Magnetic spin structures in epitaxial BiFeO₃ single layer and an epitaxial BaTiO₃/BiFeO₃ multilayer thin film have been studied by means of nuclear resonant scattering of synchrotron radiation. We demonstrate a spin reorientation in the 15 × [BaTiO₃/BiFeO₃] multilayer compared to the single BiFeO₃ thin film. Whereas in the BiFeO₃ film, the net magnetic moment \vec{m} lies in the (1–10) plane, identical to the bulk, \vec{m} in the multilayer points to different polar and azimuthal directions. This spin reorientation indicates that strain and interfaces play a significant role in tuning the magnetic spin order. Furthermore, large difference in the magnetic field dependence of the magnetoelectric coefficient observed between the BiFeO₃ single layer and multilayer can be associated with this magnetic spin reorientation. © 2015 AIP Publishing LLC.

The coupling between magnetic and ferroelectric orders, known as magnetoelectric (ME) effect,¹ attracts growing interest in science and technology due to the rich fundamental physics behind the phenomenon and its promising application potential.^{2,3} Control of magnetization without the need for a magnetic field offers possibilities for novel ME memory and spintronic devices^{1–4} with reduced energy consumption and higher speed. Many new multiferroic materials with coupled (anti-)ferromagnetic and ferroelectric orders have been discovered recently,^{5–7} however, there are very few systems with ordering temperatures above 300 K. In most cases, these are BiFeO₃-based multiferroics, in which the ferroelectric and antiferromagnetic transition temperatures are $T_C \sim 1150$ K and $T_N \sim 640$ K, respectively. It has long been known that BiFeO₃ has a G-type canted antiferromagnetic structure. A net magnetic moment arising from this canted spin structure is averaged out to zero due to the spin cycloid (62 ± 2 nm period) propagating along the [110] direction; its spin rotation plane is (1–10), as established by neutron diffraction.^{8,9} Using the same technique, it has been demonstrated by Béa *et al.*¹⁰ that this cycloidal spiral modulation is suppressed by high epitaxial strain in thin films. Furthermore, the magnetic spin structure of BiFeO₃ films is sensitive to minor changes in its crystal structure arising from a varying degree of strain relaxation, depending on the substrate material¹¹ and orientation.¹²

Recently,⁷ we have demonstrated a remarkable magnetoelectric response in BaTiO₃/BiFeO₃ composite thin films and multilayers, where the value of the magnetoelectric coefficient α_{ME} reaches 20.75 V/cmOe, comparable to the highest value reported in literature.¹³ We have also

correlated the magnetoelectric coefficient of BaTiO₃/BiFeO₃ multilayers grown at different oxygen partial pressures to oxygen vacancies and antiphase octahedral rotations.¹⁴ The saturation magnetization of the multilayer film consisting of 15 × [BaTiO₃/BiFeO₃] is substantially larger than that of the single-phase BaTiO₃ and BiFeO₃ films. Additionally, it was shown by Toupet *et al.*¹⁵ that the magnetization in such multilayers increases with an increasing number of interfaces in the superlattice. As the magnetic properties of BiFeO₃ are highly dependent on the changes in strain, a detailed study of the local magnetic structure in such multilayer films is critically important.

In this letter, on the one hand, we report on the determination of the local magnetic spin structure of a BiFeO₃ film and a 15 × [BaTiO₃/BiFeO₃] multilayer by means of nuclear resonant scattering (NRS) of synchrotron radiation and demonstrate that the BiFeO₃ layer has different magnetic spin structures in the single film compared to the multilayer. On the other hand, the crystal structure and strain state in the films are studied using x-ray reciprocal space maps (RSMs). We demonstrate that the magnetoelectric response of these thin films strongly depends on the variations of strain and on the presence of interfaces. This local information helps to understand the relationship between the magnetic spin structure in BiFeO₃ layers and strain-mediated magnetoelectric coupling in multilayers.

The 500 nm-thick BiFeO₃ thin film (referred to as the “thin film”) and 15 × [BaTiO₃/BiFeO₃] multilayer with the double layer thickness of 14 nm (referred to as the “multilayer”) were grown by pulsed laser deposition (PLD) both on single-crystalline SrTiO₃ (STO) (001) and SrTiO₃:0.5% Nb (001) substrates. A KrF excimer laser was used to grow films at a substrate temperature of 680 °C and oxygen partial pressure of 0.25 mbar. For more details of the

PLD growth, film structure, magnetic and ferroelectric response of the films, see Lorenz *et al.*^{7,14} The crystalline structure and elastic strain of the films used for NRS were characterized by X-ray diffraction (XRD) using a PANalytical X'pert PRO MRD with parabolic mirror (Cu K_α line focus) and a PIXcel^{3D} detector with variable channel number. Figure 1 shows RSMs around the symmetric (002) and asymmetric (-103) STO substrate peaks, together with the weaker thin film and multilayer peaks, respectively. From the vertical alignment (i.e., close by q_{\parallel} [110] values) of the film and substrate peaks, the in-plane lattice match can be deduced. The BiFeO₃ thin film grown on STO is nearly in-plane lattice matched, while the lack of vertical alignment of (-103) film and substrate peaks in case of the multilayer indicates the relaxation of its lattice. The sharp peaks of the multilayer indicate its higher crystalline quality as opposed to the pronounced horizontal and vertical peak broadening in the BiFeO₃ film due to higher tilt mosaicity and variation of lattice constants.

The superlattice periodicity creates multilayer satellite peaks, visible up to the fourth order. A superlattice period $L_{\text{BiFeO}_3+\text{BaTiO}_3} = (13.9 \pm 0.7)$ nm is obtained from $L = \lambda / (2\Delta\theta \cdot \cos \theta_B)$, where λ is the X-ray wavelength, $\Delta\theta$ is the angular separation between two adjacent satellite peaks (i.e., vertical direction in the RSMs), and θ_B is the Bragg angle of the zero-order satellite peak. Consistent thickness values of 6.1 nm (BaTiO₃) and 7.7 nm (BiFeO₃) were obtained from scanning transmission electron microscopy cross sections¹⁴ in which an excellent stacking of BaTiO₃ and BiFeO₃ layers is evident.

The local magnetic spin structure in non ⁵⁷Fe-enriched BiFeO₃ layers was investigated at room temperature using NRS in forward scattering geometry, known as nuclear forward scattering (NFS),¹⁶ at the nuclear resonance beamline (ID18), European Synchrotron Radiation Facility (ESRF).

The interference patterns were collected in grazing incidence geometry at a fixed angle of 0.2° (the beam direction \vec{k} is indicated in Figs. 2(c) and 2(d)). A high-resolution monochromator with 1 meV bandwidth was tuned to the nuclear resonance energy 14.413 keV of the Mössbauer (MB) transition in ⁵⁷Fe. Because of the large bandwidth compared to typical hyperfine splittings (~ 10 neV), the synchrotron X-ray beam impinging on the sample coherently scatters in forward direction via excitation of all hyperfine nuclear levels with the characteristic lifetime of the ⁵⁷Fe MB transition (141 ns). The delayed re-emitted photons are collected as a function of time and as a result of the minor relative differences in their energy ($\sim 10^{-12}$ eV), an interference pattern is obtained (see Fig. 2), which reveals at the atomic level the magnetic moment structure and chemical environment. Since, in case of ⁵⁷Fe, the hyperfine field is antiparallel to the magnetic moment of the atoms, the NFS time spectra contain direct information about the orientation of the Fe magnetic moment, which is not available through conventional Mössbauer spectroscopy.

The measured time decay spectra for the thin film and the multilayer are shown in Figs. 2(a) and 2(b), clearly revealing that the beat patterns are different for the multilayer and the thin film. To extract the chemical and magnetic structure of BiFeO₃ layers, a model was applied to the measured time spectra. The fittings (also shown in Figs. 2(a) and 2(b)) were done based on the dynamical theory of nuclear resonant scattering with the program package CONUSS.^{16,17} In this model, the polar angle θ is defined as the angle between the sample normal, i.e., the [001] crystallographic direction and the magnetic moment \vec{m} , see Figs. 2(c) and 2(d). The azimuthal angle φ defines the in-plane rotation of the magnetic moment, i.e., the angle of the \vec{m} projection in the sample plane with respect to the [110] direction.

The same model was applied to fit both spectra. During the fitting, two types of chemical states (sites) of Fe were

FIG. 1. XRD reciprocal space maps around symmetric (002) (a) and (c), and asymmetric (-103) (b) and (d) reflections of typical BiFeO₃ film and $15 \times [\text{BaTiO}_3/\text{BiFeO}_3]$ multilayer samples, as indicated. The BiFeO₃ film is grown in-plane lattice matched, as the vertical alignment of film and STO (-103) peaks in (b) show. The RSMs of the multilayer (c) and (d) show superlattice peaks. BFO stands for BiFeO₃ and BTO for BaTiO₃.

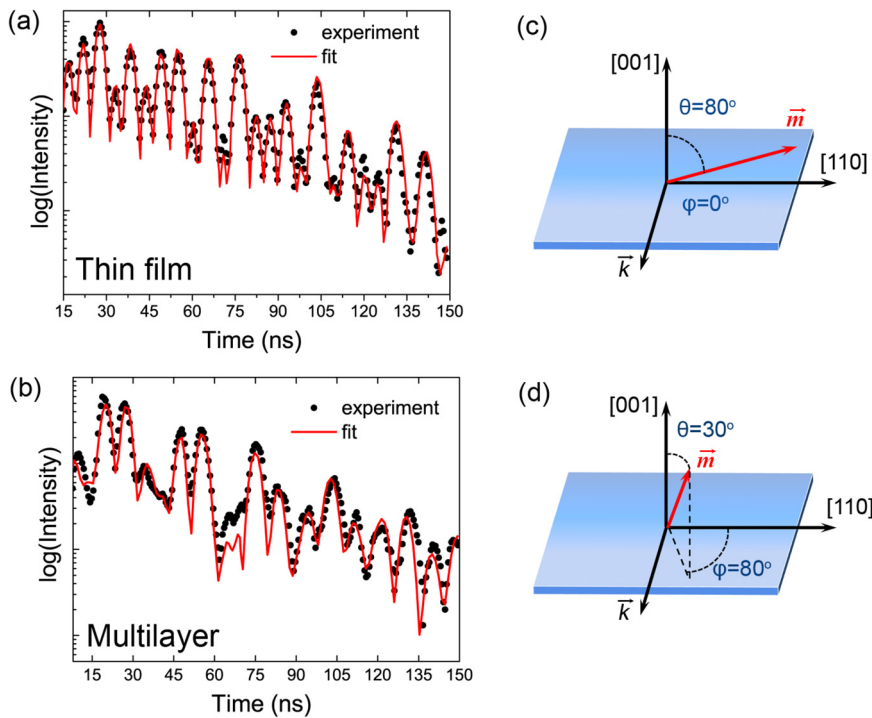

FIG. 2. (a) NFS time spectra of the BiFeO₃ thin film and (b) $15 \times$ [BaTiO₃/BiFeO₃] multilayer. The spectra were recorded at room temperature and zero external magnetic field. The solid lines are the model fits of the spectra. (c) and (d) Schematical representation of the fitting model for (c) the thin film and (d) the multilayer. \vec{m} is the magnetic moment of the BiFeO₃ layer(s) and \vec{k} is the wave vector along the photon beam.

taken into account. The main site, appearing as a single component, is attributed to the BiFeO₃ phase with hyperfine fields of 49 T and 49.5 T and isomer shift values of 0.4 mm/s and 0.33 mm/s for the thin film and the multilayer, respectively. The second site with zero isomer shift and a smaller hyperfine field of 24 T is ascribed to the magnetic Fe site formed in the proximity of the surface and/or interface due to the breaking of the crystal symmetry in BiFeO₃. The isomer shift values are given relative to the second Fe site. As the number of interfaces increases for the multilayer, the fraction of this site increases from 5% in the thin film to 15% in the multilayer. The isomer shift reflects the electron density in the vicinity of the ⁵⁷Fe nucleus, and therefore the valence states of Fe in the films. From the similarity in the hyperfine fields and isomer shifts values associated with the different Fe sites in the film and multilayer, we can conclude that there is no substantial difference in the electronic configurations of these Fe atoms. Furthermore, based on the hyperfine parameters, a valence state of Fe³⁺ was determined both in the thin film and multilayer. These values of hyperfine parameters are in good agreement with conventional Mössbauer studies performed by Lebeugle *et al.*,⁹ Sando *et al.*,¹¹ Tanaka *et al.*,¹⁸ and Prado-Gonjal *et al.*¹⁹

The only parameters which differ between the thin film and the multilayer are associated with the orientation of the magnetic moment, i.e., the θ and φ angles. Figures 2(c) and 2(d) show the orientation of the magnetic moment in the single film and multilayer, respectively. In the thin film, the in-plane angle $\varphi = 0^\circ$, implying that \vec{m} lies in the (1–10) plane, i.e., the plane of spin-rotation in bulk BiFeO₃ according to Lebeugle *et al.*⁹ However, a spin reorientation occurs in the multilayer, see Fig. 2(d), and the magnetic moment does not belong to the spiral (1–10) plane, which might be an indication of the spin spiral suppression. The results are in line with the work of Sando *et al.*,¹¹ where it is shown that the bulk-like spiral spin structure in BiFeO₃ films is

suppressed when the lattice mismatch between BiFeO₃ and substrate exceeds 1%. Moreover, it has been demonstrated^{20,21} that BiFeO₃ films grown on STO substrate are pseudomorphic (fully strained) when their thickness is less than 30 nm. As the film thickness reaches 1 μ m, the lattice parameter gradually approaches the bulk BiFeO₃ value.²¹ Hence, in highly strained BiFeO₃ layers within the multilayer, the spiral structure seems to be suppressed.

Previously,⁷ we have found that the saturation magnetization of the multilayer is substantially larger than that of the single-phase BiFeO₃ and BaTiO₃. Hence, the origin of the enhanced magnetization can be the suppression of the spiral spin magnetic structure due to high epitaxial strain in the BiFeO₃ layers, which has been debated in the literature since the work of Wang *et al.*²² Moreover, as both BiFeO₃ and BaTiO₃ thin films possess weak net magnetic moments,⁷ a magnetic interaction between these layers at the interface may also contribute to the increased magnetic moment in the multilayers in comparison with the single-phase films.

The effect of strain and interfaces on the magnetoelectric coupling in BiFeO₃ was studied for a number of thin films and multilayers. To this end, a direct longitudinal AC method was used to measure the ME coefficient α_{ME} as a function of static magnetic field. For details of this method, see Refs. 7 and 23. From Fig. 3(a), it is clear that α_{ME} of the multilayer is notably larger than that of the thin film. In addition, the temperature dependence (not shown here) and the magnetic field dependence of their ME response differ. While for the multilayer, the ME coefficient increases with magnetic field and saturates around 4 T, α_{ME} for the BiFeO₃ film reaches its maximum at 0.5 T with a subsequent decrease. The reason behind these trends is still unclear and under investigation. It is worth noting that the α_{ME} value and its behavior in DC magnetic field for the single-phase BiFeO₃ thin film resemble those of BiFeO₃/BaTiO₃ composite films grown from mixed phase PLD targets.⁷ Since the

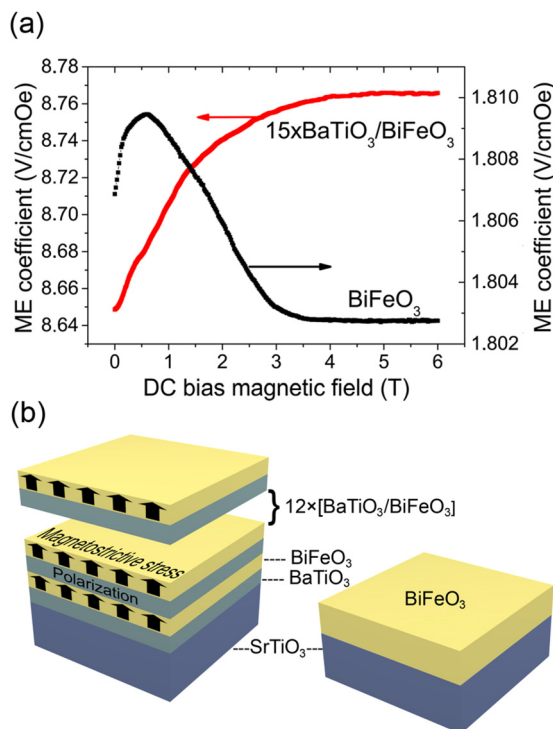

FIG. 3. (a) ME coefficient α_{ME} as a function of DC magnetic field (at 300 K) for the $15 \times [\text{BaTiO}_3/\text{BiFeO}_3]$ multilayer and the BiFeO₃ thin film. (b) Schematic of a ferroelectric-multiferroic multilayer (left) showing the development of the ME effect through magnetostrictive-piezoelectric interface coupling (arrows represent magnetostrictive stress); and a BiFeO₃ thin film (right).

multilayer additionally contains piezoelectric/piezomagnetic interfaces, an extra ME coupling in multilayers may occur via the horizontal interfaces through strain-mediated interface coupling. In this case, upon application of an external magnetic field, magnetostrictive stress is produced in the weak ferromagnetic BiFeO₃ layer and is transferred to ferroelectric BaTiO₃ layer through the interface, see Fig. 3(b). This mechanical stress generates an electric potential difference in the ferroelectric layer via a piezoelectric effect.²⁴ Evidently, two main factors affect ME coupling in the multilayer compared to the BiFeO₃ single layer: suppression of the spiral spin structure in highly strained BiFeO₃ layers observed through reorientation and increase of the net magnetic moment, and strain-mediated interface coupling via ferroelectric/multiferroic interfaces.

In conclusion, the local magnetic spin structure of a BiFeO₃ single film and a $15 \times [\text{BaTiO}_3/\text{BiFeO}_3]$ multilayer grown epitaxially on SrTiO₃ substrates have been studied using nuclear resonant forward scattering. While the electronic configuration of the Fe atoms does not undergo substantial changes, a spin reorientation occurs in the highly strained BiFeO₃ layers within the multilayer compared to the single film. Furthermore, we correlate the enhanced magnetic and magnetoelectric properties observed in the multilayers with the suppression of the spiral spin magnetic structure, which is due to high epitaxial strain in the multilayer and interfacial interaction between ferroelectric

BaTiO₃ and multiferroic BiFeO₃. These multilayer heterostructures, consisting of multiferroic and ferroelectric layers, have promising perspectives due to their tailored properties (through epitaxial strain and interfacial coupling) and are good candidates for advanced devices with tunable magnetoelectric functionalities.
