#### Abstract

In this paper, the dynamics and control of a novel class of aerial manipulator for the purpose of end effector full pose trajectory tracking are investigated. The 6 D pose of the end effector is set as a part of the flat output, from which the conditions that the system has the proposed flat output is obtained. The control law for the end effector tracking purpose is designed. The core part of the controller is an almost global controller in the configuration space of the system. From the transformation between the state space and the output space, the tracking control of the end effector in $S E(3)$ is also achieved. The stability of the controlled system is analyzed. A numerical example is presented to demonstrate the theoretical analysis.

INDEX TERMS Aerial manipulator, task space, tracking control, differential flatness.

## I. INTRODUCTION

## A. BACKGROUND AND MOTIVATION

Recently, aerial manipulation has attracted great interests in robotics research community [1]. Several groups demonstrated aerial grasping using grippers attached to aerial manipulators [2]-[4]. Lee and Kim, Kim et al. show cooperative aerial manipulators grasping with unknown payload in environment with obstacles [5], [6]. Orsag et al. demonstrate pick-place and peg-in-hole tasks using quadrotor platform and dual arms attached in the platform [7]. The EU 7-th Framework program funds several projects on aerial manipulators, investigating the motion planning and impedance control with aerial manipulator when interacting with the environment [8]-[10]. A research group in German Aerospace Center presents the potential application of a 7 DOFs anthropomorphic arm attached to a helicopter [11]. Delta-like mechanism [12] and parallel manipulator [13] are also considered in aerial manipulators. Such existing works present a prospective future of research on aerial manipulation. However, compared to ground-based manipulators, the tasks that aerial manipulators can achieve are still in a very preliminary stage. This is due to many factors, such as

[^0]the end effector of the current aerial manipulators is difficult to achieve 6 D pose trajectory tracking.

## B. RELATED WORK

It has been shown that the aircraft itself is fully controllable if it is actuated by 1D force and 3D torque. A typical example of such aircraft is quadrotor. In [14], the mechanics and control problem of the quadrotor with a rigidly attached tool effector has been considered. It is found that the 3D force-position control of the quadrotor tool system is possible. However, the end effector needs to be positioned carefully to prevent the unstable internal dynamics induced by the feedback linearization.

In aerial articulated manipulator, the added manipulator joints may compensate for the unstable internal dynamics. By reducing the 3 D condition into a 2 D condition, the planar quadrotor manipulator presents some good properties [15]-[17]. It was found that the end effector of planar aerial manipulator can achieve trajectory tracking control in $S E$ (2). However, the 3D conditions are different. Most of the previous work on control of 3D aerial articulated manipulator is finished in its configuration space [18]. A regulator for such system is derived and the stability is proven using singular perturbation theory [19]. However the aerial manipulator based on this kind of aircraft is difficult to achieve 6D
pose trajectory tracking in task space, because of the dynamic coupling between the position and the attitude of such type of aircraft [10]. Yang and Lee propose a back stepping control for position tracking of end effector of quadrotor-based aerial manipulator in [20], where the torque of the aircraft and the joint torque should satisfy dynamic constraints. This makes the joint position difficult to be independently controlled. A method to allocate the joint torque in order to independently control the joint position is also proposed [20], but no proof of controllability is provided.

It is believed that the traditional under-actuated aerial vehicle is not ideal for aerial manipulation, some researchers considered the fully actuated aerial platform-based manipulator. The fully actuated aerial vehicle platform can track the trajectory in $S E(3)$ without any constraints. Franchi et al. propose a fully actuated aerial vehicle where the actuated force and torque is produced by 6 rotors that point to different directions [21]. Other fully actuated aerial platform includes tilting aerial vehicle [22], omni-directional aerial vehicles [23], and aerial vehicles with extra actuators [24]. In summary, the actuators of this class of aerial vehicle can produce 6 D independent force and torque. However, the extra actuators also decrease the energy efficiency.

Several researchers also investigated aerial manipulation based on multiple aerial vehicles. It was shown that in 3D space, three quadrotors could lift a rigid body moving in $S E(3)$ [25]. By using a similar principle, Nguyen et al. propose a structure for aerial manipulation using multiple quadrotors as rotating thrust generators [26]. These multiple quadrotors connect to the manipulator via spherical joints, the manipulation platform therefore is capable to track a trajectory in $S E(3)$. Six et al. propose a flying parallel robot with three quadrotors [27]. This aerial manipulator is composed of three quadrotors which connect to the end effector through light-weight legs. The legs then connect the quadrotor via passive spherical joints and the end effector via passive revolute joints. The multiple aerial vehicle-based manipulator is a possible solution for the 6 D pose tracking control of an end effector, though it may also be concluded that it needs a more complex structure.

## C. CONTRIBUTIONS

In this paper, the trajectory tracking of the end effector in $S E(3)$ by a single 3 D aerial manipulator is investigated. It is well studied that differentially flat systems are input-state feedback linearizable, and are thus controllable [28]. In order to investigate the 6 D pose tracking control problem using aerial manipulator, in this paper we set the pose of the end effector as the flat output. The conditions that the 6D pose of the end effector is the flat output are derived and analyzed. It does not need the aircraft base to be fully actuated. In order to deal with the 6D pose trajectory tracking, the flat output is transformed into the state. By designing the state feedback controller, the 6 D pose tracking for the end effector is thus achieved. Considering the configuration space of the floating

FIGURE 1. Configuration of an aerial manipulator. The first joint locates at the COM of the aircraft base. $F_{0}$ and $\tau_{0}$ are expressed in the floating base fixed frame. The pose of link-i of the manipulator is denoted as $h_{i} \in S E(3)$. The axis of joint-i expressed in based fixed frame is $z_{i} \in \boldsymbol{S}^{\mathbf{2}}$. Note the COM of the base is not the COM of the entire system.
base manipulator is non-Euclidean space, a hybrid controller is designed in order to achieve almost global stability.

Overall, the main contribution of this paper can be summarized as follows. 1) To the authors' best of knowledge, this paper proposes a new class of aerial manipulator for 6D pose task trajectory tracking for the first time. Unlike the fully actuated aerial platform which usually needs three linear actuation force, the proposed aerial platform needs only two actuation force. 2) The fact that the task space of the proposed aerial manipulator is 6 D is proven from differential flatness. 3) For the 6D pose task trajectory tracking purpose, a control framework for the proposed class of aerial manipulator is designed and analyzed.

This paper is organized as follows: The dynamics and the analysis of the differential flatness of the system are presented in Section II. In Section III, the controller for full pose tracking in task space is designed and analyzed. In Section IV, a numerical simulation for the proposed class of aerial manipulator is demonstrated.

## II. PROBLEM FORMULATION

A. SYSTEM MODELING OF AERIAL MANIPULATOR

## 1) CONFIGURATION, VELOCITY AND DYNAMICS

As shown in Fig. 1, for an aerial manipulator system composed with a floating base and a $n$-joint manipulator, the configuration of the system is denoted by $q=\left(h_{0}, r\right) \in$ $S E(3) \times \mathbb{R}^{n}$, where $h_{0}=\left[\begin{array}{cc}R_{0} & p_{0} \\ 0 & 1\end{array}\right]$ is the pose of the floating base, $r \in \mathbb{R}^{n}$ is the joint position. The system's velocity is given by $\zeta=(V, \dot{r}) \in \mathbb{R}^{6} \times \mathbb{R}^{n}$, where $V=\left(v_{0}, \omega_{0}\right)$ is the body velocity of the aircraft base. The dynamic equation of the system can thus be expressed in these notations as [1],

$$
\begin{equation*}
M_{t}(r) \dot{\zeta}+C_{t}(r, \zeta) \zeta+G_{t}\left(r, R_{0}\right)=u \tag{1}
\end{equation*}
$$

where $M_{t}(r), C_{t}(r, \zeta), G_{t}(r, R)$ are the mass matrix, Coriolis matrix, and gravity vector respectively, and $u=\left(F_{0}, \tau_{0}, \tau_{r}\right)$ is the input of the system. The mass matrix $M_{t}(r)$ is symmetric positive definite.

## 2) PASSIVE DECOMPOSITION OF DYNAMICS

The system equation (1) reveals the properties of underactuation and coupling. In order to investigate the planning and
control solution of this system, we split the tangent space of (1) using the passive decomposition method presented in [20] as

$$
\zeta=\left[\begin{array}{ll}
\Delta_{\perp} & \Delta_{\top}
\end{array}\right]\left[\begin{array}{c}
b \dot{p}  \tag{2}\\
\mu
\end{array}\right]:=\underbrace{\left[\begin{array}{cc}
I_{3} & S_{E}(r) \\
0 & I_{n+3}
\end{array}\right]}_{S(r)} \eta
$$

where $\mu=\left(\omega_{0}, \dot{r}\right) \in \mathbb{R}^{3+n},{ }^{b} \dot{p}$ is the linear velocity of the center of mass (COM) of the entire system expressed in floating base fixed frame, $I$ represents the identity matrix, $S_{E}(r) \in \mathbb{R}^{3 \times(n+3)}, S(r) \in \mathbb{R}^{(n+6) \times(n+6)}$. Transforming the body linear velocity ${ }^{b} \dot{p}$ to spatial linear velocity $\dot{p}$, we can thus obtain the decoupled equation of motion (EOM) as [20],
locked system $\left\{\begin{array}{l}\dot{p}=v \\ \dot{v}=\frac{1}{m} R_{0} F_{0}+g e_{3}\end{array}\right.$
shape system $\left\{\begin{array}{l}\dot{\sigma}=\sigma \hat{\mu} \\ M(r) \dot{\mu}+C(r, \mu) \mu=S_{E}^{T} F_{0}+\left[\begin{array}{l}\tau_{0} \\ \tau_{r}\end{array}\right] \triangleq \tau_{E}\end{array}\right.$
where $\sigma=\left(R_{0}, r\right) \in S O(3) \times \mathbb{R}^{n}, m$ is the total mass, $g$ is the acceleration due to gravity, $e_{i}$ denotes the canonical basis vector in $\mathbb{R}^{3}$, e.g., $e_{3}=(0,0,1)^{T}$, the operation $\sigma \hat{\mu}=\left(R_{0}^{T} \hat{\omega}_{0}, \dot{r}\right)$ represents the tangent map induced by the left translation on $S O(3) \times \mathbb{R}^{n}$. This decomposition partitions the whole system into two subsystems: the locked system describing the translational motion of the COM defined on $\mathbb{R}^{3}$, and the shape system describing the rotational motion of the whole system on $S O(3) \times \mathbb{R}^{n}$. Note that in (3), $p$ and $v$ are the position and velocity of COM of the entire system expressed in Earth frame.

## B. FLAT OUTPUT DEFINITION

In order to let the end effector be able to track the trajectory in $S E(3)$, and also to let the joint angles track the reference trajectories, a natural selection of the flat output of the system is $\left(h_{t}, r\right)$, where $h_{t}=\left[\begin{array}{cc}R_{t} & p_{t} \\ 0 & 1\end{array}\right] \in S E(3)$ is the task space coordinate which is the pose of the end effector. However, this choice needs the aircraft to be fully actuated. In this paper, we consider the following flat output $y_{1}=\left(h_{t},\left(r_{2}, r_{3}, \ldots, r_{n}\right)\right)^{T}$.

Problem 1: Given the system dynamics (1) and the reference flat output $y_{1, d}: t \mapsto y_{1}(t) \in S E(3) \times \mathbb{R}^{n-1}$, design control $u$ such that $y_{1} \rightarrow y_{1, d}$ along the trajectory defined by (1).

Lemma 1: Given a constant $z \in S^{2}$, define the following sets, $\Omega_{R}=\{R \in S O(3) \mid R z \neq-z\}, \tilde{S}^{2}=S^{2} /(-z)$, and $\Omega_{R_{p}}=\{R \in S O(3) \mid R=\exp (\theta \hat{z}), \theta \in \mathbb{R}\}$. Then there exists a mapping $f_{z}: \Omega_{R} \mapsto \tilde{S}^{2} \times \Omega_{R_{p}}$ which is a diffeomorphism.

Proof: In the proof, first we will define smooth functions: $f_{z}$ and its inverse $f_{z}^{-1}$, then we will show $f_{z}$ is bijection.
(i) For all $R \in \Omega_{R}$, one can define

$$
\begin{equation*}
z_{b}=R z \tag{4}
\end{equation*}
$$

And $\forall z_{b} \neq-z$ one can define a unique rotation matrix

$$
R_{l}=\left\{\begin{array}{l}
\exp (\vartheta \hat{q}), z_{b} \neq z  \tag{5}\\
I, z_{b}=z
\end{array} \quad:=f_{R_{l}}(R, z)\right.
$$

where the $\vartheta \in[0, \pi]$ is the eigen-angle of $R_{l}$, it is defined as the angle from $z$ to $z_{b}$

$$
\vartheta=\cos ^{-1}\left(1-\frac{1}{2}\left\|z-z_{b}\right\|^{2}\right)
$$

and the eigen-axis $q \in S^{2}$ of $R_{l}$ is defined by

$$
q=\frac{z \times z_{b}}{\left\|z \times z_{b}\right\|}, \quad z \neq z_{b}
$$

Expanding the expression of $\exp (\vartheta \hat{q})$ we have,

$$
f_{R_{l}}(R, z)=\left\{\begin{array}{l}
I+(z \times R z) \hat{}  \tag{6}\\
+\frac{1}{1+z^{T} R z}\left((z \times R z) \hat{)^{2}}, \quad z_{b} \neq z\right. \\
I, z_{b}=z
\end{array}\right.
$$

Then we define

$$
\begin{equation*}
R_{p}=R_{l}^{T} R \tag{7}
\end{equation*}
$$

It is seen from (5)

$$
\begin{equation*}
R_{l} z=z_{b}=R z . \tag{8}
\end{equation*}
$$

Then from (7) and (8) we have

$$
\begin{equation*}
R_{p} z=z \tag{9}
\end{equation*}
$$

Therefore the eigen-axis of $R_{p}$ is $z$, which means $R_{p} \in \Omega_{R_{p}}$. From (4)-(7) we have defined the smooth mapping $f_{z}: \Omega_{R} \ni$ $R \mapsto\left(z_{b}, R_{p}\right) \in \tilde{S}^{2} \times \Omega_{R_{p}}$.
(ii) For any element $\left(z_{b}, R_{p}\right) \in \tilde{S}^{2} \times \Omega_{R_{p}}$, one can calculate $R_{l} \in S O$ (3) from $z_{b}$ according to (5), then calculate $R=R_{l} R_{p}$ which is an element in $\Omega_{R}$. The smooth mapping $f_{z}^{-1}:\left(\tilde{S}^{2} \times\right.$ $\left.\Omega_{R_{p}}\right) \ni\left(z_{b}, R_{p}\right) \mapsto R \in \Omega_{R}$ is therefore obtained.
(iii) Then we will show $f_{z}$ is bijection.

Consider $R_{1}, R_{2} \in S O(3), R_{1} \neq R_{2}$. If $R_{1} z=R_{2} z$, calculate $R_{1, l}$ and $R_{2, l}$ from $R_{1}$ and $R_{2}$ according to (5), we have $R_{1, p}=R_{1, l}^{T} R_{1}, R_{2, p}=R_{2, l}^{T} R_{2}$, it is seen $R_{1, l}=R_{2, l}$, but $R_{1, p} \neq R_{2, p}$ because $R_{1} \neq R_{2}$, therefore $f_{z}\left(R_{1}\right) \neq f_{z}\left(R_{2}\right)$. Else if $R_{1} z \neq R_{2} z$, it is obvious that $f_{z}\left(R_{1}\right) \neq f_{z}\left(R_{2}\right)$. Therefore $f_{z}$ is one-to-one.

During the previous proof, it has shown that $f_{z}$ is onto, since $\forall\left(z_{b}, R_{p}\right) \in\left(\tilde{S}^{2} \times \Omega_{R_{p}}\right), f_{z}^{-1}\left(z_{b}, R_{p}\right) \in \Omega_{R}$. Therefore we can conclude that $f_{z}$ is bijection. This completes the proof.

Remark 1: The physical meaning of Lemma 1 is that the attitude of a rigid body can be represented as the attitude of a body-fixed axis, and a rotational angle around the axis, as shown in Fig. 2. Considering an attitude trajectory of the rigid body $R(t): \mathbb{R} \geq 0 \mapsto \Omega_{R}$. From Lemma 1, one can also obtain the corresponding trajectory $R_{l}(t), R_{p}(t): \mathbb{R} \geq 0 \mapsto$ $\left(\Omega_{R_{l}} \times \Omega_{R_{p}}\right.$ ), where $\Omega_{R_{l}} \subset S O(3)$ denotes the set of $R_{l}$ defined in (5). The smooth mapping $f_{z}$ also induces the tangent mapping $f_{z, * R}: \dot{R} \in T_{R} \Omega_{R} \mapsto T_{f_{z}(R)}\left(\tilde{S}^{2} \times \Omega_{R_{p}}\right) \ni\left(\dot{z}_{b}, \dot{R}_{p}\right)$, where $\dot{z}_{b}=\dot{R} z, \dot{R}_{p}=R_{p} \hat{z} \dot{\theta}$, therefore we can express $\dot{\theta}$ as

$$
\begin{equation*}
\dot{\theta}=\left\langle\left(R_{p}^{T} \dot{R}_{p}\right)^{\vee}, z\right\rangle \quad:=f_{\dot{\theta}}(\dot{R}, R) \tag{10}
\end{equation*}
$$

FIGURE 2. The attitude of a rigid body can be represented by the attitude of a body-fixed axis, and the rotational motion around the body-fixed axis.
where $\langle.$, . $\rangle$ represents the inner product of two vectors.
Remark 2: In Lemma 1, $\Omega_{R}$ is a subset of $S O$ (3). It should be noticed that for $R \in \Omega_{s}=\{R \in S O(3) \mid R z=-z\}$, we cannot define $R_{p}$ using Lemma 1 , as $R_{l}$ calculated through (5) has infinite possibilities. This singularity will not be considered in this paper.

Proposition 1: Consider the aerial manipulation system with configuration shown in Fig. 1 and dynamics (1), suppose $R_{0} \quad z_{1} \neq-z_{1}$. Define variable $y_{2}=$ $\left(p, R_{0, l}, r_{1}^{a}, r_{2}, r_{3}, \ldots, r_{n}\right)$, where $R_{0, l}=f_{R_{l}}\left(R_{0}, z_{1}\right), r_{1}^{a}=$ $r_{1}+\phi$, and $\phi$ is determined from $\exp \left(\phi \hat{z}_{1}\right)=R_{0, l}^{T} R_{0}$. Then $\Omega_{y_{1}}=\left\{y_{1}\right\}$ is diffeomorphic to $\Omega_{y_{2}}=\left\{y_{2}\right\}$.

Proof: It is seen that $\Omega_{y_{1}}$ and $\Omega_{y_{2}}$ are both $n+5$ dimensional. In order to prove this proposition, first we will show that $y_{2} \mapsto h_{t}$ is smooth function, second we will show that $y_{1} \mapsto p$ and $y_{1} \mapsto R_{0, l}$ are also smooth functions.

First we show the transformation from $y_{2}$ to $y_{1}$. The attitude of the first link of the manipulator is given by

$$
\begin{equation*}
R_{1}=R_{0, l} \exp \left(r_{1}^{a} \hat{z}_{1}\right) \tag{11}
\end{equation*}
$$

The attitude of the remaining links of the manipulator is determined as

$$
\begin{equation*}
R_{i}=R_{1} \prod_{j=2}^{i} \exp \left(r_{j} \hat{z}_{j}\right), \quad i=2, \ldots, n \tag{12}
\end{equation*}
$$

Because joint-1 locates in the COM of the base, the attitude of the base has no effect on $p$, the position of the end effector can thus be expressed as

$$
\begin{equation*}
p_{t}=f_{p_{t}}\left(p, R_{1}, R_{2}, \ldots, R_{n}\right) \tag{13}
\end{equation*}
$$

Combining (11), (12), and (13), we conclude $y_{2} \mapsto h_{t}$ is a smooth function.

Then, we show the transformation from $y_{1}$ to $y_{2}$. Given $y_{1}$, it is easy to solve $h_{1}$. Therefore, $p$ is expressed as $p=f_{p}\left(h_{1}, r_{2}, \ldots, r_{n}\right)$. Furthermore, from Lemma 1 we have $R_{0, l}=R_{1, l}=f_{R_{l}}\left(R_{1}, z_{1}\right)$, and $r_{1}^{a}=\left\langle\left(\exp ^{-1}\left(R_{1, p}\right)\right)^{\vee}, z_{1}\right\rangle$. The smooth map $y_{1} \mapsto y_{2}$ is thus achieved. Therefore the diffeomorphism between $\Omega_{y_{1}}$ and $\Omega_{y_{2}}$ is proven.

Theorem 1: Consider the system dynamics (1), suppose $R_{0} z_{1} \neq-z_{1}$, and $\left(\ddot{p}-g e_{3}\right) \times\left(R_{0} z_{1}\right) \neq 0$. If $\left\{\left(\tau_{0}, \tau_{r}\right)\right\}=\mathbb{R}^{3+n}$ and $\left\{F_{0}\right\}=\operatorname{span}\left(z_{1}, z_{1}^{\perp}\right)$, where $z_{1}^{\perp} \in S^{2}$ is s.t. $z_{1}^{\perp} \perp z_{1}$,
$\operatorname{span}(*)$ represents the space spanned by each column of $*$, then $y_{1}$ is the flat output of the system (1).

Proof: First we prove that $y_{2}$ is the flat output of the system.

For brevity, we write $F_{d}=m \ddot{p}$, it is seen

$$
\begin{equation*}
F_{d}=R_{0} F_{0}+m g e_{3} \tag{14}
\end{equation*}
$$

where $R_{0}$ can be expressed using Lemma 1 as

$$
R_{0}=R_{0, l} \exp \left(\phi \hat{z}_{1}\right)
$$

Therefore

$$
\begin{equation*}
\exp \left(\phi \hat{z}_{1}\right) F_{0}=R_{0, l}^{T}\left(F_{d}-m g e_{3}\right) \tag{15}
\end{equation*}
$$

If $F_{0} \in \operatorname{span}\left(z_{1}, z_{1}^{\perp}\right)$, assuming $\phi$ is unbounded, then from the flat output $\left(R_{0, l}, \ddot{p}\right)$ we can always solve input $F_{0}$ along $z_{1}$ and $z_{1}^{\perp}$ as

$$
\begin{align*}
\left\langle F_{0}, z_{1}\right\rangle & =\left[\left(F_{d}-m g e_{3}\right)^{T} R_{0, l} z_{1}\right] \\
\left\langle F_{0}, z_{1}^{\perp}\right\rangle & =\sqrt{\left\|R_{0, l}^{T}\left(F_{d}-m g e_{3}\right)\right\|^{2}-\left\|\left\langle F_{0}, z_{1}\right\rangle\right\|^{2}} \tag{16}
\end{align*}
$$

We define $R_{z}=\left(z_{1}, z_{1}^{\perp} \times z_{1}, z_{1}^{\perp}\right)$, because $z_{1}=R_{z} e_{1}$ we can rewrite the force allocation (15) as follows,

$$
R_{z} \exp \left(\phi \hat{e}_{1}\right) R_{z}^{T} R_{z}\left[\begin{array}{c}
F_{0}^{T} z_{1}  \tag{17}\\
0 \\
F_{0}^{T} z_{1}^{\perp}
\end{array}\right]=R_{0, l}^{T}\left(F_{d}-m g e_{3}\right)
$$

where $\exp \left(\phi \hat{e}_{1}\right)=\left(e_{1}, e_{2 \phi}, e_{3 \phi}\right)$ can be solved as,

$$
e_{3 \phi}=\frac{R_{z}^{T} R_{0, l}^{T}\left(F_{d}-m g e_{3}\right)-\left(F_{0}^{T} z_{1}\right) e_{1}}{F_{0}^{T} z_{1}^{\perp}}, \quad F_{0}^{T} z_{1}^{\perp} \neq 0
$$

and $e_{2 \phi}=e_{3 \phi} \times e_{1}$. Then, the attitude of the aircraft base can be calculated as

$$
\begin{equation*}
R_{0}=R_{0, l} R_{z} \exp \left(\phi \hat{e}_{1}\right) R_{z}^{T} \tag{18}
\end{equation*}
$$

The joint angle of the first joint is then solved as

$$
\begin{equation*}
r_{1}=r_{1}^{a}-\phi \tag{19}
\end{equation*}
$$

By now, we have shown that $R_{0}$ and $r_{1}$ are algebraic functions of $\ddot{p}$ and $R_{0, l}$. Since $\hat{\omega}_{0}=R_{0}^{T} \dot{R}_{0}$, it is not difficult to derive $\omega_{0}$ and $\dot{r}$ from $\ddot{p}, R_{0, l}, \dddot{p}, \dot{R}_{0, l}$, and ( $\dot{r}_{2}, \ldots, \dot{r}_{n}$ ). And since $\left\{\left(\tau_{0}, \tau_{r}\right)\right\}=\mathbb{R}^{3+n}$, the shape system is fully actuated, therefore ( $\tau_{0}, \tau_{r}$ ) can also be derived from $\ddot{p}, R_{0, l}, \dddot{p}, \dot{R}_{0, l}$, $\dddot{p}, \ddot{R}_{0, l},\left(\dot{r}_{2}, \ldots, \dot{r}_{n}\right)$, and $\left(\ddot{r}_{2}, \ldots, \ddot{r}_{n}\right)$. For brevity the detailed derivation is not presented here. The proof that $y_{2}$ is the flat output is thus finished.

Since $\Omega_{y_{1}}$ and $\Omega_{y_{2}}$ are diffeomorphic, once $y_{2}$ is the flat output, $y_{1}$ is also the flat output.

Remark 3: $\left\{F_{0}\right\}=\operatorname{span}\left(z_{1}, z_{1}^{\perp}\right)$ is possible to be realized in physical systems. The approach includes adding tilting actuators, or extra actuators on the aircraft base. As seen in Theorem 1, the force acting on the aircraft body is restricted to 2D space. Therefore the aircraft platform is not a fully actuated aerial vehicle which usually needs three independent forces, thus is more efficient than the fully actuated aerial vehicle.

Remark 4: Another approach to contain $h_{t} \in S E(3)$ in flat output space is to let $\left\{\tau_{1}\right\}=\mathbb{R}^{2}$ [29]. The proof can be correspondingly derived. However, it is seen that this condition is not easy to be realized in physical systems. Therefore, this paper focuses on the aerial manipulator with conditions shown in Theorem 1.

Remark 5: Both $y_{1}$ and $y_{2}$ contain the joint position $r_{2}, \ldots, r_{n}$. It is seen under the conditions in Theorem 1, $r_{2}, \ldots, r_{n}$ is redundant for tracking $h_{t}$. However, $r_{2}, \ldots, r_{n}$ is useful for increasing the flexibility of the manipulation, e.g., it can increase the workspace of the end effector.

## III. GLOBAL CONTROL DESIGN AND STABILITY ANALYSIS

## A. CONTROL STRATEGY

Theorem 1 gives conditions for $u$, in order to solve Problem 1, we need to design the control law for $u$. To let $h_{t} \rightarrow h_{t, d}$, one needs to express the system dynamics with respect to $p_{t}$ and $R_{t}$. It is seen that $\dot{p}_{t}$ and $\dot{R}_{t}$ are highly coupled with the rotational part of the body dynamics, as well as the joint position dynamics. The system dynamics with respect to $h_{t}$ thus is quite complex. To avoid the complex expressions, the control strategy is to ensure $y_{2} \rightarrow y_{2, d}$, then use the diffeomorphism between $\Omega_{y_{1}}$ and $\Omega_{y_{2}}$ to let $y_{1} \rightarrow y_{1, d}$. The overall control strategy is shown in Fig. 3.

FIGURE 3. Overall control strategy.

In order to achieve $y_{2} \rightarrow y_{2, d}$, a controller with a cascade structure is designed. Given the smooth trajectory $y_{2, d}, R_{0, d}$ can be calculated from the flatness of the system. The inner loop control is to guarantee $R_{0} \rightarrow R_{0, d}$ and $r_{f} \rightarrow r_{f, d}$, where $r_{f}=\left(r_{1}^{a}, r_{2}, \ldots, r_{n}\right)^{T}$, the outer loop control is to guarantee $p \rightarrow p_{d}$. In this way, the controller is possible to stabilize the entire $12+2 n$ dimensional state.

First we write the dynamics of the shape system with respect to $r_{f}$. Differentiate (19) and combine (10), we can obtain the expression of $\dot{r}_{1}$ as

$$
\begin{equation*}
\dot{r}_{1}=\dot{r}_{1}^{a}-f_{\dot{\theta}}\left(\dot{R}_{0}, R_{0}\right) \tag{20}
\end{equation*}
$$

Substituting (19) and (20) into (3), we can write the dynamics of the shape system with respect to $r_{f}$ as,

$$
\begin{equation*}
M(r) \dot{\mu}_{f}+C_{f}\left(r_{f}, R_{0}, \mu_{f}\right) \mu_{f}=\tau_{E} \tag{21}
\end{equation*}
$$

where $\mu_{f}=\left(\omega_{0}, \dot{r}_{f}\right) \in \mathbb{R}^{3+n}$ represents the velocity, and the Coriolis part becomes:

$$
C_{f}\left(r_{f}, R_{0}, \mu_{f}\right) \mu_{f}=C(r, \mu) \mu-M(r)\left[\begin{array}{c}
0 \\
f_{\dot{\theta}}\left(\dot{R}_{0}, R_{0}\right) \\
0
\end{array}\right]
$$

## B. DEFINITION OF THE TRACKING ERROR FOR SHAPE SYSTEM

The configuration space of the shape system is $S O(3) \times \mathbb{R}^{n}$ which is a non-Euclidean space [30]. In order to achieve almost global control at $S O(3) \times \mathbb{R}^{n}$, considering the topological structure of the manifold $S O(3)$, we use exponential coordinate to represent the attitude, and with the help of hybrid system theory, we construct the hybrid formulation of the dynamics. The reason why to use such a structure is that the expression physically reveals the geometric properties of the error on $S O(3)$. The property can be seen in [31, Lemma 1].

We rewrite the equation of rotational motion of a rigid body with inertia tensor $I_{r} \in \mathbb{R}^{3 \times 3}$ in a hybrid form as,

$$
\mathcal{H}:\left\{\begin{array}{ll}
\left\{\begin{array}{l}
\dot{\xi}=J_{a}(\xi) \omega \\
\dot{\omega}=I_{r}^{-1}\left(\tau-\hat{\omega} I_{r} \omega\right)
\end{array}\right. & , \quad(\xi, \omega) \in S_{C}  \tag{22}\\
\left\{\begin{array}{l}
\xi^{+}=\xi^{-}-2 \pi \frac{\xi^{-}}{\|\xi-\|} \\
\omega^{+}=\omega^{-}
\end{array}, \quad(\xi, \omega) \in S_{D}\right.
\end{array} .\right.
$$

with flow set $S_{C}$ and jump set $S_{D}$,

$$
\begin{align*}
& S_{D}=\{(\xi, \omega):\|\xi\|=r,\langle\dot{\xi}, \xi\rangle>0\} \\
& S_{C}=\left\{(\xi, \omega):(\xi, \omega) \notin S_{D}\right\} \tag{23}
\end{align*}
$$

where $\xi$ is the exponential coordinates of $R$, and is restricted in a ball $B_{a}=\left\{\xi \in \mathbb{R}^{3}:\|\xi\| \leq r, \pi \leq a<2 \pi\right\}$.

Based on (22), the tracking error EOM of the shape system with respect to $r_{f}$ can be expressed as,

$$
\begin{align*}
& \left\{\begin{array}{l}
\dot{\gamma}_{e}=J\left(\gamma_{e}\right) \mu_{f, e} \\
\dot{\mu}_{f, e}=\varphi\left(\tau_{E}, \mu_{f, e}, \gamma_{e}, R_{0, d}, \dot{R}_{0, d}, \ddot{R}_{0, d}\right)
\end{array},\left(\gamma_{e}, \mu_{f, e}\right) \in S_{C}\right. \\
& \left\{\begin{array}{l}
\gamma_{e}^{+}=\left(\xi_{e}^{-}-\frac{2 \pi}{a} \xi_{e}^{-}, r_{f}^{-}\right) \\
\mu_{f, e}^{+}=\left(\mu_{f, e}^{-}, \dot{r}_{f, e}^{-}\right)
\end{array} \quad, \quad\left(\gamma_{e}, \mu_{f e}\right) \in S_{D}\right. \tag{24}
\end{align*}
$$

where $\xi_{e}$ is the attitude tracking error calculated from $\exp \left(\xi_{e}\right)=R_{0, d}^{T} R_{0}:=R_{0, e}, \gamma_{e}=\left(\xi_{e}, r_{f, e}\right)$ is the representation of configuration error, $\mu_{f e}=\left(\omega_{e}, \dot{r}_{f, e}\right)$ is the velocity tracking error, $J\left(\gamma_{e}\right)=\left[\begin{array}{cc}J_{\alpha}\left(\xi_{e}\right) & 0 \\ 0 & I_{n}\end{array}\right]$.

Considering in real-time systems, there are always noises, which may make the hybrid system chatter frequently. Therefore the definition of the set of $\xi_{e}$ is modified to,

$$
\begin{equation*}
\Omega_{\xi_{e}}=\left\{\xi_{e} \in \mathbb{R}^{3}:\left\|\xi_{e}\right\| \leq \pi+\delta\right\}:=B_{\pi+\delta} \tag{25}
\end{equation*}
$$

where $\delta$ is a small positive constant to prevent frequent jump due to the noises. $S_{D}$ for $\xi_{e}$ is then revised to,

$$
\begin{equation*}
S_{D}=\left\{\xi_{e} \in B_{\pi+\delta}:\left\|\xi_{e}\right\|=\pi+\delta,\left\langle\omega_{e}, \xi_{e}\right\rangle>0\right\} \tag{26}
\end{equation*}
$$

## C. GLOBAL TRACKING CONTROL OF SHAPE SYSTEM

Assumption 1: For every $j=1, \ldots, n$, the joint velocity $\dot{r}_{j}$ is bounded, and the Jacobian matrix $J_{j}(r)$ expressed in aircraft base fixed frame is smooth function with respect to $r$.

Lemma 2: The eigenvalue of $\dot{M}(r)$ is bounded under Assumption 1.

Proof: The mass matrix $M_{t}(r)$ can be expressed as $M_{t}(r)=\left(m_{0} J_{v 0}^{T} J_{v 0}+J_{\omega 0}^{T} I_{r, 0} J_{\omega 0}\right)+\sum_{j=1}^{n}\left(m_{j} J_{v j}^{T} J_{v j}+\right.$ $J_{\omega j}^{T 0} R_{j} I_{r, j}{ }^{0} R_{j}^{T} J_{\omega j}$, where $J_{v j}$ and $J_{\omega j}$ represent the translational and rotational Jacobian matrix of link-j. If $J_{v j}$ and $J_{\omega j}$ are smooth function of $r$ and $\dot{r}$ is bounded, then $\dot{M}_{t, i j}=$ $\frac{\partial M_{i j}(r)}{\partial r} \dot{r}$ is also bounded, where $M_{t, i j}$ is the $(i, j)$ element of $M_{t}(r)$. Similarly, we can also obtain that each element of $\dot{S}_{E}(r)$ is bounded. This implies that $\|\dot{M}\|_{1}$ is bounded. From the equivalence of 1-norm and 2-norm, we can conclude the boundedness of $\|\dot{M}\|_{2}$, which implies that $\lambda(\dot{M})$ is bounded.

We denote $\lambda_{m}($.$) and \lambda_{M}($.$) the min and max eigen-$ value function of a matrix. By defining the tracking error dynamics, the global tracking control of shape system is the same to the stabilization control of (24) at $\left(\gamma_{e}, \mu_{f, e}\right)=$ $(0,0)$. For this purpose, we design the following control law,

$$
\begin{align*}
\tau_{E}=-k_{\gamma} \gamma_{e} & -k_{\mu} \mu_{f, e}+C_{f} \mu_{f} \\
& -M\left[\begin{array}{c}
\hat{\omega}_{0} \exp \left(-\hat{\xi}_{e}\right) \omega_{0, d}-\exp \left(-\hat{\xi}_{e}\right) \dot{\omega}_{0, d} \\
-\ddot{r}_{f, d}
\end{array}\right] \tag{27}
\end{align*}
$$

where $k_{\gamma}$ and $k_{\mu}$ are positive constants s.t.

$$
\begin{equation*}
k_{\mu}>\frac{1}{2} \lambda_{M}(\dot{M}) \tag{28}
\end{equation*}
$$

Theorem 2: Consider the tracking error system expressed by (24), the control input $\tau_{E}$ is given by (27), suppose the positive definite constants $k_{\gamma}, k_{\mu}$ s.t. (28). Then the equilibrium point $\left(\gamma_{e}, \mu_{f, e}\right)=(0,0)$ is the only equilibrium point, and it is exponentially stable (ES) on $\left(B_{\pi+\delta} \times \mathbb{R}^{n}\right) \times \mathbb{R}^{3+n}$.

Proof: Substituting the control law (27) into (24) obtains the following closed loop equation for the shape system,

$$
\begin{align*}
\dot{\gamma}_{e} & =J\left(\gamma_{e}\right) \mu_{f, e} \\
M \dot{\mu}_{f, e} & =-k_{\gamma} \gamma_{e}-k_{\mu} \mu_{f, e} \tag{29}
\end{align*}
$$

Since the attitude error is defined in a compact set, $J\left(\gamma_{e}\right)$ is always non-singular, therefore $J\left(\gamma_{e}\right) \mu_{f, e}=0,-k_{\gamma} \gamma_{e}-$ $k_{\mu} \mu_{f, e}=0$ has only one solution $\left(\gamma_{e}, \mu_{f, e}\right)=(0,0)$.

Consider the following Lyapunov candidate with a positive constant $c$,

$$
\begin{equation*}
V=\frac{1}{2}\left\langle\mu_{f, e}, M \mu_{f, e}\right\rangle+\frac{1}{2} k_{\gamma}\left\langle\gamma_{e}, \gamma_{e}\right\rangle+c\left\langle\gamma_{e}, \mu_{f, e}\right\rangle \tag{30}
\end{equation*}
$$

In order to investigate the positive definite property of $V$, construct the positive definite matrix candidate
$W_{1}=\left[\begin{array}{cc}\frac{1}{2} k_{\gamma} & \frac{c}{2} \\ \frac{c}{2} & \frac{1}{2} \lambda_{M}(M)\end{array}\right]$ and $W_{2}=\left[\begin{array}{cc}\frac{1}{2} k_{\gamma} & -\frac{c}{2} \\ -\frac{c}{2} & \frac{1}{2} \lambda_{m}(M)\end{array}\right]$, The boundedness of $V$ can be expressed as,

$$
\begin{equation*}
e_{s}^{T} W_{2} e_{s} \leq V \leq e_{s}^{T} W_{1} e_{s} \tag{31}
\end{equation*}
$$

where $e_{s}=\left(\left\|\gamma_{e}\right\|,\left\|\mu_{f, e}\right\|\right)^{T}$.
The stability analysis is finished in two steps. First, we differentiate (30) to investigate $\dot{V}$ in $S_{C}$. Because $\langle\dot{\xi}, \xi\rangle=$ $\langle\omega, \xi\rangle$, we have,

$$
\begin{align*}
\dot{V}= & \left\langle\mu_{f, e}, M \dot{\mu}_{f, e}\right\rangle+\left\langle k_{\gamma} \gamma_{e}, \dot{\gamma}_{e}\right\rangle+\left\langle c \dot{\gamma}_{e}, \mu_{f, e}\right\rangle+ \\
& \left\langle c \gamma_{e}, \dot{\mu}_{f, e}\right\rangle+\frac{1}{2}\left\langle\mu_{f, e}, \dot{M} \mu_{f, e}\right\rangle \\
= & -\left(\left\langle c \gamma_{e}, M^{-1} k_{\gamma} \gamma_{e}\right\rangle+\left\langle c \gamma_{e}, M^{-1} k_{\mu} \mu_{f, e}\right\rangle\right)+ \\
& -\left(\left\langle\mu_{f, e}, k_{\mu} \mu_{f, e}\right\rangle-\left\langle c J\left(\gamma_{e}\right) \mu_{f e}, \mu_{f, e}\right\rangle-\frac{1}{2}\left\langle\mu_{f, e}, \dot{M} \mu_{f, e}\right\rangle\right) . \tag{32}
\end{align*}
$$

We also construct a matrix $W_{3}$,

$$
W_{3}=\left[\begin{array}{cc}
\frac{c k_{\gamma}}{\lambda_{M}(M)} & -\frac{c k_{\mu}}{2 \lambda_{m}(M)} \\
-\frac{c k_{\mu}}{2 \lambda_{m}(M)} & k_{\mu}-c \max _{\xi \in B}^{\left\|J\left(\gamma_{e}\right)\right\|_{2}-\frac{1}{2} \lambda_{M}(\dot{M})}
\end{array}\right]
$$

Then we have

$$
\begin{equation*}
\dot{V} \leq-e_{1}^{T} W_{3} e_{1} \tag{33}
\end{equation*}
$$

If $c$ satisfies
$c<\min \left\{\sqrt{k_{\gamma} \lambda_{m}(M)}, \frac{\lambda_{m}^{2}(M) k_{\gamma}\left(k_{\mu}-\frac{1}{2} \lambda_{M}(\dot{M})\right)}{\lambda_{m}^{2}(M) k_{\gamma} \max _{\xi \in B}\left\|J\left(\gamma_{e}\right)\right\|_{2}+\frac{1}{4} \lambda_{M}(M) k_{\mu}^{2}}\right\}$,
and let $k_{\gamma}, k_{\mu}$ s.t. (28), then $W_{1}, W_{2}, W_{3}$ are all positive definite matrix. Then $V$ and $\dot{V}$ satisfy

$$
\begin{equation*}
V>0, \quad \dot{V}<0 \tag{35}
\end{equation*}
$$

In order to show the exponential stability, define $\alpha=$ $\frac{\lambda_{m}\left(W_{3}\right)}{\lambda_{M}\left(W_{1}\right)}$, it can be found that $\dot{V}$ during the flow map further satisfies

$$
\begin{equation*}
\dot{V} \leq-\alpha V \tag{36}
\end{equation*}
$$

The second step is to investigate the flow of $V$ during the jump map. From the definition of $S_{D}$ in (24) we have,

$$
\left.\begin{array}{rl}
V^{+}-V^{-}= & \frac{1}{2} k_{\gamma}\left\langle\gamma_{e}^{+}, \gamma_{e}^{+}\right\rangle
\end{array} \quad-\frac{1}{2} k_{\gamma}\left\langle\gamma_{e}^{-}, \gamma_{e}^{-}\right\rangle\right) .
$$

Considering the jump conditions, it is concluded

$$
\begin{equation*}
V^{+}<V^{-} \tag{38}
\end{equation*}
$$

is always found for any jump of $\left(\gamma_{e}, \mu_{f, e}\right)$.

Combining (35), (36), (38), from the stability of hybrid systems [32], the ES of the system (22) on $\left(B_{\pi+\delta} \times \mathbb{R}^{n}\right) \times$ $\mathbb{R}^{3+n}$ is achieved.

Remark 6: Considering the properties of exponential map, the ES at $\left(\gamma_{e}, \mu_{f, e}\right)=(0,0)$ is the same as the global exponential stability (GES) of $\left(R_{0, e}, r_{f, e}, \mu_{f, e}\right)=(I, 0,0)$ on $\left(S O(3) \times \mathbb{R}^{n}\right) \times \mathbb{R}^{3+n}$.

## D. TRACKING CONTROL OF END EFFECTOR

In order to let $y_{2} \rightarrow y_{2, d}$, we design the locked controller to ensure $p \rightarrow p_{d}$. For this purpose, design the control law for $F_{d}$

$$
\begin{equation*}
F_{d}=m\left(-k_{T} e_{l}+\ddot{p}_{d}\right) \tag{39}
\end{equation*}
$$

where $e_{l}=\left[p_{e}^{T}, \dot{p}_{e}^{T}\right]^{T}, p_{e}=p-p_{d}$, and $k_{T}=$ $\left(k_{p}, k_{v}\right) \in \mathbb{R}^{3 \times 6}$ is composed of positive definite diagonal matrix $k_{p}$ and $k_{v}$.

Theorem 3: Consider the system dynamics (1), given smooth reference trajectory $y_{2, d}=\left(p_{d}, R_{0, l, d}, r_{f, d}\right)$, the control law is designed from (27) and (39), $R_{0, d}$ is transformed from ( $R_{0, l, d}, F_{d}$ ) using (18), $F_{d}$ and $R_{0, d}$ satisfies $R_{0, d} z_{1} \neq$ $-z_{1}$ and $\left(F_{d}-m g e_{3}\right) \times\left(R_{0, d} z_{1}\right) \neq 0$. Then $y_{2} \rightarrow y_{2, d}$ asymptotically.

Proof: By considering the tracking error $R_{0 e}$, the position tracking error dynamics of the COM can be expressed as,

$$
\dot{e}_{l}=\left[\begin{array}{ll}
0 & I  \tag{40}\\
0 & 0
\end{array}\right] e_{l}+\left[\begin{array}{l}
0 \\
I
\end{array}\right]\left(\frac{F_{d}}{m}-\ddot{p}_{d}\right)+\left[\begin{array}{c}
0 \\
\Delta_{p}
\end{array}\right]
$$

Once $R_{0} \rightarrow R_{0, d}$ exponentially, the boundedness of $\Delta_{p}$ can be proven [31]. Then system (40) is stable at $e_{l}=0$. From the stability of the system in cascade, it is shown $p \rightarrow p_{d}, R_{0} \rightarrow$ $R_{0, d}, r_{f} \rightarrow r_{f, d}$ asymptotically for the entire system.

Remark 7: Because $\Omega_{y_{1}}$ is diffeomorphic to $\Omega_{y_{2}}$. From the fact that $y_{2} \rightarrow y_{2, d}$ asymptotically, we can also conclude that $y_{1} \rightarrow y_{1, d}$ asymptotically. Problem 1 is therefore solved. This controller is stable except at $\left(F_{d}-m g e_{3}\right) \times\left(R_{0, d} z_{1}\right)=0$, or $R_{0} z_{1}=-z_{1}$.

Remark 8: Theorem 3 does not consider the external perturbations. However, it can be proven that for bounded regular perturbations, the tracking error of the closed loop system can be kept in an invariant set containing origin [33]. Moreover, there are some methodologies which enable us to add adaptive control law on (27) and (39) to force the tracking error to converge to origin at the presence of bounded perturbations [31], [34]. The details are not discussed here due to the fact that it is not the focus of this paper.

## IV. NUMERICAL EXAMPLE

In the simulation, an aerial manipulator system with a two-joint manipulator is adopted as an example. The inertial tensors of the system are

$$
\begin{aligned}
I_{r, 0} & =\operatorname{diag}(0.0294853,0.0636259,0.0809362) \\
I_{r, 1} & =\operatorname{diag}(0.00001992,0.00022247,0.0002224) \\
I_{r, 2} & =\operatorname{diag}(0.00001868,0.00040523,0.00041661)
\end{aligned}
$$

FIGURE 4. The 3D snapshots from 5 s to 6 s . The cyan, green, and blue color line represent $R_{0} \mathrm{e}_{1}, R_{0} \mathrm{e}_{2}$, and $R_{0} \mathrm{e}_{3}$ respectively. The red and black line represent link-1 and link-2 of the manipulator.

FIGURE 5. Tracking profile of $\boldsymbol{r}_{\boldsymbol{f}}$. Dot-dashed line represents $\boldsymbol{r}_{\boldsymbol{f}, \boldsymbol{d}}$.
with unit of $\mathrm{kg} \cdot \mathrm{m}^{3}$. The force $F_{0}$ is on the plane $\operatorname{span}\left(e_{2},-e_{3}\right)$. The joint axes are all set to $e_{2}$. In the simulation, the system's initial configuration is given by

$$
q=\left(\left[\begin{array}{ll} 
& 1 \\
I & 0 \\
& 0 \\
0 & 1
\end{array}\right],[-0.5,0.5]\right)
$$

The desired pose of the end effector is given by $p_{t, d}=$ $(2 \cos (\sqrt{2} t)-2,2 \sin (\sqrt{2} t), t)$. which is a screw-like trajectory. The desired attitude of the end effector is $R_{t, d}=$ $\exp ((\sqrt{2} t+\pi) \hat{a})$, where $a=(0,0.5,1)^{T} / \frac{\sqrt{5}}{2}$. The desired position of the second joint is $r_{2, d}=0.2 \mathrm{rad}$.

Equation (1) is adopted as the plant EOM in the simulation. In order to test the robustness of the controller, the following factors are added in the simulation.

1) $20 \%$ uncertainties are added to the inertial parameters used in the controller.
2) Random external disturbances with maximum absolute value of $d_{m}=(2,2,2,0.2,0.2,0.2,0.1,0.1)^{T}$ is added on $F_{0}$ and $\tau_{0}$, with units in SI.

FIGURE 6. Joint position $\boldsymbol{r}(\boldsymbol{t})$.

FIGURE 7. Tracking profile of the end effector position.

FIGURE 8. The attitude tracking error of the end effector.
3) The following first-order plus delay system is added between the output of the controller and the input of the plant,

$$
G(s)=\frac{1}{1+0.041 s} e^{-0.0015 s}
$$

In the global controller, we use the method presented in [31] to calculate $\xi_{e}$ from $R_{0, e}$. Simulation results of this example are presented in Figs. 4-9. The results show that the end effector tracks the 6D pose trajectory well. From Figs. 7-8, it is seen that the position and attitude of the end effector can be tracked separately, which cannot be realized in a general quadrotor-based aerial manipulator. The two

FIGURE 9. The force acting on the aircraft base.
elements of $F_{0}$ are shown in Fig. 9. In this example, $\left\langle F_{0}, e_{3}\right\rangle$ is still the primary force, as there should exists force which is needed to compensate for the gravity. Because of big initial tracking error, $\left\langle F_{0}, e_{2}\right\rangle$ is also big at initial stage. Figure 8 shows the evolution of the attitude error of the end effector. The attitude error is stabilized from biggest value. It is noted that because of the complex uncertainties, the attitude error is actually bounded, e.g., it converges to a small set containing origin but not zero. This numerical example demonstrates the theoretical analysis.

## v. CONCLUSIONS

This paper has investigated the dynamics and control of a class of aerial manipulator for the purpose of 6 D pose trajectory of the end effector. The differential flatness of the system has been analyzed. The conditions of the system with the proposed flat output have been obtained. It has been shown that it requires the aircraft platform to have a 2D actuation force. Although such a class of aircraft platform differs from the traditional under-actuated aerial vehicle. It is believed that the proposed kind of aircraft is still more efficient than the fully actuated aerial vehicle. A cascade structure controller has been designed. It has been proven that this controller archives independent 6 D pose trajectory tracking for the end effector. It has also been shown that the proposed controller can stabilize all the states of the system, thus no unstable internal dynamics is induced. The proposed work provides a control framework for possible advanced tasks using aerial manipulators.

Future work can be conducted in several directions. First, real time implementation of the proposed aerial manipulator on a physical prototype is of interests. This will be a work in the area of mechatronics. Second, the trajectory planning and the force control using the proposed aerial manipulator can be further investigated.

YUSHU YU received the B.S., M.S., and Ph.D. degrees in mechanical engineering from the Beijing University of Aeronautics and Astronautics (BUAA), Beijing, China, in 2007, 2010, and 2013, respectively. From 2013 to 2014, he was an Engineer with China Aerospace Science and Industry Corporation. He conducted research at the BUAA, Nanyang Technological University, Singapore, and the Chalmers University of Technology, Sweden, from 2014 to 2019. He is currently an Associate Professor with the Beijing Institute of Technology (BIT), China. His research interest includes control and robotics. He received the 2012 IEEE International Conference on Mechatronics and Automation Toshio Fukuda Best Award in Mechatronics, and the Excellent Doctoral Dissertation of BUAA, in 2014.

VINCENZO LIPPIELLO (SM'17) was born in Naples, Italy, in 1975. He received the Laurea degree in electronic engineering and the Research Ph.D. degree in information engineering from the University of Naples Federico II, Naples, in 2000 and 2004, respectively, where he is currently an Associate Professor of automatic control with the Department of Electrical Engineering and Information Technology. He has authored or coauthored more than 120 journal and conference papers and book chapters. His research interests include visual serving of robot manipulators, hybrid visual/force control, adaptive control, grasping and manipulation, aerial robotics, and visual object tracking and reconstruction.
