Background: Specific immunoglobulin E (IgE) sensitization to staphylococcal enterotoxin (SE) has been recently considered to be related to allergic disease, including asthma. Despite studies on specific IgE (sIgE) to SE and its relationship to asthma diagnosis and severity, the association of sIgE to SE with airway hyperresponsiveness (AHR) remains unclear.

Methods: We enrolled 81 asthma patients admitted to the Severance Hospital in Korea from March 1, 2013, to February 28, 2015 and retrospectively reviewed the electronic medical records of the enrolled subjects. The serum levels of sIgE to SE (A/B) of all subjects was measured using the ImmunoCAP 250 (Phadia) system with SE-sIgE positive defined as >0.10 kU/mL.

Results: The SE-sIgE level was not significantly correlated with asthma severity (forced expiratory volume in 1 second [FEV₁], FEV₁/forced vital capacity, sputum eosinophils, and serum eosinophils), whereas the SE-sIgE level in patients with positive AHR (mean±standard error of the mean, 0.606±0.273 kU/mL) was significantly higher than that in patients with negative AHR (0.062±0.015 kU/mL, p=0.034). In regression analysis, SE sensitization (sIgE to SE ≥0.010 kU/mL) was a significant risk factor for AHR, after adjustment for age, sex, FEV₁, and sputum eosinophils (odds ratio, 7.090; 95% confidence interval, 1.180–42.600; p=0.032). Prevalence of SE sensitization was higher in patients with allergic rhinitis and non-atopic asthma patients, as compared to patients without allergic rhinitis and atopic asthma patients, respectively, but without statistical significance.

Conclusion: SE sensitization is significantly associated with AHR.

Introduction

Staphylococcus aureus is a human commensal microorganism, and frequent colonizer of airways and skin. *S. aureus* releases a wide range of enterotoxins¹. While bacterial infection commonly stimulates the innate immune system, staphylococcal enterotoxin (SE) can act as an antigen, in particular, a superantigen². SE binds to the variable β -chain of the T-cell receptor, independent of the antigen-specific groove, so that it is called a "superantigen." This allows the polyclonal activation of T cells and also B cells, resulting in the formation of specific immunoglobulin E (sIgE) to SE, called "SE sensitization"²⁻⁴. These superantigenic properties of SE are considered to have a role in the pathophysiology of allergic disease.

The first allergic disease to be studied for association with SE was atopic dermatitis⁵. Since then, evidence has been gathered that SE also has an important role in upper and lower airway disease^{1,2,6}. The bacterial allergy, sensitization to SE, is considered to be more important than bacterial infection as a cause and aggravating factor for allergic airway disease⁷. Recent studies have revealed that SE sensitization is an independent risk factor for asthma and, especially, the severe asthma entity^{4,8-10}. In severe asthmatics, inability to cope with *S. aureus* colonization in airways by impaired macrophages leads to impairment of mucosal immunity and sensitization to SE¹¹. Asthma represents an inflammatory airway disease with features of mucosal edema and mucus secretion, after allergen stimulation. Airway hyperresponsiveness (AHR), which is measured as increased airway resistance following provocation with stimuli, reflects impairment of mucosal immunity and might be associated with SE sensitization. However, the correlation of SE sensitization with AHR in common asthma patients has never been researched in human clinical studies.

We aimed to evaluate the correlation of SE sensitization with asthma severity, especially AHR, in asthma patients.

Materials and Methods

1. Study population

We retrospectively enrolled 81 asthma patients whose sIgE to SE data were available and admitted to the Severance Hospital in Korea from March 1, 2013, to February 28, 2015. We retrospectively reviewed the electronic medical records of the enrolled subjects. Asthma was diagnosed by an allergy specialist, based on clinical guidelines, using a bronchodilator test and/or bronchial provocation test¹². This study was approved by the Institutional Review Board of Yonsei University College of Medicine (approval number: 4-2013-0397). All enrolled patients provided written informed consent.

2. Laboratory tests

The complete blood count test was performed using an automated analyzer to determine blood eosinophil counts. The eosinophil percentages in induced sputum were assessed as follows. The obtained sputum was centrifuged, and the supernatant was collected. Samples were diluted in phosphate-buffered saline and centrifuged at 450 rpm for 6 minutes to prepare cytology slides. After staining the slides with Wright's stain, a differential count was performed using a light microscope, as reported previously¹³. Forced expiratory volume in 1 second (FEV₁) and FEV₁/forced vital capacity (FVC) were evaluated by pulmonary function test using commercially available equipment (MS-IOS, Masterlab-IOS; Jaeger, Wurzburg, Germany). AHR was assessed by methacholine challenge test or mannitol challenge test, using a titration protocol as in previous reports. The methacholine challenge started with an inhalation of saline, followed by increasing the concentration of methacholine serially, up to a maximum concentration of 25 mg/mL. We defined positive as the provocative concentration of methacholine required to decrease FEV₁ by 20% (PC₂₀), being achieved at less than or equal to 25 mg/mL. The mannitol challenge test ended when a cumulative dose of 635 mg had been inhaled. We defined positive as PD15, the provocative concentration of mannitol required to decrease FEV₁ by 15%, less than or equal to 635 mg. All of these tests were conducted before chart review. We retrospectively reviewed the results of the tests.

3. Clinical parameters

Allergic rhinitis was clinically diagnosed, based on international guidelines which recommend identifying symptoms, including sneezing, rhinorrhea, nasal obstruction, and itching with specific IgE possession confirmed by skin prick test or ImmunoCAP 250 (Phadia, Uppsala, Sweden) system¹⁴. Atopy was defined as positive response to any one of the inhalant allergens (birch, oak, ragweed, mugwort, cat dander, house dust mite, etc.) by ImmunoCAP 250 (Phadia) system, as previously described¹⁵.

4. Serum preparation and measurement of sIgE to SE

We measured the levels of sIgE to SE (A/B) in all subjects. First, whole blood was collected in a vacuum tube for serum separation. Serum was separated by centrifugation, and allergen sIgE detection performed using ImmunoCAP 250 (Phadia) system. The system was operated according to the manufacturer's instructions. The sIgE to SE detection range was 0.1 to 100 kU/L.

5. Statistical analysis

We assessed correlation between two continuous variables using Pearson's test. The t test was used to compare levels of sIgE to SE according to AHR. We selected, as the parameters, sex and age, which are most commonly among the variables considered, and FEV₁ and sputum eosinophil count, which are known to be highly related to asthma severity. We determined the odds ratio (OR) using logistic regression analysis, including univariate and multivariate analysis. Cross-correlation analysis was performed using chi-square tests to analyze the correlation between categorized variables in SPSS version 18.0 (SPSS Inc., Chicago, IL, USA). We considered a p<0.05 to be significant.

Table 1. Demographics of subjects

Parameter	Value
Age, yr	56.1±15.9
sIgE to SE, kU/mL	0.260±0.701
Parameters associated with asthma	
FEV ₁ , %	76.3±22.1

Results

1. Demographics of subjects

We enrolled a total of 81 asthma patients. The mean age of subjects and the standard deviation from the mean was 56.1 years old. The mean value of sIgE to SE and the standard deviation from the mean was 0.260 kU/mL. The FEV₁ and FEV₁/FVC were assessed by pulmonary function tests and represented a mildly obstructive pattern. The percentage of sputum eosinophils and the standard deviation was elevated beyond the normal range. There was a predominance of females. The prevalence of allergic rhinitis and atopy was 75.3% and 59.5%, respectively. Airway hyperresponsiveness was evaluated in 44 patients, and the results were positive in 45.5%. We defined positive to SE-sIgE as more than 0.10 kU/mL, so that the positivity rate is about 40% (39.5% exactly) (Table 1).

2. Correlation of sIgE to SE with parameters associated with asthma

We evaluated the correlation of SE-sIgE with parameters

Table 2. Correlation of sIgE to SE with parameters associated with asthma

Parameter	Pearson's coefficient	p-value
FEV ₁	0.099	0.385
FEV ₁ /FVC	0.149	0.206
Serum eosinophil, %	0.091	0.417
Sputum eosinophil, %	0.027	0.815

sIgE: specific immunoglobulin E; SE: staphylococcal enterotoxin; FEV₁: forced expiratory volume in 1 second; FVC: forced vital capacity.

Figure 1. Comparison of specific immunoglobulin E (sIgE) to staphylococcal enterotoxin (SE) levels according to airway hyperresponsiveness (AHR) (p=0.034). *p-value<0.05 obtained by t-test.

representing asthma severity. The FEV₁ (%) and FEV₁/FVC (%) were not significantly correlated with the levels of sIgE (p=0.385 and p=0.206, respectively). The serum eosinophils (%) and sputum eosinophil (%) were also not significantly associated with the levels of SE-sIgE (p=0.417 and p=0.815, respectively) (Table 2).

3. Comparison of sIgE to SE levels according to AHR

We compared the levels of sIgE to SE according to AHR as assessed by the mannitol challenge test or methacholine challenge test. The sIgE to SE levels in patients with positive AHR (sample size, 20; mean±standard error of the mean, 0.606±0.273 kU/mL) was significantly higher than that in patients with negative AHR (sample size, 24; 0.062±0.015 kU/mL; p=0.034) (Figure 1).

4. Univariate and multivariate analysis for airway hyperresponsiveness

We aimed to identify which parameters could be significant predictive factors for AHR, as assessed by logistic regression. Using univariate analysis, sex (OR, 1.500; 95% confidence interval [CI], 0.400–5.620; p=0.547) and age (OR, 0.714; 95% CI, 0.202–2.528; p=0.602) were not significant predictive factors. The increase in FEV₁ (%), indicating better lung function status, was a significant preventive factor (OR, 0.955; 95% CI, 0.914–0.998; p=0.041). The increase in sputum eosinophils

(%), sputum eosinophilia, was a significant risk factor (OR, 1.047; 95% CI, 1.009–1.087; p=0.015). Being positive for sensitization to SE (≥0.010 kU/mL) was not statistically significant risk factor for AHR (OR, 2.455; 95% CI, 0.685–8.798; p=0.168). Using multivariate analysis, to control for the other factors, being female was a significant risk factor for AHR (OR, 8.908; 95% CI, 1.009–78.624; p=0.049). The increase in FEV₁, which univariate analysis showed to be significant, was not a significant protective factor after adjustment for the other variables (OR, 0.955; 95% CI, 0.906–1.006; p=0.084). The percentage of sputum eosinophils was an independent risk factor for AHR (OR, 1.059; 95% CI, 1.007–1.114; p=0.025). Although positive sensitization to SE was not a significant risk factor when the other factors were not taken into account, it was a significant risk factor for AHR (OR, 7.090; 95% CI, 1.180–42.600; p=0.032) after adjusting for age, sex, FEV₁, and sputum eosinophils (Table 3).

When we adjust the cut-off value to 0.014 kU/mL to define 30% of patients as positive to SE sensitization, SE sensitization was a significant risk factor without adjustment (OR, 4.667; 95% CI, 1.037–21.010; p=0.045) and also with adjustment (OR, 14.096; 95% CI, 1.823–108.970; p=0.011).

5. Prevalence of positive to sIgE to SE according to allergic rhinitis and atopy

We assessed whether the prevalence of positive sensitization to SE will be different according to the presence of allergic rhinitis and atopy or not. The positive sensitization rate to

Table 4. Prevalence of positive to sIgE to SE according to allergic rhinitis and atopy

	sIgE to SE		Total	p-value*
	<0.10 kU/mL	≥0.10 kU/mL		
Allergic rhinitis				
Without	14 (70.0)	6 (30.0)	20 (100)	
With	35 (57.4)	26 (42.6)	61 (100)	0.431
Atopy				
Negative	9 (60.0)	6 (40.0)	15 (100)	
Positive	15 (68.2)	7 (31.8)	22 (100)	0.730

Values are presented as number (%).

*p-value was obtained by chi-square test.

sIgE: specific immunoglobulin E; SE: staphylococcal enterotoxin.

SE in patients without allergic rhinitis was 30.0%, and that in patients with allergic rhinitis was 42.6% without statistically significant difference ($p=0.431$). The positive sensitization rate to SE in non-atopic asthma patients was 40.0%, whereas that in atopic asthma patients was 31.8% ($p=0.730$) (Table 4).

Discussion

The novel finding of this study is that SE sensitization might be significantly associated with AHR. Although some researchers have shown the correlation of SE sensitization with asthma diagnosis and severity, effects of SE sensitization on AHR have not been well studied. An allergen-provocation test is a clear-cut way to prove the allergen causes the allergic disease. The direct cause of asthma can be proven by AHR induced by specific allergens. Although the result presented in this study was not a measure of AHR with SE challenge, we revealed that SE sensitization is significantly associated with AHR. This finding, when considered against the significant correlation between SE sensitization and asthma diagnosis and severity described in the literature, more pointedly supports the hypothesis that SE sensitization might lead to asthma.

Actually, study of asthma in the mouse model has already shown that AHR was able to be induced following SE sensitization^{16,17}. These studies have explained the mechanism by which SE sensitization induces AHR as follows. SE acts as a superantigen to activate T cells independent of the peptide-binding groove area. SE induces airway inflammation, characterized by increased numbers of lymphocytes and eosinophils and by increased levels of the Th2 cytokine, interleukin 4, together with marked upregulation of tumor necrosis factor α production by macrophages. This inflammatory response may lead to AHR.

Although AHR was assessed in only 44 patients, we found that SE sensitization is significantly associated for AHR. We used a cut-off value of positive sensitization, 0.010 kU/mL,

which is widely used in analogous studies^{8,18,19}. When we adjust the cut-off value to 0.014 kU/mL, SE sensitization showed more significant power. SE sensitization might be shown to be a significant independent risk factor for AHR, when a larger number of subjects is examined.

Previous studies revealed that the SE positivity rate is higher in severe asthma than in control and non-severe asthma, but this is still controversial^{4,19,22}. Rossi and Monesterolo²² reported the significant correlation of SE sensitization with serum eosinophil cationic protein levels, indicating that SE sensitization might be correlated with asthma severity. Kowalski et al.¹⁹ found that SE sensitization is significantly correlated with lung function parameters, following adjustment for age. Song et al.¹⁰ indicated that SE sensitization may be correlated with sputum eosinophilia. However, the present study could not demonstrate a significant correlation of SE sensitization with asthma parameters, including sputum eosinophilia. We found SE sensitization is significantly correlated with AHR, regardless of asthma parameters. SE sensitization might be more associated with AHR rather than other asthma parameters, such as lung function and eosinophilia.

We found that SE sensitization was frequently observed in patients with allergic rhinitis (42.6%) compared to patients without (30.0%), but without statistical significance. The failure of this result to reach statistical significance might be due to the small number of subjects studied. Further study with larger sample of allergic rhinitis patients should be performed to evaluate whether SE sensitization is frequently observed in patients with allergic rhinitis rather than patients without.

We also found that the prevalence of SE sensitization was lower in patients with atopic asthma, but without statistical significance. This unresolved association also might yield statistically significant results, were more subjects enrolled. In contrast to atopic asthma, non-atopic asthma is usually associated with elderly age, non-eosinophilic asthma, and severe refractory asthma. Song et al.¹⁰ previously described a positive correlation of SE sensitization rate with aging, positive correla-

tion of total IgE with SE sensitization, and inverse correlation of SE sensitization with atopic status⁹. Our results concerning the inverse correlation of SE sensitization with atopic status are concordant with the previous study described by Song et al.¹⁰ Although data are not shown, highly significant correlation between total IgE with SE sensitization (Pearson's coefficient, 0.696; $p < 0.001$) was also concordant with the previous study described by Song et al.¹⁰ Further detailed study concerning total IgE and SE sensitization should be conducted to reveal this unresolved issue.

This study was limited to a small patient group. In addition, we could not conduct AHR test in the all enrolled subjects. More significant conclusions concerning asthma severity and AHR will be achieved if we conduct a larger study. Assessment of AHR, when challenged by SE, is likely to reveal the direct association between SE and asthma development. Further basic study should be followed to reveal the mechanisms how the SE sensitization induce AHR and asthma. Although the data are not shown due to the insignificance of results, we found that total IgE ($n=7$, 713.8 ± 345.9 kU/mL) in AHR positive patients tend to be slightly higher than those ($n=5$, 182.5 ± 132.3 kU/mL) in AHR negative patients ($p=0.244$). Further study concerning total IgE with AHR might be interesting. This study has additional limitation concerning severity parameters. The most important severity parameter, medication type and dose used in subjects to control symptoms, was not included in this study. This is due to the deviated distribution to the medium dose inhaled corticosteroid and long-acting β -agonist complex inhaler in almost subjects.

We have, for the first time, revealed that SE sensitization is significantly associated with AHR in common asthma patients, despite the small number of subjects studied. This result implies that SE sensitization might be associated with development of asthma. Further large-scale studies should be conducted to harden these results.

Conflicts of Interest

No potential conflict of interest relevant to this article was reported.
