(Received 18 June 2018; accepted 20 November 2018)

Among the wild canids, the red fox (*Vulpes vulpes*) is recognised as an important reservoir species for a range of parasites, including cardiopulmonary nematodes of public health and veterinary importance. As cross-host transmission between the red fox and domestic carnivores can play an important role in the epizootiology of cardiopulmonary parasitic diseases, the aim of the present investigations was to obtain data on the geographical distribution of cardiopulmonary nematodes of the red fox. The material for examination consisted of 83 foxes which were legally hunted at different locations during a three-month period from December 2017 to February 2018. The presence of four emerging species in Europe (*Angiostrongylus vasorum*, *Crenosoma vulpis*, *Dirofilaria immitis* and *Eucoleus aerophilus*) was revealed in red foxes of Serbia. *Crenosoma vulpis* and *E. aerophilus* were detected in foxes in both the plain and the mountainous areas across the country. *Dirofilaria immitis* is distributed in red foxes near alluvial rivers in Vojvodina province (northern Serbia). Angiostrongylosis caused by *A. vasorum* was demonstrated to exist in two enzootic foci with a high percentage of infected foxes in a plain area of northern Serbia. To the best of our knowledge, *C. vulpis* and *A. vasorum* were discovered for the first time in red foxes in central Serbia. The results provide strong evidence for veterinarians to take into consideration the parasitic nematodes discovered in red foxes in the differential diagnosis of diseases of companion animals. In the context of the ‘One Health’ approach the results related to the distribution of the zoonotic species *E. aerophilus* and *D. immitis* can be useful for medical epidemiology.

Key words: *Angiostrongylus vasorum*, *Crenosoma vulpis*, *Dirofilaria immitis*, *Eucoleus aerophilus*, red fox, Serbia

*Corresponding author; E-mail: pavlelula@yahoo.com; Phone: 00381-65-8334604; Fax: 00381-13-313208

Cardiopulmonary parasitic diseases of Canidae species have recently become timely issues due to their emergence in European countries and their spread into previously non-endemic regions, which has been particularly well documented for diseases caused by *Angiostrongylus vasorum*, *Crenosoma vulpis*, *Dirofilaria immitis* and *Eucoleus aerophilus* (Traversa et al., 2010). Among the wild canids, the red fox is recognised as an important reservoir species for a range of parasites, including cardiopulmonary nematodes. This role of the red fox has become much more pronounced in Europe after the success of oral vaccination against rabies, which has resulted in an increase of its populations (Vos, 1995; Chautan et al., 2000) and in the tendency of extending its habitat into urban areas (Schweiger et al., 2007). In this respect, the importance of cardiopulmonary parasitic diseases of the red fox is mostly reflected in their potential risk to human and companion animal health.

The zoonotic potential of *E. aerophilus* as the cause of parasitic pneumonia has been confirmed in several European countries (Lalošević et al., 2008). *Dirofilaria immitis* is also considered a zoonotic agent, although humans are only accidental carriers of its larval forms. The disease in humans most often takes a pulmonary form and manifests itself in small, solitary peripheral pulmonary granulomas which may be very important in the differential diagnosis of pulmonary coin lesions (Echeverri et al., 1999).

With their increasing frequency reported in domestic carnivores, cardiopulmonary parasitic diseases occupy an increasingly important place in current veterinary practice (Traversa et al., 2010). The French heartworm, *A. vasorum*, has been shown to be very pathogenic for domestic dogs, causing cardiovascular and pulmonary disorders with potentially fatal outcome (Jolly et al., 2015; Benda et al., 2017). The fox lungworm, *C. vulpis*, can cause bronchitis with a dry, unproductive cough in dogs (Cobb and Fisher, 1992), while infection with the zoonotic lungworm *E. aerophilus* results in a similar condition in both dogs and cats (Conboy, 2009).

As the cross-host transmission between red foxes and domestic carnivores can play an important role in the epidemiology of cardiopulmonary parasitic diseases of public health and veterinary importance, the aim of the present investigations was to expand the knowledge relating to the geographical distribution of cardiopulmonary nematodes in red foxes.

Materials and methods

Area and animals included in the study

The investigations included samples from four epizootiological areas, three of which were from central Serbia and one from Vojvodina province (Fig. 1). Vojvodina province is predominantly the plains area located in the north of Ser-

bia and demarcated by the rivers Danube and Sava from central Serbia, which consists mainly of hills and mountains. The material for examination consisted of 83 foxes which were legally hunted at different locations during a three-month period from December 2017 to February 2018. The foxes were delivered to the veterinary institutes (Veterinary Specialised Institute ‘Pančevo’, Veterinary Specialised Institute ‘Požarevac’, Veterinary Specialised Institute ‘Kraljevo’ and Scientific Veterinary Institute of Serbia, Belgrade) within the Programme for the Control and Eradication of Rabies in Serbia.

Fig. 1. The investigated epizootiological areas of Serbia

Methods

The foxes were partially necropsied and the organs of the thoracic cavity were taken out with the associated blood vessels. The heart, the pulmonary artery and its branches were cut open and the noted parasites were removed. Subsequently, the right heart ventricle, the right atrium and the pulmonary artery were washed with tap water into a kidney dish, the coagulated blood was removed and the fluid was thoroughly examined for the presence of additional parasites. The lungs were placed into a separate large kidney dish; the trachea and bronchi were cut open and the noted parasites were removed. Subsequently, the cut-open pulmonary tree was washed with tap water and the lungs were cut into small, 1 cm wide pieces, which were squeezed by hand under the water. The obtained fluid was sedimented for 2 h, after which the sediment was transferred into Petri dishes and examined under a stereomicroscope (at 40 × magnification). The parasites were identified on the basis of the characteristic morphological features described by Soulsby (1965) and Furtado et al. (2010).

Results

In the territory of Serbia four species of cardiopulmonary parasitic nematodes (*D. immitis*, *A. vasorum*, *C. vulpis* and *E. aerophilus*; Fig. 2) were identified in red foxes. The presence of cardiopulmonary nematodes was detected in 69.9% of the 83 examined foxes hunted in different locations. Overall, *D. immitis*, *A. vasorum*, *C. vulpis* and *E. aerophilus* were found in 4.8%, 13.2%, 26.5% and 53.0% of the samples, respectively. *Eucoleus aerophilus* was prevalent in red foxes from all the four epizootiological areas examined, *C. vulpis* was detected in red foxes from three epizootiological areas, *A. vasorum* was found in red foxes from two epizootiological areas, while *D. immitis* was discovered in foxes from one epizootiological area located in northern Serbia (Table 1).

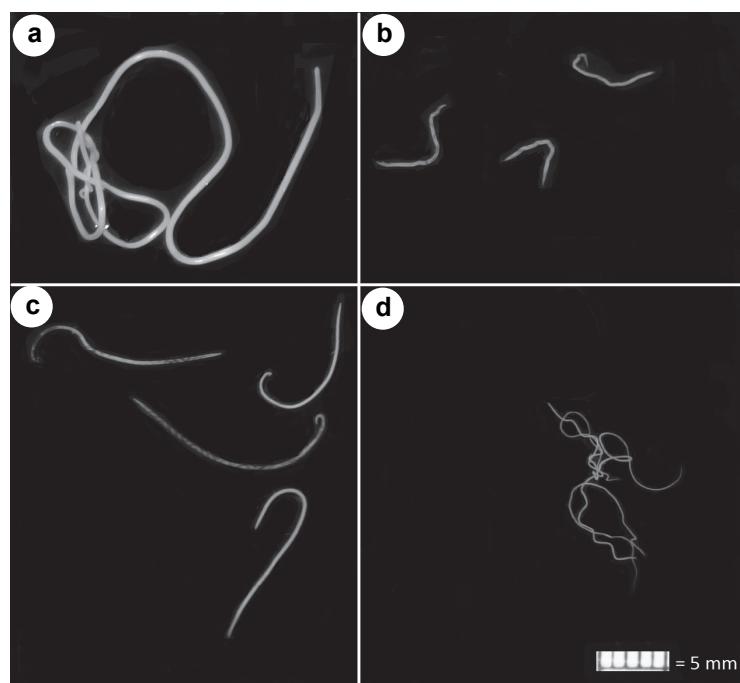

Fig. 2. Cardiopulmonary parasitic nematodes discovered in red foxes in Serbia. (a) *Dirofilaria immitis*, (b) *Crenosoma vulpis*, (c) *Angiostrongylus vasorum*, (d) *Eucoleus aerophilus*

Co-infections were detected in 19 foxes (22.9%). Co-infection with *C. vulpis* and *E. aerophilus* (15/18.1%) was the most frequent, followed by co-infection with *E. aerophilus* and *A. vasorum* (2/2.4%), co-infection with *C. vulpis* and *A. vasorum* (1/1.2%) and co-infection with *D. immitis* and *E. aerophilus* (1/1.2%). Mixed infection with *C. vulpis*, *A. vasorum* and *E. aerophilus* was observed in two foxes (2.4%).

Table 1
Cardiopulmonary parasitic nematodes in red foxes in four epizootiological areas of Serbia

Epizootiological area (region)	Number of foxes examined (n)	Positive samples n (%)	<i>D. immitis</i> n (%)	<i>A. vasorum</i> n (%)	<i>E. aerophilus</i> n (%)	<i>C. vulpis</i> n (%)
South Banat (Vojvodina)	20	16 (80.0%)	4 (20.0%)	9 (45.0%)	6 (30.0%)	3 (15.0%)
Braničevo (central Serbia)	21	9 (42.9%)	0 (0.0%)	0 (0.0%)	7 (33.3%)	3 (14.3%)
Kolubara (central Serbia)	10	3 (30.0%)	0 (0.0%)	0 (0.0%)	3 (30.0%)	0 (0.0%)
Zlatibor (central Serbia)	32	30 (93.7%)	0 (0.0%)	2 (6.2%)	28 (87.5%)	16 (50.0%)
Total	83	58 (69.9%)	4 (4.8%)	11 (13.2%)	44 (53.0%)	22 (26.5%)

The highest intensity of infection was observed for *E. aerophilus* and the lowest for *D. immitis* (Table 2). The infection with *D. immitis* was unisexual in all the four infected foxes. In two foxes single male specimens were found, in one fox two female specimens were detected, while one fox harboured four female specimens. In the populations of *E. aerophilus*, *C. vulpis* and *A. vasorum* both sexes were present and gravid females were found in 41%, 19.3% and 9.6% of the red foxes examined, respectively.

All the four cardiopulmonary parasitic nematodes detected were approximately equally distributed in both sexes. The prevalence of *D. immitis*, *A. vasorum*, *C. vulpis* and *E. aerophilus* was 6%, 14%, 28% and 54% in male foxes and 3%, 12.1%, 24.2% and 51.5% in female foxes, respectively.

Table 2
Prevalence and intensity of infection with *Dirofilaria immitis*, *Angiostrongylus vasorum*, *Eucoleus aerophilus* and *Crenosoma vulpis* in red foxes in Serbia

	Prevalence, %	Range	Mean intensity	Median intensity
<i>D. immitis</i>	4.8	1–4	2	1.5
<i>A. vasorum</i>	13.2	1–17	5.6	4
<i>E. aerophilus</i>	53.0	1–33	8.7	6
<i>C. vulpis</i>	26.5	1–18	4.8	3

Discussion

The investigations confirmed that cardiopulmonary nematodes are widespread in red foxes in Serbia. The most widespread is the zoonotic species *E. aerophilus*, found in all the four epizootiological areas examined. The highest prevalence of infection (87.5%, 28/32) was determined in the Zlatibor epizootiological area, which is a mountainous region of central Serbia. In different European countries, the prevalence of infection ranges from 0.3% in central Poland (Borecka et al., 2009) to 88% in Norway (Davidson et al., 2006). The present findings, coupled with previous studies reporting a prevalence of *E. aerophilus* within a range of 30–84% for different regions of Serbia (Lalošević et al., 2013; Ilić et al., 2016; Bjelić Čabrilović et al., 2018) imply that there is a potential risk of infection for susceptible animals and humans across the whole country. Pulmonary capillariasis in humans is a very rare disease, and there are only a few cases, including just one from Serbia (Lalošević et al., 2008), reported in the international literature. Despite the wide distribution of *E. aerophilus* in Serbia, there have been no data related to eucoleosis in dogs and cats. In neighbouring Romania, for instance, the prevalence of eucoleosis in household cats has been estimated at 3.1% (Mircean et al., 2010).

The relatively high prevalence of *D. immitis* in red foxes in the South Banat epizootiological area, northern Serbia, coincides with an enzootic area of canine dirofilariasis around the rivers Danube and Tamiš. The first case of heartworm disease in a dog in South Banat was reported in 1995 in the City of Pančevo (Blitva-Mihajlović et al., 1995), and in the subsequent two decades this area proved to be enzootic for canine dirofilariasis caused by *D. immitis* (Tasić et al., 2012; Gavrilović et al., 2015).

Although the reproduction of *D. immitis* in the red fox has been confirmed (Magi et al., 2008), the role of this host species in the epizootiology of the disease is still obscure. The maximum number of adult parasites (four) found in red foxes in the present study is lower as compared with dogs in the investigated area (Gavrilović, unpublished data), which may indicate that the red fox is a less susceptible host species. This opinion is supported by the fact that *D. immitis* was not found in red foxes in central Serbia, although the disease is prevalent in dogs (Tasić et al., 2012). A high prevalence of infection suggests the possibility that *D. immitis* is also maintained, in South Banat, in a sylvatic cycle in which the role of definitive host has been taken by the red fox. However, the reproduction of *D. immitis*, which would support such an opinion, could not be demonstrated in the animals examined. In the neighbouring countries, dirofilariasis has been reported in red foxes with a prevalence of 3.7% in Hungary (Tolnai et al., 2014) and 25.2% in Bulgaria (Panayotova-Pencheva et al., 2016).

In the present investigations *A. vasorum* was found for the first time in the territory of central Serbia, Zlatibor epizootiological area. The infected foxes orig-

inated from villages adjacent to the municipality of Gornji Milanovac. Similarly, all the infected foxes from South Banat (Vojvodina) originated from the area of Pančevo municipality, confirming that the disease exists in Serbia in enzootic foci. This is the most probable reason why, unlike the present investigations, Bjelić Čabrilović et al. (2018) found *A. vasorum* in only three individual foxes (1.8%) from Vojvodina, each of which carried a single worm. In addition to red foxes, the disease has been described in a dog (Simin et al., 2014) and in a golden jackal (Gavrilović et al., 2017) in Vojvodina province.

The trend towards a higher incidence of angiostrongylosis observed in some European countries indicates that *A. vasorum* is actually emerging in Europe. A high prevalence of infection (17.9%) has been recorded in Hungary, the country bordering Serbia to the north (Tolnai et al., 2015). In Croatia, bordering Serbia to the west, the prevalence of infection in red foxes is less than 5% (Rajković-Janje et al., 2002) and, similarly, in West Romania bordering Serbia to the east the prevalence was estimated at 4.2% (Deak et al., 2017).

Although angiostrongylosis may be fatal in domestic dogs (Jolly et al., 2015; Benda et al., 2017), the disease is still neglected among practitioners in Serbia. Based on the present investigations dogs from two municipalities, Pančevo and Gornji Milanovac, should be considered to be at a high risk of angiostrongylosis. Currently, canine angiostrongylosis is endemic in many areas of Europe (Elsheikha et al., 2014), and in neighbouring Hungary, for instance, Schnyder et al. (2015) found 1.36% *Angiostrongylus* antibody- and antigen-positivity in dogs.

The fox lungworm, *C. vulpis*, was found in three epizootiological areas and for the first time in the territory of central Serbia. Previous investigations reported the occurrence of this agent with a prevalence of 13.1% (Simin et al., 2012) and 16.6% (Bjelić Čabrilović et al., 2018) in Vojvodina province. The prevalence of infection in Europe ranges from 2 to 58% (Davidson et al., 2006; Morgan et al., 2008), and in some regions such as the Pyrenees in north-eastern Spain, it is the most frequent cardiopulmonary nematode (44.8%) (Garrido-Castañé et al., 2015). Of the neighbouring countries, a prevalence of 24% was reported in red foxes in Hungary (Srēter et al., 2003).

Due to the unspecific clinical signs and difficulties in making a diagnosis, crenosomosis can be an important health issue for veterinary medicine (Cobb and Fisher, 1992; Rinaldi et al., 2007). Individual cases of the disease were recorded in domestic dogs (Cobb and Fisher, 1992; Reilly et al., 2000) and the prevalence of infection was estimated in some countries such as Germany (6.0%; Barutzki and Schaper, 2009), and the Czech Republic (2.0%; Hajnalová et al., 2018).

In conclusion, cardiopulmonary nematodes *D. immitis*, *A. vasorum*, *C. vulpis* and *E. aerophilus* are widespread in red foxes in Serbia. *Crenosoma vulpis* and *E. aerophilus* are detected in foxes in both the plains and mountainous areas across the country. *Dirofilaria immitis* is distributed in red foxes near alluvial

rivers. Angiostrongylosis has been demonstrated to exist in two enzootic foci with a high percentage of infected foxes in the plains area of northern Serbia. To the best of our knowledge, *C. vulpis* and *A. vasorum* were discovered for the first time in red foxes in central Serbia in the present study.

The results provide strong evidence for veterinarians to take into consideration the parasitic nematodes discovered in red foxes in the differential diagnosis of diseases of companion animals. In the context of the 'One Health' approach the results related to the distribution of the zoonotic species *E. aerophilus* and *D. immitis* can be useful for medical epidemiology.
