68 **Abstract**

69 While progress has been made in characterizing humoral immunity to Zika virus
70 (ZIKV) in humans, little is known regarding the corresponding T cell responses to
71 ZIKV. Here we investigate the kinetics and viral epitopes targeted by T cells
72 responding to ZIKV and address the critical question of whether pre-existing dengue
73 virus (DENV) T cell immunity modulates these responses. We find that memory T
74 cell responses elicited by prior infection with DENV or vaccination with Tetravalent
75 Dengue Attenuated Vaccines (TDLAV) recognize ZIKV-derived peptides. This cross-
76 reactivity is explained by the sequence similarity of the two viruses, as the ZIKV
77 peptides recognized by DENV-elicited memory T cells are identical or highly
78 conserved in DENV and ZIKV. DENV exposure prior to ZIKV infection also influences
79 the timing and magnitude of the T cell response. ZIKV-reactive T cells in the acute
80 phase of infection are detected earlier and in greater magnitude in DENV-immune
81 patients. Conversely, the frequency of ZIKV-reactive T cells continues to rise in the
82 convalescent phase in DENV-naïve donors, but declines in DENV pre-exposed
83 donors, compatible with more efficient control of ZIKV replication and/or clearance
84 of ZIKV antigen. The quality of responses is also influenced by previous DENV
85 exposure, and ZIKV-specific CD8 T cells from DENV pre-exposed donors selectively
86 up-regulated granzyme B and PD1, as compared to DENV-naïve donors. Finally, we
87 discovered that ZIKV structural proteins (E, prM and C) are major targets of both the
88 CD4 and CD8 T cell responses, whereas DENV T cell epitopes are found primarily in
89 nonstructural proteins.
90

91 **Importance**

92 The issue of potential ZIKV and DENV cross-reactivity and how pre-existing DENV
93 T cell immunity modulates ZIKA T cell responses is of great relevance as the two
94 viruses often co-circulate and ZIKA virus has been spreading in geographical regions
95 where DENV is endemic or hyper-endemic. Our data show that memory T cell
96 responses elicited by prior infection with DENV recognize ZIKV-derived peptides
97 and that DENV exposure prior to ZIKV infection influences the timing, magnitude
98 and quality of the T cell response. Additionally we show that ZIKV-specific
99 responses target different proteins than DENV-specific responses, pointing towards
100 important implications for vaccine design against this global threat.

101

102

103 **Introduction**

104 The pandemic rise of Zika virus (ZIKV) has recently commanded the attention of the
105 general public and medical research community alike
106 (13, 15, 31, 33).

107 ZIKV is a flavivirus most closely related to dengue virus (DENV)(24, 53) but also
108 related with Japanese encephalitis virus (JEV), West Nile virus (WNV), and yellow
109 fever virus (YF), all of which are transmitted primarily by mosquitoes (54). .

110 Understanding host protective immunity to this virus is critical for the design of
111 optimal vaccines, but little is currently known about the immune responses to ZIKV
112 in humans since infections with ZIKV have not been frequent in the past (27, 29).
113 This is in contrast to a substantial wealth of information related to T cell immunity
114 against the closely related DENV(44, 45, 49).

115

116 In the case of DENV, CD8 T cell responses target mostly non-structural (NS) proteins
117 such as NS3, NS4B and NS5, while CD4 T cell responses are focused on the C, E and
118 NS5 proteins, even though serotype specific differences have been noted (1, 2, 43,
119 44, 46). The main protein targets of CD4 and CD8 T cell immunity are presently
120 unknown for ZIKV. This dearth of information is a severe knowledge gap as robust T
121 cell responses may be required for optimal ZIKV vaccine efficacy (29).

122

123 The issue of potential ZIKV and DENV cross-reactivity is of relevance for
124 development of both diagnostic tests and vaccines. ZIKV and DENV have significant
125 sequence similarity, share the same arthropod host and the geographic range of

126 ZIKV overlaps largely with areas where DENV is endemic or hyper-endemic (53)
127 (52). The concomitant co-circulation of DENV and ZIKV represents yet another
128 biomedical challenge since this phenomenon of common dual exposure increases
129 the potential for cross-reaction. Serological cross-reactivity has been addressed by
130 several reports (5, 9, 20, 28, 36, 37). However, it is currently unknown as to what
131 extent ZIKV and DENV may cross-react with each other at the level of T cell
132 immunity.

133

134 According to the well established phenomenon of heterologous immunity(32, 50), It
135 is possible that pre-existing DENV immunity will affect T cell responses to ZIKV and
136 hence influence the dynamics and severity of ZIKV epidemics. Importantly, previous
137 DENV infection can in some instances increase severity of a second DENV infection
138 with a heterologous serotype, likely through antibody dependent enhancement
139 (ADE) of infection and disease (30). In the Phase IIb/III clinical trials of the first
140 licensed tetravalent dengue vaccine, increased vaccine efficacy in DENV pre-
141 exposed as opposed to DENV-naive vaccinees was observed, suggesting a possible
142 protective role of pre-existing cross-reactive DENV-specific T cells that are boosted
143 upon vaccination (29). Thus, it is also possible that pre-exposure to either ZIKV or
144 DENV infection will influence the disease course following infection with the other
145 virus in either a favorable or detrimental fashion. For all these reasons, it is
146 necessary to gain insight into human T cell responses to ZIKV.

147 **Material and Methods**

148

149 **Human blood samples**

150 All samples have been collected after informed consent and the study has
151 been approved by the LJI IRB committee (IRB#: VD-154). An overview of the clinical
152 and serological characteristics of all ZIKA samples is provided in **Table 1**. The
153 sample allocation was provided by collaborators that collected the samples. The
154 investigators were aware of the group allocation during the experiment and when
155 assessing the outcome. In addition **Supplementary Table 1** provides a summary of
156 the HLA typing data of the PBMC donor and DENV infection history were available
157 of all the donors analyzed in this study.

158

159 *Samples from flavivirus naive controls*

160 Healthy adult male and non-pregnant female volunteers 18–50 years of age were
161 enrolled from Baltimore, Maryland, Washington, DC, and Burlington, Vermont and
162 tested for the presence of serum antibodies to all DENV serotypes, yellow fever
163 virus, West Nile virus, and St. Louis encephalitis virus, as previously described (11).

164

165 *Samples from DENV endemic areas*

166 Blood donations from healthy adult blood donors of both sexes between the age of
167 18 and 65 were collected by the National Blood Center, Ministry of Health, Colombo,
168 Sri Lanka collected in anonymous fashion between the years of 2010 and 2016 and
169 processed at the Genetech Research Institute as previously described(45). Similarly,

170 National Blood Center (NBC) of the Nicaraguan Red Cross in Managua, Nicaragua
171 has provided anonymous blood samples collected between 2010 and 2014 prior to
172 the introduction of ZIKV to the country(46).

173

174 *Samples from DENV tetravalent vaccination.*

175 Healthy donors were enrolled and vaccinated with TV005, a tetravalent DENV
176 vaccine formulation. Blood samples were collected as a part of a phase I clinical
177 trials (registration numbers NCT01506570 and NCT01436422) at the Johns
178 Hopkins Bloomberg School of Public Health (JHSPH) and at the University of
179 Vermont (UVM) Vaccine Testing Center and the Center for Immunization as
180 previously reported(3, 17, 43).

181

182 *Samples from ZIKV virus endemic areas*

183 Blood samples were collected from patients displaying symptoms of a suspected
184 ZIKV infection in Brazil, Nicaragua and Mexico. Samples were also collected from
185 blood donors identified through routine donor screening in Puerto Rico and Florida.
186 Infection with ZIKV was confirmed using RT-PCR as described in more detail below.
187 All samples were screened for previous DENV exposure by measuring DENV-
188 specific IgG titers and/or neutralizing antibodies or from documented history of
189 DENV infection. Depending on the time of sample collection after onset of
190 symptoms, samples were either classified as acute (2-14 days post onset of
191 symptoms or hospitalization) or convalescent (more than 15 days post onset of
192 symptoms). Blood samples collected within the Recipient Epidemiology and Donor

193 Evaluation Study-III (REDSIII) were collected approximately 3 months following
194 ZIKV RNA pos. blood donation.

195

196 *Samples from the Nicaraguan Pediatric Dengue Cohort Study (PDCS)*

197 A total of 14 children RT-PCR-pos. for ZIKV who experienced signs and symptoms of
198 Zika, from the Nicaraguan Pediatric Dengue Cohort Study (PDCS) were included.

199 The PDCS is a community-based prospective study of children 2 to 14 years of age
200 that has been ongoing since August 2004 in Managua, Nicaragua (19). Participants

201 present at the first sign of illness to the Health Center Sócrates Flores Vivas and are
202 followed daily during the acute phase of illness. Acute and convalescent (~14-21

203 days after onset of symptoms) blood samples are drawn for dengue, chikungunya
204 and Zika diagnostic testing from patients meeting the case definition for dengue or

205 Zika (starting in January 2016) or presenting with undifferentiated febrile illness. In
206 the PDCS, a healthy blood sample is collected annually from participants; anti-DENV

207 antibody titers are measured in paired annual samples using an Inhibition ELISA
208 (EI)(4, 14), and infections are defined by seroconversion or a ≥ 4 -fold rise in anti-

209 DENV titers. In this study, confirmed ZIKV cases were classified as DENV-naïve if
210 they entered the cohort study with no detectable anti-DENV antibodies (as

211 measured by EI) and had no documented DENV infections (symptomatic or
212 inapparent) during their time in the cohort or were classified as DENV-immune if

213 they either entered the cohort with detectable anti-DENV EI antibodies or entered
214 the cohort study with no detectable anti-DENV antibodies and had one or more

215 documented DENV infections during their time in the cohort. All Zika suspected

216 cases were confirmed by RT-PCR in serum and/or urine using triplex assays that
217 simultaneously screen for DENV and CHIKV infections (ZCD assay (42), CDC
218 Trioplex or in some cases the CDC ZIKV monoplex assay(20) in parallel with a DENV-
219 CHIKV multiplex assay(41)). The PDCS was approved by the Institutional Review
220 Boards of the Nicaraguan Ministry of Health and the University of California,
221 Berkeley. Parents or legal guardians of all subjects provided written informed
222 consent, and subjects ≥ 6 years old provided assent.

223

224 *Samples from ZIKV virus infected US travellers*

225 Blood samples were collected at the University of North Carolina, University of
226 Miami, Vanderbilt University and the National Institute of Health, from patients
227 displaying symptoms of a suspected ZIKV infection following return to the US from
228 ZIKV endemic areas. One donor had not traveled outside of the US and thus locally
229 acquired ZIKV infection in Miami, FL. All samples were screened for previous DENV
230 exposure by measuring DENV-specific serum IgG titers and/or neutralizing
231 antibodies. Depending on the time of sample collection post onset of symptoms,
232 samples were either classified as acute or convalescent as described above.

233

234 **PBMC isolation**

235 Peripheral blood mononuclear cells (PBMC) were isolated by density-
236 gradient sedimentation using Ficoll-Paque (Lymphoprep, Nycomed Pharma, Oslo,
237 Norway) as previously described (44). Isolated PBMC were cryopreserved in cell
238 recovery media containing 10% DMSO (Gibco), supplemented with 10-50% heat

239 inactivated fetal bovine serum, depending on the processing laboratory, (FBS;
240 Hyclone Laboratories, Logan UT) and stored in liquid nitrogen until used in the
241 assays. PBMC collected in Sri Lanka were stored in Synth-a-Freeze
242 Cryopreservation medium (Cat A1254201 Thermo Fisher Scientific, USA).

243 Volunteers from the National Institutes of health were enrolled into protocol
244 VRC200 (NCT00067054) and leukapheresed. PBMC were processed and
245 cryopreserved as described previously (22).

246

247 **Serology**

248 In general, DENV seropositivity was determined by DENV IgG or an
249 Inhibition ELISA, as previously described(14, 16). Flow cytometry-based or Vero
250 cell-based focus reduction neutralization assays were performed for further
251 characterization of Pos. donors, as previously described (18, 38).

252

253 **rRT-PCR assays for ZIKV determination**

254 RNA was extracted from serum or urine using the QIAamp Viral RNA Mini kit
255 (Qiagen). Samples were tested for ZIKV, and/or DENV using the ZCD assay, as
256 previously described(42). DENV-pos. samples were serotyped, using a serotype-
257 specific DENV multiplex assay(40, 42). In some laboratories samples were tested by
258 RT-PCR for ZIKV as previously described(20). At BSRI Blood donors were identified
259 as ZIKV RNA pos. through routine donor screening using the cobas Zika test (Roche
260 Molecular Systems, Inc., Pleasanton, CA (RMS) under IND.

261 **HLA typing**

262 Donors were HLA typed by an ASHI-accredited laboratory at Murdoch
263 University (Western Australia) as previously described(45). HLA typing was
264 performed for Class I (HLA A; B; C) and Class II (DQA1; DQB1, DRB1; DPB1) using
265 locus-specific PCR amplification on genomic DNA. Primers used for amplification
266 employed patient-specific barcoded primers. Amplified products were quantitated
267 and pooled by subject, and up to 48 subjects were pooled. An unindexed (454
268 technique 8-lane runs) or indexed (8 indexed MiSeq technique runs) library then
269 was quantitated using kappa universal qPCR library quantification kits. Sequencing
270 was performed using either a Roche 454 FLX+ sequencer with titanium chemistry or
271 an Illumina MiSeq using a 2 x 300 paired-end chemistry. Reads were quality-filtered
272 and passed through a proprietary allele-calling algorithm and analysis pipeline
273 using the latest IMGT HLA allele database as a reference.

274

275 **MHC class I binding predictions and peptide selection**

276 The BeH818995 ZIKV isolate (GenBank accession no. AMA12084.1) was used
277 to perform ZIKV peptide selection. We selected a set of 9- and 10-mers ZIKV
278 peptides predicted to bind one or more of 27 HLA class I A and B allelic variants
279 chosen because of their high prevalence in the general population, as previously
280 described(44). Class I binding predictions were done with Tepitool using the
281 consensus method(26) (23). For each allele, and considering 9- and 10-mers
282 separately, the top 2% scoring peptides (n=68) based on predicted percentile rank
283 were selected; the final set synthesized had 1836 (68 X 27) 9-mers and 10-mers
284 each, for a total of 3672 peptides (A&A, San Diego, CA). For screening studies, the

285 class I peptides were combined into pools of approximately 10 to 11 individual
286 peptides, according to their predicted HLA restriction, resulting in approximately 13
287 pools per HLA allele. **Table 2** lists the number of peptides synthesized for each allele
288 as a function of protein of provenance. In addition, we synthesized a panel of 15-mer
289 peptides, overlapping by 10 residues, spanning the entire sequence of the ZIKV
290 BeH818995 isolate. The sequence homology between ZIKV and DENV for each
291 protein is listed in **Table 3**. For screening studies, these peptides were combined
292 into 10 megapools of 25-180 peptides according to the ZIKV protein from which
293 they were derived (C, prM, E, NS1, NS2A, NS2B, NS3, NS4A+2k, NS4B, NS5). For
294 deconvolution studies, pos. peptide pools were deconvoluted to identify individual
295 epitopes, often going to an intermediate step of screening smaller pools before the
296 individual peptide tests. To assess DENV reactivity pools of previously identified
297 and described DENV epitopes were utilized (i.e. DENV megapools, see
298 references(45, 48)). Epitopes identified in this study have been submitted to the
299 Immune Epitope Database (IEDB; Submission ID_1000720).

300

301 **IFN γ ELISPOT assay**

302 A total of 20×10^4 PBMC were incubated in triplicate with 0.1 ml complete
303 RPMI 1640 medium in the presence of peptide pools [1 $\mu\text{g}/\text{ml}$] or individual
304 peptides [10 $\mu\text{g}/\text{ml}$]. Following a 20 h incubation at 37°C, the plates were incubated
305 with biotinylated IFN γ mAb (mAb 7-B6-1 Mabtech, Stockholm, Sweden) for 2h and
306 developed as previously described (44, 47). In CD4 experiments, CD8 cells were
307 depleted before incubation using magnetic beads and pos. selection (MACS Miltenyi

308 Biotec, Auburn, CA). Cells from donors with PHA values below 250 SFC / 10⁶ PBMC
309 have been excluded from the analysis.

310

311 **Flow Cytometry**

312 Detailed information of all monoclonal antibodies used in this study is listed
313 in **Table 4**. For the intracellular cytokine staining, PBMC were cultured in the
314 presence of HLA-matched peptide pools [1 µg/ml] and Golgi-Plug containing
315 brefeldin A (BD Biosciences, San Diego, CA for 6 hours and subsequently
316 permeabilized, stained and analyzed with the same monoclonal antibody panel as
317 described previously (44). Cells from donors have been excluded from the analysis if
318 the IFN γ response to PMA and ionomycin stimulation was lower than 1% in the
319 CD3+ cells. All data shown are background subtracted.

320

321 **Statistical analysis**

322 All statistical analyses were performed using the program Prism 7 (Graph-Pad
323 Software, San Diego, CA). Data are expressed as Geometric mean with 95% CI or
324 percent of frequency and data comparison has been performed with Mann-Whitney
325 or Fisher test respectively.

326 **Results**

327

328 **DENV T cell responses are cross-reactive with ZIKV peptides**

329 To address the interplay between DENV- and ZIKV-specific T cell responses,
330 we studied HLA-typed PBMC donations from Sri Lanka obtained between 2010 and
331 2016. We also studied PBMC from Nicaraguan donors obtained between 2010 and
332 2014, thus preceding the current ZIKV epidemic(8, 44, 48). To study CD8 responses,
333 we selected nine DENV-Pos. donors who had been infected by DENV multiple times
334 (secondary infections) based on serum neutralization titers and whose samples
335 showed appreciable *ex vivo* response to a pool of previously defined CD8 DENV
336 epitopes (CD8-megapool)(48). A similar approach was used for CD4 responses,
337 retrieving 5 DENV Pos. donors with *ex vivo* responses to a previously defined DENV
338 CD4-megapool(45). As neg. controls, we used PBMC from donors who were DENV
339 neg. from the same sites.

340 We tested PBMC from these groups for reactivity against ZIKV peptides in *ex*
341 *vivo* IFN γ ELISPOT assays. In the case of CD8 T cell responses (HLA class I), we
342 tested panels of ZIKV-derived peptides predicted to bind each donors HLA
343 molecules(44). HLA restrictions were assigned based on testing short 9-10 mers
344 that are predicted to bind with high affinity to the HLA allotypes of the responding
345 donors. In the case of CD4 T cell responses (HLA class II), we tested a panel of 684
346 overlapping peptides spanning the entire ZIKV proteome. CD8-depleted PBMCs
347 were used in these experiments to avoid inadvertently identifying CD8 epitopes
348 nested in the 15mer peptide tested. In both cases, peptide pools were tested, and the

349 total reactivity observed in each donor was recorded. The peptide sets used in this
350 study are summarized in **Table 2**.

351 As expected for CD8, T cells from the DENV neg. donors did not respond to
352 either the previously defined DENV epitopes, nor to the ZIKV peptides. The cells
353 were viable and responsive to stimulation, as shown by vigorous responses to PHA
354 mitogen stimulation. Interestingly, CD8 T cells from one third of the DENV-Pos.
355 donors recognized ZIKV-derived peptides (**Figure 1A**). Higher level of cross-
356 reactivity emerged from the study of the CD4 T cells, as ZIKV derived peptides were
357 recognized by CD4 T cells from 4 out of 5 DENV-Pos. individuals (**Figure 1B**).

358 In a further series of experiments, we analyzed responses from two
359 additional cohorts of donors, a cohort of donors recently vaccinated with a
360 Tetravalent Dengue Attenuated Vaccine (TDLAV) and a control cohort of donors
361 negative for responses to DENV and other flaviviruses provided for the University of
362 Vermont Clinical site. Responses against the DENV CD8-megapool and pools of ZIKV
363 predicted peptides matching the HLA A and B alleles expressed in each donor were
364 tested in IFN-gamma ICS assays (**Figure 1C**). CD8 T cells from the Flavivirus neg.
365 donors did not respond to either the previously defined DENV epitopes, nor to the
366 ZIKV peptides. By contrast CD8 T cells from TDLAV donors recognized, as expected
367 the DENV CD8 megapool, but also in more than 50% of the cases the ZIKV-derived
368 peptides. In conclusion, analysis of *ex vivo* responses of ZIKV naive and DENV Pos.
369 donors revealed substantial cross-reactivity to ZIKV derived peptides.

370

371 **Identification of ZIKV epitopes cross-reactive with DENV responses**

372 Individual epitopes were mapped in representative cases. Where sufficient
373 cell numbers were available, pos. pools were deconvoluted to identify ZIKV-specific
374 epitopes across the ZIKV genome including all structural and nonstructural (NS)
375 proteins. The mapping of CD4 and CD8 response was performed by sequential
376 testing of pools and deconvolution to identify the positive peptides (**Figure 2A**). The
377 HLA-B*35:01 CD8 epitope encoded by ZIKV NS3₂₈₆₇₋₂₈₇₆ was recognized by PBMC
378 from a DENV-Pos. Nicaraguan donor (**Figure 2B**). This epitope was found to be
379 highly similar (a single Y>F substitution) in DENV1-4 serotypes consensus
380 sequences obtained as previously described(44). A Sri Lankan donor recognized the
381 B*07:02 ZIKV NS3₁₇₂₅₋₁₇₃₄ epitope (**Figure 2C**). The same epitope was also
382 recognized by a different DENV-Pos. Sri Lankan donor (**Figure 2D**). The identical
383 sequence was found in DENV2, 3 and 4.

384 In the case of CD4 (**Figure 2E**), the ZIKV NS5₂₉₈₆₋₃₀₀₀ epitope, 100%
385 conserved in DENV1-4 sequences, was recognized by PBMC from a DENV-Pos. Sri
386 Lankan donor. PBMC from a Nicaraguan donor recognized the ZIKV NS1₉₈₆₋₁₀₀₀
387 epitope (**Figure 2F**). Here, the recognized 15 mer contained a core NS1₉₈₉₋₉₉₈
388 sequence that was also highly conserved in all DENV serotypes, with A>S and M>L
389 conservative substitutions. A different pattern was observed for the ZIKV E₄₈₆₋₅₀₀
390 epitope, which was recognized by PBMC from a different DENV-Pos. Nicaraguan
391 donor (**Figure 2G**). In this case the most homologous 9-mer (sequence
392 LYYLTMNNK), shared only 4 identities, with DENV1 sequences, 2 are conservative
393 (L>M and N>E) and 3 semiconservative (Y>V, Y>L and K>N) substitutions.
394 Additional sequence homology analysis using Genbank sequences did not reveal any

395 sequences with higher homology from other common flaviviruses, such as JEV,
396 WNV, DENV, and YFV.

397 In conclusion, in 5 out of 6 instances the cross-reactivity from the DENV-pos.
398 (and presumably ZIKV-neg.) donors was directed to ZIKV sequences found to be
399 identical or highly conserved with sequences in DENV serotypes.

400

401 **Recruitment of donor cohorts differing in ZIKV and DENV pre-exposure status**

402 To address the effect of pre-existing immunity on T cell responses to
403 secondary flavivirus infection, we investigated six donor groups, namely ZIKV acute,
404 convalescent or neg., and for each of these cohorts we further subdivided our
405 cohorts into DENV-Pos. or -neg. individuals. For the purpose of classification in the
406 various cohorts, the following criteria were used. Infection with ZIKV was confirmed
407 using RT-PCR performed on acute infection samples as described in more detail
408 below. Depending on the time of sample collection after the onset of symptoms or
409 ZIKV RNA-pos. blood donation, samples were either classified as acute or
410 convalescent as described in more detail in Materials and Methods. ZIKV negativity
411 was inferred based on donations being obtained before- or outside of the area
412 affected by the epidemic. DENV pos. or neg. status was determined on the basis of
413 IgG status at the time of clinical presentation or blood donation, or in the case of the
414 Nicaraguan samples, from documented history of DENV infection in the longitudinal
415 cohort study. The subjects studied spanned a very diverse breadth of ethnicities and
416 clinical sites, including Brazil (Rio de Janeiro and Sao Paulo), Nicaragua, Puerto Rico,
417 Mexico, returned US travelers, and a US flavivirus-neg. cohort. The general features

418 of the subjects are detailed in **Table 1**. The relative proportion of females across all
419 cohorts was 60% and the average age was 34 (range 3-70).

420 **ZIKV-specific responses are modulated by previous DENV exposure**

421 Next, we compared ZIKV T cell reactivity in the subjects described above as a
422 function of ZIKV status (i.e. neg., acute infection or convalescent status), and also
423 considering prior DENV infection as a variable. To assess T cell reactivity, we
424 devised a strategy to account for the fact that in most cases the amount of PBMC was
425 limiting. Accordingly, the overlapping 15-mers spanning the entire ZIKV proteome
426 were divided into ten pools corresponding to the ten encoded ZIKV proteins.
427 Intracellular cytokine staining (ICS) assays and CD8/CD4 gating allowed assessment
428 of CD8 and CD4 responses in parallel without the need to know the HLA phenotype
429 of the donor. All the ZIKV CD8 responses in ZIKV samples have been assessed using
430 these pools of overlapping peptides and gating on CD8+ responding T cells in the ICS
431 assay. In a few instances where the number of PBMC available from each donor did
432 not allow testing of all pools, a factorial design was utilized: while not all pools were
433 tested in all donors, all pools were tested in the same number of donors. Whenever
434 sufficient cell numbers were available, pos. pools were deconvoluted, and specific
435 epitopes identified. Overall, PBMC from 17-33 donors/patients were tested for each
436 of the different categories (**Table 5**).

437 The frequency of *ex vivo* responses in ZIKV-infected patients was 30-40% for
438 both CD4 and CD8 responses, with the exception of CD8 responses in acutely
439 infected donors, which were detected in approximately 90% of the cases (**Figure 3A**
440 **and D left panels**). Marginal CD8 responses to the ZIKV peptides were noted in the

441 case of the ZIKV-neg. DENV-neg. donors (**Figure 3A**). However, ZIKV-neg. DENV-
442 Pos. donors showed appreciable reactivity both in terms of increased frequency and
443 magnitude of responses, confirming a degree of T cell cross-reactivity between
444 DENV-ZIKV responses observed above (**Figures 1 and 2**). In the acute ZIKV-
445 pos./DENV-Pos. donors, CD8 responses to ZIKV peptides were of significantly higher
446 magnitude compared to those acute ZIKV subjects who were DENV neg. (**Figure 3B**
447 **and C**). After ZIKV convalescence, the CD8 responses to ZIKV-restricted peptides
448 were still elevated as compared to ZIKV-neg. donors, but were not significantly
449 different by DENV serostatus (**Figure 3B and C**). The pattern of CD4 responses to
450 ZIKV-restricted class II peptides was remarkably similar with regard to ZIKV acute
451 and convalescence phase and impact of DENV seropositivity, with trends for *ex vivo*
452 ZIKV T cell responses being delayed in DENV neg. donors and lower frequency and
453 magnitude of responses observed in respect to the CD8 counterpart. (**Figure 3D-F**).

454

455 **Different proteins are targeted by ZIKV versus DENV immunity**

456 We next determined whether DENV serostatus affected the antigenic targets
457 of ZIKV-reactive T cells across the ZIKV polyprotein. A breakdown of ZIKV CD8
458 responses in acute and convalescent ZIKV pos. donors (combined in this plot) as a
459 function of the antigen targeted is presented in **Figure 4**. In the case of ZIKV-specific
460 CD8 responses in DENV-neg. donors 57% of the response was directed against
461 structural proteins (**Figure 4A**). In the context of a previous DENV-exposure,
462 however, only 30% of the ZIKV-specific responses were directed against structural
463 proteins (**Figure 4B**). This can be compared to historical data regarding DENV

464 responses from presumably ZIKV-neg. donors (since samples were collected prior to
465 the 2015-2016 ZIKV epidemic) where only 14.9% of the response was directed
466 against structural proteins(44). Thus, the CD8 response to ZIKV is more focused on
467 structural proteins compared to the focus on nonstructural proteins by DENV-
468 specific T cells. Nonetheless, DENV pre-exposure modulates the ZIKV-reactive
469 immunodominance pattern for CD8 cells, resulting in a broad recognition across the
470 ZIKV proteome.

471 In the context of CD4, responses were directed in approximately equal
472 proportions against structural and non-structural proteins (**Figure 4B**). Differences
473 between DENV and ZIKV patterns of immunodominance were not prominent, which
474 was not surprising since, according to published data, the DENV-specific response is
475 already focused almost equally (50%) on structural and non-structural
476 proteins(45). In the present study, the fraction of ZIKV-specific responses directed
477 against structural proteins was 58% or 67% for DENV-neg. subjects and DENV-Pos.
478 ZIKV-pos. donors, respectively (**Figure 4C-D**).

479 As above, whenever possible, peptides pools were deconvoluted and specific
480 epitopes mapped using same mapping approach previously shown in **Figure 2A**.
481 Two ZIKV NS5 epitopes (NS5₂₈₁₉₋₂₈₂₈ and NS5₂₈₆₈₋₂₈₈₇₆) both predicted to be
482 restricted by HLA B*35:01, were recognized in an HLA matched DENV Pos. donor
483 (**Figure 5A-B**). One of these epitopes was independently identified in a DENV-Pos.,
484 ZIKV-neg. donor (**Figure 2B**). In both cases, the ZIKV epitope differed from DENV
485 sequences by a single conservative substitution. A second DENV pos. donor
486 responded to the ZIKV ENV₇₁₉₋₇₂₈ epitope (predicted B*40:01 restriction), which

487 differs from DENV3 sequences by one single conservative substitution (**Figure 5C**).
488 Another E protein epitope was identified in the same donor (E₄₈₁₋₄₉₅; restricted by
489 HLA A*01:01), which in this case had more limited homology to DENV sequences
490 (**Figure 5D**).

491 Independent experiments showed that the very same ZIKV E₄₈₅₋₄₉₃ HLA
492 A*01:01 epitope also was recognized in a DENV-neg. subject (**Figure 5E**; Ricciardi *et*
493 *al.* manuscript submitted). Interestingly longer version of this peptide were not
494 recognized. It is possible that both 9 mer and 10 mer bind with high affinity, but in
495 somewhat different registers. Additional epitopes recognized in DENV-neg. donors
496 were mapped to a ZIKV C₂₃₋₃₂ epitope restricted by HLA A*03:01, showing again
497 limited homology to DENV sequences, and two additional ZIKV NS3 epitopes
498 restricted by HLA B*0801 and B*41:02 (**Figure 5F-H**). Additionally, we selected two
499 ZIKV peptides TPYGQQRVF and APTRVVAEM that were recognized by DENV
500 seropositive donors (**Figures 2A-C**), and synthesized the corresponding DENV
501 peptides. These peptides were then tested in parallel with the original ZIKV
502 peptides with PBMCs from the donor originally utilized to map the responses in
503 standard IFN- γ Elispot assays. Likewise we also tested the ZIKV ENV GLDFSDLYY
504 epitope defined in a DENV seronegative donor (**Figure 5E**), and tested the
505 corresponding DENV peptides in parallel with the originally identified ZIKV peptide.
506 The ZIKV TPYGQQRVF and APTRVVAEM peptides as well as the corresponding
507 highly homologous DENV TPFQQRVF and APTRVVAEM peptides were recognized
508 by the DENV seropositive donor with comparable magnitude. In contrast, the ZIKV
509 Env GLDFSDLYY, but not the fairly discordant corresponding DENV epitopes

510 GLDFNEMVL and GIDFNEMVL were recognized by the DENV seronegative donor
511 response (**Table 6**).

512

513 **Phenotype analysis of CD8 T cell responsive to ZIKV peptides**

514 To gain further insights into the potential biological significance of these
515 patterns of reactivity, we determined cell surface phenotypes of the CD8 T cells
516 producing IFN γ in response to the ZIKV peptide pools. As expected (**Figure 6A**),
517 these cells were predominantly TEM (CCR7+CD45RA-; approximately 60% on
518 average) and TEMRA (CCR7+CD45RA+; approximately 30% on average).
519 Approximately 50% of the IFN γ + CD8 T cells were TNF α + as compared to less than
520 1% of the IFN γ - cells (**Figure 6B**), thus establishing that a large fraction of the
521 responding cells are polyfunctional. Similar patterns were observed for
522 ZIKA+DENV- and ZIKA+DENV+ donors in terms of both memory phenotypes and
523 polyfunctionality.

524 By contrast, significant differences were seen between ZIKA+DENV- and
525 ZIKA+DENV+ donors when the granzyme B and PD1 markers were considered. The
526 expression of granzyme B in CD8 T cells from ZIKA+DENV- was not significantly
527 increased in IFN γ + cells as compared to the background level of approximately 30%
528 seen in IFN γ - cells, while in the case of ZIKA+DENV+ approximately 80% of the
529 IFN γ + cells were also granzyme positive (**Figure 6C**). Similarly, PD1 was only mildly
530 expressed in IFN γ + cells from ZIKA+DENV-, while 60% on average of the
531 ZIKA+DENV+ IFN γ + cells also upregulated PD1 (**Figure 6D**). These data indicates

532 that DENV pre-exposure affect not only the quantity but also the quality of
533 responses observed following ZIKV infection.
534

535 **Discussion**

536 We report the first characterization in humans of both ZIKV-specific and
537 ZIKV/DENV cross-reactive T cell responses, and the influence of DENV serostatus on
538 T cell immunity to ZIKV. Our study established three main points. First, pre-existing
539 T cell responses against DENV recognize peptide sequences encoded in the ZIKV
540 proteome. Second, cross-reactivity is immunologically consequential, as DENV-Pos.
541 individuals at the time of ZIKV infection respond more strongly to ZIKV both in
542 terms of CD4 and CD8 T cell responses. Third, patterns of immunodominance are
543 different in the case of DENV and ZIKV infection with, ZIKV-specific CD8 T cell
544 responses predominantly targeting structural proteins such as E, prM, and C. Our
545 study involves samples from ZIKV-infected donors derived from a variety of
546 different geographical locations, including mainland USA (travelers returning from
547 affected areas), Puerto Rico, Brazil, Nicaragua, and Mexico. As such we believe that
548 the pattern of responses we observed is of general relevance, and not limited to a
549 specific population or clinical context. In the present study we did not isolate
550 representative viruses from the different cohorts and compared the sequences in
551 terms of the percentage of similarity/differences to the peptide libraries used. Thus,
552 it is possible that intra ZIKV sequence variation might influence some of the results,
553 which should be interpreted with this caveat in mind.

554 We established that DENV-specific memory T cells recognize peptide
555 sequences encoded in the ZIKV proteome. This point was established with a
556 separate set of PBMC donations obtained either in Sri Lanka, where ZIKV has not
557 been reported, as well as from Nicaragua collected between 2010 and 2014 before

558 the introduction of ZIKV into the country. In this study we did not test recognition of
559 the DENV peptides corresponding to the ZIKV epitopes. We note this limitation in
560 our interpretation, as for example, recognition of the corresponding DENV peptide
561 could be much higher than for the ZIKV peptide. The molecular basis of this cross-
562 reactivity was established by mapping several different CD4 and CD8 epitopes.
563 These epitopes represent the first mapping of DENV/ZIKV cross-reactive epitopes in
564 humans, and in most cases the cross-reactivity could be explained by identity or
565 high similarity to sequences previously identified in one or more DENV serotypes.
566 This finding was predicted by previous analysis conducted by the IEDB analysis
567 resource(53), and by a recent study utilizing HLA transgenic mice (51). Nonetheless,
568 identification of specific sequences here allows for a comprehensive assessment of
569 whether the cross-reactivity is focused on regions that are highly conserved. Most
570 importantly, we demonstrate that DENV-specific CD8 responses induced by TD LAV
571 vaccination recognize ZIKV derived peptides. This cross-reactivity indicates a
572 potential for the TD LAV to provide some degree of protection against ZIKV infection.

573 An average homology level of 77% was observed between the sequences of
574 DENV and ZIKV cross-reactive epitopes (defined as ZIKV sequences recognized in
575 DENV-Pos. donors), as compared with an overall 56% level of homology detected
576 when the overall sequences of ZIKV and DENV proteomes were compared (**Table**
577 **3**). We conclude that sequential exposure to DENV and ZIKV sequences
578 preferentially expands responses against conserved sites between the viruses.
579 Similar observations were made in previous studies that showed that secondary
580 DENV infections are associated with preferential recognition of epitopes conserved

581 amongst different DENV serotypes that showed that secondary DENV infections are
582 associated with preferential recognition of epitopes conserved amongst different
583 DENV serotypes(44). Also, sequential exposure to different DENV serotypes in
584 animal DENV models results in expansion of T cells recognizing cross-reactive
585 epitopes (12, 46). It would have been interesting to examine if primary versus
586 secondary DENV infection or the time interval between DENV and ZIKV infection
587 influences T cell responses to ZIKV peptides. However this information is not
588 available to us from all different sites and an analysis of this variable could be
589 addressed in future studies specifically designed to examine this issue.

590 It is also noteworthy that three out of eleven of the identified epitopes were
591 identified in multiple independent donors (ZIKV NS3-1725-1734, NS5₂₈₆₈₋₂₈₇₆ and E₄₈₅₋₄₉₃).
592 Albeit based on a limited number of subjects, these results indicate that ZIKV
593 responses may be associated with strong immunodominance of particular epitopes.
594 In addition, NS5₂₈₆₈₋₂₈₇₆ was identified in DENV+ZIKV+ and DENV+ZIKV- individuals
595 but no reactivity was detected in pools containing this peptide in DENV-ZIKV+
596 donors. Conversely, ZIKA E₄₈₅₋₄₉₃ with lower homology level with DENV, was
597 identified in DENV+ZIKV+ and DENV-ZIKV+ individuals but not in DENV+ZIKV-
598 donors.

599 Significant differences in frequency or magnitude of T cell responses to ZIKV
600 peptides in PBMCs from ZIKV-DENV+ donors compared with ZIKV-DENV- donors
601 were detected in the acute phase of infection with ZIKV. This parallels similar
602 observations made in terms of antibody responses that showed that ZIKV/DENV
603 cross reactivity is most readily detected close to infection and wane afterwards (7).

604 We also find that DENV pre-exposure influences ZIKV responses. This could be
605 understood in the context of the well recognized phenomenon of heterologous
606 immunity(32, 50). Specifically, ZIKV-specific T cells responses for both CD4 and CD8
607 T cells responses develop more rapidly in DENV-Pos. individuals and are already
608 apparent in the acute phase of the disease. These responses subside at
609 convalescence, but remain elevated compared to those in ZIKV-neg. individuals. The
610 percentage of subjects with confirmed ZIKV infection who showed a positive T cell
611 response (**Figures 3A and 3D**) is relatively low, consistent with a primary infection
612 and with ZIKV being in most cases associated with a milder clinical presentation
613 than DENV(46). This pattern is reflective and characteristic of the differences in a
614 primary compared to a classic secondary response (55). Here we demonstrate how
615 prior DENV infection alters ZIKV-specific immune responses and we provide the
616 first evidence that prior DENV infection leads to stronger and faster responses thus
617 providing evidence of a biological outcome. This is the first evidence in humans that
618 previous exposure to dengue virus can influence subsequent infection with ZIKA
619 virus by mounting a cross-reactive memory T cell response against ZIKA virus.
620 Recent data in HLA transgenic mice demonstrated that ZIKV challenge following
621 immunization of mice with ZIKV-specific and ZIKV/DENV cross-reactive epitopes
622 elicited CD8⁺ T cell responses that reduced infectious ZIKV levels, and CD8⁺ T cell
623 depletions confirmed that CD8⁺ T cells mediated this protection (51). In addition a
624 recent paper has shown that Zika virus pathogenesis in rhesus macaques is
625 unaffected by pre-existing immunity to dengue virus (25). Together these data
626 underline important implications for ZIKV vaccine development.

627 We have previously shown that stronger T cell responses are associated with
628 certain HLA alleles associated with protection in case of heterologous infection with
629 DENV pointing to a protective effect of these cross-reactive responses (44). Given
630 that the groups were drawn from different study populations (age and genetic
631 background), which could influence the magnitude of the T cell responses further
632 studies will provide more evidence on the generality of our findings. It remains to be
633 seen whether this effect will be mimicked by DENV-or ZIKV-vaccination.
634 Importantly, our data indicates that DENV pre-exposure also alters the quality of
635 responses. While no difference was seen between DENV pre-exposed and DENV-
636 naïve donors at the level of composition of memory subsets in the responding cells
637 or the degree of multifunctionality, DENV specific CD8 responses from DENV pre-
638 exposed donors significantly upregulated granzyme B and PD1, suggesting a more
639 differentiated phenotype, similar to what detected in secondary DENV infection (6,
640 8).

641 Our data provide an example of adaptive heterologous immunity, where
642 cross-reactive memory Dengue-specific CD8 T cells are enhancing the T cell
643 responses to ZIKA virus. At this time these studies do not yet address whether this
644 will be beneficial in the majority of cases while at other times it could be detrimental
645 based on the specific cross-reactive pattern of each patient. However identifying key
646 cross-reactive epitopes in humans and demonstrating that they influence the
647 characteristics of the subsequent T cell response to ZIKA virus as this study does is
648 an important step, toward understanding potential immunopathology in ZIKA virus
649 infection.

650 An unexpected result of our analysis is that almost 60% of the ZIKV-specific CD8
651 responses in ZIKA-pos. but DENV-neg. individuals are directed against structural
652 proteins. This is in contrast to the relative paucity of structural protein-directed T
653 cell responses observed in DENV infection where only 15% of CD8 T cell responses
654 are directed against structural proteins (44), even though serotype specific
655 differences have been noted (1, 2, 43, 44, 46). Interestingly, the percentage of CD8 T
656 cell responses directed against structural proteins in DENV-Pos. ZIKV patients is
657 30%, thus suggesting that previous DENV exposure may alter the patterns of
658 immunodominance, skewing it towards a pattern more similar (but still not
659 identical) to that observed in DENV Pos. donors in absence of ZIKV infection.

660 The degree of homology (conservation) between NS proteins of DENV and ZIKV is
661 on average 51%, compared to 49% for structural proteins and 58% compared to
662 51% when accounting for size difference, so a higher degree of homology does not
663 itself drive or focus cross-reactive responses on these antigens. The conclusion that
664 T cell epitopes for ZIKV and DENV differ in their distribution between structural and
665 non-structural proteins requires the caveat that is based on comparing data
666 generated in separate studies, which have used different methods (e.g., ELISPOT
667 versus flow cytometry). In addition, It can not be excluded that the strong
668 magnitude of one donor may have an substantial effect on the percent of the total
669 response directed towards nonstructural proteins.

670 It would have been of interest to determine the number of epitopes detected in the
671 structural and nonstructural regions on a per donor basis. This analysis could
672 provide additional support for the notion that pre-existing immunity to DENV

673 broadens recognition across the ZIKV proteome. Due to the small volume of blood
674 samples collected we were not able to deconvolute all positive pools to identify the
675 exact epitope. Future studies where larger amounts of blood are collected will allow
676 to comprehensively address this point. It is also worth noting that significant CD8+
677 responses directed against structural proteins were reported in the case of West
678 Nile and Japan Encephalitis (21, 39). These two flaviviruses are both associated with
679 neurological complications(34). Further, we previously shown in an HLA-transgenic
680 model a trend towards higher recognition of structural proteins for DENV3 (as
681 compared to other DENV strains)(46), which previously also was reported to be
682 associated with neurological symptoms(10, 35). Similarly, we have previously
683 shown that human DENV3-serotype specific CD8+ T cell responses preferentially
684 recognize structural proteins. Conversely, DENV 1 and DENV4 serotypes
685 preferentially recognized non-structural proteins. Finally DENV2 serotype showed a
686 broader recognition of all proteins but still elicited the strongest CD8+ T cell
687 response against non-structural proteins(48). As no higher level of homology is
688 observed between ZIKV and DENV3 respect to the other DENV serotypes that could
689 explain the preferential recognition of structural proteins (**Table 3**), we could
690 hypothesize that common processing pathways or similar CD8+ T cell elicitation
691 might occur that differs from the other DENV serotypes and will need further
692 investigation.

693 Mapping of over ten different ZIKV epitopes suggest that DENV-Pos. donors
694 tend to recognize DENV/ZIKV highly conserved epitopes, while DENV neg. subjects
695 may recognize more divergent targets. An average 76% level of homology existed

696 between DENV and ZIKV sequences among cross-reactive epitopes (defined as ZIKV
697 sequences recognized in DENV-Pos. donors), as compared with an average 55%
698 level of homology between DENV and ZIKV sequences at the level of ZIKV epitopes
699 recognized in DENV-neg. donors, and an overall 56% level of homology detected
700 when the overall sequences of ZIKV and DENV proteomes were compared. These
701 results emphasize that previous exposure to DENV influences the fine repertoire of
702 epitopes being recognized. It remains to be seen if cross-reactivity of T cells can also
703 be detected between ZIKV and other related flaviviruses. In the present study we
704 have not characterized WNV or JEV exposure. It is possible that cross reactivity at
705 the T cell level may exist between ZIKV and other more distantly related
706 flaviviruses, and this point will be address in future studies.

707 In the majority of cases, the degree of homology between ZIKV and DENV
708 was very high, suggesting that a ZIKV diagnostic assay based on T cell responses is
709 not immediately practical, and conversely reemphasizing that DENV pre-exposure
710 (or vaccination) might influence ZIKV immunity. Vaccines against ZIKV that are
711 currently under development and focus on structural protein antigens rather than
712 live virus may have logistical (no need for cold chain) and safety (no risk of virulent
713 reversion and safe to administer to pregnant and immune-compromised patients)
714 advantages; however, these vaccines may not comprise the full set of antigens
715 required to induce protective immunity. Our results that approximately 55-60% of
716 the ZIKV-specific CD4 and CD8 response is directed against structural proteins is
717 encouraging that cellular responses necessary to directly limit ZIKV infection and

718 support T-dependent antibody responses may be achievable with vaccine
719 approaches being pursued.

731 básica SEP-CONACyT 256235 and Fosiss-CONACyT 233697 to HVC. Blood donor
732 samples from Puerto Rico and Florida were collected as part of the National Heart,
733 Lung and Blood Institute REDS III (Recipient Epidemiology and Donor Evaluation
734 Study-III).

735 A.G., J.P., P.H.O., C.G.T.S., A.M., P.R.C., L.M.D-O.-P., and E.L.D.A. performed
736 experiments, reviewed data, and planned the experimental strategy. J.S., S.P., and
737 B.P. performed bioinformatics analyses. E.P. and S.M. performed and coordinated
738 HLA typing and related analysis. S.R.M., M.S., J.C., A.D.D.S., M.J.R., D.M.M., E.G.K.,
739 P.V.D., A.M.D.S., M.C., A.D., S.A.D., C.C., A.B., G.K., J.C., E.H., J.E.C., M.S., P.J.N., M.B., H.V.-
740 C., J.C., B.S.G., J.E.L., L.T., T.S., and D.I.W. collected samples and provided analysis of

741 clinical information and interpretation of the data. A.G., D.W., and A.S. conceived and
742 directed the study and wrote the manuscript. All authors have critically read and
743 edited the manuscript.

972 **Figure Legends**

973 **Figure 1. *Ex-vivo* reactivity to ZIKV derived peptides and previously defined**

974 **DENV epitopes in DENV-Pos., -neg. donors and DENV vaccines.** CD8 (A) and CD4

975 (B) T cell reactivity to DENV epitopes and ZIKA peptides in ELISPOT *ex-vivo*

976 experiments are shown for donors DENV Pos. (red) or neg. (black). Responses were

977 expressed as the number of IFN γ secreting cells per 10⁶ PBMC and were considered

978 pos. if the net spot-forming cells (SFC) per 10⁶ were ≥ 20 , had a stimulation index of

979 ≥ 2 , and a $p < 0.05$ in a t test or in Poisson test comparing replicates with those from

980 the neg. control. Donors with PHA values < 250 SFC per 10⁶ PBMC have been

981 excluded from the analysis. Data are expressed as geomean with 95% CI. CD8 (C) T

982 cell reactivity to DENV megapool and ZIKA HLA-restricted pools in ICS experiments

983 are shown in DENV vaccinees (green) in comparison with flavivirus naïve donors

984 (black). Data are expressed as average \pm SD of the percentage of CD3+CD8+IFN γ +

985 cells.

986

987 **Figure 2. Mapping of CD8 and CD4 cross-reactive DENV-ZIKV T cell epitopes.**

988 Panel A shows an example of the mapping strategy. CD8 (B-D) and CD4 (E-G)

989 restricted epitopes were mapped by peptide deconvolution in ELISPOT *ex-vivo*

990 experiments in individual donors. ZIKV epitope sequences were aligned with

991 consensus sequences of DENV1, 2, 3 and 4 serotypes. Amino acid mismatches

992 between the ZIKV sequence and the DENV consensus sequences are shown in red.

993

994 **Figure 3. Ex-vivo reactivity of ZIKV donors to ZIKV peptides.** CD8 (A-C) and CD4
995 (D-F) ZIKV-restricted responses in ZIKV-neg., acute and convalescent donors are
996 shown in intra cellular cytokine experiments. Each group is further divided in
997 DENV-Pos. (red) or -neg. (black). Each donor has been tested with at least 5 protein
998 pools (C-NS2A or NS2B-NS5) or the full set of protein pools depending on the
999 availability of cells (A-B; D-E). Each data points represents the response of a single
1000 donor response if all 10 protein have been tested or the combined response of two
1001 donors tested with the two different sets of 5 protein pools. **Panels C and F** show all
1002 the responses against individual pools regardless of the donor it has been tested.
1003 Statistical significance for differences in frequency of responders (left panels) was
1004 performed using a Fisher test. Magnitude of responses (central and right panels) is
1005 expressed as geometric means with 95% CI, and statistical analyses were performed
1006 with Mann-Whitney U test.

1007

1008 **Figure 4. Immunodominance pattern of CD8 and CD4 responses against ZIKV-**
1009 **derived peptides.** ZIKV CD8 (A and B) and CD4 (C and D) responses to 10 ZIKV
1010 proteins are shown in ZIKV-pos. DENV-neg. subjects (left panels, A and C), or DENV-
1011 Pos. subjects (right panels, B and D). Structural (C, prM, E) and non-structural (NS1,
1012 NS2A, NS2B, NS3, NS4A, NS4B, NS5) proteins are divided by a dotted line, and their
1013 magnitude in percentage shown in each graph. The total magnitude of the responses
1014 has been calculated and the resulting percentage of responses for structural and non
1015 structural proteins shown respectively in the upper left and right of each figure
1016 panel. Data are expressed as geometric means with 95% CI.

1017

1018 **Figure 5. Mapping of CD8 ZIKV epitopes in ZIKV-pos. donors.**

1019 ZIKV-restricted epitopes mapped by peptide deconvolution in ELISPOT *ex-vivo*
1020 experiments in DENV-Pos. (A-D) or DENV-neg. (E-H) individuals. ZIKV epitope
1021 sequences were aligned with consensus sequences of DENV1, 2, 3 and 4 serotypes.
1022 Amino acid mismatches between the ZIKV sequence and the DENV consensus
1023 sequences are shown in red. Boxes indicate the optimal epitope restricted by the
1024 specific HLA phenotype present in this donor.

1025

1026 **Figure 6. Phenotype characterization of CD8- ZIKV specific immune responses**
1027 **in ZIKV -pos. donors.**

1028 Memory phenotype (A) and polyfunctionality (B-D) of ZIKV CD8 T cells were
1029 compared in donors ZIKV-pos. DENV-neg (black) and ZIKV-pos. DENV-pos (red). A)
1030 Average of percentage of memory phenotype populations (naïve: CD45RA+CCR7+,
1031 central memory: CD45RA-CCR7+, effector memory: CD45RA-CCR7- and Temra:
1032 CD45RA+CCR7-) in CD8-ZIKV specific IFN γ producing cells. IFN γ - (oblique lines)
1033 and IFN γ + (blank pattern) CD8 T cells were analyzed for the co-expression of TNF α
1034 (B), Granzyme B (C) and PD1 (D). Data were expressed as average \pm SD of the
1035 percentage of CD3+CD8+ cells. Statistical analysis was performed with Mann-
1036 Whitney U test. * P<0.05, ** P<0.01, ***P<0.005, ****P<0.001.
