± 25.5 ± 12.4)% isospin-1/2 and (40.5 ± 9.6 ± 3.2)% isospin-3/2 — with large interference between the two. The isospin-1/2 component includes the κ (or $\bar{K}_0^*(800)^0$) and $\bar{K}_0^*(1430)^0$.

 $\Gamma(\bar{K}_0^*(800)^0\pi^+, \bar{K}_0^*(800) \rightarrow K-\pi^+)/\Gamma(K-2\pi^+)$ Γ_{42}/Γ_{40}

This is the "fit fraction" from the Dalitz-plot analysis.

 $\Gamma(K_S^0 2\pi^+ \pi^-) / \Gamma_{\text{total}}$ Γ_{61} / Γ

See our 2008 Review (Physics Letters **B667** 1 (2008)) for measurements of submodes of this mode. There is nothing new since 1992, and the two papers, ANJOS 92c, with 229 ± 17 events above background, and COFFMAN 92b, with 209 ± 20 such events, could not determine submode fractions with much accuracy.

D[±] χ² TESTS OF CP-VIOLATION (CPV)

We list model-independent searches for local CP violation in phase-space distributions of multi-body decays.

Most of these searches divide phase space (Dalitz plot for 3-body decays, five-dimensional equivalent for 4-body decays) into bins, and perform a χ² test comparing normalised yields N_i, \bar{N}_i in CP-conjugate bin pairs i: χ² = Σ_i(N_i - α \bar{N}_i)/σ(N_i - α \bar{N}_i). The factor α = (Σ_iN_i)/(Σ_i \bar{N}_i) removes the dependence on phase-space-integrated rate asymmetries. The result is used to obtain the probability (p-value) to obtain the measured χ² or larger under the assumption of CP conservation [AUBERT 08AO, BEDIAGA 09]. Alternative methods obtain p-values from other test variables based on unbinned analyses [WILLIAMS 11, AAIJ 14c]. Results can be combined using Fisher's method [MOSTELLER 48].

CP VIOLATING ASYMMETRIES OF P-ODD (T-ODD) MOMENTS

A_{T,viol}(K_S⁰K[±]π[±]π⁻) in D[±] → K_S⁰K[±]π[±]π⁻}

C_T ≡ $\bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$ is a parity-odd correlation of the K⁺, π⁺, and π⁻ momenta for the D⁺. $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$ is the corresponding quantity for the D⁻. Then

A_T ≡ [Γ(C_T > 0) - Γ(C_T < 0)] / [Γ(C_T > 0) + Γ(C_T < 0)], and $\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$, and

A_{T,viol} ≡ $\frac{1}{2}(A_T - \bar{A}_T)$. C_T and \bar{C}_T are commonly referred to as T-odd moments, because they are odd under T reversal. However, the T-conjugate process K_S⁰K[±]π[±]π⁻ → D[±] is not accessible, while the P-conjugate process is.

• • • We do not use the following data for averages, fits, limits, etc. • • •

¹DEL-AMO-SANCHEZ 11i finds the pole mass m_A = (2.63 ± 0.10 ± 0.13) GeV (m_V is fixed at 2 GeV).

²LINK 02L includes the effects of interference with an S-wave background. This much improves the goodness of fit, but does not much shift the values of the form factors.

³This is slightly different from the AITALA 98B value: see ref. [5] in AITALA 98F.

WEIGHTED AVERAGE
1.51 ± 0.07 (Error scaled by 2.2)

 $D^0 - \bar{D}^0$ MIXING

Revised August 2015 by D. M. Asner (Pacific Northwest National Laboratory)

The detailed formalism for $D^0 - \bar{D}^0$ mixing is presented in the note on “ CP Violation in Meson Decays” in this Review. For completeness, we present an overview here. The time evolution of the $D^0 - \bar{D}^0$ system is described by the Schrödinger equation

$$i \frac{\partial}{\partial t} \begin{pmatrix} D^0(t) \\ \bar{D}^0(t) \end{pmatrix} = \begin{pmatrix} M & -\frac{i}{2}\Gamma \\ \frac{i}{2}\Gamma & M \end{pmatrix} \begin{pmatrix} D^0(t) \\ \bar{D}^0(t) \end{pmatrix}, \quad (1)$$

where the M and Γ matrices are Hermitian, and CPT invariance requires that $M_{11} = M_{22} \equiv M$ and $\Gamma_{11} = \Gamma_{22} \equiv \Gamma$. The

off-diagonal elements of these matrices describe the dispersive and absorptive parts of the mixing.

Because CP violation is expected to be quite small here, it is convenient to label the mass eigenstates by the CP quantum number in the limit of CP conservation. Thus, we write

$$|D_{1,2}\rangle = p|D^0\rangle \pm q|\bar{D}^0\rangle, \quad (2)$$

where

$$\left(\frac{q}{p}\right)^2 = \frac{M_{12}^* - \frac{i}{2}\Gamma_{12}^*}{M_{12} - \frac{i}{2}\Gamma_{12}}. \quad (3)$$

The normalization condition is $|p|^2 + |q|^2 = 1$. Our phase convention is $CP|D^0\rangle = +|\bar{D}^0\rangle$, and the sign is chosen so that D_1 has CP even, or nearly so.

The corresponding eigenvalues are

$$\omega_{1,2} \equiv m_{1,2} - \frac{i}{2}\Gamma_{1,2} = \left(M - \frac{i}{2}\Gamma\right) \pm \frac{q}{p} \left(M_{12} - \frac{i}{2}\Gamma_{12}\right), \quad (4)$$

where $m_{1,2}$ and $\Gamma_{1,2}$ are the masses and widths of the $D_{1,2}$.

We define dimensionless mixing parameters x and y by

$$x \equiv (m_1 - m_2)/\Gamma = \Delta m/\Gamma \quad (5)$$

and

$$y \equiv (\Gamma_1 - \Gamma_2)/2\Gamma = \Delta\Gamma/2\Gamma, \quad (6)$$

where $\Gamma \equiv (\Gamma_1 + \Gamma_2)/2$. If CP is conserved, then M_{12} and Γ_{12} are real, $\Delta m = 2M_{12}$, $\Delta\Gamma = 2\Gamma_{12}$, and $p = q = 1/\sqrt{2}$. The signs of Δm and $\Delta\Gamma$ are to be determined experimentally.

The parameters x and y are measured in several ways. The most precise values are obtained using the time dependence of D decays. Since $D^0 - \bar{D}^0$ mixing is a small effect, the identifying tag of the initial particle as a D^0 or a \bar{D}^0 must be extremely accurate. The usual tag is the charge of the distinctive slow pion in the decay sequence $D^{*+} \rightarrow D^0 \pi^+$ or $D^{*-} \rightarrow \bar{D}^0 \pi^-$. In current experiments, the probability of mistagging is about 0.1%. The large data samples produced at the B -factories allow the production flavor to also be determined by fully reconstructing charm on the “other side” of the event—significantly reducing the mistag rate [1]. Another tag of comparable accuracy is identification of one of the D 's produced from $\psi(3770) \rightarrow D^0 \bar{D}^0$ decays. Although time-dependent analyses are not possible at symmetric charm-threshold facilities (the D^0 and \bar{D}^0 do not travel far enough), the quantum-coherent $C = -1$ $\psi(3770) \rightarrow D^0 \bar{D}^0$ state provides time-integrated sensitivity [2,3].

Time-Dependent Analyses: We extend the formalism of this Review's note on “ CP Violation in Meson Decays.” In addition to the “right-sign” instantaneous decay amplitudes $\bar{A}_f \equiv \langle f|H|\bar{D}^0\rangle$ and $A_{\bar{f}} \equiv \langle \bar{f}|H|D^0\rangle$ for final states $f = K^+ \pi^-, \dots$ and their CP conjugate $\bar{f} = K^- \pi^+, \dots$, we include “wrong-sign” amplitudes $\bar{A}_{\bar{f}} \equiv \langle \bar{f}|H|\bar{D}^0\rangle$ and $A_f \equiv \langle f|H|D^0\rangle$.

It is conventional to normalize the wrong-sign decay distributions to the integrated rate of right-sign decays and to express time in units of the precisely measured neutral D -meson mean lifetime, $\tau_{D^0} = 1/\Gamma = 2/(\Gamma_1 + \Gamma_2)$. Starting from a pure $|D^0\rangle$ or $|\bar{D}^0\rangle$ state at $t = 0$, the time-dependent rates of decay

Meson Particle Listings

D^0

to wrong-sign final states relative to the integrated right-sign decay rates are, to leading order:

$$r(t) \equiv \frac{|\langle f|H|D^0(t)\rangle|^2}{|\bar{A}_f|^2} = \left|\frac{q}{p}\right|^2 \left|g_+(t)\lambda_f^{-1} + g_-(t)\right|^2, \quad (7)$$

and

$$\bar{r}(t) \equiv \frac{|\langle \bar{f}|H|\bar{D}^0(t)\rangle|^2}{|A_{\bar{f}}|^2} = \left|\frac{p}{q}\right|^2 \left|g_+(t)\lambda_{\bar{f}} + g_-(t)\right|^2. \quad (8)$$

where

$$\lambda_f \equiv q\bar{A}_f/pA_f, \quad \lambda_{\bar{f}} \equiv q\bar{A}_{\bar{f}}/pA_{\bar{f}}, \quad (9)$$

and

$$g_{\pm}(t) = \frac{1}{2} (e^{-iz_1 t} \pm e^{-iz_2 t}), \quad z_{1,2} = \frac{\omega_{1,2}}{\Gamma}. \quad (10)$$

Note that a change in the convention for the relative phase of D^0 and \bar{D}^0 would cancel between q/p and \bar{A}_f/A_f and leave λ_f unchanged. We expand $r(t)$ and $\bar{r}(t)$ to second order in x and y for modes in which the ratio of decay amplitudes, $R_D = |A_f/\bar{A}_f|^2$, is very small.

Semileptonic decays: Consider the final state $f = K^+\ell^-\bar{\nu}_\ell$, where $A_f = \bar{A}_{\bar{f}} = 0$ in the Standard Model. The final state f is only accessible through mixing and $r(t)$ is

$$r(t) = |g_-(t)|^2 \left|\frac{q}{p}\right|^2 \approx \frac{e^{-t}}{4} (x^2 + y^2) t^2 \left|\frac{q}{p}\right|^2. \quad (11)$$

For $\bar{r}(t)$ q/p is replaced by p/q . In the Standard Model, CP violation in charm mixing is small and $|q/p| \approx 1$. In the limit of CP conservation, $r(t) = \bar{r}(t)$, and the time-integrated mixing rate relative to the time-integrated right-sign decay rate for semileptonic decays is

$$R_M = \int_0^\infty r(t) dt = \left|\frac{q}{p}\right|^2 \frac{x^2 + y^2}{2 + x^2 - y^2} \approx \frac{1}{2} (x^2 + y^2). \quad (12)$$

HFAG [10]			0.13 ± 0.27	

*These measurements are excluded from the HFAG average. The FOCUS result is unpublished, the statistical correlation of the BaBar result with Ref. 1 has not been established, and the Belle result is superseded by Ref. 4. The HFAG average assumes reported statistical and systematic uncertainties are uncorrelated.

Table 1 summarizes results for R_M from semileptonic decays; the world average from the Heavy Flavor Averaging Group (HFAG) [10] is $R_M = (1.30 \pm 2.69) \times 10^{-4}$.

Wrong-sign decays to hadronic non-CP eigenstates: Consider the final state $f = K^+\pi^-$, where A_f is doubly Cabibbo-suppressed. The ratio of decay amplitudes is

$$\frac{A_f}{\bar{A}_f} = -\sqrt{R_D} e^{-i\delta_f}, \quad \left|\frac{A_f}{\bar{A}_f}\right| \sim O(\tan^2 \theta_c), \quad (13)$$

where R_D is the doubly Cabibbo-suppressed (DCS) decay rate relative to the Cabibbo-favored (CF) rate, δ_f is the strong phase difference between DCS and CF processes, and θ_c is the Cabibbo angle. The minus sign originates from the sign of V_{us} relative to V_{cd} .

We characterize the violation of CP with the real-valued parameters A_M , A_D , and ϕ . We adopt the parametrization (see Refs. 11 and 12)

$$\left|\frac{q}{p}\right|^2 = \sqrt{\frac{1+A_M}{1-A_M}}, \quad (14)$$

$$\lambda_f^{-1} \equiv \frac{pA_f}{q\bar{A}_f} = -\sqrt{R_D} \left(\frac{(1+A_D)(1-A_M)}{(1-A_D)(1+A_M)} \right)^{1/4} e^{-i(\delta_f+\phi)}, \quad (15)$$

$$\lambda_{\bar{f}} \equiv \frac{q\bar{A}_{\bar{f}}}{pA_{\bar{f}}} = -\sqrt{R_D} \left(\frac{(1-A_D)(1+A_M)}{(1+A_D)(1-A_M)} \right)^{1/4} e^{-i(\delta_f-\phi)}, \quad (16)$$

and A_D is a measure of direct CP violation, while A_M is a measure of CP violation in mixing. From these relations, we obtain

$$\sqrt{\frac{1+A_D}{1-A_D}} = \frac{|A_f/\bar{A}_f|}{|\bar{A}_{\bar{f}}/A_{\bar{f}}|}, \quad (17)$$

The angle ϕ measures CP violation in interference between mixing and decay. While A_M is independent of the decay process, A_D and ϕ , in general, depend on f .

In general, $\lambda_{\bar{f}}$ and λ_f^{-1} are independent complex numbers. More detail on CP violation in meson decays can be found in Ref. 13. To leading order, for A_D and $A_M \ll 1$,

$$r(t) = e^{-t} \left[R_D(1+A_D) + \sqrt{R_D(1+A_M)(1+A_D)} y'_- t + \frac{1}{2} (1+A_M) R_M t^2 \right] \quad (18)$$

and

$$\bar{r}(t) = e^{-t} \left[R_D(1-A_D) + \sqrt{R_D(1-A_M)(1-A_D)} y'_+ t + \frac{1}{2} (1-A_M) R_M t^2 \right] \quad (19)$$

Here

$$\begin{aligned} y'_\pm &\equiv y' \cos \phi \pm x' \sin \phi \\ &= y \cos(\delta_{K\pi} \mp \phi) - x \sin(\delta_{K\pi} \mp \phi), \end{aligned} \quad (20)$$

where

$$\begin{aligned} x' &\equiv x \cos \delta_{K\pi} + y \sin \delta_{K\pi}, \\ y' &\equiv y \cos \delta_{K\pi} - x \sin \delta_{K\pi}, \end{aligned} \quad (21)$$

and $R_M = (x^2 + y^2)/2 = (x'^2 + y'^2)/2$ is the mixing rate relative to the time-integrated Cabibbo-favored rate.

The three terms in Eq. (18) and Eq. (19) probe the three fundamental types of CP violation. In the limit of CP conservation, A_M , A_D , and ϕ are all zero. Then

$$r(t) = \bar{r}(t) = e^{-t} \left(R_D + \sqrt{R_D} y' t + \frac{1}{2} R_M t^2 \right), \quad (22)$$

and the time-integrated wrong-sign rate relative to the integrated right-sign rate is

$$R = \int_0^\infty r(t) dt = R_D + \sqrt{R_D} y' + R_M. \quad (23)$$

The ratio R is the most readily accessible experimental quantity. In Table 2 are reported the measurements of R , R_D and A_D in $D^0 \rightarrow K^+ \pi^-$, and their HFAG average [24] from a general fit; that allows for both mixing and CP violation. Typically, the fit parameters are R_D , x'^2 , and y' . Table 3 summarizes the results for x'^2 and y' . Allowing for CP violation, the separate contributions to R can be extracted by fitting the $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^- \pi^+$ decay rates.

Table 2: Results for R , R_D , and A_D in $D^0 \rightarrow K^+ \pi^-$.

†These measurements are excluded from the HFAG average due to poor precision.

Extraction of the mixing parameters x and y from the results in Table 3 requires knowledge of the relative strong phase $\delta_{K\pi}$. An interference effect that provides useful sensitivity to $\delta_{K\pi}$ arises in the decay chain $\psi(3770) \rightarrow D^0 \bar{D}^0 \rightarrow (f_{CP})(K^+ \pi^-)$, where f_{CP} denotes a CP -even or -odd eigenstate from D^0 decay, such as $K^+ K^-$ or $K_S^0 \pi^0$, respectively [26]. Here, the amplitude relation

Table 3: Results on the time-dependence of $r(t)$ in $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^- \pi^+$ decays. The Belle 2014, LHCb and CDF results assume no CP violation. The FOCUS, CLEO, and Belle 2006 results restrict x'^2 to the physical region. The confidence intervals from FOCUS, CLEO, and BaBar are obtained from the fit, whereas Belle uses a Feldman-Cousins method, and CDF uses a Bayesian method.

Year	Exper.	y' (%)	$x'^2 (\times 10^{-3})$

2005*	FOCUS [21]	$-11.2 < y' < 6.7$	< 8.0 (95% C.L.)
2000*	CLEO [22]	$-5.8 < y' < 1.0$	< 0.81 (95% C.L.)

*These measurements are excluded from the HFAG average. The CDF result is superseded by Ref. 16 and the LHCb result has been superseded by Ref. 15. The CLEO and FOCUS results are excluded due to poor precision.

† This Belle result allows for CP violation. HFAG uses this result for the CP -violation allowed fit. This result is not superseded by Ref. 14.

*† This Belle result does not allow for CP violation. HFAG uses this result for the CP -conserving fit. This result does not supersede Ref. 20.

$$\sqrt{2} A(D_\pm \rightarrow K^- \pi^+) = A(D^0 \rightarrow K^- \pi^+) \pm A(\bar{D}^0 \rightarrow K^- \pi^+). \quad (24)$$

where D_\pm denotes a CP -even or -odd eigenstate, implies that

$$\cos \delta_{K\pi} = \frac{|A(D_+ \rightarrow K^- \pi^+)|^2 - |A(D_- \rightarrow K^- \pi^+)|^2}{2\sqrt{R_D} |A(D^0 \rightarrow K^- \pi^+)|^2}. \quad (25)$$

This neglects CP violation and uses $\sqrt{R_D} \ll 1$.

The asymmetry of CP -tagged D decays rates to $K^- \pi^+$ is denoted as

$$A_{K\pi}^{CP} \equiv \frac{|A(D_- \rightarrow K^- \pi^+)|^2 - |A(D_+ \rightarrow K^- \pi^+)|^2}{|A(D_- \rightarrow K^- \pi^+)|^2 + |A(D_+ \rightarrow K^- \pi^+)|^2}. \quad (26)$$

To lowest order in the mixing parameters [2,3]

$$2\sqrt{R_D} \cos \delta_{K\pi} + y = (1 + R) \dot{A}_{K\pi}^{CP} \quad (27)$$

where R is the time-integrated wrong-sign rate relative to the integrated right-sign rate from Eq. (23).

For multibody final states, Eqs. (13)–(23) apply separately to each point in phase-space. Although x and y do not vary across the space, knowledge of the resonant substructure is needed to extrapolate the strong phase difference δ from point to point to determine x and y . Model-independent methods to measure D mixing parameters require input related to the relative phases of the D^0 and \bar{D}^0 decay amplitudes across the

Meson Particle Listings

D^0

phase-space distribution [25]. The required phase information is accessible at the charm threshold, where CLEO-c and BESIII operate [26,27].

A time-dependent analysis of the process $D^0 \rightarrow K^+\pi^-\pi^0$ from BaBar [28,29] determines the *relative* strong phase variation across the Dalitz plot and reports $x'' = (2.61_{-0.68}^{+0.57} \pm 0.39)\%$, and $y'' = (-0.06_{-0.64}^{+0.55} \pm 0.34)\%$, where x'' and y'' are defined as

$$\begin{aligned} x'' &\equiv x \cos \delta_{K\pi\pi^0} + y \sin \delta_{K\pi\pi^0}, \\ y'' &\equiv y \cos \delta_{K\pi\pi^0} - x \sin \delta_{K\pi\pi^0}, \end{aligned} \quad (28)$$

in parallel to x' , y' , and $\delta_{K\pi}$ of Eq. (21). Here $\delta_{K\pi\pi^0}$ is the remaining strong phase difference between the DCS $D^0 \rightarrow K^+\rho^-$ and the CF $\overline{D}^0 \rightarrow K^+\rho^-$ amplitudes and does not vary across the Dalitz plot. Both strong phases, $\delta_{K\pi}$ and $\delta_{K\pi\pi^0}$, can be determined from time-integrated CP asymmetries in correlated $D^0\overline{D}^0$ produced at the $\psi(3770)$ [26,27].

Both the sign and magnitude of x and y without phase or sign ambiguity may be measured using the time-dependent resonant substructure of multibody D^0 decays [30,31]. In $D^0 \rightarrow K_S^0\pi^+\pi^-$, the DCS and CF decay amplitudes populate the same Dalitz plot, which allows direct measurement of the relative strong phases. CLEO [32], Belle [31,34], and BaBar [33] have measured the relative phase between $D^0 \rightarrow K^*(892)^-\pi^+$ and $D^0 \rightarrow K^*(892)^+\pi^-$ to be $(189 \pm 10 \pm 3_{-5}^{+15})^\circ$, $(173.9 \pm 0.7$ (stat. only) $^\circ$, and $(177.6 \pm 1.1$ (stat. only) $^\circ$, respectively. These results are close to the 180° expected from Cabibbo factors and a small strong phase. Table 4 summarizes the results of a time-dependent Dalitz-plot analyses.

Table 4: Results from time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0\pi^+\pi^-$ (CLEO and Belle) and $D^0 \rightarrow K_S^0\pi^+\pi^-, K_S^0K^+K^-$ (BaBar). The errors are statistical, experimental systematic, and decay-model systematic, respectively.

No CP Violation

Year	Exper.	$ q/p $	ϕ
2014	Belle [34]	$0.90_{-0.15}^{+0.16+0.05+0.06}$	$(-6 \pm 11 \pm 3_{-4}^{+3})^\circ$
2007	Belle [31]	$0.86_{-0.29}^{+0.30+0.06} \pm 0.08$	$(-14_{-18}^{+16+5+2})^\circ$

In addition, Belle [31,34] has results for both the relative phase (statistical errors only) and ratio R (central values only) of the DCS fit fraction relative to the CF fit fractions for $K^*(892)^+\pi^-, K_0^*(1430)^+\pi^-, K_2^*(1430)^+\pi^-, K^*(1410)^+\pi^-$, and $K^*(1680)^+\pi^-$. Similarly, BaBar [33,35,36] has reported central values for R for $K^*(892)^+\pi^-, K_0^*(1430)^+\pi^-$, and

$K_2^*(1430)^+\pi^-$. The systematic uncertainties on R must be evaluated. The large differences in R among these final states could point to an interesting role for hadronic effects.

Decays to CP Eigenstates: When the final state f is a CP eigenstate, there is no distinction between f and \bar{f} , and $A_f = A_{\bar{f}}$ and $\overline{A}_{\bar{f}} = \overline{A}_f$. We denote final states with CP eigenvalues ± 1 by f_\pm and write λ_\pm for λ_{f_\pm} .

The quantity y may be measured by comparing the rate for D^0 decays to non- CP eigenstates such as $K^-\pi^+$ with decays to CP eigenstates such as K^+K^- [12]. If decays to K^+K^- have a shorter effective lifetime than those to $K^-\pi^+$, y is positive.

In the limit of slow mixing ($x, y \ll 1$) and the absence of direct CP violation ($A_D = 0$), but allowing for small indirect CP violation ($|A_M|, |\phi| \ll 1$), we can write

$$\lambda_\pm = \left| \frac{q}{p} \right| e^{\pm i\phi}. \quad (29)$$

In this scenario, to a good approximation, the decay rates for states that are initially D^0 and \overline{D}^0 to a CP eigenstate have exponential time dependence:

$$r_\pm(t) \propto \exp(-t/\tau_\pm), \quad (30)$$

$$\bar{r}_\pm(t) \propto \exp(-t/\bar{\tau}_\pm), \quad (31)$$

where τ is measured in units of $1/\Gamma$.

The effective lifetimes are given by

$$1/\tau_\pm = 1 \pm \left| \frac{q}{p} \right| (y \cos \phi - x \sin \phi), \quad (32)$$

$$1/\bar{\tau}_\pm = 1 \pm \left| \frac{p}{q} \right| (y \cos \phi + x \sin \phi). \quad (33)$$

The effective decay rate to a CP eigenstate combining both D^0 and \overline{D}^0 decays is

$$r_\pm(t) + \bar{r}_\pm(t) \propto e^{-(1 \pm y_{CP})t}. \quad (34)$$

Here

$$y_{CP} = \frac{1}{2} \left(\left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left(\left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) x \sin \phi \quad (35)$$

$$\approx y \cos \phi - A_M x \sin \phi. \quad (36)$$

If CP is conserved, $y_{CP} = y$.

All measurements of y_{CP} are relative to the $D^0 \rightarrow K^-\pi^+$ decay rate. Table 5 summarizes the current status of measurements. Belle [41], BaBar [42], LHCb [43], CDF [39] have reported y_{CP} and the decay-rate asymmetry for CP even final states (assuming $A_D = 0$)

$$A_\Gamma = \frac{\bar{\tau}_+ - \tau_+}{\bar{\tau}_+ + \tau_+} = \frac{(1/\tau_+) - (1/\bar{\tau}_+)}{(1/\tau_+) + (1/\bar{\tau}_+)} \quad (37)$$

$$= \frac{1}{2} \left(\left| \frac{q}{p} \right| - \left| \frac{p}{q} \right| \right) y \cos \phi - \frac{1}{2} \left(\left| \frac{q}{p} \right| + \left| \frac{p}{q} \right| \right) x \sin \phi \quad (38)$$

$$\approx A_M y \cos \phi - x \sin \phi. \quad (39)$$

Belle [45] has also reported y_{CP} for the final state $K_S^0K^+K^-$ which is dominated by the CP odd final state $K_S^0\phi$. If CP is conserved, $A_{\Gamma} = 0$.

Substantial work on the time-integrated CP asymmetries in decays to CP eigenstates are summarized in this *Review* [53]. Table 6 summarizes the current status of measurements of the difference in time-integrated CP asymmetry, $\Delta A_{CP} = A_K - A_{\pi}$, between $D^0 \rightarrow K^+K^-$ and $D^0 \rightarrow \pi^+\pi^-$. The HFAG fit is marginally consistent with no CP violation at the 5.1% Confidence Level [24].

Coherent $D^0\bar{D}^0$ Analyses: Measurements of R_D , $\cos\delta_{K\pi}$, $\sin\delta_{K\pi}$, x , and y can be determined simultaneously from a combined fit to the time-integrated single-tag (ST) and double-tag (DT) yields in correlated $D^0\bar{D}^0$ produced at the $\psi(3770)$ [26,27].

Due to quantum correlations in the $C = -1$ and $C = +1$ $D^0\bar{D}^0$ pairs produced in the reactions $e^+e^- \rightarrow D^0\bar{D}^0(\pi^0)$ and $e^+e^- \rightarrow D^0\bar{D}^0\gamma(\pi^0)$, respectively, the time-integrated $D^0\bar{D}^0$

decay rates are sensitive to interference between amplitudes for indistinguishable final states. The size of this interference is governed by the relevant amplitude ratios and can include contributions from $D^0-\bar{D}^0$ mixing.

The following categories of final states are considered:

f or \bar{f} : Hadronic states accessed from either D^0 or \bar{D}^0 decay but that are not CP eigenstates. An example is $K^-\pi^+$, which results from Cabibbo-favored D^0 transitions or DCS \bar{D}^0 transitions.

ℓ^+ or ℓ^- : Semileptonic or purely leptonic final states, which, in the absence of mixing, tag unambiguously the flavor of the parent D^0 .

f^+ or f^- : CP -even and CP -odd eigenstates, respectively.

The decay rates for $D^0\bar{D}^0$ pairs to all possible combinations of the above categories of final states are calculated in Ref. 2, for both $C = -1$ and $C = +1$, reproducing the work of Ref. 3. Such $D^0\bar{D}^0$ combinations, where both D final states are specified, are double tags. In addition, the rates for single tags, where either the D^0 or \bar{D}^0 is identified and the other neutral D decays generically are given in Ref. 2.

BESIII has reported results using 2.92 pb^{-1} of $e^+e^- \rightarrow \psi(3770)$ data where the quantum-coherent $D^0\bar{D}^0$ pairs are in the $C = -1$ state. The values of $y_{CP} = (-2.0 \pm 1.3 \pm 0.7)\%$ [38] and $A_{K\pi}^{CP} = (12.7 \pm 1.3 \pm 0.7)\%$ [61] are determined from DT yields including a CP eigenstate vs semileptonic and vs $K\pi$, respectively. For y_{CP} , the CP eigenstates included are K^-K^+ (f_+), $\pi^+\pi^-$ (f_+), $K_S^0\pi^0\pi^0$ (f_+), $K_S^0\pi^0$ (f_-), $K_S^0\eta$ (f_-), and $K_S^0\omega$ (f_-). For $A_{K\pi}^{CP}$, the additional CP eigenstates included are $\pi^0\pi^0$ (f_+) and $\rho^0\pi^0$ (f_+). Using the external inputs from R_D and y from HFAG [62] and R from PDG [63]- see Eq. (27), they obtain $\cos\delta_{K\pi} = 1.02 \pm 0.11 \pm 0.06 \pm 0.01$ [61] where the third uncertainty is due to the external inputs.

CLEO-c has reported results using 818 pb^{-1} of $e^+e^- \rightarrow \psi(3770)$ data [58–60]. The values of y , R_M , $\cos\delta_{K\pi}$, and $\sin\delta_{K\pi}$ are determined from a combined fit to the ST (hadronic only) and DT yields. The hadronic final states included are $K^-\pi^+$ (f), $K^+\pi^-$ (\bar{f}), K^-K^+ (f_+), $\pi^+\pi^-$ (f_+), $K_S^0\pi^0\pi^0$ (f_+), $K_L^0\pi^0$ (f_+), $K_L^0\eta$ (f_+), $K_L^0\omega$ (f_+), $K_S^0\pi^0$ (f_-), $K_S^0\eta$ (f_-), $K_S^0\omega$ (f_-), and $K_L^0\pi^0\pi^0$ (f_-), and $K_S^0\pi^+\pi^-$ (mixture of f, \bar{f}, f_+ , and f_-). The two flavored final states, $K^-\pi^+$ and $K^+\pi^-$, can be reached via CF or DCS transitions.

Semileptonic DT yields are also included, where one D is fully reconstructed in one of the hadronic modes listed above, and the other D is partially reconstructed in either $D \rightarrow K\ell\nu$ or $D \rightarrow K\mu\nu$. When the lepton is accompanied by a flavor tag ($D \rightarrow K^-\pi^+$ or $K^+\pi^-$), both the “right-sign” and “wrong-sign” DT samples are used, where the electron and kaon charges are the same and opposite, respectively.

The main results of the CLEO-c analysis are the determination of $\cos\delta_{K\pi} = 0.81^{+0.22+0.07}_{-0.18-0.05}$, $\sin\delta_{K\pi} = -0.01 \pm 0.49 \pm 0.04$, and World Averages for the mixing parameters from an “extended” fit that combines the CLEO-c data with previous mixing and branching-ratio measurements [60]. These fits allow $\cos\delta_{K\pi}$, $\sin\delta_{K\pi}$ and x^2 to be unphysical. Constraining

Meson Particle Listings

D^0

$\cos \delta_{K\pi}$ and $\sin \delta_{K\pi}$ to $[-1, +1]$ —that is interpreting $\delta_{K\pi}$ as an angle—yields $\delta_{K\pi} = (18^{+11}_{-17} \pm 7)^\circ$. Note that measurements of y (Table 4 and Table 5) and y' (Table 3) contribute to the determination of $\delta_{K\pi}$.

Summary of Experimental Results: Several recent results indicate that charm mixing is at the upper end of the range of Standard Model estimates.

For $D^0 \rightarrow K^+\pi^-$, LHCb [15,17], CDF [16], and Belle [14] each exclude the no-mixing hypothesis by more than 5 standard deviations.

For y_{CP} in $D^0 \rightarrow K^+K^-$ and $\pi^+\pi^-$, Belle [41] and BaBar [42] find 4.5σ and 3.3σ effects. The most sensitive measurement of x and y is in $D^0 \rightarrow K_S^0\pi^+\pi^-$ from Belle [34] and the no mixing solution is only excluded at 2.5σ . In a similar analysis using $D^0 \rightarrow K_S^0\pi^+\pi^-$ and $D^0 \rightarrow K_S^0K^+K^-$ BaBar [33] also finds the no mixing solution excluded at 1.9σ .

The current situation would benefit from better knowledge of the strong phase difference $\delta_{K\pi}$ than provided by the current CLEO-c [60] and BESIII [61] results. This would allow one to unfold x and y from the $D^0 \rightarrow K^+\pi^-$ measurements of x'^2 and y' , and directly compare them to the $D^0 \rightarrow K_S^0\pi^+\pi^-$ results.

The experimental data consistently indicate that the D^0 and \bar{D}^0 do mix. The mixing is presumably dominated by long-range processes. Under the assumption that the observed mixing is due entirely to non-Standard Model processes, significant constraints on a variety of new physics models are obtained [64]. A serious limitation to the interpretation of charm oscillations in terms of New Physics is the theoretical uncertainty of the Standard Model prediction. The evidence for time integrated CP -violation, $\Delta A_{CP} \neq 0$ is intriguing. This result is marginally consistent with Standard Model expectation [65–67].

HFAG Averaging of Charm Mixing Results:

The Heavy Flavor Averaging Group (HFAG) has made a global fit to all mixing measurements to obtain values of x , y , $\delta_{K\pi}$, $\delta_{K\pi\pi^0}$, R_D , $A_D \equiv (R_D^+ - R_D^-)/(R_D^+ + R_D^-)$, $|q/p|$, $\text{Arg}(q/p) \equiv \phi$, and the time-integrated CP asymmetries A_K and A_π . Correlations among observables are taken into account by using the error matrices from the experiments. The measurements of $D^0 \rightarrow K^{(*)}\ell^-\bar{\nu}$, K^+K^- , $\pi^+\pi^-$, $K^+\pi^-$, $K^+\pi^-\pi^0$, $K^+\pi^-\pi^+\pi^-$, $K_S^0\pi^+\pi^-$, and $K_S^0K^+K^-$ decays, as well as CLEO-c and BESIII results for double-tagged branching fractions measured at the $\psi(3770)$ are used.

For the global fit, confidence contours in the two dimensions (x, y) and $(|q/p|, \phi)$ are obtained by letting, for any point in the two-dimensional plane, all other fit parameters take their preferred values. Figures 1 and 2 show the resulting 1-to-5 σ contours. The fits exclude the no-mixing point ($x = y = 0$) at more than 11.5σ , when CP violation is allowed. The fits are consistent with no CP violation at the 27% Confidence Level. The parameters x and y differ from zero by 2.1σ and 6.8σ , respectively. One-dimensional likelihood functions for parameters are obtained by allowing, for any value of the parameter, all other fit parameters to take their preferred values. The

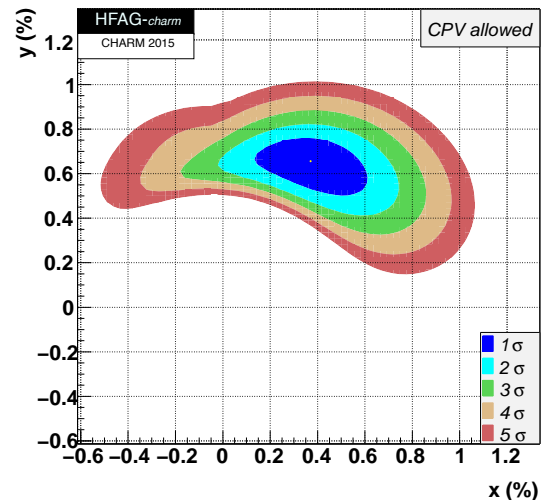

Figure 1: Two-dimensional 1σ - 5σ contours for (x, y) from measurements of $D^0 \rightarrow K^{(*)}\ell\nu$, h^+h^- , $K^+\pi^-$, $K^+\pi^-\pi^0$, $K^+\pi^-\pi^+\pi^-$, $K_S^0\pi^+\pi^-$, and $K_S^0K^+K^-$ decays, and double-tagged branching fractions measured at the $\psi(3770)$ resonance (from HFAG [24]).

Table 7: HFAG Charm Mixing Averages [24].

Parameter	No CP	CP Violation	95% C.L. Interval
	Violation	Allowed	
$x(\%)$	$0.49^{+0.14}_{-0.15}$	0.37 ± 0.16	$[0.06, 0.67]$
$y(\%)$	0.61 ± 0.08	$0.66^{+0.07}_{-0.10}$	$[0.46, 0.79]$
$R_D(\%)$	0.349 ± 0.004	0.349 ± 0.004	$[0.342, 0.357]$
$\delta_{K\pi}(\circ)$	$6.9^{+9.7}_{-11.2}$	$11.8^{+9.5}_{-14.7}$	$[-21.1, 29.3]$
$\delta_{K\pi\pi^0}(\circ)$	$18.1^{+23.2}_{-23.8}$	$27.3^{+24.4}_{-25.4}$	$[-23.3, 74.8]$
$A_D(\%)$	—	$-0.39^{+1.01}_{-1.05}$	$[-2.4, 1.5]$
$ q/p $	—	$0.91^{+0.12}_{-0.08}$	$[0.77, 1.14]$
$\phi(\circ)$	—	$-9.4^{+11.9}_{-9.8}$	$[-28.3, 12.9]$
A_K	—	-0.15 ± 0.14	$[-0.42, 0.12]$
A_π	—	0.10 ± 0.15	$[-0.19, 0.38]$

resulting likelihood functions give central values, 68.3% C.L. intervals, and 95% C.L. intervals as listed in Table 7. The χ^2 for the HFAG fit is 69 for 45 degrees of freedom indicating some disagreement among among the measurements included in the combination.

From the results of the HFAG averaging, the following can be concluded: (1) Since CP violation is small and y_{CP} is positive, the CP -even state is shorter-lived, as in the $K^0\bar{K}^0$ system; (2) However, since x appears to be positive, the CP -even state is heavier, unlike in the $K^0\bar{K}^0$ system; (3) The strong phase difference $\delta_{K\pi}$ is consistent with the SU(3) expectation of zero but large values are not excluded; (4) There is no evidence yet for CP -violation in $D^0\bar{D}^0$ mixing. Observing CP -violation in mixing ($|q/p| \neq 1$) at the current level of sensitivity would indicate new physics.

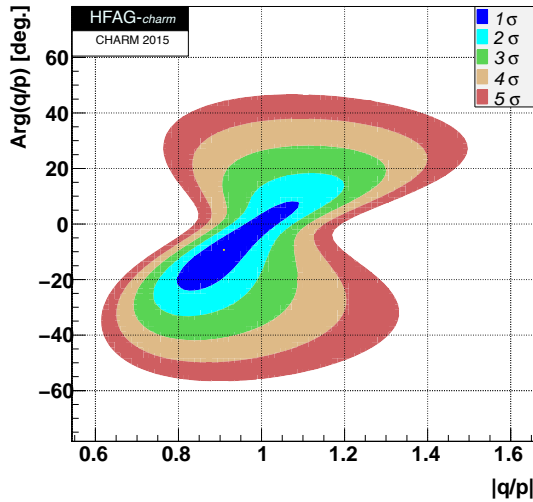

Figure 2: Two-dimensional 1σ - 5σ contours for $(|q/p|, \text{Arg}(q/p))$ from measurements of $D^0 \rightarrow K^{(*)+} \ell \nu, h^+ h^-, K^+ \pi^-, K^+ \pi^- \pi^0, K^+ \pi^- \pi^+ \pi^-, K_S^0 \pi^+ \pi^-,$ and $K_S^0 K^+ K^-$ decays, and double-tagged branching fractions measured at the $\psi(3770)$ resonance (from HFAG [24]).

The author would like to acknowledge helpful input from Bostjan Golob, Marco Gersabeck, and especially Alan Schwartz of the Heavy Flavor Averaging Group.

$$|m_{D_1^0} - m_{D_2^0}| = x \Gamma$$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson, as described in the note on “ D^0 - \bar{D}^0 Mixing,” above. The experiments usually present $x \equiv \Delta m/\Gamma$. Then $\Delta m = x \Gamma = x \hbar/\tau$.

“OUR EVALUATION” comes from CPV allowing averages provided by the Heavy Flavor Averaging Group, see the note on “ D^0 - \bar{D}^0 Mixing.”

¹ Based on 976 fb^{-1} of data collected at $Y(nS)$ resonances. Assumes no CP violation. Reported $x'^2 = (0.09 \pm 0.22) \times 10^{-3}$ and $y' = (4.6 \pm 3.4) \times 10^{-3}$, where $x' = x \cos(\delta) + y \sin(\delta)$, $y' = y \cos(\delta) - x \sin(\delta)$ and δ is the strong phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$.

² The time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ is employed. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow K^* \pi^-$ and $\bar{D}^0 \rightarrow K^* \pi^-$. This value allows CP violation and is sensitive to the sign of Δm .

³ Based on 3 fb^{-1} of data collected at $\sqrt{s} = 7, 8$ TeV. Assumes no CP violation. Reported $x'^2 = (5.5 \pm 4.9) \times 10^{-4}$ and $y' = (4.8 \pm 1.0) \times 10^{-3}$, where $x' = x \cos(\delta) + y \sin(\delta)$, $y' = y \cos(\delta) - x \sin(\delta)$ and δ is the strong phase between the $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$.

⁴ Based on 9.6 fb^{-1} of data collected at the Tevatron. Assumes no CP violation. Reported $x'^2 = (0.08 \pm 0.18) \times 10^{-3}$ and $y' = (4.3 \pm 4.3) \times 10^{-3}$, where $x' = x \cos(\delta) + y \sin(\delta)$, $y' = y \cos(\delta) - x \sin(\delta)$ and δ is the strong phase between the $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$.

⁵ DEL-AMO-SANCHEZ 10D uses 540,800 ± 800 $K_S^0 \pi^+ \pi^-$ and 79,900 ± 300 $K_S^0 K^+ K^-$ events in a time-dependent amplitude analysis of the D^0 and \bar{D}^0 Dalitz plots. No evidence was found for CP violation, and the values here assume no such violation.

⁶ Based on 1 fb^{-1} of data collected at $\sqrt{s} = 7$ TeV in 2011. Assumes no CP violation. Reported $x'^2 = (-0.9 \pm 1.3) \times 10^{-4}$ and $y' = (7.2 \pm 2.4) \times 10^{-3}$, where $x' = x \cos(\delta) + y \sin(\delta)$, $y' = y \cos(\delta) - x \sin(\delta)$ and δ is the strong phase between the $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$.

⁷ The AUBERT 09AN values are inferred from the branching ratio $\Gamma(D^0 \rightarrow K^+ \pi^- \pi^0)$ via $\bar{D}^0/\Gamma(D^0 \rightarrow K^- \pi^+ \pi^0)$ given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between $D^0 \rightarrow K^+ \pi^- \pi^0$ and $\bar{D}^0 \rightarrow K^+ \pi^- \pi^0$ is assumed to be small. The width difference here is y'' , which is not the same as y_{CP} in the note on D^0 - \bar{D}^0 mixing.

⁸ LOWREY 09 uses quantum correlations in $e^+ e^- \rightarrow D^0 \bar{D}^0$ at the $\psi(3770)$. See below for coherence factors and average relative strong phases for both $D^0 \rightarrow K^- \pi^+ \pi^0$ and $D^0 \rightarrow K^- \pi^- 2\pi^+$. A fit that includes external measurements of charm mixing parameters gets $\Delta m = (2.34 \pm 0.61) \times 10^{10} \hbar s^{-1}$.

⁹ The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0 \pi^+ \pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow K^* \pi^-$ and $\bar{D}^0 \rightarrow K^* \pi^-$. This value allows CP violation and is sensitive to the sign of Δm .

¹⁰ The AUBERT 03Z, LI 05A, and ZHANG 06 limits are inferred from the D^0 - \bar{D}^0 mixing ratio $\Gamma(K^+ \pi^- \text{ (via } \bar{D}^0))/\Gamma(K^- \pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0 - \bar{D}^0 mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. AUBERT 03Z assumes the strong phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$ amplitudes is small; if an arbitrary phase is allowed, the limit degrades by 20%. The LI 05A and ZHANG 06 limits are valid for an arbitrary strong phase.

¹¹ This LINK 05H limit is inferred from the D^0 - \bar{D}^0 mixing ratio $\Gamma(K^+ \pi^- \text{ (via } \bar{D}^0))/\Gamma(K^- \pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0 - \bar{D}^0 mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$ is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by 25%.

¹² This GODANG 00 limit is inferred from the D^0 - \bar{D}^0 mixing ratio $\Gamma(K^+ \pi^- \text{ (via } \bar{D}^0))/\Gamma(K^- \pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from D^0 - \bar{D}^0 mixing. The limit allows interference between the DCS and mixing ratios, and also allows CP violation. The strong phase between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$ is assumed to be small. If an arbitrary relative strong phase is allowed, the limit degrades by a factor of two.

¹³ AITALA 98 allows interference between the doubly Cabibbo-suppressed and mixing amplitudes, and also allows CP violation in this term, but assumes that $A_D = A_R = 0$. See the note on “ D^0 - \bar{D}^0 Mixing,” above.

¹⁴ This limit is inferred from R_M for $f = K^+ \pi^-$ and $f = K^+ \pi^- \pi^+ \pi^-$. See the note on “ D^0 - \bar{D}^0 Mixing,” above. Decay-time information is used to distinguish doubly Cabibbo-suppressed decays from D^0 - \bar{D}^0 mixing.

¹⁵ This limit is inferred from R_M for $f = K^+ \ell^- \bar{\nu}_\ell$. See the note on “ D^0 - \bar{D}^0 Mixing,” above.

¹⁶ ANJOS 88c assumes that $\gamma = 0$. See the note on “ D^0 - \bar{D}^0 Mixing,” above. Without this assumption, the limit degrades by about a factor of two.

$$(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma = 2y$$

The D_1^0 and D_2^0 are the mass eigenstates of the D^0 meson, as described in the note on “ D^0 - \bar{D}^0 Mixing,” above.

Due to the strong phase difference between $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$, we exclude from the average those measurements of y' that are inferred from the D^0 - \bar{D}^0 mixing ratio $\Gamma(K^+ \pi^- \text{ via } \bar{D}^0) / \Gamma(K^+ \pi^-)$ given near the end of this D^0 Listings.

Some early results have been omitted. See our 2006 Review (Journal of Physics **G33** 1 (2006)).

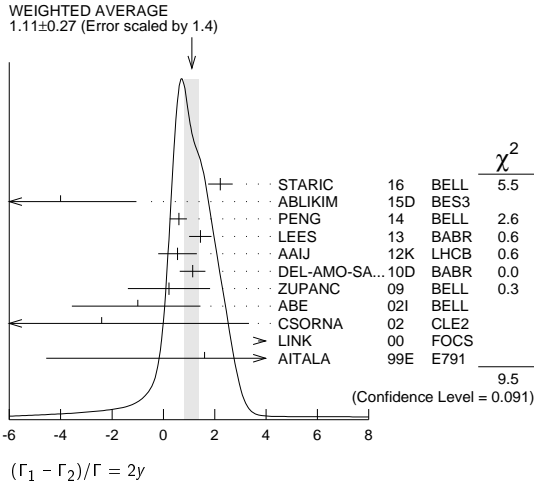

“OUR EVALUATION” comes from CPV allowing averages provided by the Heavy Flavor Averaging Group, see the note on “ D^0 - \bar{D}^0 Mixing.”

Meson Particle Listings

D^0

- 1 An improved measurement of $\overline{D}^0 - D^0$ mixing and a search for CP violation in D^0 decays to CP -even final states $K^+ K^-$ and $\pi^+ \pi^-$ using the final Belle data sample of 976 fb^{-1} .
- 2 ABLIKIM 15D uses quantum correlations in $e^+ e^- \rightarrow D^0 \overline{D}^0$ at the $\psi(3770)$.
- 3 Based on 976 fb^{-1} of data collected at $Y(nS)$ resonances. Assumes no CP violation. Reported $x'^2 = (0.09 \pm 0.22) \times 10^{-3}$ and $y' = (4.6 \pm 3.4) \times 10^{-3}$, where $x' = x \cos(\delta) + y \sin(\delta)$, $y' = y \cos(\delta) - x \sin(\delta)$ and δ is the strong phase between $D^0 \rightarrow K^+ \pi^-$ and $\overline{D}^0 \rightarrow K^+ \pi^-$.
- 4 The time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ is employed. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow K^+ \pi^-$ and $\overline{D}^0 \rightarrow K^+ \pi^-$. This value allows CP violation and is sensitive to the sign of Δm .
- 5 Based on 3 fb^{-1} of data collected at $\sqrt{s} = 7, 8 \text{ TeV}$. Assumes no CP violation. Reported $x'^2 = (5.5 \pm 4.9) \times 10^{-4}$ and $y' = (4.8 \pm 1.0) \times 10^{-3}$, where $x' = x \cos(\delta) + y \sin(\delta)$, $y' = y \cos(\delta) - x \sin(\delta)$ and δ is the strong phase between the $D^0 \rightarrow K^+ \pi^-$ and $\overline{D}^0 \rightarrow K^+ \pi^-$.
- 6 Based on 9.6 fb^{-1} of data collected at the Tevatron. Assumes no CP violation. Reported $x'^2 = (0.08 \pm 0.18) \times 10^{-3}$ and $y' = (4.3 \pm 4.3) \times 10^{-3}$, where $x' = x \cos(\delta) + y \sin(\delta)$, $y' = y \cos(\delta) - x \sin(\delta)$ and δ is the strong phase between the $D^0 \rightarrow K^+ \pi^-$ and $\overline{D}^0 \rightarrow K^+ \pi^-$.
- 7 Obtained $y_{CP} = (0.72 \pm 0.18 \pm 0.12)\%$ based on three effective D^0 lifetimes measured in $K^+ \pi^-$, $K^- K^+$, and $\pi^- \pi^+$. We list $2y_{CP} = \Delta\Gamma/\Gamma$.
- 8 Compared the lifetimes of D^0 decay to the CP eigenstate $K^+ K^-$ with D^0 decay to $\pi^+ K^-$. The values here assume no CP violation.
- 9 DEL-AMO-SANCHEZ 10D uses $540,800 \pm 800 K_S^0 \pi^+ \pi^-$ and $79,900 \pm 300 K_S^0 K^+ K^-$ events in a time-dependent amplitude analyses of the D^0 and \overline{D}^0 Dalitz plots. No evidence was found for CP violation, and the values here assume no such violation.
- 10 ZUPANC 09 uses a method based on measuring the mean decay time of $D^0 \rightarrow K_S^0 K^+ K^-$ events for different $K^+ K^-$ mass intervals.
- 11 LINK 00, AITALA 99E, and ABE 02I measure the lifetime difference between $D^0 \rightarrow K^- K^+$ (CP -even) decays and $D^0 \rightarrow K^- \pi^+$ (CP -mixed) decays, or $y_{CP} = [\Gamma(CP+) - \Gamma(CP-)] / [\Gamma(CP+) + \Gamma(CP-)]$. We list $2y_{CP} = \Delta\Gamma/\Gamma$.
- 12 CSORNA 02 measures the lifetime difference between $D^0 \rightarrow K^- K^+$ and $\pi^- \pi^+$ (CP -even) decays and $D^0 \rightarrow K^- \pi^+$ (CP -mixed) decays, or $y_{CP} = [\Gamma(CP+) - \Gamma(CP-)] / [\Gamma(CP+) + \Gamma(CP-)]$. We list $2y_{CP} = \Delta\Gamma/\Gamma$.
- 13 Based on 1 fb^{-1} of data collected at $\sqrt{s} = 7 \text{ TeV}$ in 2011. Assumes no CP violation. Reported $x'^2 = (-0.9 \pm 1.3) \times 10^{-4}$ and $y' = (7.2 \pm 2.4) \times 10^{-3}$, where $x' = x \cos(\delta) + y \sin(\delta)$, $y' = y \cos(\delta) - x \sin(\delta)$ and δ is the strong phase between the $D^0 \rightarrow K^+ \pi^-$ and $\overline{D}^0 \rightarrow K^+ \pi^-$.
- 14 This combines the $y_{CP} = (\tau_{K^+ \pi^+} / \tau_{K^+ K^+}) - 1$ using untagged $K^- \pi^+$ and $K^- K^+$ events of AUBERT 09A1 with the disjoint y_{CP} using tagged $K^- \pi^+$, $K^- K^+$, and $\pi^- \pi^+$ events of AUBERT 08U.
- 15 The AUBERT 09AN values are inferred from the branching ratio $\Gamma(D^0 \rightarrow K^+ \pi^- \pi^0) / \Gamma(D^0 \rightarrow K^- \pi^+ \pi^0)$ given near the end of this Listings. Mixing is distinguished from DCS decays using decay-time information. Interference between mixing and DCS is allowed. The phase between $D^0 \rightarrow K^+ \pi^- \pi^0$ and $\overline{D}^0 \rightarrow K^+ \pi^- \pi^0$ is assumed to be small. The width difference here is y' , which is not the same as y_{CP} in the note on $D^0 - \overline{D}^0$ mixing.
- 16 LOWREY 09 uses quantum correlations in $e^+ e^- \rightarrow D^0 \overline{D}^0$ at the $\psi(3770)$. See below for coherence factors and average relative strong phases for both $D^0 \rightarrow K^- \pi^+ \pi^0$ and $D^0 \rightarrow K^- \pi^- 2\pi^+$. A fit that includes external measurements of charm mixing parameters gets $2y = (1.62 \pm 0.32) \times 10^{-2}$.
- 17 The GODANG 00, AUBERT 03Z, LINK 05H, LI 05A, ZHANG 06, AUBERT 07W, and AALTONEN 08E limits are inferred from the $D^0 - \overline{D}^0$ mixing ratio $\Gamma(K^+ \pi^- \text{ (via } \overline{D}^0)) / \Gamma(K^- \pi^+)$ given near the end of this D^0 Listings. Decay-time information is used to distinguish DCS decays from $D^0 - \overline{D}^0$ mixing. The limits allow interference between the DCS and mixing ratios, and all except AUBERT 07W and AALTONEN 08E also allow CP violation. The phase between $D^0 \rightarrow K^+ \pi^-$ and $\overline{D}^0 \rightarrow K^+ \pi^-$ is assumed to be small. This is a measurement of y' and is not the same as the y_{CP} of our note above on " $D^0 - \overline{D}^0$ Mixing."
- 18 This value combines the results of AUBERT 08U and AUBERT 03P.

- 19 STARIC 07 compares the lifetimes of D^0 decay to the CP eigenstates $K^+ K^-$ and $\pi^+ \pi^-$ with D^0 decay to $K^- \pi^+$.
- 20 The ASNER 05 and ZHANG 07B values are from the time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0 \pi^+ \pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow K^+ \pi^-$ and $\overline{D}^0 \rightarrow K^+ \pi^-$. This limit allows CP violation.
- 21 The ranges of AUBERT 03Z, LINK 05H, LI 05A, and ZHANG 06 measurements are for 95% confidence level.
- 22 AUBERT 03P measures $Y \equiv 2\tau^0 / (\tau^+ + \tau^-) - 1$, where τ^0 is the $D^0 \rightarrow K^- \pi^+$ (and $\overline{D}^0 \rightarrow K^+ \pi^-$) lifetime, and τ^+ and τ^- are the D^0 and \overline{D}^0 lifetimes to CP -even states (here $K^- K^+$ and $\pi^- \pi^+$). In the limit of CP conservation, $Y = y \equiv \Delta\Gamma / 2\Gamma$ (we list $2y = \Delta\Gamma/\Gamma$). AUBERT 03P also uses $\tau^+ - \tau^-$ to get $\Delta Y = -0.008 \pm 0.006 \pm 0.002$.

|q/p|

The mass eigenstates D_1^0 and D_2^0 are related to the $C = \pm 1$ states by $|D_{1,2}^0\rangle = p|D^0\rangle + q|\overline{D}^0\rangle$. See the note on " $D^0 - \overline{D}^0$ Mixing" above.

"OUR EVALUATION" comes from CPV allowing averages provided by the Heavy Flavor Averaging Group. This would include as-yet-unpublished results, see the note on " $D^0 - \overline{D}^0$ Mixing."

- 1 The time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ is employed. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow K^+ \pi^-$ and $\overline{D}^0 \rightarrow K^+ \pi^-$. This value allows CP violation and is sensitive to the sign of Δm .
- 2 Based on 3 fb^{-1} of data collected at $\sqrt{s} = 7, 8 \text{ TeV}$. Allowing for CP violation, the direct CP violation in mixing is reported $0.75 < |q/p| < 1.24$ at the 68.3% CL for the $D^0 \rightarrow K^+ \pi^-$ and $\overline{D}^0 \rightarrow K^+ \pi^-$.
- 3 The phase of p/q is $(-14^{+16}_{-18} \pm 5)^\circ$. The ZHANG 07B value is from the time-dependent Dalitz-plot analysis of $D^0 \rightarrow K_S^0 \pi^+ \pi^-$. Decay-time information and interference on the Dalitz plot are used to distinguish doubly Cabibbo-suppressed decays from mixing and to measure the relative phase between $D^0 \rightarrow K^+ \pi^-$ and $\overline{D}^0 \rightarrow K^+ \pi^-$. This value allows CP violation.

A_r

A_r is the decay-rate asymmetry for CP -even final states $A_r = (\overline{\tau}_+ - \tau_+) / (\overline{\tau}_+ + \tau_+)$. See the note on " $D^0 - \overline{D}^0$ Mixing" above.

Meson Particle Listings

D^0

¹ Uses quantum correlations in $e^+e^- \rightarrow D^0\bar{D}^0$ at the $\psi(3770)$ to measure the asymmetry of the branching fraction of $D^0 \rightarrow K^-\pi^+$ in CP -odd and CP -even eigenstates to be $(12.7 \pm 1.3 \pm 0.7)\%$. A fit that includes external measurements of charm mixing parameters finds the value quoted above.

² Uses quantum correlations in $e^+e^- \rightarrow D^0\bar{D}^0$ at the $\psi(3770)$, where decay rates of CP -tagged $K\pi$ final states depend on the strong phases between the decays of $D^0 \rightarrow K^+\pi^-$ and $\bar{D}^0 \rightarrow K^+\pi^-$. The measurements obtained $\sin(\delta) = -0.01 \pm 0.41 \pm 0.04$ and $|\delta| = (10^{+28+13}_{-53-00})^\circ$ as well. A fit that includes external measurements of charm mixing parameters finds $\cos(\delta) = 1.15^{+0.19+0.00}_{-0.17-0.08}$, $\sin(\delta) = 0.56^{+0.32+0.21}_{-0.31-0.20}$, and $|\delta| = (18^{+11}_{-17})^\circ$.

³ ASNER 08 uses quantum correlations in $e^+e^- \rightarrow D^0\bar{D}^0$ at the $\psi(3770)$, where decay rates of CP -tagged $K\pi$ final states depend on $\cos \delta$ because of interfering amplitudes. The above measurement implies $|\delta| < 75^\circ$ with a confidence level of 95%. A fit that includes external measurements of charm mixing parameters finds $\cos \delta = 1.10 \pm 0.35 \pm 0.07$. See also the note on " D^0 - \bar{D}^0 Mixing" p. 783 in our 2008 Review (PDG 08).

$D^0 \rightarrow K^-\pi^+\pi^0$ COHERENCE FACTOR $R_{K\pi\pi^0}$

See the note on ' D^0 - \bar{D}^0 Mixing' for the definition. $R_{K\pi\pi^0}$ can have any value between 0 and 1. A value near 1 indicates the decay is dominated by a few intermediate states with limited interference.

D^0 DECAY MODES

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S^0 modes, not as \bar{K}^0 modes. Nearly always it is a K_S^0 that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$.

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 3 measurements and one constraint to determine 4 parameters. The overall fit has a $\chi^2 = 0.0$ for 0 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

0.299 ± 0.011 ± 0.009		3 DOBBS	08 CLEO	See BESSON 09	
0.262 ± 0.025 ± 0.008	117	COAN	05 CLEO	See DOBBS 08	

¹ See the form-factor parameters near the end of this D^0 Listing.

² The $\pi^- e^+ \nu_e$ and $K^- e^+ \nu_e$ results of WIDHALM 06 give $|\frac{V_{cd}}{V_{cs}} \cdot \frac{f_+^{\pi}(0)}{f_+^{K}(0)}|^2 = 0.042 \pm 0.003 \pm 0.003$.

³ DOBBS 08 establishes $|\frac{V_{cd}}{V_{cs}} \cdot \frac{f_+^{\pi}(0)}{f_+^{K}(0)}| = 0.188 \pm 0.008 \pm 0.002$ from the D^+ and D^0 decays to $\bar{K} e^+ \nu_e$ and $\pi e^+ \nu_e$.

$\Gamma(\pi^- e^+ \nu_e)/\Gamma(K^- e^+ \nu_e)$					Γ_{28}/Γ_{18}
VALUE	EVTS	DOCUMENT ID	TECN	COMMENT	
0.0823 ± 0.0014 OUR FIT	Error	includes scale factor of 1.1.			
0.085 ± 0.007 OUR AVERAGE					
0.082 ± 0.006 ± 0.005		1 HUANG	05 CLEO	e ⁺ e ⁻ ≈ $\Upsilon(4S)$	
0.101 ± 0.020 ± 0.003	91	2 FRABETTI	96B E687	γ Be, $\bar{E}_\gamma \approx 200$ GeV	
0.103 ± 0.039 ± 0.013	87	3 BUTLER	95 CLE2	< 0.156 (90% CL)	

¹ HUANG 05 uses both e and μ events, and makes a small correction to the μ events to make them effectively e events. This result gives $|\frac{V_{cd}}{V_{cs}} \cdot \frac{f_+^{\pi}(0)}{f_+^{K}(0)}|^2 = 0.038^{+0.006+0.005}_{-0.007-0.003}$.

² FRABETTI 96B uses both e and μ events, and makes a small correction to the μ events to make them effectively e events. This result gives $|\frac{V_{cd}}{V_{cs}} \cdot \frac{f_+^{\pi}(0)}{f_+^{K}(0)}|^2 = 0.050 \pm 0.011 \pm 0.002$.

³ BUTLER 95 has 87 ± 33 $\pi^- e^+ \nu_e$ events. The result gives $|\frac{V_{cd}}{V_{cs}} \cdot \frac{f_+^{\pi}(0)}{f_+^{K}(0)}|^2 = 0.052 \pm 0.020 \pm 0.007$.

3.95 ± 0.08 ± 0.17	4.2k	^{2,7} AKERIB	93 CLE2	See ARTUSO 98
4.5 ± 0.8 ± 0.5	56	² ABACHI	88 HRS	$e^+ e^-$ 29 GeV
4.2 ± 0.4 ± 0.4	0.9k	ADLER	88c MRK3	$e^+ e^-$ 3.77 GeV
4.1 ± 0.6	0.3k	⁸ SCHINDLER	81 MRK2	$e^+ e^-$ 3.771 GeV
4.3 ± 1.0	130	⁹ PERUZZI	77 LGW	$e^+ e^-$ 3.77 GeV

¹ This combines the CLEO results of ARTUSO 98, COAN 98, and AKERIB 93.

² ABACHI 88, DECAMP 91J, AKERIB 93, ALBRECHT 94F, and BARATE 97c use $D^*(2010)^+ \rightarrow D^0 \pi^+$ decays. The π^+ is both slow and of low p_T with respect to the event thrust axis or nearest jet ($\approx D^{*+}$ direction). The excess number of such π^+ 's over background gives the number of $D^*(2010)^+ \rightarrow D^0 \pi^+$ events, and the fraction with $D^0 \rightarrow K^- \pi^+$ gives the $D^0 \rightarrow K^- \pi^+$ branching fraction.

³ DOBBS 07 and HE 05 use single- and double-tagged events in an overall fit. DOBBS 07 supersedes HE 05.

⁴ ARTUSO 98, following ALBRECHT 94, uses D^0 mesons from $\bar{B}^0 \rightarrow D^*(2010)^+ X \ell^- \bar{\nu}_\ell$ decays. Our average uses the CLEO average of this value with the values of COAN 98 and AKERIB 93.

⁵ COAN 98 assumes that $\Gamma(B \rightarrow \bar{D} X \ell^+ \nu)/\Gamma(B \rightarrow X \ell^+ \nu) = 1.0 - 3|V_{ub}/V_{cb}|^2 - 0.010 \pm 0.005$, the last term accounting for $\bar{B} \rightarrow D_s^+ K X \ell^- \bar{\nu}$. COAN 98 is included in the CLEO average in ARTUSO 98.

⁶ ALBRECHT 94 uses D^0 mesons from $\bar{B}^0 \rightarrow D^{*+} \ell^- \bar{\nu}_\ell$ decays. This is a different set of events than used by ALBRECHT 94F.

⁷ This AKERIB 93 value includes radiative corrections; without them, the value is $0.0391 \pm 0.0008 \pm 0.0017$. AKERIB 93 is included in the CLEO average in ARTUSO 98.

⁸ SCHINDLER 81 (MARK-2) measures $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$ branching fraction to be 0.24 ± 0.02 nb. We use the MARK-3 (ADLER 88c) value of $\sigma = 5.8 \pm 0.5 \pm 0.6$ nb.

⁹ PERUZZI 77 (MARK-1) measures $\sigma(e^+ e^- \rightarrow \psi(3770)) \times$ branching fraction to be 0.25 ± 0.05 nb. We use the MARK-3 (ADLER 88c) value of $\sigma = 5.8 \pm 0.5 \pm 0.6$ nb.

 $\Gamma(K^*(892)^0 \pi^+ \pi^- \pi^0)/\Gamma_{\text{total}}$ Γ_{76}/Γ_{35}

Branching fractions for submodes of this mode with narrow resonances (the η , ω , η') are fairly well determined (see below). COFFMAN 92B gives fractions of K^* and ρ submodes, but with only 140 ± 28 events above background could not determine them with much accuracy. We omit those measurements here; they are in our 2008 Review (Physics Letters **B667** 1 (2008)).

¹BARLAG 92c computes the branching fraction using topological normalization.

This is R , the time-integrated wrong-sign rate compared to the right-sign rate. See the note on " D^0 - \bar{D}^0 Mixing," near the start of the D^0 Listings.

The experiments here use the charge of the pion in $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0) \pi^\pm$ decay to tell whether a D^0 or a \bar{D}^0 was born. The $D^0 \rightarrow K^+ \pi^-$ decay can occur directly by doubly Cabibbo-suppressed (DCS) decay, or indirectly by $D^0 \rightarrow \bar{D}^0$ mixing followed by $\bar{D}^0 \rightarrow K^+ \pi^-$ decay. Some of the experiments can use the decay-time information to disentangle the two mechanisms. Here, we list the experimental branching ratio, which if there is no mixing is the DCS ratio. See the next data block for values of the DCS ratio R_D , and the following data block for limits on the mixing ratio R_M . See the section on CP -violating asymmetries near the end of this D^0 Listing for values of A_D , and the note on " D^0 - \bar{D}^0 Mixing" for limits on x' and y' .

<18	90		³ ANJOS	88c E691 Photoproduction

¹ AMMAR 91 cannot and DYTMAN 01, TIAN 05, and WHITE 13 do not distinguish between doubly Cabibbo-suppressed decay and D^0 - \bar{D}^0 mixing.
² This AITALA 98 result assumes no D^0 - \bar{D}^0 mixing (R_M in the note on " D^0 - \bar{D}^0 Mixing"). It becomes $-0.0020 \pm_{-0.0106}^{+0.0117} \pm 0.0035$ when mixing is allowed and decay-time information is used to distinguish doubly Cabibbo-suppressed decays from mixing.
³ ANJOS 88c uses decay-time information to distinguish doubly Cabibbo-suppressed (DCS) decays from D^0 - \bar{D}^0 mixing. However, the result assumes no interference between the DCS and mixing amplitudes ($\gamma = 0$ in the note on " D^0 - \bar{D}^0 Mixing" near the start of the D^0 Listings). When interference is allowed, the limit degrades to 0.033.

$\Gamma(K^+\pi^+2\pi^- \text{ via } \bar{D}^0)/\Gamma(K^-2\pi^+\pi^-)$

Γ_{232}/Γ_{67}

This is a D^0 - \bar{D}^0 mixing limit. The experiments here (1) use the charge of the pion in $D^*(2010)^\pm \rightarrow (D^0 \text{ or } \bar{D}^0)\pi^\pm$ decay to tell whether a D^0 or a \bar{D}^0 was born; and (2) use the decay-time distribution to disentangle doubly Cabibbo-suppressed decay and mixing. For the limits on $|m_{D_1^0} - m_{D_2^0}|$ and $(\Gamma_{D_1^0} - \Gamma_{D_2^0})/\Gamma_{D_0}$ that come from the best mixing limit, see near the beginning of these D^0 Listings.

<0.0085	90	¹ AITALA	98 E791	π^- nucleus, 500 GeV
<0.0037	90	² ANJOS	88c E691	Photoproduction

- ¹ AITALA 98 uses decay-time information to distinguish doubly Cabibbo-suppressed decays from D^0 - \bar{D}^0 mixing. The fit allows interference between the two amplitudes, and also allows CP violation in this term. The central value obtained is $0.0039 \pm_{-0.0032}^{+0.0036} \pm 0.0016$. When interference is disallowed, the result becomes $0.0021 \pm 0.0009 \pm 0.0002$.
² This combines results of ANJOS 88c on $K^+\pi^-$ and $K^+\pi^-\pi^+\pi^-$ (via \bar{D}^0) reported in the data block above (see footnotes there). It assumes no interference.

D^0 CP-VIOLATING DECAY-RATE ASYMMETRIES

This is the difference between D^0 and \bar{D}^0 partial widths for the decay to state f , divided by the sum of the widths:

$$A_{CP}(f) = [\Gamma(D^0 \rightarrow f) - \Gamma(\bar{D}^0 \rightarrow \bar{f})] / [\Gamma(D^0 \rightarrow f) + \Gamma(\bar{D}^0 \rightarrow \bar{f})].$$

$A_{CP}(K^+ K^-)$ in $D^0, \bar{D}^0 \rightarrow K^+ K^-$

¹ Based on 3 fb⁻¹ of data collected at $\sqrt{s} = 7, 8$ TeV. Allowing for CP violation, the direct CP -violation in mixing is reported for the $D^0 \rightarrow K^+ \pi^-$ and $\bar{D}^0 \rightarrow K^+ \pi^-$.

² This ZHANG 06 result allows mixing.

³ This LINK 05H result assumes no mixing. If mixing is allowed, it becomes $0.13^{+0.33}_{-0.25} \pm 0.10$.

⁴ This AUBERT 03Z limit assumes no mixing. If mixing is allowed, the 95% confidence-level interval is $(-2.8 < A_D < 4.9) \times 10^{-3}$.

⁵ This GODANG 00 result assumes no D^0 - \bar{D}^0 mixing and becomes $-0.43 < A_{CP} < +0.34$ at 95% CL. If mixing is allowed $A_{CP} = -0.01^{+0.16}_{-0.17} \pm 0.01$.

⁶ This LI 05A result allows mixing.

D^0 CP-EVEN FRACTIONS

The CP-even fraction F_+ , defined for self-conjugate final states, like the coherence factor is useful for measuring the unitary triangle angle γ in $B \rightarrow DK$ decays. A purely CP-even state has $F_+ = 1$, a CP-odd one has $F_+ = 0$. For details, see NAYAK 15.

D^0 CP-VIOLATING ASYMMETRY DIFFERENCES

$\Delta A_{CP} = A_{CP}(K^+ K^-) - A_{CP}(\pi^+ \pi^-)$
 CP violation in these modes can come from the decay amplitudes (direct) and/or from mixing or interference of mixing and decay (indirect). The difference ΔA_{CP} is primarily sensitive to the direct component, and only retains a second-order dependence on the indirect component for measurements where the mean decay time of the $K^+ K^-$ and $\pi^+ \pi^-$ samples are not identical. The results below are averaged assuming the indirect component can be neglected.

D^0 χ^2 TESTS OF CP-VIOLATION (CPV)

We list model-independent searches for local CP violation in phase-space distributions of multi-body decays.

Most of these searches divide phase space (Dalitz plot for 3-body decays, five-dimensional equivalent for 4-body decays) into bins, and perform a χ^2 test comparing normalised yields N_i, \bar{N}_i in CP-conjugate bin pairs i : $\chi^2 = \sum_i (N_i - \alpha \bar{N}_i) / \sigma(N_i - \alpha \bar{N}_i)$. The factor $\alpha = (\sum_i N_i) / (\sum_i \bar{N}_i)$ removes the dependence on phase-space-integrated rate asymmetries. The result is used to obtain the probability (p-value) to obtain the measured χ^2 or larger under the assumption of CP conservation [AUBERT 08AO, BEDIAGA 09]. Alternative methods obtain p-values from other test variables based on unbinned analyses [WILLIAMS 11, AAJ 14C]. Results can be combined using Fisher's method [MOSTELLER 48].

CP VIOLATING ASYMMETRIES OF P-ODD (T-ODD) MOMENTS

The CP-sensitive P-odd (T-odd) correlation in $D^0, \bar{D}^0 \rightarrow K^+ K^- \pi^+ \pi^-$ decays. D^0 and \bar{D}^0 are distinguished by the charge of the parent D^* : $D^{*+} \rightarrow D^0 \pi^+$ and $D^{*-} \rightarrow \bar{D}^0 \pi^-$.

$A_{Tviol}(K^+ K^- \pi^+ \pi^-) \text{ in } D^0, \bar{D}^0 \rightarrow K^+ K^- \pi^+ \pi^-$
 $C_T \equiv \bar{p}_{K^+} \cdot (\bar{p}_{\pi^+} \times \bar{p}_{\pi^-})$ is a parity-odd correlation of the K^+, π^+ , and π^- momenta (evaluated in the D^0 rest frame) for the D^0 . $\bar{C}_T \equiv \bar{p}_{K^-} \cdot (\bar{p}_{\pi^-} \times \bar{p}_{\pi^+})$ is the corresponding quantity for the \bar{D}^0 . Then
 $A_T \equiv [\Gamma(C_T > 0) - \Gamma(C_T < 0)] / [\Gamma(C_T > 0) + \Gamma(C_T < 0)]$, and
 $\bar{A}_T \equiv [\Gamma(-\bar{C}_T > 0) - \Gamma(-\bar{C}_T < 0)] / [\Gamma(-\bar{C}_T > 0) + \Gamma(-\bar{C}_T < 0)]$, and
 $A_{Tviol} \equiv \frac{1}{2}(A_T - \bar{A}_T)$. C_T and \bar{C}_T are commonly referred to as T-odd moments, because they are odd under T reversal. However, the T-conjugate process $K^+ K^- \pi^+ \pi^- \rightarrow D^0$ is not accessible, while the P-conjugate process is.

D⁰ CPT-VIOLATING DECAY-RATE ASYMMETRIES

A_{CPT}(K[±]π[±]) in D⁰ → K⁻π⁺, D⁰ → K⁺π⁻

A_{CPT}(t) is defined in terms of the time-dependent decay probabilities P(D⁰ → K⁻π⁺) and P(D⁰ → K⁺π⁻) by A_{CPT}(t) = (P - P)/(P + P). For small mixing parameters x ≡ Δm/Γ and y ≡ ΔΓ/2Γ (as in the case), and times t, A_{CPT}(t) reduces to [y Re ξ - x Im ξ] Γt, where ξ is the CPT-violating parameter.

The following is actually y Re ξ - x Im ξ.

$D^{*0}(2007)^0$ DECAY MODES

$\bar{D}^{*0}(2007)^0$ modes are charge conjugates of modes below.

Mode	Fraction (Γ_i/Γ)
Γ_1 $D^0\pi^0$	(64.7 ± 0.9) %
Γ_2 $D^0\gamma$	(35.3 ± 0.9) %

CONSTRAINED FIT INFORMATION

An overall fit to 2 branching ratios uses 5 measurements and one constraint to determine 2 parameters. The overall fit has a $\chi^2 = 2.5$ for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$$x_2 \begin{vmatrix} -100 & \\ & x_1 \end{vmatrix}$$

$D^*(2010)^\pm$ DECAY MODES

$D^*(2010)^-$ modes are charge conjugates of the modes below.

Mode	Fraction (Γ_i/Γ)
Γ_1 $D^0 \pi^+$	(67.7 ± 0.5) %
Γ_2 $D^+ \pi^0$	(30.7 ± 0.5) %
Γ_3 $D^+ \gamma$	(1.6 ± 0.4) %

CONSTRAINED FIT INFORMATION

An overall fit to 3 branching ratios uses 6 measurements and one constraint to determine 3 parameters. The overall fit has a $\chi^2 = 0.3$ for 4 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i/\Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$D_1(2420)^0$ POLARIZATION AMPLITUDE A_{D_1}

A polarization amplitude A_{D_1} is a parameter that depends on the initial polarization of the D_1 and is sensitive to a possible S-wave contribution to its decay. For D_1 decays the helicity angle, θ_h , distribution varies like $1 + A_{D_1}\cos^2\theta_h$, where θ_h is the angle in the D^* rest frame between the two pions emitted by the $D_1 \rightarrow D^*\pi$ and the $D^* \rightarrow D\pi$.

Unpolarized D_1 decaying purely via D-wave is predicted to give $A_{D_1} = 3$.

$D_1(2420)^\pm$ POLARIZATION AMPLITUDE A_{D_1}

A polarization amplitude A_{D_1} is a parameter that depends on the initial polarization of the D_1 and is sensitive to a possible S-wave contribution to its decay. For D_1 decays the helicity angle, θ_h , distribution varies like $1 + A_{D_1} \cos^2 \theta_h$, where θ_h is the angle in the D^* rest frame between the two pions emitted by the $D_1 \rightarrow D^* \pi$ and the $D^* \rightarrow D \pi$.

Unpolarized D_1 decaying purely via D-wave is predicted to give $A_{D_1} = 3$.

D_s^\pm

CHARMED, STRANGE MESONS ($C = S = \pm 1$)

$$D_s^+ = c\bar{s}, D_s^- = \bar{c}s, \text{ similarly for } D_s^{*\pm}$$

D_s^\pm

$$J(P) = 0(0^-)$$

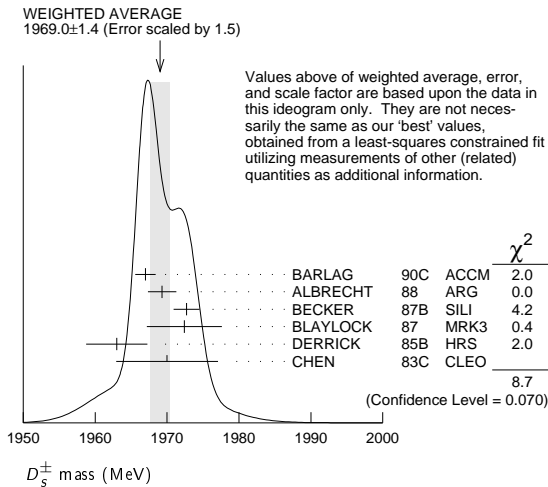

The angular distributions of the decays of the ϕ and $\bar{K}^*(892)^0$ in the $\phi\pi^+$ and $K^+\bar{K}^*(892)^0$ modes strongly indicate that the spin is zero. The parity given is that expected of a $c\bar{s}$ ground state.

D_s^\pm MASS

The fit includes $D_s^\pm, D^0, D_s^{*\pm}, D^{*0}, D_s^{*0}, D_1(2420)^0, D_2^*(2460)^0$, and $D_{s1}(2536)^\pm$ mass and mass difference measurements. Measurements of the D_s^\pm mass with an error greater than 10 MeV are omitted from the fit and average. A number of early measurements have been omitted altogether.

[a] This is the purely e^+ semileptonic branching fraction: the e^+ fraction from τ^+ decays has been subtracted off. The sum of our (non- τ) e^+ exclusive fractions — an $e^+ \nu_e$ with an $\eta, \eta', \phi, K^0, K^{*0},$ or $f_0(980)$ — is 7.0 ± 0.4 %

[b] This fraction includes η from η' decays.

[c] Two times (to include μ decays) the $\eta' e^+ \nu_e$ branching fraction, plus the $\eta' \pi^+, \eta' \rho^+,$ and $\eta' K^+$ fractions, is (18.6 ± 2.3) %, which considerably exceeds the inclusive η' fraction of (11.7 ± 1.8) %. Our best guess is that the $\eta' \rho^+$ fraction, (12.5 ± 2.2) %, is too large.

[d] This branching fraction includes all the decay modes of the final-state resonance.

[e] A test for $u\bar{u}$ or $d\bar{d}$ content in the D_s^+ . Neither Cabibbo-favored nor Cabibbo-suppressed decays can contribute, and ω - ϕ mixing is an unlikely explanation for any fraction above about 2×10^{-4} .

[f] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers.

[g] We decouple the $D_s^+ \rightarrow \phi \pi^+$ branching fraction obtained from mass projections (and used to get some of the other branching fractions) from the $D_s^+ \rightarrow \phi \pi^+, \phi \rightarrow K^+ K^-$ branching fraction obtained from the Dalitz-plot analysis of $D_s^+ \rightarrow K^+ K^- \pi^+$. That is, the ratio of these two branching fractions is not exactly the $\phi \rightarrow K^+ K^-$ branching fraction 0.491.

[h] This is the average of a model-independent and a K -matrix parametrization of the $\pi^+ \pi^-$ S -wave and is a sum over several f_0 mesons.

[i] This mode is not a useful test for a $\Delta C=1$ weak neutral current because both quarks must change flavor in this decay.

[j] This is *not* a test for the $\Delta C=1$ weak neutral current, but leads to the $\pi^+ \ell^+ \ell^-$ final state.

 D_s^\pm

CONSTRAINED FIT INFORMATION

An overall fit to 14 branching ratios uses 18 measurements and one constraint to determine 12 parameters. The overall fit has a $\chi^2 = 8.1$ for 7 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\langle \delta x_i \delta x_j \rangle / (\delta x_i \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

D_s^+ BRANCHING FRACTIONS

Updated November 2015 by J.L. Rosner (University of Chicago) and C.G. Wohl (LBNL).

Figure 1 shows a partial breakdown of the D_s^+ branching fractions. The rest of this note is about how the figure was constructed. The values shown make heavy use of CLEO measurements of inclusive branching fractions [1]. For references to other data cited in the following, see the Listings.

Modes with leptons: The bottom ($19.9 \pm 0.9\%$) of Fig. 1 shows the fractions for the modes that include leptons. Measured $Xe^+\nu_e$ semileptonic fractions have been doubled to include the $X\mu^+\nu_\mu$ fractions. The sum of the exclusive $Xe^+\nu_e$ fractions is $(6.9 \pm 0.4)\%$, consistent with an inclusive semileptonic measurement of $(6.5 \pm 0.4)\%$. There seems to be little missing here.

Inclusive hadronic $K\bar{K}$ fractions: The Cabibbo-favored $c \rightarrow s$ decay in D_s^+ decay produces a final state with both an s and an \bar{s} ; and thus modes with a $K\bar{K}$ pair or with an η , ω , η' , or ϕ predominate (as may already be seen in Fig. 1 in the semileptonic fractions). We consider the $K\bar{K}$ modes first. A complete picture of the exclusive $K\bar{K}$ charge modes is not yet possible, because branching fractions for many of those modes have not yet been measured. However, CLEO has measured the inclusive K^+ , K^- , K_S^0 , K^+K^- , $K^+K_S^0$, $K^-K_S^0$, and $2K_S^0$ fractions (these include modes with leptons) [1]. And each of these inclusive fractions with a K_S^0 is equal to the corresponding fraction with a K_L^0 : $f(K^+K_L^0) = f(K^+K_S^0)$, $f(2K_L^0) = f(2K_S^0)$, etc. Therefore, of all inclusive fractions pairing a K^+ , K_S^0 , or K_L^0 with a K^- , K_S^0 , or K_L^0 , we know all but $f(K_S^0K_L^0)$.

We can get that fraction. The total K_S^0 fraction is

$$f(K_S^0) = f(K^+K_S^0) + f(K^-K_S^0) + 2f(2K_S^0) + f(K_S^0K_L^0) + f(\text{single } K_S^0),$$

where $f(\text{single } K_S^0)$ is the sum of the branching fractions for modes such as $K_S^0\pi^+2\pi^0$ with a K_S^0 and no second K . The $K_S^0\pi^+2\pi^0$ mode is in fact the only unmeasured single- K_S^0 mode

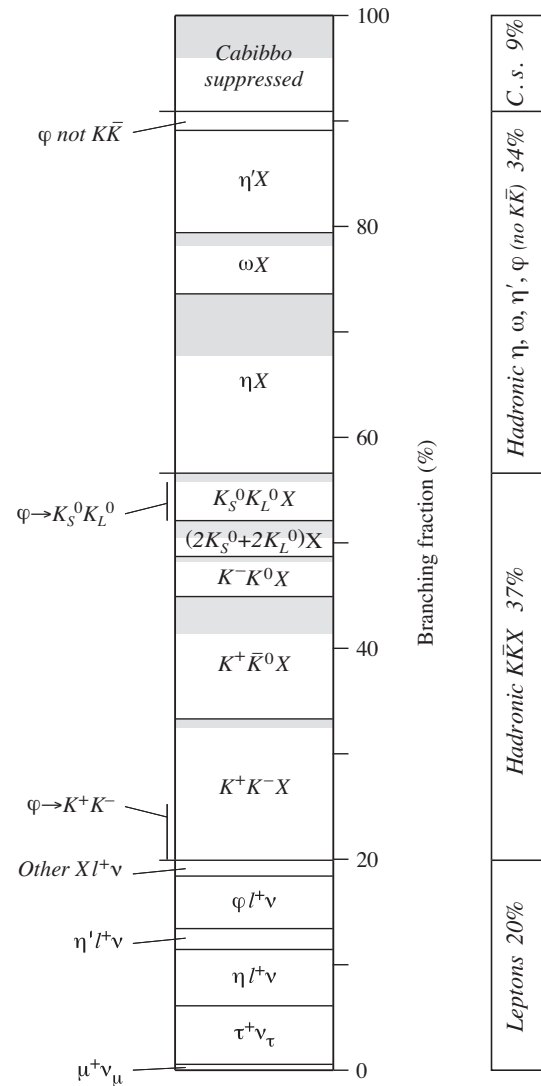

Figure 1: A partial breakdown of D_s^+ branching fractions. The hadronic bins in the left column show inclusive fractions. Shading within a bin shows how much of the inclusive fraction is not yet accounted for by adding up all the relevant exclusive fractions. The inclusive hadronic ϕ fraction is spread over three bins, in proportion to its decay fractions into K^+K^- , $K_S^0K_L^0$, and no- $K\bar{K}$ modes.

(throughout, we shall assume that fractions for modes with a K or $K\bar{K}$ and more than three pions are negligible), and we shall take its fraction to be the same as for the $K_S^0 2\pi^+\pi^-$ mode, $(0.30 \pm 0.11)\%$. Any reasonable deviation from this value would be too small to matter much in the following. Adding the several small single- K_S^0 branching fractions, including those from semileptonic modes, we get $f(\text{single } K_S^0) = (1.65 \pm 0.26)\%$.

Using this, we have:

$$\begin{aligned} f(K_S^0K_L^0) &= f(K_S^0) - f(K^+K_S^0) - f(K^-K_S^0) \\ &\quad - 2f(2K_S^0) - f(\text{single } K_S^0) \\ &= (19.0 \pm 1.1) - (5.8 \pm 0.5) - (1.9 \pm 0.4) \end{aligned}$$

$$\begin{aligned} & -2 \times (1.7 \pm 0.3) - (1.7 \pm 0.3) \\ & = (6.2 \pm 1.4)\% . \end{aligned}$$

Here and below we treat the errors as uncorrelated, although often they are not. However, our main aim is to get numbers for Fig. 1; errors are secondary.

There is a check on our result: The ϕ inclusive branching fraction is $(15.7 \pm 1.0)\%$, of which 34%, or $(5.34 \pm 0.34)\%$ of D_s^+ decays, produces a $K_S^0 K_L^0$. Our $f(K_S^0 K_L^0) = (6.2 \pm 1.4)\%$ has to be at least this large—and it is.

We now have all the inclusive $K\bar{K}$ fractions. We use $f(K^+ \bar{K}^0) = 2 f(K^+ K_S^0)$, and likewise for $f(K^- K^0)$. For $K^+ K^-$ and $K_S^0 K_L^0$, we subtract off the contributions from $\phi \ell^+ \nu$ decay to get the purely hadronic $K\bar{K}$ inclusive fractions:

$$\begin{aligned} f(K^+ K^-, \text{hadronic}) &= (15.8 \pm 0.7) - (2.44 \pm 0.14) \\ &= (13.4 \pm 0.7)\% \\ f(K^+ \bar{K}^0, \text{hadronic}) &= (11.6 \pm 1.0)\% \\ f(K^- K^0, \text{hadronic}) &= (3.8 \pm 0.8)\% \\ f(2K_S^0 + 2K_L^0, \text{hadronic}) &= (3.4 \pm 0.64)\% \\ f(K_S^0 K_L^0, \text{hadronic}) &= (6.2 \pm 1.4) - (1.70 \pm 0.10) \\ &= (4.5 \pm 1.4)\% . \end{aligned}$$

The fractions are shown in Fig. 1. They total $(36.7 \pm 2.1)\%$ of D_s^+ decays.

We can add more information to the figure by summing up measured branching fractions for exclusive modes within each bin:

$K^+ K^-$ modes—The sum of measured $K^+ K^- \pi^+$, $K^+ K^- \pi^+ \pi^0$, and $K^+ K^- 2\pi^+ \pi^-$ branching fractions is $(12.6 \pm 0.6)\%$. That leaves $(0.8 \pm 0.9)\%$ for the $K^+ K^- \pi^+ 2\pi^0$ mode, which is the only other $K^+ K^-$ mode with three or fewer pions. In Fig. 1, this unmeasured part of the $K^+ K^-$ bin is shaded.

$K^+ \bar{K}^0$ modes—Two times the sum of the measured $K^+ K_S^0$, $K^+ K_S^0 \pi^0$, and $K^+ K_S^0 \pi^+ \pi^-$ branching fractions is $(8.1 \pm 0.5)\%$. This leaves $(3.5 \pm 1.1)\%$ for the unmeasured $K^+ \bar{K}^0$ modes (there are three such modes with three or fewer pions). This is shaded in the figure.

$K^- K^0$ modes—Twice the $K^- K_S^0 2\pi^+$ fraction is $(3.34 \pm 0.20)\%$, which leaves about $(0.5 \pm 0.8)\%$ for $K^- K^0 2\pi^+ \pi^0$, the only other $K^- K^0$ mode with three or fewer pions.

$2K_S^0 + 2K_L^0$ modes—The $2K_S^0 \pi^+$ and $2K_S^0 2\pi^+ \pi^-$ fractions sum to $(0.86 \pm 0.07)\%$; this times two (for the corresponding $2K_L^0$ modes) is $(1.72 \pm 0.14)\%$. This leaves about $(1.7 \pm 0.7)\%$ for other $2K_S^0 + 2K_L^0$ modes.

$K_S^0 K_L^0$ modes—Most of the $K_S^0 K_L^0$ fraction is accounted for by ϕ decays (see below).

Inclusive hadronic η , ω , η' , and ϕ fractions: These are easier. We start with the inclusive branching fractions, and then, to avoid double counting, subtract: (1) fractions for modes

with leptons; (2) η mesons that are included in the inclusive η' fraction; and (3) $K^+ K^-$ and $K_S^0 K_L^0$ from ϕ decays:

$$\begin{aligned} f(\eta \text{ hadronic}) &= f(\eta \text{ inclusive}) - 0.65 f(\eta' \text{ inclusive}) \\ -f(\eta \ell^+ \nu) &= (17.0 \pm 3.1)\% \\ f(\omega \text{ hadronic}) &= f(\omega \text{ inclusive}) - 0.0275 f(\eta' \text{ inclusive}) \\ &= (5.8 \pm 1.4)\% \\ f(\eta' \text{ hadronic}) &= f(\eta' \text{ inclusive}) - f(\eta' \ell^+ \nu) \\ &= (9.7 \pm 1.9)\% \\ f(\phi \text{ hadronic, } \not\rightarrow K\bar{K}) &= 0.17 [f(\phi \text{ inclusive}) - f(\phi \ell^+ \nu)] \\ &= (1.8 \pm 0.2)\% . \end{aligned}$$

The factors 0.65, 0.0275, and 0.17 are the $\eta' \rightarrow \eta$, $\eta' \rightarrow \omega$, and $\phi \not\rightarrow K\bar{K}$ branching fractions. Figure 1 shows the results; the sum is $(34.2 \pm 3.9)\%$, which is about equal to the hadronic $K\bar{K}$ total.

Note that the bin marked ϕ near the top of Fig. 1 includes neither the $\phi \ell^+ \nu$ decays nor the 83% of other ϕ decays that produce a $K\bar{K}$ pair. There is twice as much ϕ in the $K_S^0 K_L^0$ bin, and nearly three times as much in the $K^+ K^-$ bin. These contributions are indicated in those bins.

Again, we can show how much of each bin is accounted for by measured exclusive branching fractions:

η modes—The sum of $\eta \pi^+$, $\eta \rho^+$, and ηK^+ branching fractions is $(11.1 \pm 1.2)\%$, which leaves a good part of the inclusive hadronic η fraction, $(17.0 \pm 3.1)\%$, to be accounted for. This is shaded in the figure.

ω modes—The sum of $\omega \pi^+$, $\omega \pi^+ \pi^0$, and $\omega 2\pi^+ \pi^-$ fractions is $(4.6 \pm 0.9)\%$, which is nearly as large as the inclusive hadronic ω fraction, $(5.8 \pm 1.4)\%$.

η' modes—The sum of $\eta' \pi^+$, $\eta' \rho^+$, and $\eta' K^+$ fractions is $(9.7 \pm 1.9)\%$, which agrees with the inclusive hadronic η' fraction, $(9.7 \pm 1.9)\%$. (An old measurement of the $\eta' \rho^+$ fraction, $(12.5 \pm 2.2)\%$, has been abandoned [2].)

Cabibbo-suppressed modes: The sum of the fractions for modes with a $K\bar{K}$, η , ω , η' , or leptons is $(90.8 \pm 4.5)\%$. The remaining $(9.2 \pm 4.5)\%$ is to Cabibbo-suppressed modes, mainly single- K + pions and multiple-pion modes (see below). However, it should be noted that some small parts of the modes already discussed are Cabibbo-suppressed. For example, the $(1.10 \pm 0.24)\%$ of D_s^+ decays to $K^0 \ell \nu$ or $K^{*0} \ell \nu$ is already in the $X \ell \nu$ bin in Fig. 1. And the inclusive measurements of η , ω , and η' fractions do not distinguish between (and therefore include both) Cabibbo-allowed and -suppressed modes. We shall not try to make a separation here.

$K^0 + \text{pions}$ —Above, we found that $f(\text{single } K_S^0) = (1.65 \pm 0.26)\%$. Subtracting leptonic fractions with a K_S^0 leaves $(1.22 \pm 0.28)\%$. The hadronic single- K^0 fraction is twice this, $(2.44 \pm 0.56)\%$. The sum of measured $K^0 \pi^+$, $K^0 \pi^+ \pi^0$, and $K^0 2\pi^+ \pi^-$ fractions is $(1.84 \pm 0.28)\%$.

$K^+ + \text{pions}$ —The $K^+ \pi^0$ and $K^+ \pi^+ \pi^-$ fractions sum to $(0.72 \pm 0.05)\%$. Much of the $K^+ n\pi$ modes, where $n \geq 3$, is

Meson Particle Listings

 D_s^\pm

already in the η , ω , and η' bins, and the rest is not measured. The total K^+ fraction wanted here is probably in the 1-to-2% range.

Multi-pions—The $2\pi^+\pi^-$, $\pi^+2\pi^0$, and $3\pi^+2\pi^-$ fractions total $(2.54 \pm 0.16)\%$. Modes not measured might double this.

The sum of the actually measured fractions is $(5.1 \pm 0.3)\%$, which is not inconsistent with the Cabibbo-suppressed total of $(9.2 \pm 4.5)\%$.

A model: With CLEO about to publish inclusive branching fractions [1], Gronau and Rosner predicted those fractions using a “statistical isospin” model [3]. Consider, say, the $D_s^+ \rightarrow K\bar{K}\pi$ charge modes: the $K^+K^-\pi^+$ branching fraction is measured, the $K^+\bar{K}^0\pi^0$ and $K^0\bar{K}^0\pi^+$ fractions are not. The statistical isospin model assumes that all the independent isospin amplitudes for $D_s^+ \rightarrow K\bar{K}\pi$ decay are equal in magnitude and incoherent in phase—in which case, the ratio of the three fractions here is 3:3:2. (Actually, use was also made of the fact that $D_s^+ \rightarrow K\bar{K}\pi$ decay is dominated by $\phi\pi^+$, $K^+\bar{K}^{*0}$, and $K^{*+}\bar{K}^0$ submodes; but the estimated charge-mode ratios were not far from 3:3:2.) A different, quark-antiquark pair-production model was used to estimate systematic uncertainties.

In this way, unmeasured exclusive fractions were calculated from measured exclusive fractions (the latter were taken from the 2008 Review, and so did not benefit from recent results). In the hadronic sector, the measured total of 59.4% of D_s^+ decays led to an estimated total of 24.2% for unmeasured modes. Weighted counts of π^+ , K_S^0 , etc., were then made to get the inclusive fractions.

Of interest here is that the sum of all the exclusive fractions—a way-stop in getting the inclusive values—was a nearly correct 103%. In the absence of complete measurements, the model is a way to, in effect, average over ignorance. It probably works better summed over a number of charge-mode sets than in detail. It is known to sometimes give incorrect results when there are sufficient measurements to test it.

———— Leptonic and semileptonic modes ————

LEPTONIC DECAYS OF CHARGED PSEUDO-SCALAR MESONS

Revised March 2016 by J. Rosner (Univ. Chicago), S. Stone (Syracuse Univ.), and R. Van de Water (FNAL).

We review the physics of purely leptonic decays of π^\pm , K^\pm , D^\pm , D_s^\pm , and B^\pm pseudoscalar mesons. The measured decay rates are related to the product of the relevant weak-interaction-based CKM matrix element of the constituent quarks and a strong interaction parameter related to the overlap of the quark and antiquark wave-functions in the meson, called the decay constant f_P . The leptonic decay constants for π^\pm , K^\pm , D^\pm , D_s^\pm , and B^\pm mesons can be obtained with controlled theoretical uncertainties and high precision from *ab initio* lattice-QCD simulations. The combination of experimental leptonic decay-rate measurements and theoretical decay-constant calculations enables the determination of several elements of the CKM matrix within the standard model. These determinations are competitive with those obtained from semileptonic decays, and also complementary because they are sensitive to axial-vector (as opposed to vector) quark flavor-changing currents. They can also be used to test the unitarity of the first and second rows of the CKM matrix. Conversely, taking the CKM elements predicted by unitarity, one can infer “experimental” values for f_P that can be compared with theory. These provide tests of lattice-QCD methods, provided new-physics contributions to leptonic decays are negligible at the current level of precision. This review was prepared for the Particle Data Group’s 2016 edition, updating the versions in Refs. 1–3.

I. INTRODUCTION

Charged mesons formed from a quark and an antiquark can decay to a charged lepton pair when these objects annihilate via a virtual W boson. Fig. 1 illustrates this process for the purely leptonic decay of a D^+ meson.

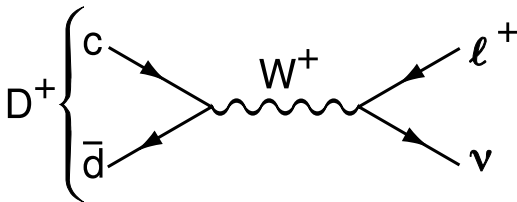

Figure 1: The annihilation process for pure D^+ leptonic decays in the Standard Model.

Similar quark-antiquark annihilations via a virtual W^+ to the $\ell^+\nu$ final states occur for the π^+ , K^+ , D_s^+ , and B^+ mesons. (Whenever pseudoscalar-meson charges are specified in this article, use of the charge-conjugate particles and corresponding decays are also implied.) Let P be any of these pseudoscalar mesons. To lowest order, the decay width is

$$\Gamma(P \rightarrow \ell\nu) = \frac{G_F^2}{8\pi} f_P^2 m_\ell^2 M_P \left(1 - \frac{m_\ell^2}{M_P^2}\right)^2 |V_{q_1 q_2}|^2. \quad (1)$$

Here M_P is the P mass, m_ℓ is the ℓ mass, $V_{q_1 q_2}$ is the Cabibbo-Kobayashi-Maskawa (CKM) matrix element between the constituent quarks $q_1 \bar{q}_2$ in P , and G_F is the Fermi coupling constant. The decay constant f_P is proportional to the matrix element of the axial current between the one- P -meson state and the vacuum:

$$\langle 0 | \bar{q}_1 \gamma_\mu \gamma_5 q_2 | P(p) \rangle = i p_\mu f_P, \quad (2)$$

and can be thought of as the “wavefunction overlap” of the quark and antiquark. In this article we use the convention in which $f_\pi \approx 130$ MeV.

The decay P^\pm starts with a spin-0 meson, and ends up with a left-handed neutrino or right-handed antineutrino. By angular momentum conservation, the ℓ^\pm must then also be left-handed or right-handed, respectively. In the $m_\ell = 0$ limit, the decay is forbidden, and can only occur as a result of the finite ℓ mass. This helicity suppression is the origin of the m_ℓ^2 dependence of the decay width. Radiative corrections are needed when the final charged particle is an electron or muon; for the τ they are greatly suppressed due to the large lepton mass, and hence negligible.

Measurements of purely leptonic decay branching fractions and lifetimes allow an experimental determination of the product $|V_{q_1 q_2}| f_P$. If the decay constant f_P is known to sufficient precision from theory, one can obtain the corresponding CKM element within the standard model. If, on the other hand, one takes the value of $|V_{q_1 q_2}|$ assuming CKM unitarity, one can infer an “experimental measurement” of the decay constant that can then be compared with theory.

The importance of measuring $\Gamma(P \rightarrow \ell\nu)$ depends on the particle being considered. Leptonic decays of charged pseudoscalar mesons occur at tree level within the standard model. Thus one does not expect large new-physics contributions to measurements of $\Gamma(P \rightarrow \ell\nu)$ for the lighter mesons $P = \pi^+, K^+$, and these processes in principle provide clean standard-model determinations of V_{ud} and V_{us} . The situation is different for leptonic decays of charm and bottom mesons. The presence of new heavy particles such as charged Higgs bosons or leptoquarks could lead to observable effects in $\Gamma(P \rightarrow \ell\nu)$ for $P = D_{(s)}^+, B^+$ [4–8]. Thus the determination of $|V_{ub}|$ from $B^+ \rightarrow \tau\nu$ decay, in particular, should be considered a probe of new physics. More generally, the ratio of leptonic decays to $\tau\nu$ over $\mu\nu$ final states probes lepton universality [4,9].

The determinations of CKM elements from leptonic decays of charged pseudoscalar mesons provide complementary

Meson Particle Listings

D_s^\pm

information to those from other decay processes. The decay $P \rightarrow \ell\nu$ proceeds in the standard model via the axial-vector current $\bar{q}_1\gamma_\mu\gamma_5q_2$, whereas semileptonic pseudoscalar meson decays $P_1 \rightarrow P_2\ell\nu$ proceed via the vector current $\bar{q}_1\gamma_\mu q_2$. Thus the comparison of determinations of $|V_{q_1q_2}|$ from leptonic and semileptonic decays tests the $V - A$ structure of the standard-model electroweak charged-current interaction. More generally, a small right-handed admixture to the standard-model weak current would lead to discrepancies between $|V_{q_1q_2}|$ obtained from leptonic pseudoscalar-meson decays, exclusive semileptonic pseudoscalar-meson decays, exclusive semileptonic baryon decays, and inclusive semileptonic decays [10,11].

Both measurements of the decay rates $\Gamma(P \rightarrow \ell\nu)$ and theoretical calculations of the decay constants f_P for $P = \pi^+, K^+, D_{(s)}^+$ from numerical lattice-QCD simulations are now quite precise. As a result, the elements of the first row of the CKM matrix $|V_{ud}|$ and $|V_{us}|$ can be obtained to sub-percent precision from $\pi^+ \rightarrow \ell\nu$ and $K^+ \rightarrow \ell\nu$, where the limiting error is from theory. The elements of the second row of the CKM matrix $|V_{cd(s)}|$ can be obtained from leptonic decays of charged pseudoscalar mesons to few-percent precision, where here the limiting error is from experiment. These enable stringent tests of the unitarity of the first and second rows of the CKM matrix.

This review is organized as follows. Because the experimental and theoretical issues associated with measurements of pions and kaons, charmed mesons, and bottom mesons differ, we discuss each one separately. We begin with the pion and kaon system in Sec. II. First, in Sec. II.A we review current measurements of the experimental decay rates. We provide tables of branching-ratio measurements and determinations of the product $|V_{ud(s)}|f_{\pi^+(K^+)}$, as well as average values for these quantities including correlations and other effects needed to combine results. Then, in Sec. II.B we summarize the status of theoretical calculations of the decay constants. We provide tables of recent lattice-QCD results for f_{π^+} , f_{K^+} , and their ratio from simulations including dynamical u, d, s , and (in some cases c) quarks, and present averages for each of these quantities including correlations and strong $SU(2)$ -isospin corrections as needed. We note that, for the leptonic decay constants in Sec. II.B, Sec. III.B, and Sec. IV.B, when available we use preliminary averages from the Flavor Lattice Averaging Group [12,13] that update the determinations in Ref. 14 to include results that have appeared since their most recent review, which dates from 2013. We next discuss the charmed meson system in Sec. III, again reviewing current experimental rate measurements in Sec. III.A and theoretical decay-constant calculations in Sec. III.B. Last, we discuss the bottom meson system in Sec. IV, following the same organization as the two previous sections.

After having established the status of both experimental measurements and theoretical calculations of leptonic charged pseudoscalar-meson decays, we discuss some implications for phenomenology in Sec. V. We combine the average $\mathcal{B}(P \rightarrow \ell\nu)$ with the average f_P to obtain the relevant CKM elements from

leptonic decays, and then compare them with determinations from other processes. We also use the CKM elements obtained from leptonic decays to test the unitarity of the first and second rows of the CKM matrix. Further, as in previous reviews, we combine the experimental $\mathcal{B}(P \rightarrow \ell\nu)$ s with the associated CKM elements obtained from CKM unitarity to infer “experimental” values for the decay constants; the comparison with theory provides a test of lattice and other QCD approaches assuming that new-physics contributions to these processes are not significant.

II. PIONS AND KAONS

A. Experimental rate measurements

The leading-order expression for $\Gamma(P \rightarrow \ell\nu)$ in Eq. (1) is modified by radiative corrections arising from diagrams involving photons, in some cases with additional quark loops. These electroweak and “hadronic” contributions can be combined into an overall factor that multiplies the rate in the presence of only the strong interaction ($\Gamma^{(0)}$) as follows (cf. Refs. 15,16, and references therein):

$$\Gamma(P \rightarrow \ell\nu) = \Gamma^{(0)} \left[1 + \frac{\alpha}{\pi} C_P \right], \quad (3)$$

where C_P differs for $P = \pi, K$. The inclusion of these corrections is numerically important given the level of precision achieved on the experimental measurements of the $\pi^\pm \rightarrow \mu^\pm\nu$ and $K^\pm \rightarrow \mu^\pm\nu$ decay widths. The explicit expression for the term in brackets above including all known electroweak and hadronic contributions is given in Eq. (114) of Ref. 17. It includes the universal short-distance electroweak correction obtained by Sirlin [18], the universal long-distance correction for a point-like meson from Kinoshita [19], and corrections that depend on the hadronic structure [20]. We evaluate $\delta_P \equiv (\alpha/\pi)C_P$ using the latest experimentally-measured meson and lepton masses and coupling constants from the Particle Data Group [3], and taking the low-energy constants (LECs) that parameterize the hadronic contributions from Refs. 17,21,22. The finite non-logarithmic parts of the LECs were estimated within the large- N_C approximation assuming that contributions from the lowest-lying resonances dominate. We therefore conservatively assign a 100% uncertainty to the LECs, which leads to a ± 0.9 error in $C_{\pi,K}$.¹ We obtain the following correction factors to the individual charged pion and kaon decay widths:

$$\delta_\pi = 0.0176(21) \quad \text{and} \quad \delta_K = 0.0107(21). \quad (4)$$

¹ This uncertainty on $C_{\pi,K}$ is smaller than the error estimated by Marciano and Sirlin in Ref. 23, which predates the calculations of the hadronic-structure contributions in Refs. 17, 20–22. The hadronic LECs incorporate the large short-distance electroweak logarithm discussed in Ref. 23, and their dependence on the chiral renormalization scale cancels the scale-dependence induced by chiral loops, thereby removing the dominant scale uncertainty of the Marciano–Sirlin analysis [23].

The error on the ratio of kaon-to-pion leptonic decay widths is under better theoretical control because the hadronic contributions from low-energy constants estimated within the large- N_c framework cancel at lowest order in the chiral expansion. For the ratio, we use the correction factor

$$\delta_{K/\pi} = -0.0069(17), \quad (5)$$

where we take the estimated error due to higher-order corrections in the chiral expansion from Ref. 24.

The sum of branching fractions for $\pi^- \rightarrow \mu^- \bar{\nu}$ and $\pi^- \rightarrow \mu^- \bar{\nu} \gamma$ is 99.98770(4)% [3]. The two modes are difficult to separate experimentally, so we use this sum. Together with the lifetime 26.033(5) ns [3] this implies $\Gamma(\pi^- \rightarrow \mu^- \bar{\nu}[\gamma]) = 3.8408(7) \times 10^7 \text{ s}^{-1}$. The right-hand side of Eq. (1) is modified by the factor 1.0176 ± 0.0021 mentioned above to include photon emission and radiative corrections [23,25]. The decay rate together with the masses from the 2014 PDG review [3] gives

$$f_{\pi^-} |V_{ud}| = (127.13 \pm 0.02 \pm 0.13) \text{ MeV}, \quad (6)$$

where the errors are from the experimental rate measurement and the radiative correction factor δ_π in Eq. (4), respectively. The uncertainty is dominated by that from theoretical estimate of the hadronic structure-dependent radiative corrections, which include next-to-leading order contributions of $\mathcal{O}(e^2 p_{\pi,K}^2)$ in chiral perturbation theory [17].

The data on $K_{\mu 2}$ decays have been updated recently through a global fit to branching ratios and lifetime measurements [26]: $\mathcal{B}(K^- \rightarrow \mu^- \bar{\nu}[\gamma]) = 63.58(11)\%$ and $\tau_{K^\pm} = 12.384(15) \text{ ns}$. The improvement in the branching ratio is primarily due to a new measurement of $\mathcal{B}(K^\pm \rightarrow \pi^\pm \pi^+ \pi^-)$ from KLOE-2 [27], which is correlated with $\mathcal{B}(K_{\mu 2}^\pm)$ through the constraint that the sum of individual branching ratios must equal unity. The sum of branching fractions for $K^- \rightarrow \mu^- \bar{\nu}$ and $K^- \rightarrow \mu^- \bar{\nu} \gamma$ and the lifetime imply $\Gamma(K^- \rightarrow \mu^- \bar{\nu}[\gamma]) = 5.134(11) \times 10^7 \text{ s}^{-1}$. Again taking the 2014 PDG masses [3], this decay rate implies

$$f_{K^+} |V_{us}| = (35.09 \pm 0.04 \pm 0.04) \text{ MeV}, \quad (7)$$

where the errors are from the experimental rate measurement and the radiative correction factor δ_K , respectively.

Short-distance radiative corrections cancel in the ratio of pion-to-kaon decay rates [28]:

$$\frac{\Gamma_{K_{\ell 2}[\gamma]}}{\Gamma_{\pi_{\ell 2}[\gamma]}} = \frac{|V_{us}|^2 f_{K^-}^2 m_K (1 - m_\ell^2/m_K^2)^2}{|V_{ud}|^2 f_{\pi^-}^2 m_\pi (1 - m_\ell^2/m_\pi^2)^2} (1 + \delta_{K/\pi}), \quad (8)$$

where $\delta_{K/\pi}$ is given in Eq. (5). The left-hand side of Eq. (8) is 1.3367(28), yielding

$$\frac{|V_{us}| f_{K^-}}{|V_{ud}| f_{\pi^-}} = 0.27599 \pm 0.00029 \pm 0.00024, \quad (9)$$

where the first uncertainty is due to the branching fractions and the second is due to $\delta_{K/\pi}$. Here the estimated error on the hadronic structure-dependent radiative corrections is commensurate with the experimental error.

In summary, the main experimental results pertaining to charged pion and kaon leptonic decays are

$$|V_{ud}| f_{\pi^-} = (127.13 \pm 0.02 \pm 0.13) \text{ MeV}, \quad (10)$$

$$|V_{us}| f_{K^+} = (35.09 \pm 0.04 \pm 0.04) \text{ MeV}, \quad (11)$$

$$\frac{|V_{us}| f_{K^+}}{|V_{ud}| f_{\pi^-}} = 0.27599 \pm 0.00029 \pm 0.00024, \quad (12)$$

where the errors are from the experimental uncertainties in the branching fractions and the theoretical uncertainties in the radiative correction factors δ_P , respectively.

B. Theoretical decay-constant calculations

Table 1 presents recent lattice-QCD calculations of the charged pion and kaon decay constants and their ratio from simulations with three ($N_f = 2+1$) or four flavors ($N_f = 2+1+1$) of dynamical quarks. The results have been obtained using several independent sets of gauge-field configurations, and a variety of lattice fermion actions that are sensitive to different systematic uncertainties.² The lattice-QCD uncertainties on both the individual decay constants and their ratio have now reached sub-percent precision. The SU(3)-breaking ratio f_{K^+}/f_{π^+} can be obtained with especially small errors because statistical errors associated with the Monte Carlo simulations are correlated between the numerator and denominator, as are some systematics. The good agreement between these largely independent determinations indicates that the lattice-QCD uncertainties are controlled and that the associated error estimates are reliable.³

Table 1 also shows the 2015 preliminary three- and four-flavor averages for the pion and kaon decay constants and their ratio from the Flavour Lattice Averaging Group (FLAG) [12,13] in the lines labeled ‘‘FLAG 15 average.’’ These preliminary updates of the 2013 FLAG averages [14] include only those results from Table 1 that are published in refereed journals, or that are straightforward conference updates of published analyses. In the (2+1+1)-flavor averages, the statistical errors of HPQCD and Fermilab/MILC were conservatively treated as 100% correlated because the calculations employed some of the same gauge-field configurations. The errors have also been increased by the $\sqrt{\chi^2/\text{dof}}$ to reflect a slight tension between the results. There are no four-flavor lattice-QCD results for the pion decay constant in Table 1 because all of the calculations listed use the quantity f_{π^+} to fix the absolute lattice scale needed to convert from lattice-spacing units to GeV [31–33].

² See the PDG mini-review on ‘‘Lattice Quantum Chromodynamics’’ [29] for a general review of numerical lattice-QCD simulations. Details on the different methods used in modern lattice-QCD calculations are provided in Appendix A of the FLAG ‘‘Review of lattice results concerning low energy particle physics’’ [14].

³ The recent review [30] summarizes the large body of evidence validating the methods employed in modern lattice-QCD simulations.

 D_s^\pm

Table 1: Recent lattice-QCD results for f_{π^+} , f_{K^+} , and their ratio. The upper and lower panels show $(2+1+1)$ -flavor and $(2+1)$ -flavor determinations, respectively. When two errors are shown, they are statistical and systematic, respectively. Results for f_π and f_K in the isospin-symmetric limit $m_u = m_d$ are noted with an “*”; they are corrected for isospin breaking via Eq. (13)–Eq. (15) before computing the averages. Unpublished results noted with a “†” or “‡” are not included in the averages.

‡ Lattice 2011 conference proceedings.

All of the results in Table 1 were obtained using isospin-symmetric gauge-field configurations, *i.e.*, the dynamical up and down quarks have the same mass. Most calculations of pion and kaon decay constants now include the dominant effect of nondegenerate up- and down-quark masses by evaluating the masses of the constituent light (valence) quarks in the pion at the physical up- and down-quark masses, respectively, and evaluating the mass of the valence light quark in the kaon at the physical m_u . Those results obtained with degenerate up and down valence quarks are corrected for isospin breaking using chiral perturbation theory (χ PT) before being averaged. The isospin-breaking corrections at next-to-leading order in χ PT can be parameterized as [24,40]

$$f_\pi = f_{\pi^+}, \quad (13)$$

$$f_K = f_{K^+} (1 - \delta_{\text{SU}(2)}/2), \quad (14)$$

$$\frac{f_K}{f_\pi} = \frac{1}{\sqrt{\delta_{\text{SU}(2)} + 1}} \frac{f_{K^+}}{f_{\pi^+}} \quad (15)$$

where the expression for $\delta_{\text{SU}(2)}$ in terms of the quark masses, meson masses, and decay constants, is given in Eq. (37) of Ref. 14. Numerically, values of $\delta_{\text{SU}(2)} \approx -0.004$ were employed by FLAG to obtain the $(2+1)$ -flavor averages in Table 1,

but some direct lattice-QCD calculations of $\delta_{\text{SU}(2)}$ give larger values [31,33,41] and further studies are needed.

To obtain the best decay-constant values for comparison with experimental rate measurements and other phenomenological applications, we combine the available $(2+1)$ - and $(2+1+1)$ -flavor lattice-QCD results, first accounting for the omission of charm sea quarks in the three-flavor simulations. The error introduced by omitting charm sea quarks can be roughly estimated by expanding the charm-quark determinant in powers of $1/m_c$ [42]; the resulting leading contribution is of order $\alpha_s (\Lambda_{\text{QCD}}/2m_c)^2$ [43]. Taking the $\overline{\text{MS}}$ values $\overline{m}_c(\overline{m}_c) = 1.275$ GeV, $\overline{\Lambda}_{\text{QCD}} \sim 340$ MeV from FLAG [14], and $\overline{\alpha}(\overline{m}_c) \sim 0.4$, leads to an estimate of about 0.7% for the contribution to the decay constants from charm sea quarks. The charm sea-quark contribution to ratios of decay constants is expected to be further suppressed by the $\text{SU}(3)$ -breaking factor $(m_s - m_d)/\Lambda_{\text{QCD}}$, and hence about 0.2%.

We can compare these power-counting estimates of charm sea-quark contributions to the observed differences between the $(2+1)$ - and $(2+1+1)$ -flavor lattice-QCD averages for kaon, $D_{(s)}$ -meson, and $B_{(s)}$ -decay constants and ratios in Table 1, Table 4, and Table 6. Of these, the kaon decay constants have been calculated most precisely, and the and three- and four-flavor averages for f_{K^+} and f_{K^+}/f_{π^+} agree within sub-percent errors. Within present uncertainties, however, effects of this

size in pseudoscalar-meson decay constants cannot be ruled out. Therefore, to be conservative, in this review we add in quadrature additional systematic errors of 0.7% and 0.2% to all (2+1)-flavor decay-constant and decay-constant-ratio averages, respectively, to account for the omission of charm sea quarks. Numerically, this increases the errors by at most about 50% for f_{K^+} and less for all other decay constants and ratios, indicating that the published (2+1)-flavor lattice-QCD results and uncertainties are reliable.

Our final preferred theoretical values for the charged pion and kaon decay constants are

$$\begin{aligned} \text{Our averages : } f_{\pi^+} &= 130.2(1.7) \text{ MeV,} \\ f_{K^+} &= 155.6(0.4) \text{ MeV,} \\ \frac{f_{K^+}}{f_{\pi^+}} &= 1.1928(26), \end{aligned} \quad (16)$$

where f_{π^+} is simply the (2+1)-flavor FLAG average with the error increased by the estimated 0.7% charm sea-quark contribution. For f_{K^+} and f_{K^+}/f_{π^+} , we take a simple weighted average of the (2+1)- and (2+1+1)-flavor FLAG values, because they are each obtained from a sufficient number of independent calculations that we do not expect there to be significant correlations. In practice, the addition of the charm sea-quark error has a tiny impact on our final values in Eq. (16), increasing the uncertainty on f_{π^+} by 0.3 MeV, and the central value for f_{K^+}/f_{π^+} by one in the last digit.

III. CHARMED MESONS

A. Experimental rate measurements

Measurements have been made for $D^+ \rightarrow \mu^+\nu$, $D_s^+ \rightarrow \mu^+\nu$, and $D_s^+ \rightarrow \tau^+\nu$. Only an upper limit has been determined for $D^+ \rightarrow \tau^+\nu$. Both CLEO-c and BES have made measurements of D^+ decay using e^+e^- collisions at the $\psi(3770)$ resonant energy where D^-D^+ pairs are copiously produced. They fully reconstruct one of the D 's, say the D^- . Counting the number of these events provides the normalization for the branching fraction measurement. They then find a candidate μ^+ , and then form the missing-mass squared, $MM^2 = (E_{\text{CM}} - E_{D^-})^2 - (\vec{p}_{\text{CM}} - \vec{p}_{D^-} - \vec{p}_{\mu^+})^2$, taking into account their knowledge of the center-of-mass energy, E_{CM} , and momentum, p_{CM} , that equals zero in e^+e^- collisions. A peak at zero MM^2 implies the existence of a missing neutrino and hence the $\mu^+\nu$ decay of the D^+ . CLEO-c does not explicitly identify the muon, so their data consists of a combination of $\mu^+\nu$ and $\tau^+\nu$, $\tau^+ \rightarrow \pi^+\nu$ events. This permits them to do two fits: in one they fit for the individual components, and in the other they fix the ratio of $\tau^+\nu/\mu^+\nu$ events to be that given by the standard-model expectation. Thus, the latter measurement should be used for standard-model comparisons and the other for new-physics searches. Our average uses the fixed ratio value. The measurements are shown in Table 2.

Table 2: Experimental results for $\mathcal{B}(D^+ \rightarrow \mu^+\nu)$, $\mathcal{B}(D^+ \rightarrow \tau^+\nu)$, and $|V_{cd}|f_{D^+}$. Numbers for $|V_{cd}|f_{D^+}$ have been extracted using updated values for masses (see text). Radiative corrections are included. Systematic uncertainties arising from the D^+ lifetime and mass are included. For the average $\mu^+\nu$ number we use the CLEO-c result for $\mu^+\nu + \tau^+\nu$.

Experiment	Mode	\mathcal{B}	$ V_{cd} f_{D^+}$ (MeV)
CLEO-c [44,45]	$\mu^+\nu$	$(3.93 \pm 0.35 \pm 0.09) \times 10^{-4}$	$47.07 \pm 2.10 \pm 0.57$
CLEO-c [44,45]	$\mu^+\nu + \tau^+\nu$	$(3.82 \pm 0.32 \pm 0.09) \times 10^{-4}$	$46.41 \pm 1.94 \pm 0.57$
BES [46]	$\mu^+\nu$	$(3.71 \pm 0.19 \pm 0.06) \times 10^{-4}$	$45.73 \pm 1.17 \pm 0.38$
Our average	Lines 2+3	$(3.74 \pm 0.17) \times 10^{-4}$	45.91 ± 1.05
CLEO-c [47,48]	$\tau^+\nu$	$< 1.2 \times 10^{-3}$	

To extract the value of $|V_{cd}|f_{D^+}$ we use the well-measured D^+ lifetime of 1.040(7) ps. The $\mu^+\nu$ results include a 1% correction (lowering) of the rate due to the presence of the radiative $\mu^+\nu\gamma$ final state based on the estimate by Dobrescu and Kronfeld [8].

We now discuss the D_s^+ . Measurements of the leptonic decay rate have been made by several groups and are listed in Table 3 [47–53]. We exclude older values obtained by normalizing to D_s^+ decay modes that are not well defined. Many measurements, for example, used the $\phi\pi^+$ mode. This decay is a subset of the $D_s^+ \rightarrow K^+K^-\pi^+$ channel which has interferences from other modes populating the K^+K^- mass region near the ϕ , the most prominent of which is the $f_0(980)$. Thus the extraction of the effective $\phi\pi^+$ rate is sensitive to the mass resolution of the experiment and the cuts used to define the ϕ mass region [54].⁴

To find decays in the $\mu^+\nu$ signal channels, CLEO, BaBar and Belle rely on fully reconstructing all the final state particles except for neutrinos and using a missing-mass technique to infer the existence of the neutrino. CLEO uses $e^+e^- \rightarrow D_s D_s^*$ collisions at 4170 MeV, while Babar and Belle use $e^+e^- \rightarrow DKn\pi D_s^*$ collisions at energies near the $\Upsilon(4S)$. CLEO does a similar analysis as was done for the D^+ above. Babar and Belle do a similar MM^2 calculation by using the reconstructed hadrons, the photon from the D_s^{*+} decay and a detected μ^+ . To get the normalization they do a MM^2 fit without the μ^+ and use the signal at the D_s^+ mass squared to determine the total D_s^+ yield.

When selecting the $\tau^+ \rightarrow \pi^+\bar{\nu}$ and $\tau^+ \rightarrow \rho^+\bar{\nu}$ decay modes, CLEO uses both the calculation of the missing mass and the fact that there should be no extra energy in the event beyond that deposited by the measured tagged D_s^- and the τ^+ decay products. The $\tau^+ \rightarrow e^+\nu\bar{\nu}$ mode, however, uses only extra energy. Babar and Belle also use the extra energy to discriminate signal from background in their $\tau^+\nu$ measurements.

⁴ We have not included the BaBar result for $\mathcal{B}(D_s^+ \rightarrow \mu^+\nu)$ reported in Ref. 55 because this measurement determined the ratio of the leptonic decay rate to the hadronic decay rate $\Gamma(D_s^+ \rightarrow \ell^+\nu)/\Gamma(D_s^+ \rightarrow \phi\pi^+)$.

Meson Particle Listings

 D_s^\pm

Table 3: Experimental results for $\mathcal{B}(D_s^+ \rightarrow \mu^+\nu)$, $\mathcal{B}(D_s^+ \rightarrow \tau^+\nu)$, and $|V_{cs}|f_{D_s^+}$. Numbers for $|V_{cs}|f_{D_s^+}$ have been extracted using updated values for masses (see text). The systematic uncertainty for correlated error on the D_s^+ lifetime is included. The mass uncertainties are also common, but negligible. Common systematic errors in each experiment have been taken into account in the averages.

Experiment	Mode	$\mathcal{B}(\%)$	$ V_{cs} f_{D_s^+}$ (MeV)
CLEO-c [47,48]	$\mu^+\nu$	$0.565 \pm 0.045 \pm 0.017$	$250.8 \pm 10.0 \pm 4.2$

Belle [49]	$\tau^+\nu$ ($\pi^+\bar{\nu}$)	$6.04 \pm 0.43^{+0.46}_{-0.40}$	$262.7 \pm 9.3^{+10.2}_{-8.9}$
Belle [49]	$\tau^+\nu$ ($e^+\nu\bar{\nu}$)	$5.37 \pm 0.33^{+0.35}_{-0.31}$	$247.7 \pm 7.6^{+8.3}_{-7.4}$
Belle [49]	$\tau^+\nu$ ($\mu^+\nu\bar{\nu}$)	$5.86 \pm 0.37^{+0.34}_{-0.59}$	$258.7 \pm 8.2^{+7.4}_{-13.2}$
Our average	$\tau^+\nu$	5.56 ± 0.22	252.1 ± 5.2
Our average	$\mu^+\nu + \tau^+\nu$		250.9 ± 4.0

^aWe do not use a previous unpublished BaBar result from a subsample of data that uses a different technique for obtaining the branching fraction normalization [56].

We extract the decay constant times the CKM factor from the measured branching ratios using the D_s^+ mass of 1.96830(11) GeV, the τ^+ mass of 1.77682(16) GeV, and a D_s^+ lifetime of 0.500(7) ps [3]. CLEO has included the radiative correction of 1% in the $\mu^+\nu$ rate listed in the Table [8] (the $\tau^+\nu$ rates need not be corrected). Other theoretical calculations show that the $\gamma\mu^+\nu$ rate is a factor of 40–100 below the $\mu^+\nu$ rate for charm [57–66]. As this is a small effect we do not attempt to correct the other measurements. The values for $f_{D_s^+}|V_{cs}|$ are in good agreement for the two decay modes. Our average value including both the $\mu^+\nu$ and $\tau^+\nu$ final states is 250.9 ± 4.0 MeV.

B. Theoretical decay-constant calculations

Table 4 presents recent theoretical calculations of the charged D^+ - and D_s -meson decay constants and their ratio. The upper two panels show results from lattice-QCD simulations with three ($N_f = 2 + 1$) or four flavors ($N_f = 2 + 1 + 1$) of dynamical quarks. Although there are fewer available results than for the pion and kaon sector, both f_{D^+} and f_{D_s} have been obtained using multiple sets of gauge-field configurations with different lattice fermion actions, providing independent confirmation. For comparison, the bottom panel of Table 4 shows non-lattice determinations from QCD sum rules and the light-front quark model; only results which include uncertainty estimates are shown. The lattice and non-lattice results agree, but the uncertainties on $D_{(s)}^+$ -meson decay constants from lattice QCD have now reached significantly greater precision than those from other approaches.

The lattice-QCD results in Table 4 were all obtained using isospin-symmetric gauge-field configurations. The two calculations by the Fermilab Lattice and MILC Collaborations [69,32], however, include the dominant strong isospin-breaking contribution by evaluating the mass of the valence light quark in the D^+ -meson decay constant at the physical down-quark mass. Reference 32 provides a determination of the size of this correction,

$$f_{D^+} - f_D = 0.47(1)_{(-6)}^{(+25)} \text{ MeV}, \quad (17)$$

where f_D is the value of the D -meson decay constant evaluated at the average up-down quark mass. Eq. (17) implies that the correction to the $SU(3)_f$ -breaking ratio is

$$\frac{f_{D_s}}{f_{D^+}} - \frac{f_{D_s}}{f_D} = -0.0026, \quad (18)$$

taking the central values for f_{D^+} and f_{D_s} from the same work. Because the errors on the calculations listed in Table 4 that neglect isospin breaking are still about 5–8 \times larger than the sizes of the shifts in Eqs. (17)–(18), we do not correct any results *a posteriori* for this effect in the current review. Nevertheless, we strongly encourage future lattice-QCD publications to present results for both the D^+ - and D^0 -meson decay constants. Including the effect of isospin breaking will be essential once lattice-QCD calculations of f_D and f_{D_s}/f_D reach the level of precision in Eqs. (17)–(18).

We average the lattice-QCD results in Table 4 accounting for possible correlations between them following the approach established by Laiho *et al.* [77]. Whenever we have reason to believe that a source of uncertainty is correlated between two

Table 4: Recent theoretical determinations of f_{D^+} , f_{D_s} , and their ratio. The upper panels show results from lattice-QCD simulations with $(2+1+1)$ and $(2+1)$ dynamical quark flavors, respectively. Statistical and systematic errors are quoted separately. Lattice-QCD results for f_D and f_{D_s}/f_D in the isospin-symmetric limit $m_u = m_d$ are noted with an “*”. The bottom panel shows estimates from QCD sum rules (QCD SR) and the light-front quark model (LFQM). These are not used to obtain our preferred decay-constant values.

§ Obtained using $m_c^{\overline{\text{MS}}}$; results using m_c^{pole} are also given in the paper.

¶ Obtained by combining PDG value $f_D = 205.8(8.9)$ MeV [76] with f_{D_s}/f_D from this work.

results, we conservatively take the correlation to be 100% when calculating the average. We then construct the correlation matrix for the set of lattice-QCD results using the prescription of Schmelling [78].

We first separately average the three- and four-flavor results for the charged $D_{(s)}^+$ -meson decay constants and their ratio. There have been no new three-flavor lattice-QCD calculations of f_{D^+} or $f_{D_s^+}/f_{D^+}$ since 2013, so we take the $(2+1)$ -flavor averages from FLAG [14]. In this average, the statistical errors were treated as 100% correlated between the results of Fermilab/MILC [69] and HPQCD [68] because the calculations employed some of the same ensembles of gauge-field configurations. For f_{D_s} , we average the $(2+1)$ -flavor results given in Table 4, again treating the Fermilab/MILC [69] and HPQCD [70] statistical errors as correlated, and taking the χ QCD result [67] to be independent. For the $(2+1+1)$ -flavor $D_{(s)}$ -meson decay constants, we take a simple weighted average of the ETM [31] and Fermilab/MILC 14 results [32] in Table 4. We expect them to be independent because the calculations use different light-quark and gluon actions and different treatments of the chiral-continuum extrapolation. Our separate three- and four-flavor averages are listed in the lines labeled “Average” in Table 4, where the errors on the $(2+1)$ -flavor f_{D_s} and

$(2+1+1)$ -flavor f_D averages have been rescaled by the factors $\sqrt{(\chi^2/\text{dof})} = 1.1$ and $\sqrt{(\chi^2/\text{dof})} = 1.3$, respectively.⁵

To obtain the single-best values of the $D_{(s)}^+$ -meson decay constants for phenomenology applications, we combine the available $(2+1)$ - and $(2+1+1)$ -flavor lattice-QCD results, which are compatible within the current level of precision. We account for the omission of charm sea-quark contributions in the three-flavor calculations by adding to the errors on the $(2+1)$ -flavor averages in Table 4 our power-counting estimates of charm sea-quark errors from Sec. II.B. Because the estimated charm sea-quark errors of 0.7% for decay constants and 0.2% for decay-constant ratios are less than those on the $(2+1)$ -flavor averages, adding them in quadrature has a small impact on the total uncertainties. The error increase is at most about 25% for f_{D_s} , and below 10% for both f_{D^+} and f_{D_s}/f_{D^+} . Our final preferred theoretical values for the charged $D_{(s)}^+$ -meson decay constants are given by the weighted average of the entries in the two lines labeled “Average” in Table 4, after including the additional charm sea-quark errors in the $(2+1)$ -flavor entries:

$$\text{Our averages : } f_{D^+} = 211.9(1.1) \text{ MeV ,}$$

⁵ After this article was submitted for review, preliminary $(2+1)$ - and $(2+1+1)$ -flavor FLAG averages for f_D , f_{D_s} , and f_{D_s}/f_D were presented in Ref. 79 that are identical to our separate averages in Table 4.

Meson Particle Listings

 D_s^\pm

$$f_{D_s} = 249.0(1.2) \text{ MeV},$$

$$\frac{f_{D_s}}{f_{D^+}} = 1.173(3). \quad (19)$$

In practice, the errors on the (2+1+1)-flavor averages are so much smaller than on the (2+1)-flavor averages that the combination in Eq. (19) is almost identical to the (2+1+1)-flavor average in Table 4. The most precise result from Fermilab/MILC, in particular, has a large weight in the average.

IV. BOTTOM MESONS

A. Experimental rate measurements

The Belle and BaBar collaborations have found evidence for $B^- \rightarrow \tau^- \bar{\nu}$ decay in $e^+e^- \rightarrow B^- B^+$ collisions at the $\Upsilon(4S)$ energy. The analysis relies on reconstructing a hadronic or semileptonic B decay tag, finding a τ candidate in the remaining track and photon candidates, and examining the extra energy in the event which should be close to zero for a real τ^- decay to $e^- \nu \bar{\nu}$ or $\mu^- \nu \bar{\nu}$ opposite a B^+ tag. While the BaBar results have remained unchanged, Belle reanalyzed both samples of their data. The branching fraction using hadronic tags changed from $1.79_{-0.49-0.51}^{+0.56+0.46} \times 10^{-4}$ [80] to $0.72_{-0.25}^{+0.27} \pm 0.11 \times 10^{-4}$ [81], while the corresponding change using semileptonic tags was from $1.54_{-0.37-0.31}^{+0.38+0.29}$ to $1.25 \pm 0.28 \pm 0.27$. These changes demonstrate the difficulty of the analysis. The results are listed in Table 5.

There are large backgrounds under the signals in all cases. The systematic errors are also quite large. Thus, the significances are not that large. Belle quotes 4.6σ for their combined hadronic and semileptonic tags, while BaBar quotes 3.3σ and 2.3σ , for hadronic and semileptonic tags. Greater precision is necessary to determine if any effects beyond the Standard Model are present.

Table 5: Experimental results for $\mathcal{B}(B^- \rightarrow \tau^- \bar{\nu})$ and $|V_{ub}|f_{B^+}$.

Experiment	Tag	\mathcal{B} (units of 10^{-4})	$ V_{ub} f_{B^+}$ (MeV)
Belle [81]	Hadronic	$0.72_{-0.25}^{+0.27} \pm 0.11$	
Belle [82]	Semileptonic	$1.25 \pm 0.28 \pm 0.27$	
Belle [82]	Average	0.91 ± 0.22	0.72 ± 0.09
BaBar [83]	Hadronic	$1.83_{-0.49}^{+0.53} \pm 0.24$

To extract the value of $|V_{ub}|f_{B^+}$ we use the PDG 2014 value of the B^+ lifetime of 1.638 ± 0.004 ps, and the τ^+ and B^+ masses of 1.77684 and 5.27926 GeV, respectively.

B. Theoretical decay-constant calculations

Table 6 and Table 7 present theoretical calculations of the B^{+-} , B^0 -, and B_s -meson decay constants and their ratios. (The decay constants of the neutral B^0 and B_s mesons enter the rates for the rare leptonic decays $B_{d,s} \rightarrow \mu^+ \mu^-$.) The upper

two panels show results from lattice-QCD simulations with three ($N_f = 2+1$) or four flavors ($N_f = 2+1+1$) of dynamical quarks. For all decay constants, calculations using different gauge-field configurations, light-quark actions, and b -quark actions provide independent confirmation. For comparison, the bottom panel of Table 6 shows non-lattice determinations of the $B_{(s)}$ -meson decay constants which include error estimates. These are consistent with the lattice values, but with much larger uncertainties.

The lattice-QCD results in Table 6 and Table 7 were all obtained using isospin-symmetric gauge-field configurations. The most recent calculations of f_{B^+} by the HPQCD, Fermilab/MILC, and RBC/UKQCD Collaborations [69,86,88], however, include the dominant effect of nondegenerate up- and down-quark masses by evaluating the decay constant with the valence light-quark mass fixed to the physical up-quark mass. HPQCD and RBC/UKQCD also calculate f_{B^0} by fixing the valence light-quark mass equal to the physical down-quark mass [86,88]; they find differences between the B^+ - and B^0 -meson decay constants of $f_{B^0} - f_{B^+} \approx 4$ MeV and $f_{B_s}/f_{B^+} - f_{B_s}/f_{B^0} \approx 0.025$. Inspection of Table 6 and Table 7 shows that these differences are comparable to the error on the HPQCD 12 result for f_B [89], and to the errors on the Fermilab/MILC, HPQCD 12, and ETM results for f_{B_s}/f_B [69,89,85], none of which account for isospin breaking. Therefore, to enable comparison with experimental measurements, in this review we correct those lattice-QCD results for B -meson decay constants obtained with degenerate up and down valence quarks *a posteriori* for isospin breaking before computing our averages. For the correction factors, we use the differences obtained empirically by HPQCD in Ref. 86⁶

$$f_{B^+} - f_B = -1.9(5) \text{ MeV}, \quad (20)$$

$$\frac{f_{B_s}}{f_{B^+}} - \frac{f_{B_s}}{f_B} = 0.012(4), \quad (21)$$

$$f_{B^0} - f_B = 1.7(5) \text{ MeV}, \quad (22)$$

$$\frac{f_{B_s}}{f_{B^0}} - \frac{f_{B_s}}{f_B} = -0.011(4). \quad (23)$$

The isospin-breaking correction factors in Eqs. (20)–(23) are well determined because of cancellations between correlated errors in the differences.

We first average the published (2+1)-flavor lattice-QCD results for the charged and neutral $B_{(s)}$ -meson decay constants and their ratios in Table 6 and Table 7, accounting for possibly correlated uncertainties. We treat the statistical errors as correlated between the calculations of Aoki *et al.* and RBC/UKQCD because they employ the same gauge-field

⁶ The correlated uncertainties were provided by HPQCD via private communication.

Table 6: Recent theoretical determinations of f_{B^+} , f_{B_s} , and their ratio. The upper panels show results from lattice-QCD simulations with $(2+1+1)$ and $(2+1)$ dynamical quark flavors, respectively. For some of the lattice-QCD results, statistical and systematic errors are quoted separately. Lattice-QCD results for f_B and f_{B_s}/f_B in the isospin-symmetric limit $m_u = m_d$ are noted with an “*”; they are corrected by the factors in Eq. (20) and Eq. (21), respectively, before computing the averages. Preliminary conference results noted with a “†” are not included in the averages. The bottom panel shows estimates from QCD sum rules and the light-front quark model, which are not used to obtain our preferred decay-constant values.

* Obtained by combining f_{B_s} from HPQCD 11 with f_{B_s}/f_B from this work. Approximate statistical (systematic) error obtained from quadrature sum of individual statistical (systematic) errors.

§ Obtained using m_b^{MS} ; results using m_b^{pole} are also given in the paper.

¶ Obtained by combining PDG value $f_B = 204(31)$ MeV [76] with f_{B_s}/f_B from this work.

configurations⁷ [87,88]. We also treat the statistical errors as correlated between the HPQCD and Fermilab/MILC calculations because they analyze an overlapping set of gauge-field configurations [69,89,90]. For f_{B_s} , we include HPQCD’s results from both 2011 [90] and 2012 [89], which were obtained using different b -quark actions, but on some of the same gauge-field configurations. HPQCD 11 and 12 also use the same determination of the absolute lattice scale, which is the second-largest

⁷ There may be mild correlations between some sub-dominant systematic errors of Aoki *et al.* and RBC/UKQCD, who use the same determinations of the absolute lattice scale and the physical light- and strange-quark masses from Ref. 93, and who use the same power-counting estimates for the light-quark and gluon discretization errors. The effects of any correlations between these systematics, however, would be too small to impact the numerical values of the averages.

source of systematic uncertainty in both calculations. We therefore treat the statistical and scale errors as correlated between HPQCD’s $(2+1)$ -flavor f_{B_s} results. HPQCD also presents two results for f_B in Ref. 89. The more precise value is obtained by combining the ratio f_{B_s}/f_B from this work with f_{B_s} from Ref. 90, but an associated error budget is not provided. Because this would be needed to estimate correlations between the two f_B determinations, we include only HPQCD’s more precise $(2+1)$ -flavor result for f_B in our average. Our separate three- and four-flavor averages for the B^{+-} , B^{0-} , and B_s -meson decay constants and ratios are listed in the lines labeled “Average” in Table 6 and Table 7, where the error on the $(2+1)$ -flavor f_{B_s} average has been rescaled by the factor $\sqrt{(\chi^2/\text{dof})} = 1.2$ to account for the tension among results. Our $(2+1+1)$ -flavor “averages” are identical to the “HPQCD 13” entries in Table 6

Meson Particle Listings

* Obtained with static b quarks (*i.e.*, $m_b \rightarrow \infty$).

* Obtained by combining f_{B_s} from HPQCD 11 with f_{B_s}/f_B from this work. Approximate statistical (systematic) error obtained from quadrature sum of individual statistical (systematic) errors.

To obtain the single-best values of the $B_{(s)}$ -meson decay constants for phenomenology applications, we combine the available $(2+1)$ - and $(2+1+1)$ -flavor lattice-QCD results, which are compatible within the current level of precision. Because the four-flavor “average” is obtained from only a single result, we do not simply combine the two lines labeled “Average” in Table 6 and Table 7, which would weight the four-flavor result too heavily. Instead, we form a single average including the published $(2+1)$ -flavor results and the $(2+1+1)$ -flavor result from HPQCD 13. We account for the omission of charm sea-quark contributions in the three-flavor calculations by adding to the errors on the $(2+1)$ -flavor averages in Table 6 and Table 7 our power-counting estimates of charm sea-quark errors from Sec. II.B, taking charm sea-quark error to be 100% correlated between the three-flavor results. Because the estimated charm sea-quark errors of 0.7% for decay constants and 0.2% for decay-constant ratios are much less than those on the $(2+1)$ -flavor averages, adding them in quadrature has a tiny impact on the total uncertainties. The largest observed change is an 0.3 MeV increase on the error f_{B_s} from HPQCD 11, and most are negligible. In the combined three- and four-flavor average we also consider correlations between the results of HPQCD 12 and HPQCD 13 because, although they employ different gauge-field configurations, they both use NRQCD for the b -quark action and the bottom-light axial-vector current.⁸ We

⁸ HPQCD 13 uses a 1-loop radiatively improved b -quark action, whereas HPQCD 12 uses tree-level action coefficients.

take both the operator-matching and relativistic errors, which are the dominant uncertainties in the decay constants, to be correlated between the two calculations. Our final preferred theoretical values for the charged B^+ and neutral $B_{(s)}^0$ -meson decay constants and their ratio are

$$\text{Our averages : } f_{B^+} = 187.1(4.2) \text{ MeV ,}$$

$$f_{B_s} = 227.2(3.4) \text{ MeV , } \frac{f_{B_s}}{f_{B^+}} = 1.215(7) , \quad (24)$$

$$f_{B^0} = 190.9(4.1) \text{ MeV , } \frac{f_{B_s}}{f_{B^0}} = 1.192(6) . \quad (25)$$

The errors on f_{B^+} , f_{B^0} , and f_{B_s} after combining the three- and four-flavor results are only slightly smaller than those of the separate averages due to the correlations assumed.

V. PHENOMENOLOGICAL IMPLICATIONS

A. $|V_{ud}|$, $|V_{us}|$, and status of first-row unitarity

Using the average values for $f_{\pi^+}|V_{ud}|$, $f_{K^+}|V_{us}|$, and their ratio from Eq. (10)–Eq. (12) and for f_{π^+} , f_{K^+} , and their ratio from Eq. (16), we obtain the following determinations of the CKM matrix elements $|V_{ud}|$, $|V_{us}|$, and their ratio from leptonic decays within the standard model:

$$|V_{ud}| = 0.9764(2)(127)(10) , \quad |V_{us}| = 0.2255(3)(6)(3) ,$$

$$\frac{|V_{us}|}{|V_{ud}|} = 0.2314(2)(5)(2) , \quad (26)$$

where the errors are from the experimental branching fraction(s), the pseudoscalar decay constant(s), and radiative corrections, respectively. These results enable a precise test of the unitarity of the first row of the CKM matrix from leptonic decays alone (the contribution from $|V_{ub}|$ is negligible). Using the values of $|V_{ud}|$ and $|V_{us}|$ from Eq. (26), we find

$$|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 - 1 = 0.004(25) , \quad (27)$$

which is consistent with three-generation unitarity at the sub-percent level.

The determinations of $|V_{ud}|$ and $|V_{us}|$ from leptonic decays in Eq. (26) can be compared to those obtained from other processes. The result above for $|V_{ud}|$ agrees with the determination from superallowed β -decay, $|V_{ud}| = 0.97417(21)$ [94], but has an error more than fifty times larger that is primarily due to the uncertainty in the theoretical determination of f_{π^+} . The CKM element $|V_{us}|$ can be determined from semileptonic $K^+ \rightarrow \pi^0 \ell^+ \nu$ decay. Here experimental measurements provide a value for the product $f_+^{K\pi}(0)|V_{us}|$, where $f_+^{K\pi}(0)$ is the form-factor at zero four-momentum transfer between the initial state kaon and the final state pion. Taking the most recent experimental determination of $|V_{us}|f_+^{K\pi}(0) = 0.2165(4)$

Both include the same contributions to the currents at one loop, but renormalization details differ.

from Moulson [26]⁹ and the preliminary 2015 (2+1+1)-flavor FLAG average for $f_+(0)^{K\pi} = 0.9704(24)(22)$ [12,13]¹⁰ gives $|V_{us}| = 0.22310(74)_{\text{thy}}(41)_{\text{exp}}$ from $K_{\ell 3}$ decay. The determinations of $|V_{us}|$ from leptonic and semileptonic kaon decays are both quite precise (with the error from leptonic decay being about 20% smaller), but the central values differ by 2.2σ . Finally, the combination of the ratio $|V_{us}|/|V_{ud}|$ from leptonic decays [Eq. (26)] with $|V_{ud}|$ from β decay implies an alternative determination of $|V_{us}| = 0.2254(6)$ which agrees with the value from leptonic kaon decay, but disagrees with the $K_{\ell 3}$ -decay result at the 2.2σ level. Collectively, these results indicate that there is some tension between theoretical calculations and/or measurements of leptonic pion and kaon decays, semileptonic kaon decays, and superallowed β -decay. Although this may be due to the presence of new physics, it is also important to revisit the quoted uncertainties on both the theoretical and experimental inputs.

Finally, we combine the experimental measurements of $f_{\pi^+}|V_{ud}|$, $f_{K^+}|V_{us}|$ from leptonic pseudoscalar-meson decays in Eq. (10) and Eq. (11) with determinations of the CKM elements from other decays or unitarity to infer “experimental” values for the decay constants. Assuming that there are no significant new-physics contributions to any of the input processes, the comparison of these results with theoretical calculations of the decay constants enables a test of lattice-QCD methods. Taking $|V_{ud}|$ from superallowed β -decay [100] leads to

$$f_{\pi^-}^{\text{“exp”}} = 130.50(1)(3)(13) \text{ MeV}, \quad (28)$$

where the uncertainties are from the errors on Γ , $|V_{ud}|$, and higher-order corrections, respectively. This agrees with the theoretical value $f_{\pi^+} = 130.2(1.7)$ MeV in Eq. (16) obtained from an average of recent (2+1)-flavor lattice-QCD results [39,37,35]. We take the value $|V_{us}| = 0.22534(65)$ from the most recent global unitarity-triangle fit of the UTfit Collaboration [101] because there is tension between the values of $|V_{us}|$ obtained from leptonic and semileptonic kaon decays. This implies

$$f_{K^-}^{\text{“exp”}} = 155.72(17)(45)(16) \text{ MeV} \quad (29)$$

where the uncertainties are from the errors on Γ , $|V_{us}|$, and higher-order corrections, respectively. This agrees with the theoretical value $f_{K^+} = 155.6(0.4)$ MeV in Eq. (16) obtained from an average of recent three and four-flavor lattice-QCD results [31–33,35,37,39].

⁹ This is an update of the 2010 Flavianet review [28] that includes new measurements of the K_s lifetime [95,96], $\text{Re}(\epsilon'/\epsilon)$ [96], and $\mathcal{B}(K^\pm \rightarrow \pi^\pm \pi^+ \pi^-)$ [27]. The latter measurement is the primary source of the reduced error on $\mathcal{B}(K_{\ell 3})$, via the constraint that the sum of all branching ratios must equal unity.

¹⁰ This result comes from the calculation of FNAL/MILC in Ref. 97. For comparison, the 2015 preliminary (2+1)-flavor FLAG average based on the calculations of FNAL/MILC [98] and RBC/UKQCD [99] is $f_+(0)^{K\pi} = 0.9677(37)$.

B. $|V_{cd}|$, $|V_{cs}|$, and status of second-row unitarity

Using the average values for $|V_{cd}|f_{D^+}$ and $|V_{cs}|f_{D_s^+}$ from Table 2 and Table 3, and for f_{D^+} and $f_{D_s^+}$ from Eq. (19), we obtain the following determinations of the CKM matrix elements $|V_{cd}|$ and $|V_{cs}|$, and from leptonic decays within the standard model:

$$|V_{cd}| = 0.217(5)(1) \quad \text{and} \quad |V_{cs}| = 1.007(16)(5), \quad (30)$$

where the errors are from experiment and theory, respectively, and are currently limited by the measured uncertainties on the decay rates. The central value of $|V_{cs}|$ is greater than one, but is compatible with unity within the error. The above results for $|V_{cd}|$ and $|V_{cs}|$ do not include higher-order electroweak and hadronic corrections to the rate, in analogy to Eq. (3). These corrections have not been computed for $D_{(s)}^+$ -meson leptonic decays, but are estimated to be about to be about 1–2% for charged pion and kaon decays (see Sec. II.A). Now that the uncertainties on $|V_{cd}|$ and $|V_{cs}|$ from leptonic decays are at this level, we hope that the needed theoretical calculations will be undertaken.

The CKM elements $|V_{cd}|$ and $|V_{cs}|$ can also be obtained from semileptonic $D^+ \rightarrow \pi^0 \ell^+ \nu$ and $D_s^+ \rightarrow K^0 \ell^+ \nu$ decays, respectively. Here experimental measurements determine the product of the form factor times the CKM element, and theory provides the value for the form factor at zero four-momentum transfer between the initial $D_{(s)}$ meson and the final pion or kaon. We combine the latest experimental averages for $f_+^{D\pi}(0)|V_{cd}| = 0.1425(19)$ and $f_+^{D_s K}(0)|V_{cs}| = 0.728(5)$ from the Heavy Flavor Averaging Group (HFAG) [102] with the zero-momentum-transfer form factors $f_+^{D\pi}(0) = 0.666(29)$ and $f_+^{D_s K}(0) = 0.747(19)$ calculated in (2+1)-flavor lattice QCD by the HPQCD Collaboration [103,104] to obtain $|V_{cd}| = 0.2140(97)$ and $|V_{cs}| = 0.9746(257)$ from semileptonic $D_{(s)}$ -meson decays. The values of $|V_{cd}|$ from leptonic and semileptonic decays agree, while those for $|V_{cs}|$ are compatible at the 1.1σ level. The determinations of $|V_{cd}|$ and $|V_{cs}|$ from leptonic decays in Eq. (30), however, are $2.0\times$ and $1.6\times$ more precise than those from semileptonic decays, respectively.

The results for $|V_{cd}|$ and $|V_{cs}|$ from Eq. (30) enable a test of the unitarity of the second row of the CKM matrix. We obtain

$$|V_{cd}|^2 + |V_{cs}|^2 + |V_{cb}|^2 - 1 = 0.064(36), \quad (31)$$

which is in slight tension with three-generation unitarity at the 2σ level. Because the contribution to Eq. (31) from $|V_{cb}|$ is so small, we obtain the same result taking $|V_{cb}|^{\text{incl.}} \times 10^3 = 42.21(78)$ from inclusive $B \rightarrow X_c \ell \nu$ decay [105] or $|V_{cb}|^{\text{excl.}} \times 10^3 = 39.04(75)$ from exclusive $B \rightarrow D^* \ell \nu$ decay at zero recoil [106].

We can also combine the experimental measurements of $f_{D^+}|V_{cd}| = 45.91(1.05)$ MeV and $f_{D_s^+}|V_{cs}| = 250.9(4.0)$ MeV from leptonic pseudoscalar-meson decays from Table 2 and Table 3 with determinations of $|V_{cd}|$ and $|V_{cs}|$ from CKM unitarity to infer “experimental” values for the decay constants within

Meson Particle Listings

D_s^\pm

the standard model. For this purpose, we obtain the values of $|V_{cd}|$ and $|V_{cs}|$ by relating them to other CKM elements using the Wolfenstein parameterization [107]. We take $|V_{cd}|$ to equal the value of $|V_{us}|$ minus the leading correction [108]:

$$\begin{aligned} |V_{cd}| &= |V_{us}| \left| -1 + \frac{|V_{cb}|^2}{2} (1 - 2(\rho + i\eta)) \right| \quad (32) \\ &= |V_{us}| \left(\left[-1 + (1 - 2\rho) \frac{|V_{cb}|^2}{2} \right]^2 + \eta^2 |V_{cb}|^4 \right)^{1/2}. \quad (33) \end{aligned}$$

Using $|V_{us}| = 0.2255(3)(6)(3)$ from leptonic kaon decay, Eq. (26), inclusive $|V_{cb}|$ as above, and $(\rho, \eta) = (0.136(24), 0.361(14))$ from CKM unitarity [101] $|V_{cd}| = 0.2254(7)$. We take $|V_{cs}| = |V_{ud}| - |V_{cb}|^2/2$ [108], using $|V_{ud}| = 0.97417(21)$ from β decay [94], giving $|V_{cs}| = 0.9733(2)$. Given these choices, we find

$$\begin{aligned} f_{D^+}^{\text{exp}} &= 203.7(4.7)(0.6) \text{ MeV} \quad \text{and} \\ f_{D_s^+}^{\text{exp}} &= 257.8(4.1)(0.1) \text{ MeV}, \quad (34) \end{aligned}$$

where the uncertainties are from the errors on Γ and $|V_{us}|$ (or $|V_{ud}|$), respectively. These disagree with the theoretical values $f_{D^+} = 211.9(1.1) \text{ MeV}$ and $f_{D_s^+} = 249.0(1.2) \text{ MeV}$ in Eq. (19) obtained from averaging recently published three and four-flavor lattice-QCD results at the 1.7σ and 2.0σ levels, respectively. The significances of the tensions are sensitive, however, to the choices made for $|V_{us}|$ and $|V_{ud}|$. Thus resolving the inconsistencies between determinations of elements of the first row of the CKM matrix discussed previously in Sec. V.A may also reduce the mild tensions observed here.

C. $|V_{ub}|$ and other applications

Using the average value for $|V_{ub}|f_{B^+}$ from Table 5, and for f_{B^+} from Eq. (24), we obtain the following determination of the CKM matrix element $|V_{ub}|$ from leptonic decays within the standard model:

$$|V_{ub}| = 4.12(37)(9) \times 10^{-3}, \quad (35)$$

where the errors are from experiment and theory, respectively. We note, however, that decays involving the third generation of quarks and leptons may be particularly sensitive to new physics associated with electroweak symmetry breaking due to their larger masses [4,6], so Eq. (35) is more likely to be influenced by new physics than the determinations of the elements of the first and second rows of the CKM matrix in the previous sections.

The CKM element $|V_{ub}|$ can also be obtained from semileptonic B -meson decays. Over the past several years there has remained a persistent 2-3 σ tension between the determinations of $|V_{ub}|$ from exclusive $B \rightarrow \pi \ell \nu$ decay and from inclusive $B \rightarrow X_u \ell \nu$ decay, where X_u denotes all hadrons which contain a constituent up quark [3,102,109–111]. The currently most precise determination of $|V_{ub}|^{\text{excl}} = 3.72(16) \times 10^{-3}$ is obtained from a joint z -fit of the vector and scalar form

factors $f_+^{B\pi}(q^2)$ and $f_0^{B\pi}(q^2)$ calculated in (2+1)-flavor lattice QCD by the FNAL/MILC Collaboration [112] and experimental measurements of the differential decay rate from BaBar [113,114] and Belle [115,116]. On the other hand, the most recent PDG average of inclusive determinations obtained using the theoretical frameworks in Refs. 117–119 is $|V_{ub}|^{\text{incl}} = 4.49(16) \left(\begin{smallmatrix} +16 \\ -18 \end{smallmatrix} \right) \times 10^{-3}$ [120]. The result for $|V_{ub}|$ from leptonic $B \rightarrow \tau \nu$ decay in Eq. (35) is compatible with determinations from both exclusive and inclusive semileptonic B -meson decays.

The CKM element $|V_{ub}|$ can now also be obtained from semileptonic Λ_b decays. Specifically, the recent LHCb measurement of the ratio of decay rates for $\Lambda_b \rightarrow p \ell \nu$ over $\Lambda_b \rightarrow \Lambda_c \ell \nu$ [121], when combined with the ratio of form factors from (2+1)-flavor lattice QCD [122], enables the first determination of the ratio of CKM elements $|V_{ub}|/|V_{cb}| = 0.083(4)(4)$ from baryonic decay. Taking $|V_{cb}|^{\text{incl}} = 42.21(78) \times 10^{-3}$ [105] for the denominator,¹ we obtain $|V_{ub}| = 3.50(17)(17)(6) \times 10^{-3}$ from exclusive Λ_b semileptonic decays, where the errors are from experiment, the form factors, and $|V_{cb}|$, respectively. The result for $|V_{ub}|$ from leptonic $B \rightarrow \tau \nu$ decay in Eq. (35) is 1.4σ higher than the determination from b -baryon decays.

Given these results, the “ V_{ub} ” puzzle still stands, and the determination from leptonic B^+ -meson decay is not yet sufficiently precise to weigh in on the discrepancy. New and improved experimental measurements and theoretical calculations of other $b \rightarrow u$ flavor-changing processes, however, are providing additional information and sharpening the picture of the various tensions. Further, the error on $|V_{ub}|$ from $B \rightarrow \tau \nu$ decay will shrink once improved rate measurements from the Belle II experiment are available.

Finally, we can combine the experimental measurement of $|V_{ub}|f_{B^+}$ from leptonic B^+ -meson decays in Table 5 with a determination of the CKM element $|V_{ub}|$ from elsewhere to infer an “experimental” values for f_{B^+} within the standard model. This, of course, assumes that there are no significant new-physics contributions to $B^+ \rightarrow \tau \nu$, which may turn out not to be the case. Further, one does not know *a priori* what value to take for $|V_{ub}|$ given the inconsistencies between the various determinations discussed above. We therefore take the PDG weighted average of the determinations from inclusive and exclusive semileptonic B -meson decays $|V_{ub}|^{\text{excl+incl}} = 4.09(39) \times 10^{-3}$ [120], where

¹This differs from the choice for $|V_{cb}|$ made by LHCb [121], who use the determination from exclusive $B \rightarrow D^{(*)} \ell \nu$ decays at zero recoil [123]. The Belle Experiment recently obtained a new measurement of the $B \rightarrow D \ell \nu$ differential decay rate [124] and determination of $|V_{cb}| = 40.83(1.13) \times 10^{-3}$. They find that the inclusion of experimental and theoretical nonzero-recoil information increases the value for $|V_{cb}|$ compared to when only zero-recoil information is used, and leads to agreement with the inclusive result.

the error has been rescaled by the $\sqrt{\chi^2/\text{dof}} = 2.6$ to account for the disagreement. Using this result we obtain

$$f_{B^+}^{\text{exp}} = 188(17)(18) \text{ MeV}, \quad (36)$$

where the uncertainties are from the errors on Γ and $|V_{ub}|$, respectively. This agrees within large uncertainties with the theoretical value $f_{B^+} = 187.1(4.2) \text{ MeV}$ in Eq. (24) obtained from an average of recent three and four-flavor lattice-QCD results [69,86,88,89].

ACKNOWLEDGEMENTS

We thank V. Cirigliano, C. Davies, A. El Khadra, A. Khodjamirian, J. Laiho, W. Marciano, M. Moulson, S. Narison, S. Sharpe, and Z.-G. Wang for useful discussions and references. We thank P. Boyle, M. Della Morte, D. Lin and S. Simula for providing information on the preliminary FLAG-3 lattice averages. We gratefully acknowledge support of the U. S. National Science Foundation and the U. S. Department of Energy through Grant No. DE-FG02-13ER41598. The work of J. L. R. was performed in part at the Aspen Center for Physics, which is supported by National Science Foundation grant PHY-1066293. Fermilab is operated by Fermi Research Alliance, LLC, under Contract No. DE-AC02-07CH11359 with the U.S. Department of Energy.
