

# Harpacticoid copepods in a DEB framework: Investigating pharmaceutical effects on Nitocra spinipes

### Josef Koch<sup>1</sup>, Colin R. Janssen<sup>1</sup> and Karel De Schamphelaere<sup>1</sup>

<sup>1</sup>Laboratory of Environmental Toxicology and Aquatic Ecology, Environmental Toxicology Unit (GhEnToxLab), Ghent University, Ghent, Belgium

### Introduction

**FACULTY OF BIOSCIENCE ENGINEERING** 

- Copepods are an ideal test system in ecotoxicology studies:
  - Largest animal biomass on earth (estimate)
  - Small size

#### **Model calibration**

- **DEBKiss** ('Keep it simple, stupid') [2] was calibrated on development time and reproduction data at different food levels [3]
- Length per life stage at control conditions was measured to **convert development** time to body length over time (Asm. 1)

#### **Identification of DEB-MoA**

- Observed effects at 100 and 1000 µg/L were simulated in the DEBKiss model by means of the stress factor s
- A **slope parameter** *a* was introduced to

Easy lab culture and handling

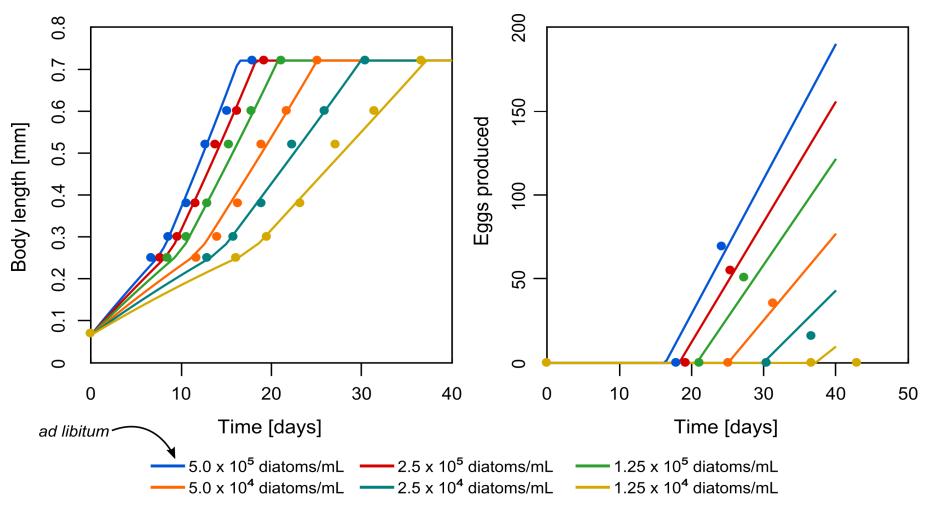

- Dynamic Energy Budget (DEB) theory can help to identify a stressor's mode of action (MoA) on energy allocation
- The copepod life cycle deviates from standard DEB:
- Complete metamorphosis after 6<sup>th</sup> molt
- Abrupt stop in growth at adult stage
- Copepods need further investigation for use in a DEB framework

## Materials & Methods

### Life cycle experiments

- Experimental setups were based on the OECD guidance document [1] for harpacticoid copepod life cycle testing

- The shape correction coefficient (vol. body length × real body length<sup>-1</sup>) was implemented as a **function of size** to account for changes in morphology
- Growth is terminated at the adult stage
- Further modifications include Asm. 2 and 3
- □ Assumption 1: The body length at a certain life stage is independent of food and chemical stress
- □ Assumption 2: Adults invest all energy not used for somatic maintenance into reproduction
- □ Assumption 3: The specific assimilation rate is shifted up at one of the early copepodite stages

the stress function to accurately cover the concentration dependent magnitude of effects

$$s = \frac{1}{c_T} \times \max(0, c_V - c_0)^a$$

s = Stress factor on MoA parameter  $c_0$  = No-effect concentration  $c_{\tau}$  = Tolerance concentration *a* = Slope parameter  $c_V$  = Scaled internal concentration

- Observed effects could be explained by the presence of two individual MoAs:
- (a) Increase in growth costs
- **Decrease in reproduction costs (b)**
- The stress function could be calibrated with just one set of parameters to describe both effects (instead of using separate fits for each MoA)

#### Test species: Nitocra spinipes

- Brackish water species
- Worldwide distribution

Test species since 70s

#### **Test compound: Citalopram**

Selective serotonin re-uptake inhibitor (antidepressant)

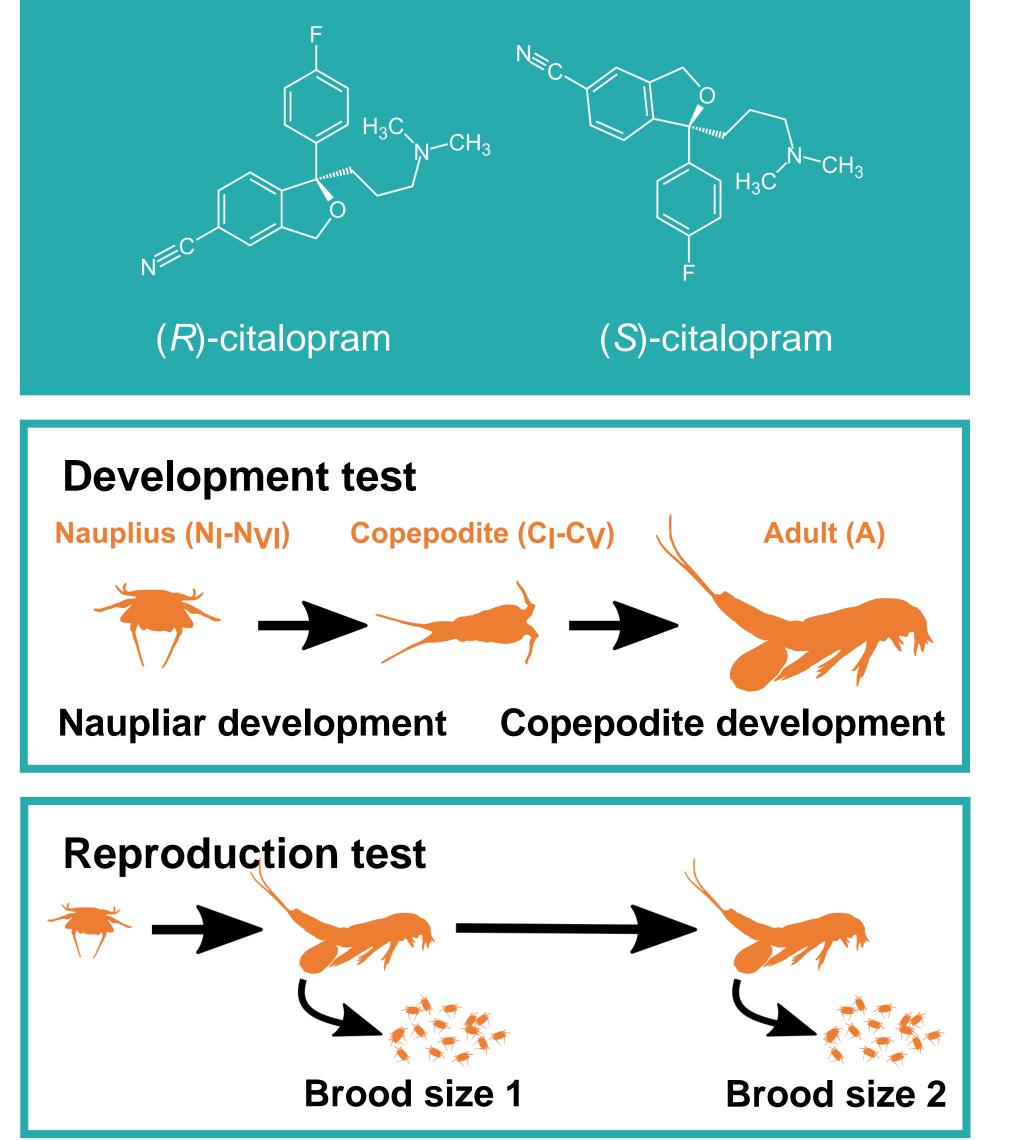

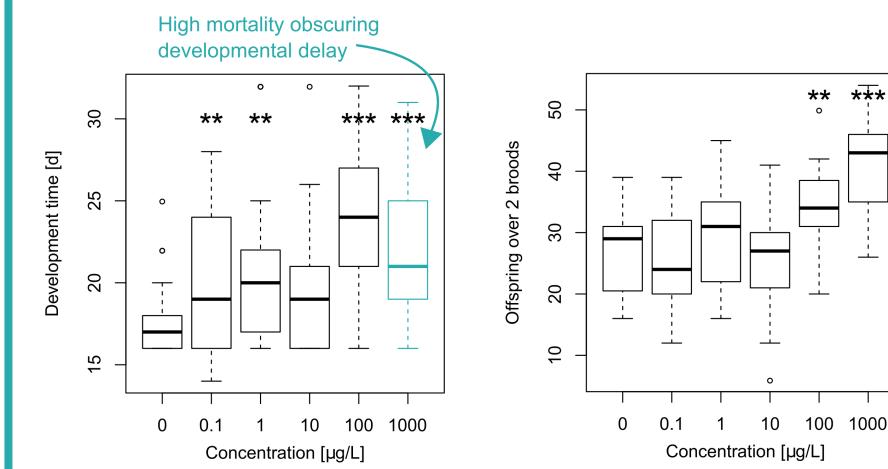

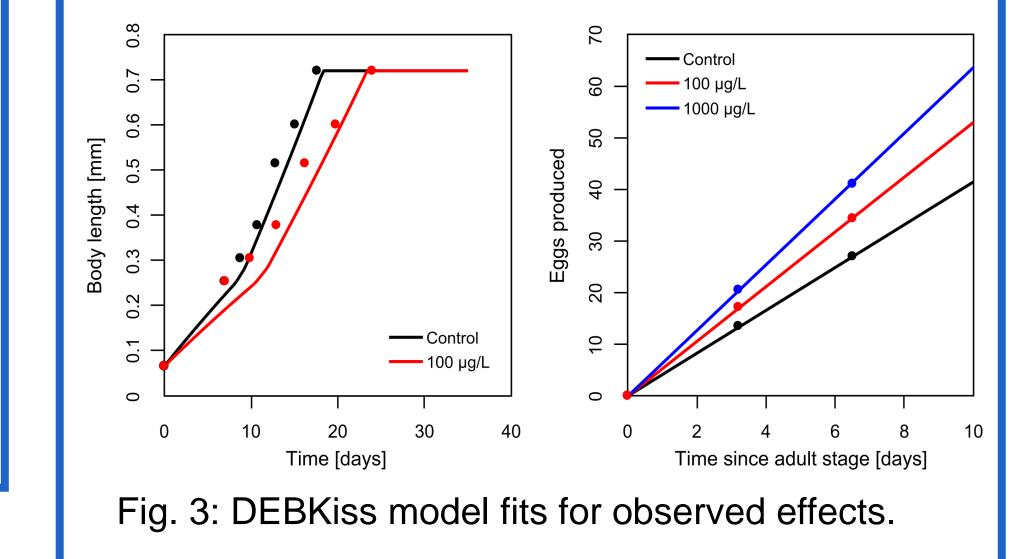

Fig. 1: DEBKiss model calibrated on development and reproduction data of *N. spinipes* at six food levels.

## **Results & Discussion**

#### Conclusions

- The N. spinipes life cycle could be captured well by just slight modifications of the DEBKiss model structure
- Effects of citalopram on development (inhibition) and reproduction (stimulation) of *N. spinipes* were explained by MoAs on energetic costs for growth and reproduction

Fig. 2: Development time from nauplius to adult (left panel) and offspring over two broods per female (right panel). Data were analyzed in one-way ANOVA with a one-sided Dunnett's test (\*\*\*p < 0.001 \*\*p < 0.01 \*p < 0.05).

- Slight **developmental delay** at 100 ng/L and stronger delay at and above 100  $\mu$ g/L
- **Brood stimulation** at and above 100 µg/L
