ABSTRACT

Objective To evaluate if obstructive sleep apnoea (OSA) modifies the risk of coronary heart disease, type 2 diabetes (T2D) and diabetic complications in a gender-specific fashion.

Design and setting A longitudinal population-based study with up to 25-year follow-up data on 36 963 individuals (>500 000 person years) from three population-based cohorts: the FINRISK study, the Health 2000 Cohort Study and the Botnia Study.

Main outcome measures Incident coronary heart disease, diabetic kidney disease, T2D and all-cause mortality from the Finnish National Hospital Discharge Register and the Finnish National Causes-of-Death Register.

Results After adjustments for age, sex, region, high-density lipoprotein (HDL) and total cholesterol, current cigarette smoking, body mass index, hypertension, T2D baseline and family history of stroke or myocardial infarction, OSA increased the risk for coronary heart disease (HR=1.36, p=0.0014, 95% CI 1.12 to 1.64), particularly in women (HR=2.01, 95% CI 1.31 to 3.07, p=0.0012). T2D clustered with OSA independently of obesity (HR=1.48, 95% CI 1.26 to 1.73, p=9.11×10⁻⁷). The risk of diabetic kidney disease increased 1.75-fold in patients with OSA (95% CI 1.13 to 2.71, p=0.013). OSA increased the risk for coronary heart disease similarly among patients with T2D and in general population (HR=1.36). All-cause mortality was increased by OSA in diabetic individuals (HR=1.35, 95% CI 1.06 to 1.71, p=0.016).

Conclusion OSA is an independent risk factor for coronary heart disease, T2D and diabetic kidney disease. This effect is more pronounced even in women, who until now have received less attention in diagnosis and treatment of OSA than men.

INTRODUCTION

Obstructive sleep apnoea (OSA) is a more common disorder than currently diagnosed in the clinic.¹ It is a serious public health problem due to its many comorbidities, including an increased risk to coronary

Strengths and limitations of this study

- A large-scale population-based study of 36 963 individuals with up to 25 years of follow-up.
- Follow-up registers have excellent validity and coverage.
- Our study takes a large amount of confounding factors related to obstructive sleep apnoea into consideration.
- Prospective study design should limit the risk of bias.
- Registry-based ascertainment through hospitalisation may miss non-hospitalised cases and treatment information.

heart disease (CHD) and type 2 diabetes (T2D).²⁻³ The main known risk factors for OSA are obesity, male gender, high age, increased neck circumference and problems of upper airway or jaw anatomy.⁴⁻⁷

Longitudinal studies have shown an association of OSA with incident or recurrent cardiovascular events and increased mortality.³⁻⁸ The risk of developing CHD is particularly increased in middle-aged men with OSA.⁹⁻¹⁰ Risk of CHD and mortality is usually increased if T2D is diagnosed before OSA.¹¹

There is mounting evidence that OSA is an independent risk factor for the development of T2D.²⁻¹²⁻¹³ Most of the available studies have been cross sectional,⁶⁻¹²⁻¹³ and not able to account for residual confounding factors.⁶⁻¹³ Other studies did not distinguish between type 1 diabetes (T1D) and T2D,¹⁴ nor to generalise the results to the overall population.⁶ In some studies, this association has been dispersed after adjustments for other risk factors.¹⁵

Also, studies investigating the synergistic effects of OSA and T2D on the progression of

diabetic kidney disease are scarce and often limited by a cross-sectional design^{16–18} or small sample size.¹⁹

To explore the role of OSA for CHD, T2D and increased mortality, we conducted a large-scale population-based study of 36 963 individuals with up to 25 years of follow-up. We specifically aimed at evaluating (1) if OSA modifies the risk of CHD and T2D independently of known risk factors like body mass index (BMI), blood pressure and lipids, (2) the role of OSA for the development of diabetic complications including diabetic kidney disease and (3) examine if OSA has similar effects in women and men.

METHODS

Study population

We included 36 963 participants in our study from national FINRISK Studies (FINRISK), Health 2000 Cohort (H2000) and a subset of the Botnia and Prevalence, Prediction and Prevention of Diabetes (PPP)-Botnia Studies (Botnia) including 1568 (4.2%) patients with OSA (ICD 10: G47.3, ICD 9: 3472A). Baseline characteristics of the participants are presented in [table 1](#).

Population-based FINRISK surveys are independent random samples drawn from the population register of six geographic areas of Finland (North Karelia, Kuopio, Lapland, Oulu, Turku/Loimaa and Helsinki/Vantaa) and stratified according to gender, 10-year age group and study area. The survey included a mailed questionnaire and a clinical examination at which a blood sample was drawn.²⁰ Participants from different survey years (1992, 1997, 2002 or 2007) were pooled together.

The total sample size for all FINRISK surveys was 29 257 and participants who had missing information (n=7) or T1D (n=297) were excluded from the study. Thus, the total sample size was 28 953 where 13 792 male and 15 161 female participants aged 24–74 years at baseline were included in the analyses. Of these participants, 1214 (4.2%) had OSA.

The H2000 Study is a comprehensive combination of health interview and health examination survey. The study was based on a nationally representative sample of 8028 persons aged ≥ 30 years living in mainland Finland.²¹ After excluding participants who had missing information (n=1331) or T1D (n=92), the final dataset consisted of 6605 participants, 2940 men and 3707 women. Out of this cohort 235 (3.6%) participants were diagnosed with OSA.

The Botnia Study was established in 1990 to investigate familial clustering of diabetes in the Ostrobothnia region in western Finland, and the non-diabetic participants have been prospectively followed.²² The population-based PPP-Botnia Study was conducted in the same geographical area.²³ From the Botnia/PPP Botnia Studies (referred to as Botnia Study), we included 1405 patients with T2D, 735 men and 670 women. In this cohort, 119 participants (8.5%) had OSA diagnosis.

Patient and public involvement

Patients and public were not involved in the designing process of this study. The patients will not be informed individually of the study results otherwise than through possible media coverage.

Prospective follow-up and event definitions

During the follow-up of the study cohorts, data for hospitalisations and causes of death were obtained from the Finnish National Hospital Discharge Register and the Finnish National Causes-of-Death Register. These registers have excellent validity and coverage.^{24 25} Follow-up for FINRISK ended on 31 December 2014, for H2000 on 31 December 2013 and for Botnia on 31 December 2015.

In the FINRISK cohorts, the follow-up was up to 22 years (median 12.9 years, IQR 8.5–17.9) and in the H2000 the follow-up was up to 14.5 years (median 13.9, IQR 13.6–14.2). In the Botnia, the follow-up was up to 25 years (median 14.7 years, IQR 10.2–21.4). Altogether we had 523 372 person years of follow-up.

OSA diagnosis is based on ICD codes which usually are based on subjective symptoms, clinical examination and sleep registration applying Apnoea–Hypopnoea Index (number of apnoeas and hypopnoeas per hour of sleep) ≥ 5 .²⁶ Incident CHD events were defined as the first occurrence of myocardial infarction, CHD death or coronary revascularisation procedure at any time between the baseline examination and final follow-up date. Incident stroke events (STR), and diabetic kidney disease (including codes from ICD 10: N18, N19, E102, E112, ICD 9: 585, 2503A, 2503B and ICD8: 58200, 25004) were defined as the first occurrence of such event during this time period in hospital discharges or causes of deaths register. In FINRISK and H2000 cohorts, incident T2D was registered as the first occurrence of T2D in hospital discharges, causes-of-deaths register or entitlement to a reimbursed diabetes medication. Also, diabetes medication purchases were checked. If diabetic medication was the only evidence, at least three separate purchases were required. Persons with gestational or T1D were excluded from the analyses. In the Botnia Study, diabetes was defined based on a 75 g oral glucose tolerance test, with plasma glucose ≥ 7.0 mmol/L at fasting plasma glucose (FPG) or ≥ 11.1 mmol/L at 2 hours or previous diagnosis and use of antidiabetic medication.

ICD codes for each endpoint definition can be found in online supplementary table 1.

Statistical methods

We tested associations between OSA and incident CHD events, diabetic kidney disease events and T2D using Cox proportional hazard models. Age at onset of OSA was used as a time-dependent covariate in our analyses and age was used as the timescale. In such Cox model, a person contributes in the model only for his/her at-risk period (ie, for a certain age range). During that period, he/she could become an OSA case, before the T2D diagnosis or cardiovascular event. In this case, using OSA as

Baseline demographics and clinical characteristics p values were based on χ^2 test. Fisher's exact test was used if the sample size was ≤ 5 . For continuous variables, we used Student's t-test. Data are mean (SD) or number (%). BMI, body mass index; CHOL, total cholesterol; CHD, coronary heart disease; CHD/T2DM, coronary heart disease among patients with type 2 diabetes; DKD, diabetic kidney disease; DKD/T2DM, diabetic kidney disease among patients with type 2 diabetes; LDL, low-density lipoprotein; OSA, obstructive sleep apnoea.

a time-dependent covariate, he/she contributes to the model as a non-OSA case until the age at OSA diagnosis, and as an OSA case for the remaining of his/her at-risk period.²⁷ Prevalent cases were excluded from the Cox regression analyses and the assumptions of the models were tested by `cox.zph`—function.

In our FINRISK raw model for CHD, we used age, gender, geographical area and cohort year as covariates. In the adjusted model, we used, in addition to aforementioned factors, traditional risk factors as covariates for cardiovascular events: HDL, total cholesterol (CHOL), current cigarette smoking, BMI, hypertension (defined as a measured blood pressure of at least 140/90 mm Hg or the use of antihypertensive medications), prevalent T2D and family history of stroke or myocardial infarction.

In the raw analysis, similar to CHD, the association between OSA and T2D was adjusted for age, gender, geographical area and cohort year. In the adjusted model, we used also BMI as a covariate. Among patients with T2D with the endpoint of diabetic kidney disease, the model was adjusted for BMI and hypertension.

In the H2000, we were not able to adjust the model for family history of stroke or myocardial infarction because that information was not determined in the study. Otherwise, the Cox time-dependent hazard model was adjusted for the same risk factors as mentioned before.

We combined the evidence from the FINRISK and H2000 to analyse CHD and T2D. To analyse T2D complications in more detail, we used the Botnia as a third cohort. The results were combined using fixed-effect meta-analysis.

Differences in baseline demographics and clinical characteristics were tested using χ^2 tests. Fisher's exact test was used if the expected cell size was ≤ 5 . For continuous variables, we used Student's t-test (table 1). We considered $p < 0.05$ as statistically significant, and all tests were two sided.

The R statistical package (V.3.2.5) was used for all analyses (www.r-project.org).²⁷

RESULTS

General results

To analyse the comorbidity of OSA and CHD, T2D outcomes and T2D complications, we combined longitudinal data from three population-based cohorts including 36 963 participants with 1568 (4.2%) patients with OSA. These cohorts included FINRISK ($n=28\,953$) with follow-up of up to 22 years (median 12.9 years, IQR 8.5–17.9), H2000 ($n=6\,605$) with the median follow-up of 13.9 (IQR 13.6–14.2) and patients with T2D from the Botnia Study ($n=1\,405$) with the median follow-up of 15.3 years (IQR 10.8–21.34). Altogether we had 6248 patients with T2D (16.9%).

We used the Finnish nationwide health registry data to construct diagnosis events. To evaluate the performance of the diagnostic events, we compared the main risk factor distributions between OSA cases and the rest of the population. In figure 1, we show that BMI and systolic blood pressure are on average higher and HDL lower in the OSA group compared with the rest of the population. Table 1. presents a more thorough comparison of the groups.

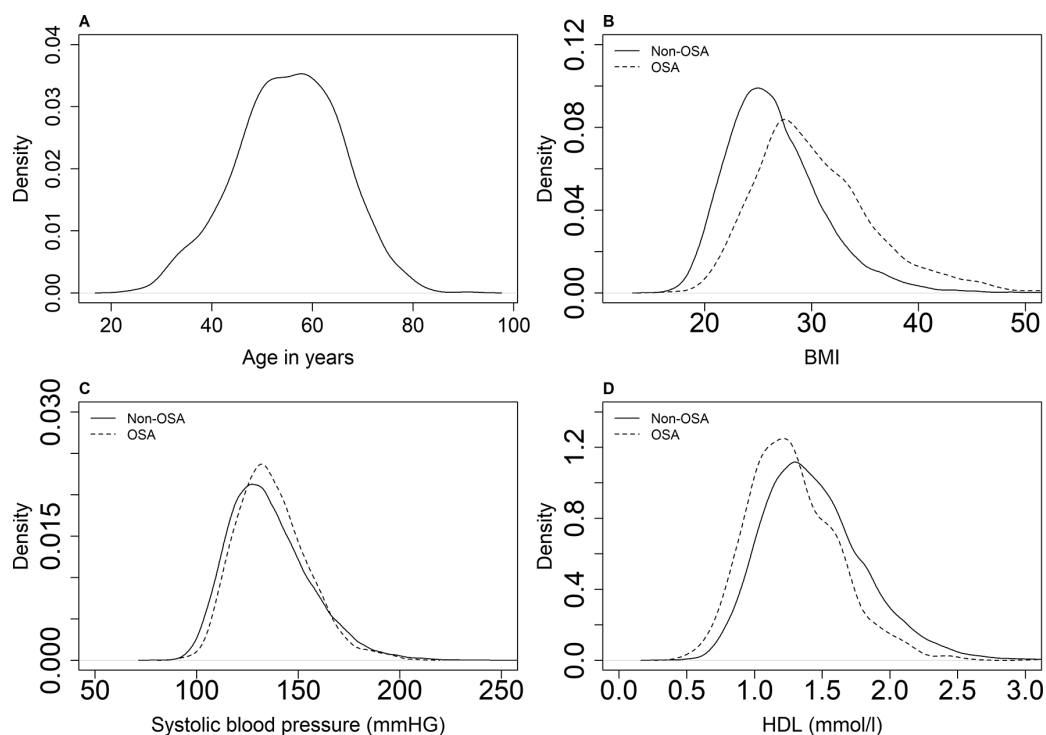

Figure 1 (A) Distributions of age at obstructive sleep apnoea (OSA) diagnosis (mean 55.31 years) and (B) significant differences in body mass index (BMI) ($p = 3.49 \times 10^{-96}$), (C) systolic blood pressure ($p = 7.78 \times 10^{-3}$) and (D) HDL ($p = 8.98 \times 10^{-53}$) among patients with OSA and non-OSA individuals in FINRISK.

Table 2 HRs between individuals with obstructive sleep apnoea and the population for incident coronary heart disease events

	Number of events/ subjects at risk	Raw model		Adjusted model

H2000	259/3519	4.12 (1.68 to 10.18)	2.06×10^{-3}	4.03 (1.62 to 10.01)	2.64×10^{-3}
Combined	908/18 401	2.33 (1.53 to 3.53)	7.19×10^{-5}	2.01 (1.31 to 3.07)	1.20×10^{-3}

The FINRISK raw model is adjusted for age, cohort year, geographical area and gender. The adjusted model is adjusted for HDL and total cholesterol, current cigarette smoking, body mass index (BMI), hypertension, prevalent type 2 diabetes and family history of stroke or myocardial infarction in addition to covariates of the raw model. The Health 2000 Cohort (H2000) raw model is adjusted for geographical area and gender. H2000-adjusted model is adjusted for HDL and total cholesterol, current cigarette smoking, BMI, hypertension and prevalent type 2 diabetes in addition to covariates of the raw model.

Cardiovascular outcomes

We first tested if OSA is associated with risk of incident CHD. In a model adjusted for age, sex and geographical region, OSA diagnosis elevates the risk of CHD (HR=1.54, 95% CI 1.28 to 1.86, $p=4.43 \times 10^{-6}$; [table 2](#), online supplementary figures 1,2).

When adjusting for CHD risk factors (age, sex, region, HDL and CHOL, current cigarette smoking, BMI, hypertension, T2D baseline and family history of stroke or myocardial infarction), the HR attenuated to 1.36 (95% CI 1.12 to 1.64, $p=1.40 \times 10^{-3}$). The estimates were similar across these cohorts and were slightly higher for women (adjusted HR=2.01, 95% CI 1.31 to 3.07, $p=1.20 \times 10^{-3}$) than for men (adjusted HR=1.25, 95% CI 1.01 to 1.54, $p=0.039$). OSA did not, however, associate with stroke risk (online supplementary table 2).

The effect of OSA on T2D and its complications

We next tested if OSA modifies the risk for T2D. Among patients with OSA, this risk was elevated (HR=2.52, $p=1.91 \times 10^{-32}$, 95% CI 2.16 to 2.93). After further adjustment for BMI, the risk remained at 1.48-fold ($p=9.11 \times 10^{-7}$, 95% CI 1.26 to 1.73) showing a similar effect in both cohorts (online supplementary figures 2,3). Again, the effect was more prominent in women (adjusted HR = 1.63, 95% CI 1.20 to 2.23, $p=2.20 \times 10^{-3}$) than in men (HR = 1.44, 95% CI 1.27 to 2.21, $p=9.62 \times 10^{-5}$) ([table 3](#)).

To analyse T2D complications more in detail, we included the Botnia cohort into the meta-analysis. H2000 lacked incident diabetic kidney disease events among patients with OSA.

Among patients with T2D, OSA elevated the risk for diabetic kidney disease (HR=2.16, 95% CI 1.40 to 3.34, $p=5.00 \times 10^{-4}$; [table 4](#)).

When adjusted for the known risk factors for diabetic kidney disease (BMI and hypertension), the HR was slightly reduced to 1.75 (95% CI 1.13 to 2.71, $p=0.013$, online supplementary figures 4,5). The effects were similar in both cohorts.

Among patients with T2D, OSA alone increased the risk for CHD by 1.40 (95% CI 1.10 to 1.81, $p=8.50 \times 10^{-3}$; [table 4](#)). This was almost unaffected by adding the following risk factors: HDL and CHOL, current cigarette smoking, BMI, hypertension and family history of stroke or myocardial infarction (HR=1.36, 95% CI 1.05 to 1.76, $p=0.019$, online supplementary figures 4,5).

The effect of OSA to mortality risk

We also examined whether OSA was an independent risk factor for all-cause mortality. OSA increased the risk in the raw model (HR=1.18, 95% CI 1.00 to 1.40, $p=0.057$) and this risk attenuated after adjustment for other risk factors. Among T2D individuals, OSA increased the all-cause mortality risk in the raw model (HR=1.40, 95% CI 1.21 to 1.62, $p=2.03 \times 10^{-6}$) and after adjustments (HR=1.35, 95% CI 1.06 to 1.71, $p=0.016$; [table 5](#), online supplementary figure 6).

DISCUSSION

Our results from three prospective population-based cohorts found a severe impact of OSA on cardiovascular health, T2D and mortality during a life course. We demonstrate that OSA is an independent risk factor for CHD and

Table 3 HRs between individuals with obstructive sleep apnoea and the population for incident type 2 diabetes

	Number of events/ subjects at risk	Raw model		Adjusted model	
		HR (95% CI)	P values	HR (95% CI)	P values
FINRISK	2435/27 161	2.40 (2.03 to 2.84)	1.53×10^{-24}	1.38 (1.16 to 1.64)	2.74×10^{-4}
H2000	455/6181	3.18 (2.20 to 4.59)	7.03×10^{-10}	2.05 (1.42 to 2.97)	1.41×10^{-4}
Combined	2890/33 342	2.52 (2.16 to 2.93)	1.91×10^{-32}	1.48 (1.26 to 1.73)	9.11×10^{-7}
Men					
FINRISK	1372/12 880	2.21 (1.81 to 2.69)	2.55×10^{-15}	1.28 (1.05 to 1.57)	0.017
H2000	257/2772	3.65 (2.44 to 5.44)	2.23×10^{-10}	2.27 (1.51 to 3.41)	8.08×10^{-5}
Combined	1629/15 652	2.43 (2.04 to 2.90)	4.16×10^{-23}	1.44 (1.27 to 2.21)	9.62×10^{-5}
Women					
FINRISK	1063/14 281	3.14 (2.28 to 4.33)	3.12×10^{-12}	1.65 (1.18 to 2.29)	2.98×10^{-3}
H2000	198/3409	2.16 (0.80 to 5.87)	0.13	1.48 (0.55 to 4.02)	0.44
Combined	1261/17 690	3.03 (2.23 to 4.12)	1.25×10^{-15}	1.63 (1.20 to 2.23)	2.20×10^{-3}

The FINRISK raw model is adjusted for age, cohort year, geographical area and gender. The adjusted model is adjusted for body mass index (BMI) in addition to covariates of the raw model. The Health 2000 Cohort (H2000) raw model is adjusted for geographical area and gender. The adjusted model is adjusted for BMI in addition to covariates of the raw model.

T2D in the general population. Using a combination of population cohorts and a T2D cohort, Botnia, we present evidence for the role of OSA in the risk of T2D complications. To our knowledge, this is the largest study of the role of OSA in CHD and T2D diseases, combining sample size of over 36 000 individuals with up to 20+ years of follow-up.

These results allow us to draw several conclusions. First, our results illustrate that nationwide health registry data can successfully be used to identify cases of OSA. Second, the registry-based OSA cases revealed an increased risk for future CHD events and T2D. This risk was surprisingly

high in women, even after adjusting for risk factors, shedding new light to the potential sex differences in OSA. This finding may provide tools to identify particularly women in high risk of CHD and T2D. Third, we observed convincing evidence indicating that T2D accumulated to patients with OSA independent of obesity.

OSA seems to increase the risk for CHD to the same extent in diabetic and non-diabetic individuals but the risk of diabetic kidney disease was 75% higher among patients with OSA compared with diabetic individuals without OSA diagnosis. All-cause mortality was increased by OSA among

Table 4 HRs for type 2 diabetes complications

	Number of events/ subjects at risk	Raw model		Adjusted model	
		HR (95% CI)	P values	HR (95% CI)	P values
DKD					
FINRISK	147/3932	2.15 (1.27 to 3.62)	4.10×10^{-3}	1.72 (1.01 to 2.93)	0.044
Botnia	91/1380	2.19 (1.003 to 4.79)	0.049	1.80 (0.82 to 3.96)	0.143
Combined	238/5312	2.16 (1.40 to 3.34)	5.00×10^{-4}	1.75 (1.13 to 2.71)	0.013
CHD					
FINRISK	640/3710	1.44 (1.07 to 1.95)	0.016	1.40 (1.04 to 1.90)	0.028
H2000	152/761	1.46 (0.74 to 2.82)	0.272	1.46 (0.74 to 2.89)	0.274
Botnia	236/1253	1.18 (0.60 to 2.31)	0.630	1.07 (0.54 to 2.11)	0.840
Combined	1028/5724	1.40 (1.10 to 1.81)	8.50×10^{-3}	1.36 (1.05 to 1.76)	0.019

The FINRISK raw models are adjusted for age, cohort year, geographical area and gender. The Health 2000 Cohort (H2000) raw models are adjusted for age, geographical area and gender. The Botnia raw models are adjusted for age and gender. The adjusted models for diabetic kidney disease (DKD) are adjusted for body mass index (BMI) and hypertension in all cohorts in addition to covariates of the raw model. The FINRISK-adjusted model for coronary heart disease (CHD) is adjusted for HDL and total cholesterol, current cigarette smoking, BMI, hypertension and family history of stroke or myocardial infarction in addition to covariates of the raw model. The H2000-adjusted and Botnia-adjusted models for CHD are adjusted for HDL and total cholesterol, current cigarette smoking, BMI and hypertension in addition to covariates of the raw model.

Table 5 HRs for all-cause mortality among general population and individuals with type 2 diabetes (T2DM)

	Number of events/ subjects at risk	Raw model		Adjusted model	
		HR (95% CI)	P values	HR (95% CI)	P values
General population					
FINRISK	3228/28666	1.08 (0.89 to 1.31)	0.438	1.01 (0.83 to 1.22)	0.949
H2000	1286/6498	1.65 (1.14 to 2.39)	7.91×10^{-3}	1.74 (1.20 to 2.52)	3.68×10^{-3}
Combined	4514/35164	1.18 (1.00 to 1.40)	0.057	1.13 (0.95 to 1.34)	0.161
T2DM					
FINRISK	719/3940	1.37 (1.01 to 1.84)	0.041	1.23 (0.91 to 1.67)	0.179
H2000	284/820	1.35 (0.68 to 2.71)	0.390	1.48 (0.74 to 2.98)	0.267
Botnia	348/1309	1.84 (1.14 to 2.99)	1.44×10^{-4}	1.62 (1.00 to 2.65)	0.052
Combined	1351/6069	1.40 (1.21 to 1.62)	2.03×10^{-6}	1.35 (1.06 to 1.71)	0.016

The FINRISK raw models are adjusted for age, cohort year, geographical area and gender. The Health 2000 Cohort (H2000) raw models are adjusted for age, geographical area and gender. The Botnia raw models are adjusted for age and gender. The FINRISK-adjusted model is adjusted for HDL and total cholesterol, current cigarette smoking, body mass index (BMI), hypertension and family history of stroke or myocardial infarction in addition to covariates of the raw model. The H2000-adjusted and Botnia-adjusted models are adjusted for HDL and total cholesterol, current cigarette smoking, BMI and hypertension in addition to covariates of the raw model. Adjusted models for general population are also adjusted for prevalent T2DM.

patients with T2D but not significantly in the general population. The main cause of mortality was CHD both in diabetics (33.8%) and in the general population (30.8%).

While previous studies mostly lacked the longitudinal dimension, also our study has limitations: (1) registry-based ascertainment through hospitalisation may miss non-hospitalised cases (false negatives) and (2) treatment information such as Continuous Positive Airway Pressure (CPAP) compliance and (3) OSA severity, emphasising more severe OSA cases affecting the hazard estimates. However, in spite of these limitations, the study design provides comprehensive estimates of the adverse effects of OSA on CHD and T2D disorders. This is supported by a recent meta-analysis reporting an risk ratio (RR) of 1.49 for the association of OSA and T2D,²⁸ which is well in line with the results from our study.

It is being increasingly recognised that OSA can accelerate loss of kidney function,²⁹ but OSA usually presents with other risk factors of kidney function like obesity, T2D and hypertension.^{30 31} It has been hypothesised that there is a bidirectional relationship between OSA and kidney disease, where kidney disease promotes OSA and OSA kidney disease.²⁹ Our study supports the latter hypothesis that in patients with diabetes OSA increased the risk for kidney disease by 1.75-fold after the adjustment for other risk factors. This is in line with previous, smaller studies.^{19 29}

An important advantage of our large sample size was that we could investigate gender differences in the CHD and T2D risk associated with OSA. While we did not observe a significantly higher risk in women than in men, our data opposite to previous studies clearly show that the severe outcome of OSA is as severe in women as in men (if not more severe).^{3 32} It is possible explanation for this finding may be delayed diagnosis of OSA in women compared with men.

Taken together, our longitudinal study with up to 523 372 person years of follow-up demonstrates that OSA

is an independent risk factor for CHD and T2D and markedly increase risk for diabetic kidney disease. This emphasises the need to search for signs of OSA in patients with T2D with rapid progression of T2D and evaluate whether this progression can be halted by CPAP therapy.

Acknowledgements The authors would like to thank Sari Kivikko, Mervi Kinnunen and Elina Kilpeläinen for management assistance. The FINRISK data used for the research were obtained from THL Biobank and the Health 2000 data from THL. The skillful assistance of the Botnia Study Group is gratefully acknowledged. The authors thank all study participants and their advisers for their generous participation in the FINRISK, the Health 2000 and the Botnia studies.

Contributors TP, AP and SR conceived the study and designed the study protocol. SS conducted the literature review, statistical analysis and drafted the manuscript. AH contributed statistical analysis and phenotyped study samples. VS acquired the

FINRISK data, TT and LG acquired the Botnia data and SK acquired the Health 2000 data. SS, TP, SR, AP, AH, LG, TT, AM, VS, SK and AB reviewed the manuscript for intellectual content, made revisions as needed and approved the final version for publication. TP, SR and AP supervised the study.

Funding This work was supported by Finnish Woman Dentists' Association, the Finnish Dental Society Apollonia, the Helsinki University Central Hospital Research Funds (HUS 369/2017), Academy of Finland Center of Excellence in Complex Disease Genetics (312062), Academy of Finland (251217 and 285380), The Finnish Foundation for Cardiovascular Research, the Sigrid Juselius Foundation and HiLIFE Fellows grants 2017-2020. The sources of funding had no role in study design, data collection, analyses, interpretation and decision to submit the article for publication. FINRISK surveys have been funded mainly by budgetary funds of the National Institute for Health and Welfare. Additional funding has been obtained as research grants from the Finnish Academy and several domestic foundations. VS was supported by the Finnish Foundation for Cardiovascular Research. The Health 2000 Study is funded by the National Institute for Health and Welfare (THL), the Finnish Centre for Pensions (ETK), The Social Insurance Institution of Finland (KELA), The Local Government Pensions Institution (KEVA) and other organizations listed on the website of the survey (<http://www.terveys2000.fi>). The Botnia and The PPP-Botnia studies (LG and TT) have been financially supported by grants from Folkhälsan Research Foundation, the Sigrid Juselius Foundation, The Academy of Finland (grants no. 263401, 267882, 312063 to LG, 312072 to TT), Nordic Center of Excellence in Disease Genetics, EU (EXGENESIS, EUPF7-MOSAIC FP7-600914), Ollqvist Foundation, Swedish Cultural Foundation in Finland, Finnish Diabetes Research Foundation, Foundation for Life and Health in Finland, Signe and Ane Gyllenberg Foundation, Finnish Medical Society, Paavo Nurmi Foundation, Helsinki University Central Hospital Research Foundation, Perklén Foundation, Närpes Health Care Foundation and Ahokas Foundation. The study has also been supported by the Ministry of Education in Finland, Municipal Health Care Center and Hospital in Jakobstad and Health Care Centers in Vasa, Närpes and Korsholm.
