2 Abstract

3 To achieve agreed targets for reducing global carbon emissions, industry must become more
 4 resource-efficient. To this end, two viable strategies exist: energy efficiency and material
 5 efficiency. Despite the inherent interdependence of energy and materials in industrial processes,
 6 policy and industry treat these two strategies as isolated pursuits, which provides only a
 7 partial insight into potential gains from resource efficiency. To resolve this disconnect, we
 8 review 34 resource efficiency metrics from the literature and evaluate their effectiveness at
 9 driving the sector's low-carbon transition. We then evaluate five selected resource efficiency
 10 metrics, in more detail, against the RACER evaluation methodology, using the criteria:
 11 Relevance, Acceptance, Credibility, Easiness and Robustness.

12 The results point to the effectiveness of employing a Resource Efficiency metric based on the
 13 thermodynamic concept of exergy. Exergy-based Resource Efficiency metrics score highest in
 14 Relevance and Robustness, traits which are inherent to the metric and cannot be changed.
 15 However, exergy efficiency scores lower for Acceptance, indicating further advocacy is required
 16 for it to be accepted as a mainstream measure of resource efficiency. More work is required to
 17 provide simple guides, training and software tools, to facilitate wider use of exergy efficiency in
 18 the resource efficiency narrative. We hope that this paper, is a first step towards demystifying
 19 exergy and will spur further discussion about the use of exergy-based metrics for measuring
 20 Resource Efficiency.

21 1 Introduction: the hidden climate instrument

22 The latest IPCC report provides a stark reminder of the challenges of mitigating climate
23 change. Pathways with higher chances of holding warming to below 1.5°C (average global
24 temperature)¹ require net zero CO₂ emissions to be reached by 2050, and a corresponding
25 45% decline in CO₂ emissions decline from 2010 to 2030 (Rogelj et al., 2018). Efforts to date
26 have focused mainly on switching to lower carbon fossil fuels, deploying renewable energy,
27 improving energy efficiency (EE), methane abatement, limiting deforestation and carbon
28 capture and storage technologies. And yet, despite these aspiring goals and considerable
29 effort, unconditional measures pledged by countries under the Paris Agreement still fall short
30 of what is required; additional decarbonisation strategies are needed.

31 In light of these challenges, a growing academic community has begun advocating for a more
32 holistic approach which addresses inefficiencies in material production. These decarbonisation
33 options fall under several banners: material efficiency (ME) (Allwood et al., 2011, Cullen
34 et al., 2012, Worrell et al., 1995), resource efficiency (RE) (EC, 2011, Gonzalez Hernandez,
35 Paoli and Cullen, 2018, Valero et al., 2015), life-cycle thinking (ISO, 2006, Pennington
36 et al., 2004, World Aluminium, 2017, worldsteel, 2017) and circular economy (CE) (Circle
37 Economy, 2017, 2019, Di Maio and Rem, 2015, Linder et al., 2017). Together they include
38 the untapped potential of recycling, product re-use, remanufacturing, product light-weighting,
39 manufacturing yield improvements, product life-extension, and by-product recovery (among
40 others) and can be leveraged to support more traditional decarbonisation strategies.

41 Overwhelming evidence suggests that the improvement potential of circular and resource
42 efficiency measures is vast. Global circularity is estimated to be only 9% by mass and this
43 fraction is trending down, rather than up (Circle Economy, 2019). This estimate includes
44 both materials and fossil fuels (measured in mass) which are either recycled or reused in a
45 circular fashion. If we consider the quality of these materials and the energy required to
46 close material loops through recycling, global circularity fractions for major energy-intensive
47 materials are: 20% for aluminium, 14% for steel, 7% for plastics, 4% for paper and 0% for
48 concrete (Cullen, 2017).

49 Such fractions point to large potential gains in efficiency, but should be read with caution, as
50 there are significant challenges to increasing the circularity of materials (e.g the mismatch
51 between available scrap supply and material demand). Yet, we can conclude that strategies to
52 improve the efficiency of energy and material systems, what we call *Resource Efficiency*, could
53 deliver significant reductions in material demand, energy use and carbon emissions.

54 A criticism of current metrics for measuring circularity and RE is their quantification of
55 material flows without considering the energy and environment impacts of interventions
56 (European Commission, 2015). Cullen (2017) explain that “material losses and energy inputs

¹This is a pathway with no or limited overshoot of 1.5°C. In contrast, pathways allowing for a temporary temperature overshoot rely on large-scale deployment of CO₂ removal measures, which remain uncertain and entail clear risks.

57 associated with recycling can usurp many of its environmental benefits.” Furthermore,
58 circularity metrics provide insight at the country or global level, yet are often difficult to
59 apply to linear sub-sections of the circle, such as resource-intensive material producers. For
60 such industries, applying circularity strategies to reduce emissions in practice means reducing
61 overall resource inputs (energy and materials) per tonne of product.

62 If the efficient use of resources is to become an inveterate climate instrument, emissions-
63 intensive producers will need to develop a proper thermodynamic understanding of their
64 production systems, including the links between materials, energy and emissions (Schalkwyk
65 et al., 2018). This is challenging as energy and material use are measured in different units
66 (tonnes versus Joules) and current organisational structures mean most producers measure
67 EE and ME separately. Energy teams are responsible for reducing energy use, and they do
68 so one asset at a time (e.g. boilers, heaters, electric motors), while material teams monitor
69 product quality, optimise material procurement costs and attempt to improve yield rates.
70 Yet, the assessment of energy efficiency and material efficiency in isolation fails to capture
71 the full improvement potential from efficiency, as interactions between energy and materials –
72 which is the whole purpose an industrial process – are overlooked.

73 Resource Efficiency entails delivering future energy and material services with reduced resource
74 use and environmental impact. Becoming more resource efficient requires clear targets and the
75 means to measure progress with appropriate metrics at multiple levels, from policymakers to
76 plant operators. This study seeks to define such a metric for RE; one that considers resource
77 interactions; is comparable across different processes and sectors; reflects both resource
78 quantity and quality; is applicable at different spatial boundaries and temporal scales.

79 The paper is structured into four sections: (1) a review of approaches to measuring resource
80 efficiency, including economic, physical, and impact-oriented metrics, followed by a review
81 of metric evaluation criteria; (2) a description of the proposed RE metric and evaluation
82 method; (3) a presentation of the results of the RE metric evaluation; (4) a discussion of the
83 usefulness and limitations of the RE metric.

84 **2 Review: resource efficiency metrics and evaluation criteria**

85 Much has been written about improving the RE of emission-intensive industries, with many
86 studies pointing to significant potential for economic and environmental gains. RE indicators
87 are employed in every sector – from policy and governance to industry firms – and for multiple
88 purposes. Unsurprisingly, a plethora of metrics is available to quantify RE, many of which are
89 expressed as ratios of two measured quantities. The differences found across RE metrics result
90 from the scope of resources considered, the targets/aspects that resource-use is measured
91 against, and the units chosen.

92 This section reviews the most relevant RE metrics proposed in academic literature, industry
93 practice and policy. Metrics are classified into three groups: economic (Section 2.1), physical
94 (Section 2.2) or impact-oriented (Section 2.3). Section 2.4 describes how six metrics are

95 selected for further evaluation, and Section 2.5 outlines the set of relevant criteria that were
 96 used for testing the RE metrics.

97 2.1 Economic-based indicators

98 Economic-based indicators are typically employed in policy to track macro-level changes
 99 in resources and economic activity. For example in energy policy, EE (energy efficiency)
 100 is often expressed as *energy productivity* (the ratio of value-added per unit of energy used
 101 (IEA, 2014b)) and is used to assess long-term interactions between economic-activity and
 102 environmental performance. Atalla and Bean (2017) claim that energy productivity is a
 103 more “direct measure of a country’s economy”, is more intuitive, and is better aligned with
 104 efficiency than physical metrics. For this reason, many countries target policies to improve
 105 energy productivity (e.g. US (Keyser et al., 2015) and Germany (BMW, 2016)). Table 2
 106 presents a summary of the economic metrics discussed.

Table 2: Review of economic-based resource efficiency metrics.

Metric	Unit	Scope	Reference
Energy Productivity	Value added per unit of energy used	From Global to Sector	(IEA, 2014b)
Domestic Resource Productivity	GDP per Domestic Material Consumption	From Global to Sector	(EC, 2011, 2015)
Resource Productivity	GDP per Raw Material Consumption	From Global to Sector	(EC, 2011, 2015)
Physical Trade Balance	Imports - Exports	Regional	(European Communities, 2001)
Exergy Productivity	GDP per Exergy	From Global to Sector	(Eisenmenger et al., 2017)
Emissions Efficiency	GDP per total emissions	Global, Regional	(IEA, 2009)

107 *Resource productivity* is the analogous metric used to explain trends in resource (rather than
 108 energy) use. It is a lead indicator in the EU’s circular economy (CE) package (EC, 2011,
 109 2015) and depicts RE as the economic output (GDP) per unit of resource input (domestic
 110 material and energy consumption, measured in mass). Many alternative definitions of resource
 111 productivity also exist. For example, GDP per input of natural resources (DMI) and GDP per
 112 Raw Material Equivalent (Etkins and Hughes, 2016) or GDP per input exergy (Eisenmenger
 113 et al., 2017).

114 Di Maio et al. (2017) propose a RE metric defined as the value added of resources output by a
 115 sector, per volume of resources used, weighted by market price. The authors argue that price
 116 reflects “both the quality and the scarcity” of resources and conclude that monetary metrics
 117 are both better at capturing local situations and easier to communicate, than mass-based
 118 equivalents. Etkins and Hughes (2016), Huysman et al. (2015), Van der Voet et al. (2005)
 119 provide reviews covering an extensive range of policy-level RE indicators.

120 A good reason to use economic measures is the “availability of detailed data for analysis”
 121 (Cullen, 2009). If the monetary value of resources, waste disposal and process operations
 122 align with the resources used, economic metrics can be a suitable proxy for RE. However,

123 if alignment is not found and inefficient resource use results in increased profitability, it is
124 “unlikely that a market operating solely according to market rules will deliver a resource-efficient
125 outcome in physical terms” (Etkins and Hughes, 2016). Economic metrics are criticised for
126 being “insensitive to changes in the environmental pressures” and scarcity (Valero et al., 2015,
127 Van der Voet et al., 2005) because environmental impacts vary significantly across materials.
128 Analysis must therefore rely on baskets of indicators, each of which is designed to measure a
129 specific aspect of RE, making cross-material comparisons difficult.

130 **2.2 Physical-based indicators**

131 A portfolio of physical metrics can be used to track resource use in emissions-intensive
132 industries. Three types are reviewed: energy-, material- and exergy-based.

133 **Energy efficiency**

134 The most well-understood physical measure of energy efficiency for industry is energy intensity
135 (EI), typically but not always, measured in units of joules per tonne of material output.
136 Energy-intensity indicators have the advantage of being applicable at any system level, from
137 individual processes through to entire regions. Table 3 summarises a selection of studies that
138 have developed or employed EE metrics for energy-intensive industries.

139 Worrell et al. (2008) published a widely-cited study on global best-practice energy use for
140 many industries. For steel, for example, it evaluates energy intensities (GJ/t, using both
141 primary and final energy) of steel products with inputs disaggregated by fuels, steam and
142 electricity. Phylipsen et al. (1997) proposed a modified energy-intensity metric called the
143 Energy Efficiency Index (EEI), which enables the comparison of EE between countries. The
144 EEI metric accounts for structural effects by measuring the ratio of average to best practice
145 energy intensity for each country. This method has been applied to benchmark industry
146 sectors Phylipsen et al. (2002); in detailed EE studies of steelmaking (Siitonen et al., 2010)
147 and to global industry benchmarks (Ke et al., 2013, Saygin et al., 2011, UNIDO, 2010).

148 EI indicators have achieved the closest to a universal acceptance, including as a policymaking
149 tool (IEA, 2008). One example is the EUs ODEX index which the European Commission
150 uses to track EE improvements (EC, 2012b). Yet EI metrics only quantify the extent to
151 which fuels are used, and material product and by-products are produced, ignoring the value
152 of material by-products and material inputs. By virtue of having different denominators, EI
153 metrics are inappropriate for comparing performance across different sectors. To capture the
154 effectiveness of material use, many other metrics have been developed under the rubric of
155 material efficiency or circular economy.

156 **Material efficiency and circular economy metrics**

157 Material efficiency (ME) and circular economy (CE) metrics can take multiple forms as shown
158 in Table 3; more extensive reviews can be found in Allwood et al. (2011), Cleveland and Ruth
159 (1998), Shahbazi et al. (2017).

Table 3: Review of physical- and impact-based resource efficiency metrics. Con (consumption); Cum (cumulative).

Metric	Unit	Scope	Reference
Energy metrics			
Final Energy Use	GJ of final energy input	Global, Regional, Sector	(IEA, 2017)
Energy Intensity	GJ of energy per tonne output	Global, Regional, Sector	(UNIDO, 2010)
Energy Efficiency	GJ of energy per GJ of energy	Site, Plant, Process, Unit	(IEA, 2008)
Energy Efficiency Index	Ratio of Current EI to Best Practice	Regional, Sector, Site	(Phylipsen et al., 1997)
Material metrics			
Raw Material Con. Intensity	Tonnes of raw material/tonnes output	Sector, Site, Plant	(Etkins and Hughes, 2016)
Domestic Material Con.	Tonnes	Global, Regional	(EC, 2016)
Total Material Requirement	Tonnes	Global, Regional, Sector	(EC, 2016)
Material Input per Service	Tonne in tonne product	Global, Regional, Sector	(Hashimoto, 2004)
Material Circularity	Percentage (%)	Sector, Supply chain	(Ellen MacArthur Foundation, 2015)
Product-Level Circularity	Cost recirculated part/Cost all parts	Product	(Linder et al., 2017)
Circularity Index	Percentage (%)	Sector, Supply chain	(Di Maio and Rem, 2015)
Waste rate	Waste produced per unit product	Sector, Plant, Product	(Gao et al., 2016)
End-of-life (EOL) recycling	recycled EOL/ EOL products	From Sector to Product	(Graedel et al., 2011)
Recycled Content	used scrap /total material input	From Sector to Plant	(Graedel et al., 2011)
Direct Material Input	Tonnes	Global, Regional	(Schandl et al., 2016)
Re-use Rate	Percentage (%)	From Global to Plant	(Densley Tingley et al., 2017)
By-product Recovery	By-prod used / by-prod produced	From Global to Plant	(Hashimoto, 2004)
Material Use Time	Stocks / used products recovered	Global, Regional, Sector	(Hashimoto, 2004)
Material Yield	Percentage (%)	Site, Plant, Process	(worldsteel, 2009)
Exergy metrics			
Exergy Efficiency	Percentage (%)	From Global to Unit	(Szargut et al., 1988)
Cum. Degree of Perfection	GJ of output exergy / cum. GJ input	Supply chain, Site, Plant	(Szargut et al., 1988)
Exergy Intensity	GJ per tonne of output	From Global to Plant	(Costa et al., 2001)

160 Material Intensity (MI) is a popular metric which is defined using several ratios, including
161 tonnes per GDP (Cleveland and Ruth, 1998, EC, 2011b) and tonnes per area, volume, hour
162 or service (Allwood et al., 2010, Eisenmenger et al., 2017, Gao et al., 2016). Industry often
163 quantifies output-to-input ratios of metal contents to measure yield improvements, such as
164 the output of steel per input of iron in steelmaking (worldsteel, 2009).

165 Recycling is, by far, the most widely studied ME intervention, and yet, it is measured by a
166 confusing array of recycling metrics: recycling rates, recycled content (Allwood, 2014, Esch
167 et al., 2010, Graedel et al., 2011), and scrap usage (BIR, 2016). Even within recycling-rate
168 metrics, multiple definitions exist, each of which is designed for different “types of material
169 cycles” and “sections of the materials life cycle” (Hashimoto, 2004).

170 Recently, ME has been re-branded as a circularity strategy. So far, however, no standardised
171 circularity metric has been defined. Linder et al. (2017) compiled a selection of metrics,
172 highlighting their benefits and shortcomings. For example, (Ellen MacArthur Foundation,
173 2015)) propose a mass-based metric, Material Circularity Indicator (MCI), for quantifying
174 product circularity. The rest of the metrics reviewed are either based on life-cycle assessments
175 (e.g. Eco-efficient Value Ratio by (Scheepens et al., 2016)), focused solely on recycling (e.g.
176 Circular Economy Index by Di Maio and Rem (2015)) or based on cost (e.g. product-level
177 circularity by Linder et al. (2017)).

178 The ME and CE indicators described above quantify specific aspects of material use but
179 provide no indication of the energy or environmental implications of a given ME intervention.
180 Cullen (2017) propose a Circularity Index to quantify the energetic implications of looping
181 materials, defined as the product of two quantities: one measures the mass of end-of-life
182 materials available relative to the total demand, while the others measures the energy needed
183 for material recovery relative to that needed in primary production.

184 In a recent study, Shahbazi et al. (2017) review ME metrics currently used by manufacturers.
185 The authors conclude that the literature does not address the practical aspects of “how to
186 manage ME performance, how other indicators interact with ME measurements, and how
187 they are connected to overall goal and strategy of company.” A significant barrier to tracking
188 resource interactions is the measurement of energy and ME indicators in different units. To
189 resolve this, some academics promote the use of exergy to measure energy and material use
190 in a single, integrated metric.

191 **Exergy metrics**

192 Exergy is defined as “the maximum theoretical useful work obtained if a system is brought
193 into thermodynamic equilibrium with the environment” (Sciubba and Wall, 2007). Exergy has
194 been predominantly applied as an engineering method to analyse the efficiency of production
195 systems, and has been recognised as a promising decision-making tool to “locate inefficiencies
196 and irreversibilities within [a] process or system” (Gaudreau et al., 2009).

197 The application of the exergy method has led to the use of exergy efficiency metrics as a

198 way of measuring a process' efficiency. Exergy efficiencies are commonly defined as the ratio
199 of exergy inputs to exergy outputs, and can include either energy or materials alone, or a
200 combination of both. The numerator and denominator are measured in joules of exergy,
201 yielding a dimensionless metric. Exergy, unlike energy, incorporates the first and second law
202 of thermodynamics, allowing both resource quantity and quality to be measured.

203 Exergy efficiency definitions can be adapted to specific applications (Brodyansky et al., 1994,
204 Marmolejo-Correa and Gundersen, 2012) depending on: the specific system level (i.e. whether
205 a device or a sector); the nature of the transformations and losses involved (i.e. whether
206 energy or materials are being transformed); and the particular purpose of the study.

207 One way of classifying exergy efficiencies is by distinguishing between total or rational
208 definitions. The total exergy efficiency is described as the ratio of total output to total input
209 exergy flows (Fratzscher and Beyer, 1981, Nesselmann, 1952). This original definition has been
210 modified to account for external exergy losses contained in waste—denoted as *useful exergy*
211 *efficiency*; its denominator is still the total amount of resource inputs, but the products are
212 instead classified into useful and wasted streams. Conversely, rational efficiencies distinguish
213 between energy and materials flows that undergo transformations—and that are therefore
214 consumed—and those that remain un-reacted (Brodyansky et al., 1994).

215 The exergy concept has been widely advocated for within the academic community as
216 a method to assess sustainability and to perform resource accounting (e.g. Costa et al.
217 (2001), Masini and Ayres (1996)). Despite the recognised versatility of exergy metrics, the
218 cumbersome nature of exergy calculations have hindered its use in production management
219 (Khattak, 2016), benchmarks, and policy targets. However, more recently academics have
220 provided clarity in the use of efficiency definitions for different processes, attempting thereby
221 to standardise use (Cornelissen, 1997, Lior and Zhang, 2007, Renaldi et al., 2011, Tanaka,
222 2008). Allowing for the variations in definitions, it is thus possible to apply the RE metric,
223 using units of exergy, across all sectors.

224 Brunner and Rechberger (2004) and Gaudreau et al. (2009) contend that using exergy to
225 describe resource quality can be biased towards energy carriers. The exergy of fuels clearly
226 reflects their function: providing heat (either directly or indirectly) to a process/reaction.
227 For materials, however, quantifying the work that can be extracted from these may not be
228 the most suitable measure for truly capturing their utility. In response to this, Bakshi et al.
229 (2011) argue that the chemical exergy of materials is meaningful because it expresses the
230 theoretical amount that can be saved if these are input as raw materials elsewhere.

231 **2.3 Impact-based indicators**

232 The multi-dimensional nature of RE means that a multitude of environmental impacts can
233 be quantified, from toxicity to eutrophication, global warming potential or ozone depletion,
234 among others. As a result, impact-oriented metrics are typically used as part of a basket of
235 indicators, often in life-cycle analyses or input-output economic assessments. For example, in

236 the EU-funded project *TOP-REF*, the authors propose a selection of 16 key indicators for
 237 use by production facilities in the process industries (Deloitte and CIRCE, 2014).

238 When addressing the challenge of decarbonisation, impact indicators often measure indirect or
 239 embodied energy (GJ/t) and emissions (tCO₂/t) for specific products. For example, Milford
 240 et al. (2011) compute the embodied energy and emissions that could be saved by improving
 241 yields, whereas Cooper et al. (2014) use these to estimate the optimum life-time of appliances.
 242 Embodied exergy indicators have also been proposed by Szargut et al. (1988), including:
 243 cumulative exergetic consumption (CExC) as the sum of resources consumed across the entire
 244 production process of a material in units of exergy per tonne.

245 Some academics believe that indicators can only meaningfully inform decisions about RE
 246 performance if they combine all three aspects: physical, economic and environmental. At one
 247 end, Huysman et al. (2015) propose a systematised framework to classify all three types of
 248 RE indicators, where physical metrics are proposed at the micro-scale (i.e. gate-to-gate) and
 249 economic/impact indicators are proposed for the macro-scale (i.e. national and international).
 250 At the other end, Aghbashlo and Rosen (2018) propose a single metric to integrate all three
 251 aspects: eco-cost per value ratio – where eco-costs “represent the virtual prevention costs of
 252 [the] environmental burden[s] of a product, while the value shows its actual price or cost in
 253 the [...] economy”.

254 Table 4 depicts a selection of impact-based metrics found in the literature. Overall, impact-
 255 oriented indicators are useful for comparing the energy or emissions savings from various
 256 RE measures, for linking impacts to products/activities and assigning responsibilities to
 257 these (Barrett and Scott, 2012, EC et al., 2012), despite the utility of such measures being
 258 questioned (Allwood and Cullen, 2009, Ayres, 1995). Yet, impact indicators fail to capture the
 259 benefits of recovering material by-products, and summation of inputs across many processes
 260 makes it challenging to diagnose the cause of the loss for an single process.

Table 4: Review of impact-based resource efficiency metrics. Rep. stands for Replacement

Metric	Unit	Scope	Reference
Exergy Rep. Cost	GJ of exergy / tonne	From Global to Supply chain	(Valero et al., 2015)
Ecological Impact	Euros / Impact	From Global to Supply chain & Product	(Huysman et al., 2015)
Emissions Intensity	Tot. emissions / GJ energy	From Global to Plant & Product	(IEA, 2017)
Embodied Energy	Cum. GJ energy / tonne	From Global to Plant & Product	(Milford et al., 2013)
Emissions-Exergy Intensity	CO ₂ emissions / GJ exergy	From Global to Site	(Eisenmenger et al., 2017)
Embodied Exergy	Cum. GJ exergy / tonne	From Global to Plant & Product	(Szargut et al., 1988)
Eco-costs	Euros / CO ₂ eqv.	From Global to Supply Chain & Product	(Aghbashlo and Rosen, 2018)

261 The diversity of measured impacts makes it challenging to draw meaningful conclusions from
 262 impact-based indicators. Several options for aggregating these metrics have been proposed,

263 including their weighting (Huppel et al., 2012), normalisation (Benini et al., 2014) and
264 monetisation (Krieg et al., 2013). However, the process of combining multiple metrics is
265 highly subjective and risks biasing one impact over another.

266 **2.4 Metrics for further study**

267 Three types of indicators were reviewed: economic, physical and impact metrics. Their relative
268 advantages and disadvantages were investigated with the aim of assessing their suitability
269 as indicators to measure and track resource efficiency in emission-intensive industries. As
270 stated at the beginning of this paper, this study seeks to define a metric for RE that is able
271 to appropriately capture the efficiency with which both energy and materials are transformed
272 in production processes. This metric should help policymakers and industry firms make
273 decisions on how to improve RE, and in doing so must: take account of resource interactions;
274 be comparable across different processes and sectors; reflect both resource quantity and
275 quality; be applicable at different spatial boundaries, and over varying temporal scales.

276 Based on this review, we conclude that economic indicators, although useful at tracking
277 macro-level trends, provide only a limited understanding of the underlying physical flows
278 involved in production. In practice, these are primarily used to inform high-level policy
279 decisions. As a result, we support the view of Huysman et al. (2015) and IEA (2014b),
280 who argue that to guarantee the transition to a resource-efficient industry it is necessary to
281 complement economic indicators with market-independent ones. In fact, we believe that to
282 conduct a sound economic analysis of an industrial system, there must first be an underlying
283 understanding of its physical flows.

284 Impact-oriented metrics are designed for tracking upstream implications of resource use (e.g.
285 emissions) and for assigning responsibilities to different products or materials. They are
286 typically used to inform design decisions or to make comparisons between products at the
287 downstream-end of the supply chain, where they can assist consumer choices. While essential
288 to quantify achieved life-cycle emissions reductions of a product, impact metrics are not
289 well-suited to stimulate and guide RE improvement actions at the operational level. Like
290 economic metrics, impact-oriented indicators cannot directly measure the true distance to
291 achieve RE goals because they fail to provide insights into process losses. Neither economic
292 nor impact metrics reflect the real function of engineering systems, and understanding which
293 is vital for identifying improvement opportunities.

294 We therefore conclude that physical, market-independent indicators are most appropriate
295 to measure the RE of production processes in emissions-intensive industries. In fact, sound
296 economic and impact-based analyses must be rooted on a detailed understanding of fully
297 balanced physical flows. Physical indicators capture the underlying drivers of RE variations,
298 can help producers “understand opportunities for action in a language that they are more
299 comfortable with” and can drive the sector’s low-carbon transformation in a more targeted
300 manner. This gives producers and policymakers increased confidence that targets are indeed

301 achievable (IEA, 2014a).

302 To limit the scope of this analysis, a set of five physical-based metrics is selected for further
 303 analysis, as shown in Table 5. This selection includes metrics from each of the three physical
 304 categories: energy-, material- and exergy-efficiency. We selected the most-widely-used metrics
 305 from each category and avoided those narrowly measuring very specific measures, such as the
 306 material re-use rates or end-of-life-recycling indicator.

Table 5: Selected list of resource efficiency metrics for further evaluation.

Metric	Unit	Scope
Energy Efficiency	GJ of energy per GJ of energy	From Site to Unit
Energy Intensity	GJ of energy per tonne output	From Site to Unit
Circularity Index	Percentage (%)	Sector, Supply chain
Material Yield	Percentage (%)	Site, Plant, Process
Exergy Efficiency	Percentage (%)	From Global to Unit

307 2.5 What makes a good resource efficiency metric?

308 There are many ways of defining a ‘good’ metric. Neuhoff et al. (2009) define good indicators
 309 as “representations of quantitative or qualitative data, which can be used to understand the
 310 state of a problem, and illustrate the progress made towards obtaining a solution”. In most
 311 cases, whether a given metric is defined as ‘good’ or ‘appropriate’ depends on the specific
 312 application under consideration. No single metric will work for all purposes and across all
 313 existing applications, and equally no unique set of criteria will satisfy all opinions about what
 314 makes a good metric. Yet, a review of known criteria provides a basis to make an informed
 315 decision about which criteria to use.

316 The literature is a rich source of information about the criteria that companies, academics and
 317 policymakers deem useful. We reviewed eight studies to compile a list of the most popular
 318 criteria used for selecting and evaluating industrial performance metrics. Table 6 portrays the
 319 list of metric requirements (or criteria) which we thought were directly relevant to our study.
 320 This table is organised in terms of the banner criteria described in the RACER methodology
 321 (Best et al., 2008, EC, 2012), which we use to later evaluate the strengths and weaknesses of
 322 resource efficiency metrics. This method has been used to evaluate the criteria for RE metrics
 323 both within the context of industry applications (MORE, 2017) and that of policymaking
 324 (Best et al., 2008, EC, 2012).

325 The largest number of criterion are found under the category of *Relevance*. This makes sense
 326 given the wide range of views on what makes a metric relevant; it means different things
 327 to the different stakeholders involved across the production chain. For this study, *relevant*
 328 criteria were chosen from the point of view of industry practitioners and managers. These
 329 should reflect the requirements, which can provide guidance for the daily operations of a site
 330 or a single process equipment. Table 6, under the *Description* column, details what we mean
 331 by each criterion and briefly explains why they were chosen.

Table 6: Selection of possible metric evaluation criteria. Sources: A (Beisheim et al., 2017), B (Sfez et al., 2017), C (Neuhoff et al., 2009), D (IEA, 2014c), E (Best et al., 2008), F (EC, 2012), G (IEA, 2014a), H (IEA, 2008)

Criteria	Description	Sources
Relevance		
Resource Coverage	Must cover all relevant resources from which improvements can be realised or which affect other improvement measures. This typically means multiple resources, e.g. energy, materials, water and emissions if possible.	A, B
Scope, granularity	Should be applicable and multiple spatial and temporal scales, and should cover a substantial section of system (e.g. at least an entire facility)	A, B, C, D
Sensitiveness	Indicator outputs should be affected by input parameters to pick up relevant changes, detect non-linearities, discontinuities, thresholds.	A, D, E
Stimulus	Indicator should incentivise the entire gamut of RE measures and incentivise improvements in the right direction. In this case, this means it must incentivise reductions in both resource use and emission generation.	B, E
Policy support Strategy support Operations support	Disaggregation – either spatial, by product, industry – must be possible as these are required for effective policy. For example, if decisions are made at local level, does the indicator provide required local information?	A, D, E
Target setting	Decision makers should be able to use indicator to track progress towards established climate objectives (e.g. GHG emission reductions). The metric should directly reflect RE and be related to the overall goal (e.g. resource or GHG emissions reduction). Must be able to define baseline.	A, E, G
Applicability	Indicator should be applicable to different process, equipment and sectors. It should allow meaningful comparisons across these systems.	A, C
Trends	It should allow for RE performance to be traced and tracked across time (i.e. using time series data).	E
Forecasting & modelling	Should be used in predictions to forecast future emissions and resource use or for modelling where impacts of different potential policies or technology progress and/or consumption patterns can be simulated.	E
Acceptance		
Policy makers Industry technical Industry financial Industry manager Academics	Underlying rationale and meaning of indicator should be accepted by multiple stakeholders (including academics, policy makers, corporate managers and technical staff). For effectiveness in communication, it should resonate with widely-held values and pains to motivate stakeholders to calculate or provide data and accept interpretations.	C, E, F
Credibility		
Easy interpretation	Message must be easily understood by decision-makers and practitioners. It should inform any RE action or decision.	C, E, G
Transparency	Underlying data and methods must be fully disclosed and reproducible.	F
Ambiguity	Should convey clear, unambiguous message, and should allow for clear conclusions to guide political & corporate action.	C, E
Easiness		
Data collection effort	Does not require data that are overly expensive or onerous to collect, or that cannot be properly measured; ideally based on data already collected & electronically available.	C, D, F
Complementary	Should complement other indicators collected and assessed by decision-makers to provide richer insights.	B, C, E
Technical feasibility	Methodology is simple enough to be deployed using software and expertise appropriate to application. Calculation methodology is clearly defined to avoid ambiguity and implementation errors.	C, D, E
Robustness		
Level of Subjectivity	Indicator should avoid use of subjective factors to weight components. If used, must at least be explicit and justified.	C, D, E, H
Theory soundness	Based on sound theory; avoids double-counting or omissions; is consistent; relies on clearly-stated assumptions, not require ill-defined parameters.	C, E
Accuracy	Should accurately depict function of the process under study and the mechanisms taking place (e.g. chemical conversions).	F
Completeness	Indicator should avoid shifting of burdens among single problem types.	D, F

332 The *Acceptance* category can include any of the stakeholders involved in the industrial sector.
333 In this study, industrial technical, financial and managerial roles were selected as the most
334 important, alongside policymakers and academics – both of which have the ability to influence
335 industrial decisions. For the categories of *Credibility*, *Easiness* and *Robustness*, the choice of
336 criterion were relatively consistent across the studies reviewed irrespective of the context in
337 which they were applied. Overall, industry practitioners seek a metric that they can feasibly
338 measure (i.e. that they have data for), understand and which they trust will take them in
339 the right direction.

340 **3 Methodology: the RACER evaluation**

341 The methodology outlines the process undertaken to select the most appropriate RE metric
342 available to support decarbonisation strategies. This process involves the selection of both
343 relevant RE metrics from the literature and appropriate evaluation criteria. This section is
344 divided into two. First, Section 3.1 where we define what we mean by resource efficiency.
345 Second, Section 3.2 where we describe the evaluation methodology used and the choice of
346 evaluation criteria.

347 **3.1 Resource efficiency definition**

348 Described generally, an efficiency provides a measure that relates the effect obtained from a
349 process (output) to the effect supplied (input). Resource efficiency considers a broader picture
350 than either energy efficiency or material efficiency by themselves. The multi-dimensional
351 nature of resource efficiency (resource can mean many different things) results in the existence
352 of many definitions of resource efficiency. To provide clarity for this paper, we define being
353 resource-efficient as:

354 *less resource inputs are required to produce a given output, be it a product or a service.*

355 We are interested in assessing the effectiveness of the use of resources in production processes
356 and the effect of resource efficiency on carbon emissions specifically. As such, we do not
357 intend to advocate for a metric that quantifies associated environmental impacts.

358 **3.2 Indicator evaluation methodology**

359 When faced with a wide choice of possible metrics, it is valuable to have a framework that can
360 assist in classifying the different metrics and providing nomenclature. This gives structure
361 to information and allows the evaluation of the strengths and weaknesses of the considered
362 indicators. In this study, we use the RACER methodology (Beisheim et al., 2017, Best
363 et al., 2008, EC, 2012). RACER is an evaluation framework, which is applied to assess
364 the effectiveness of indicators. It is normally applied in policy making, but can be equally
365 insightful when assessing metrics at the more local levels, such as corporate or operational.

366 RACER is an acronym of the key criteria groupings in the method: Relevance, Acceptance,
367 Credibility, Easiness and Robustness:

- 368 • **Relevance** – should be closely linked to the objectives to be reached;
- 369 • **Acceptance** – by process engineers, plant managers, policy makers, other stakeholders;
- 370 • **Credibility** – unambiguous, transparent and easy to interpret;
- 371 • **Easy** – monitoring and calculation of the metric should be feasible (e.g. data collection
372 should be possible at low cost and reasonable level of expertise should be required);
- 373 • **Robust** – based on a sound theory and not susceptible to manipulation (e.g. subjective
374 assumptions or allocations).

375 Figure 1 depicts the methodology followed in this study. It begins with a review in Section 2,
376 where we evaluated the wide portfolio of resource efficiency metrics proposed in the literature,
377 and provided a list of important criteria for industry practitioners and policymakers – as
378 described in previous studies. Based on these two reviews, we propose a final selection of
379 metrics and criteria to use in the evaluation process.

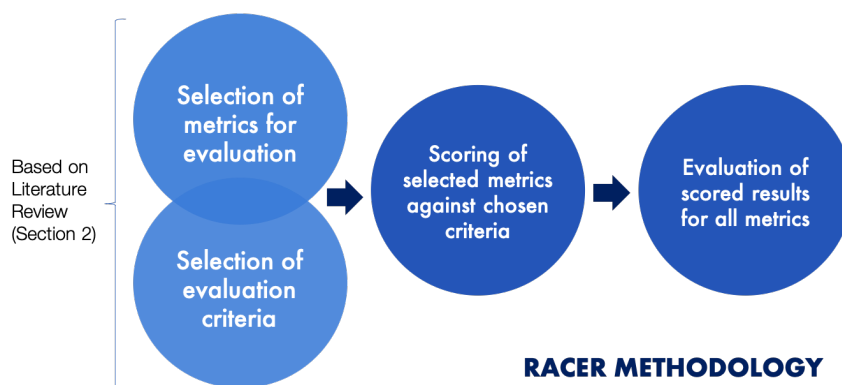

Figure 1: Implementation of RACER methodology.

380 For the selected metrics and criteria, a point-system is used to weigh the degree to which
381 these criteria are met. This provides us with a score for each criterion. Three scores are
382 used, corresponding to the level of success (2 = fully, 1 = partially or 0 = not achieved). A
383 score of two points is allocated to a criterion if this is fully achieved, one point is given if it
384 is partially achieved, and zero points if it is not achieved. It is only possible to provide one
385 answer for each of the criterion.

386 The framework is designed to help us discern the strengths and weaknesses of the indicators
387 under consideration. For this reason, it is helpful to treat the criteria as independent variables.
388 The more suitable RE metrics should have good or acceptable scores in all five dimensions,
389 with special emphasis on both its relevance and industrial acceptance. It is worth noting
390 that there is a subjective dimension in this evaluation process. Two potential sources of
391 subjectivity arise from: (1) the chosen list of criteria and (2) the different rankings for each
392 criterion, based on the opinions of the various assessors. We have striven to reduce this

393 subjectivity by reviewing the literature for suitable criteria and by allowing several assessors
 394 to score each metric.

395 4 Results

396 The results of the metric evaluation are presented in Table 7. The five chosen resource
 397 efficiency metrics are scored—0 (not achieved), 1 (partially), 2 (fully)—against 34 criteria
 398 grouped in five RACER sub-categories. The scores are presented in their raw form, without
 399 summation, to avoid any bias between sub-categories.

400 Figure 2 shows the breakdown of scores for each metric, with 0 (not achieved) in light blue,
 401 1 (partially) mid-blue, and 2 (fully) in dark blue—with darker colours indicating a more
 402 effective metric.

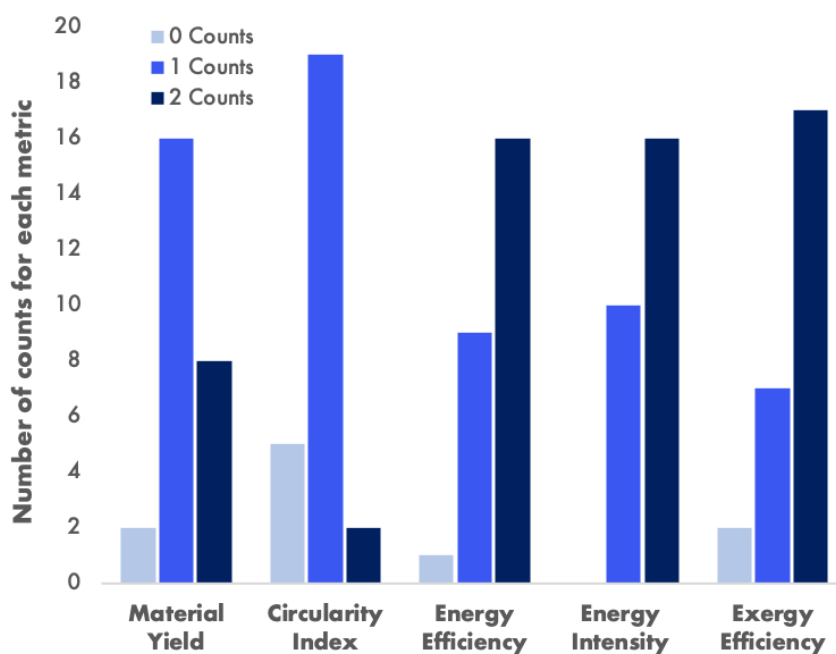

Figure 2: RACER evaluation results showing the number of counts for all the chosen metrics.

403 The Circularity Index scores the highest number of ‘not achieved’ criterion. From Table 7 we
 404 can see that this arises mainly from its lack of acceptance across stakeholders and its limited
 405 robustness. This makes sense given that the development of circularity-type metrics is in
 406 at embryonic stage. The circular economy, as is the case for RE, is a multi-faceted concept
 407 and this complicates the design of appropriate metrics to measure its progress. Circularity
 408 indices perform weakly under the *Relevance* banner. This is because most circularity metrics
 409 focus on measuring the mass ratio of recycled materials at the level of entire economies
 410 (Ellen MacArthur Foundation, 2015). They have limited scale-ability, to lower scales such as
 411 industrial processes, equipment or products, and fail to consider the energy-impacts of closing
 412 material loops (Cullen, 2017). Today, it is still early to determine whether they can provide
 413 the right type of stimulus and whether they are sensitive to changes experienced.

Table 7: Results from RACER evaluation for a selection of resource efficiency metrics. Scores: 0 (not achieved), 1 (partially), 2 (fully)

	Relevance										Acceptance				Credibility				Easiness				Robustness			
	Resource Coverage	Scope / granularity	Sensitiveness	Stimulus	Policy support	Strategy support	Operations support	Target setting	Applicability	Trends	Forecasting / modelling	Policy makers	Technical industry staff	Financial industry staff	Industry managers	Academics	Interpretation	Transparency	Ambiguity	Data collection effort	Complementary	Technical feasibility	Subjectivity	Theory soundness	Accuracy	Completeness
Material Yield	0	1	1	1	0	1	1	2	1	1	1	1	2	2	2	2	1	1	1	2	2	1	1	1	1	1
Circularity Index	1	1	1	1	1	0	1	2	1	1	1	0	0	0	1	1	1	1	1	1	2	1	1	1	0	1
Energy Efficiency	0	2	1	1	1	1	1	2	1	2	2	2	2	2	1	2	2	2	2	2	2	2	2	2	1	1
Energy Intensity	1	2	1	1	1	1	1	1	1	2	2	2	2	2	2	2	2	2	2	2	2	2	2	2	1	1
Exergy Efficiency	2	2	2	2	1	2	2	2	2	2	0	1	0	1	1	1	1	2	2	1	2	1	2	2	2	2

414 Material Yield, a mass-based ratio, is ranked as the second weakest metric, with mainly 1
 415 (partially) scores. The metric is well accepted among stakeholders, especially so in industry
 416 (and academia) where it has been widely-adopted to measure the material efficiency of specific
 417 processes (Milford et al., 2011). It scores highly on *Easiness*—precisely because companies
 418 have been collecting material yield data for a long time. However, it scores much lower in the
 419 *Credibility* category because yield rates are defined in multiple different ways, dependent on
 420 the materials involved and the choice of system boundaries (worldsteel, 2009). There is no
 421 unique, established method with which all industries, or even facilities within a given industry,
 422 measure their yield rates. This makes the metric suitable for targeting improvements at the
 423 process level, but not for comparison between processes or analysis at wider scales.

424 Energy Efficiency, Energy Intensity and Exergy Efficiency all score highly, with many 2 (fully)
 425 scores. This reflects their overall effectiveness as performance metrics in industry. Given
 426 the subjectivity of the scoring, it is difficult to discern which of these metrics constitutes a
 427 better metric of resource efficiency. For now, Energy Efficiency, Energy Intensity and Exergy
 428 Efficiency are taken forward as preferred metrics for further analysis.

429 In Figure 3 we explore the comparison between metrics in more detail. Here the scores in
 430 each of the five sub-category are summed and plotted by metric to explore how each metric
 431 scores within the five sub-categories.

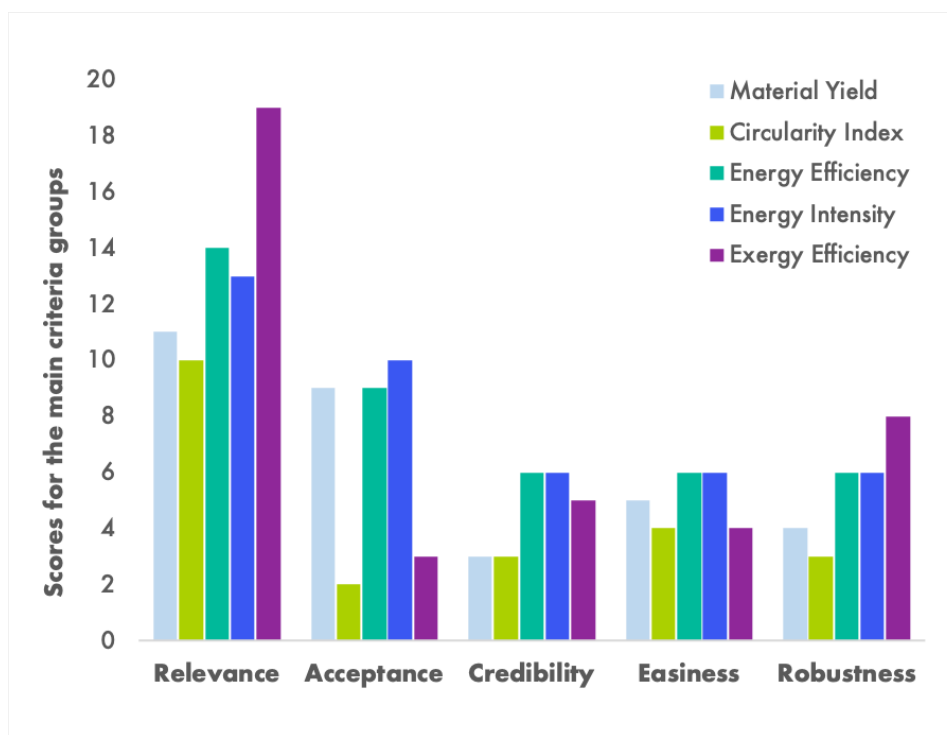

Figure 3: RACER evaluation results showing the scores of each metric under the five banner criteria.

432 Energy Efficiency and Energy Intensity score almost identically across all categories, reflecting
 433 their similarity as metrics in scope and coverage. Energy Efficiency measures the output
 434 product in units of Joules when it is applied to energy-transforming processes (e.g. motors,

435 pumps), whereas Energy Intensity measures the output product in units of mass as it is
 436 used to quantify the performance of material-transforming processes (e.g. reactors, metal
 437 furnaces etc.). Both metrics have been widely employed industry, which explains their high
 438 scores within the *Acceptance* and *Easiness* categories. In contrast to Material Yield metrics,
 439 Energy Efficiency and Energy Intensity have been widely standardised within industry sectors
 440 (UNIDO, 2010, Worrell et al., 2008), reducing the scope for manipulation and ambiguity.

441 Energy Efficiency and Energy Intensity can be applied at multiple temporal scales and scopes,
 442 as shown in Table 7. Both metrics are often used for setting targets at at varying system
 443 levels, from national objectives to corporate or operational benchmarks. Policymakers and
 444 industry managers use such metrics to help close the emissions gap (IEA, 2017) by targeting
 445 energy reduction. They are partially successful in incentivising resource efficiency, but miss
 446 most material-related interventions (e.g. reducing yields, increasing re-use, recycle, recovering
 447 material by-products). This is because the metrics omit materials from their resource coverage,
 448 beyond the product output in mass in the case of Energy Intensity. As such, they score
 449 weakly for supporting policy, strategy and operational decisions.

450 The last of the preferred metrics to evaluate is Exergy Efficiency. Figure 3 shows that Exergy
 451 Efficiency scores higher than the other metrics in the category of *Relevance*. This reflects
 452 its ability to cover a wider range of resources and its capacity to scale across temporal and
 453 spatial levels (Gonzalez Hernandez, Lupton, Williams and Cullen, 2018, Gonzalez Hernandez,
 454 Paoli and Cullen, 2018, Masini and Ayres, 1996). Whereas, Energy Efficiency and Energy
 455 Intensity score higher for *Acceptance*, the slower uptake of Exergy Efficiency as an accepted
 456 and widely used metric is revealed. Exergy Efficiency is slightly weaker across *Credibility* and
 457 *Easiness*, reflecting two considerations: (1) it requires additional data to be collected, which
 458 affects its technical feasibility; (2) it is poorly understood among practitioners.

459 These results show that, although the preferred three metrics have a similar score profile across
 460 all the criteria (Figure 2), there are clear disparities at the sub-category level. Here Exergy
 461 Efficiency is scored as having the highest *Relevance* and *Robustness*, traits which are inherent
 462 to the metric and cannot be changed, but scores much lower for *Acceptance*, *Credibility* and
 463 *Easiness* in areas which could be improved with better education and dissemination (Viglietta,
 464 1990). This would suggest that Exergy Efficiency may still have unrealised potential as a
 465 measure of resource efficiency.

466 5 Discussion

467 From the metrics reviewed, Exergy Efficiency is the only one which covers both energy and
 468 materials in a single indicator. It has been shown to rank highly as an effective metric
 469 for measuring Resource Efficiency, specifically in the areas of Robustness and Relevance –
 470 both of which are inherent traits that are key in the deployment of effective metrics at all
 471 management levels. This suggests that Exergy Efficiency could be a potential lever to drive
 472 the decarbonisation transition of resource-intensive industries.

473 The benefits of using exergy as a measure of RE can be summarised as follows:

- 474 • Exergy makes it possible to characterise energy and material-transforming processes
475 more easily and to neatly combine measures of energy and material use in a single
476 metric. Both mass and energy balances alone fail to show the upgrade in material
477 quality that is enabled through the degrading of high-value fuels into low-value heat.
- 478 • Exergy allows energy and material to be integrated into a single value. This enables
479 a dimensionless efficiency metric to be defined and allows comparison of efficiencies
480 between industry sectors.
- 481 • Exergy reflects the *quality* of a resource, giving insight into *which* material or energy
482 streams are worth recovering: streams with high exergy content have more potential
483 for value extraction. Its foundation on the second law of thermodynamics provides an
484 engineering understanding of the irreversibilities generated during production.
- 485 • Exergy captures the benefits associated with improving the recovery of material by-
486 products, such as slag or slurry, which cannot be achieved using energy-based metrics.
- 487 • Exergy studies are common in literature demonstrating that a well-established procedure
488 exists to quantify exergy efficiency. This ensures the traceability and repeatability of
489 exergy analysis measurements.

490 Tables 8 and 9 provide further evidence to support the final choice of Exergy Efficiency as the
491 most suitable Resource Efficiency metric for both policymakers and industry practitioners.
492 The evidence is comprised of academic papers where specific criterion for the Exergy Efficiency
493 metric have been met. These tables also show the scoring for the Exergy Efficiency metric
494 as presented in Table 7 (under the heading RE) and specify a description for each criterion.
495 Based on these results, the remainder of this section explores, in more detail, the implications
496 of using exergy as a measure of Resource Efficiency in industry.

497 **5.1 Integrating energy and materials**

498 Historically, efforts to reduce industry's carbon emissions (and energy use) have been limited
499 to energy efficiency measures, i.e. reducing the direct use of fuels and recovering waste
500 heat. In recent years, insights into the links between efficient material use, and energy and
501 emissions, have been created several new fields including: material efficiency (ME), resource
502 efficiency (RE), life-cycle thinking and circular economy (CE). Yet, none of these concepts
503 in practice deal with the interactions between energy and materials found in industry. The
504 production of materials involves a myriad of processes, constituting a complex network of
505 interactions between energy and materials. Savings in energy and emissions are not only
506 possible through reductions in fuel use or recovery of waste heat (energy efficiency options),
507 but are also available through reductions in material use (material efficiency options). Energy
508 and materials should be considered together.

Table 8: Evidence of criteria fulfilment from the literature

Criteria	RE	Description	Proven in, for example...
Relevance			
Resource Coverage	2	Quantifies and captures energy, materials and water flows, can also account for emissions.	(Costa et al., 2001, Gonzalez Hernandez, Paoli and Cullen, 2018, Valero et al., 2015, Wu, Wang, Pu and Qi, 2016)
Scope and granularity	2	Is applicable to measure performance at all system levels, from global analysis to equipment-level assessments.	(Costa et al., 2001, Luis and Van der Bruggen, 2014, Wu, Wang, Pu and Qi, 2016)
Sensitiveness	2	It is sensitive to changes in input variables. It will reflect a change if a relevant variable is modified.	(Costa et al., 2001, Flórez-Orrego and de Oliveira Junior, 2016)
Stimulus	2	It incentivises the entire gamut of RE measures, and allows material efficiency to be placed on equal footing to energy efficiency.	(Finnveden and Östlund, 1997, Wu, Qi and Wang, 2016)
Policy support	1	Disaggregation is possible to the required system boundary. The metric provides the required information at the level at which the decision needs to be taken. It can be used at the global, regional level at a level of years and months.	(Eisenmenger et al., 2017, Gonzalez Hernandez, Cooper-Searle, Skelton and Cullen, 2018, Valero et al., 2015)
Strategy support	2	It can be used at the yearly, monthly, weekly for sites and plants, which would be the appropriate level for strategy planning.	(Khattak, 2016, Luis and Van der Bruggen, 2014)
Operations support	2	It can be used at the daily, hourly and real-time level for plants, processes and units, which would be required for operational support.	(Flórez-Orrego and de Oliveira Junior, 2016, Ostrovski and Zhang, 2005, Wu, Wang, Pu and Qi, 2016)
Target setting	2	Decision makers can use it to track progress towards established emission reductions. There is link between RE and emissions, and can be quantified for different sectors. Baseline can be defined.	(Valero et al., 2015, Wu, Wang, Pu and Qi, 2016)
Applicability	2	Can be applied to any resource-intensive industry, and across any type of physical or chemical conversion process.	(Luis and Van der Bruggen, 2014, Masini and Ayres, 1996, Szargut, 2005, Szargut et al., 1988)
Trends	2	This metric can track resource efficiency across time and relative to other production systems. It can do so at multiple temporal scales.	(Costa et al., 2001, Gonzalez Hernandez, Lupton, Williams and Cullen, 2018, Valero et al., 2015, Wu, Wang, Pu and Qi, 2016)
Forecasting & modelling	2	Predictions of future resource efficiency can be made using this metric. CO2 emissions can then be calculated based on these. Information on specific measures improving efficiency may be needed to do this.	(Flórez-Orrego and de Oliveira Junior, 2016, ?, ?)
Acceptance			
Policy makers	0	Little awareness and some resistance, it does however resonate with many other values on circular economy and decarbonisation	(Ayres et al., 2011, Gonzalez Hernandez, Cooper-Searle, Skelton and Cullen, 2018)
Technical industry staff	1	Relatively well accepted and understood	(Gonzalez Hernandez, Lupton, Williams and Cullen, 2018)
Financial industry staff	0	Little awareness and some resistance. Yet, it mirrors value more closely than conventional energy analyses.	No evidence that of use to support financial decisions
Industry managers	1	Some awareness and relatively well accepted	
Academics	2	Widely accepted even with different interpretations & applications	(Costa et al., 2001, Masini and Ayres, 1996, Valero et al., 2015, Wu, Wang, Pu and Qi, 2016)

Table 9: Evidence of criteria fulfilment from the literature contd.

Criteria	RE	Description	Proven in, for example...
Credibility			
Easy interpretation	1	Exergy remains an esoteric concept for non-experts (including industry practitioners and policymakers), still requires some explanation, although many academics are focusing lots of efforts into socialising the concept.	(Dincer and Rosen, 2007, Gaudreau et al., 2009, Khattak, 2016)
Transparency	2	Calculation methods have been documented by many academics and many tools are available to support it (e.g. exergy calculators). Well established method.	(Bakshi et al., 2011, Brodyansky et al., 1994, Dincer and Rosen, 2007, Szargut, 2005)
Ambiguity	2	Calculation methodology is clearly defined to avoid ambiguity, although some dispute exists around how metric may be interpreted.	(Brodyansky et al., 1994, Dincer and Rosen, 2007, Szargut, 2005, Szargut et al., 1988)
Easiness			
Data collection effort	1	Requires more effort than conventional energy efficiency analysis; we require additional material flow data, temperature, pressure and composition information. A lot of this is often already measured by production plants. It does, however, require greater data integration efforts as energy and material data quality can be very different.	(Flórez-Orrego and de Oliveira Junior, 2016, Gonzalez Hernandez, Paoli and Cullen, 2018, Wu, Wang, Pu and Qi, 2016)
Complementary	2	Provides richer insights into performance of production systems. Captures interactions between resources and provides more realistic account of functionality than conventional energy or material metrics.	(Dufou et al., 2012, Masini and Ayres, 1996, Valero et al., 2015, Wall, 1988)
Technical feasibility	1	Calculation methodology is clearly defined and documented. May require additional expertise.	(Costa et al., 2001, Khattak, 2016)
Robustness			
Level of Subjectivity	2	Subjectivity often arises when allocations are required. This is not the case with this metric, as we are not assigned responsibility to downstream processes (as is the case with impact-oriented metrics)	(Bakshi et al., 2011)
Theory soundness	2	It is based on well-established thermodynamic concepts, which are market-independent	(Masini and Ayres, 1996, Szargut, 2005, Valero et al., 2015, Wall, 1988)
Accuracy	2	It offers a more realistic representation of the functionality of processes because: it is based on the 2nd law of thermodynamics; it incorporates materials into the same metric, and it captures the quality as well as the quantity of resources.	(Gaudreau et al., 2009, Khattak, 2016, Szargut et al., 1988)
Completeness	2	By virtue of covering more resource types and being applicable across many system levels and industry sectors, it helps avoid burden shifting	(Bakshi et al., 2011, Masini and Ayres, 1996, Szargut, 1986)

509 A common analytical framework is the first step towards a unified resource efficiency narrative.
510 Yet this is in fact hindered by the current widespread use of Energy Efficiency, Energy
511 Intensity and Material Yield metrics. Among the physical-based indicators, energy-intensity
512 metrics ignore the value of material by-products and material inputs, fail to reflect upgrades
513 in material quality and are difficult to compare across different processes and industries.
514 Material Efficiency and Circular Economy indicators focus solely on tracking materials and
515 the effectiveness of specific material improvement strategies (i.e. waste reduction, recycling or
516 reuse). The measurement of efficiency in mass units fails to capture changes in resource quality
517 along process chains. Furthermore, their failure to consider the energy or emissions impacts
518 of such strategies, can lead to the unintended consequences: recycling of some materials can
519 lead to even more emissions than virgin production (Cullen, 2017).

520 Many practitioners from industry, academia and policy fields have come to the conclusion that
521 an integrated metric to measure both energy and materials is required. Gonzalez Hernandez,
522 Cooper-Searle, Skelton and Cullen (2018) undertook in-depth interviews with industry
523 practitioners and policymakers, with almost all agreeing that it is either necessary or beneficial
524 to integrate the analyses of energy and materials into a single metric. One explained: *“I’m*
525 *totally bought into the idea that [...] you need a balance[d] understanding of what’s the energy*
526 *and material implications or consequence of a decision that’s made”*. Another interviewee
527 explained that it is necessary to *“broaden out the understanding that energy is just one*
528 *resource input that goes into the broader industrial production process; that there are other*
529 *materials and inputs that are associated with that and there the efficiency which with they use*
530 *and through which the waste of those resources is reduced is also very important”*.

531 Additional evidence of industry’s acceptance of exergy as a tool to measure resource efficiency
532 can be found in Khattak and Greenough (n.d.). The author also interviewed many industry
533 practitioners, and their responses can be found in the Appendix.

534 An exergy-based RE metric offers a solution to resolve these issues. Exergy allows energy and
535 material flows to be consolidated into a single metric, based on well-known thermodynamic
536 principles. Using one single number to track resource efficiency may seem overly simplistic,
537 but in this case, an appropriately-designed number can become an enhancement. Collapsing
538 energy and materials into a single measure reduces the number of variables to be tracked while
539 at the same time providing a more complete and nuanced picture of a system’s RE.

540 **5.2 Spatial and temporal scalability**

541 There are many advantages in having a single RE metric which can be applied across different
542 spatial boundaries and temporal scales. Currently, there is frequently a mismatch between
543 the indicators used at the equipment and process scale (i.e. energy efficiency and material
544 yield, calculated in real-time) and those used at the national and global scale (i.e. resource
545 productivity and circularity, calculated annually). This creates a need for expert translators,
546 who can gather bottom-up data from company surveys and convert these into high-level

547 indicators, and much effort is expended in sorting out the discrepancies that result.

548 When it comes to metrics, it is often said that what gets measured gets done. Yet, industrial
549 process systems are complicated, requiring the reinterpretation of metrics at each stage of the
550 management chain. Highly aggregated data (at a level of weeks, months or years) is commonly
551 used at high-management levels to understand general trends and the overall amount of
552 savings available. Whereas, engineering staff, typically work with detailed data at time-scales
553 of minutes, hours or days to solve safety, stability and reliability issues. If the operators at
554 the plant floor lose sight of the overall objectives of resource efficiency and decarbonisation,
555 then improving RE globally can become a challenge. Having a fully scalable RE metric is no
556 small accomplishment, as it requires complete line of sight along the management chain and
557 gives full visibility to operators at the plant floor.

558 Exergy efficiency provides a universal metric which can be applied at all spatial and temporal
559 scales. Exergy analysis is commonly used in across the full range of spatial scales, from global
560 analysis (Cullen and Allwood, 2010), to nations (Eisenmenger et al., 2017, Serrenho et al.,
561 2014), sectors (Wu, Wang, Pu and Qi, 2016), and processes (Liu et al., 2015). In addition, it
562 is simple to aggregate exergy data along the temporal scale, from seconds to years.

563 As bottom-up real-time data from equipment and devices becomes more prevalent, there is
564 an opportunity to gather raw data and aggregate this up through the spatial and temporal
565 scales for higher-level analysis. This would allow companies to see the RE of their entire fleet
566 of plants, or annual RE accounts to be collated and compared between countries. In addition,
567 any discrepancy discovered at a higher spatial or temporal scale could in turn be investigated
568 at a more granular level. In this way, the flexibility and transparency of financial metrics,
569 which can scale from individual purchase transactions to long-run economic trends, could be
570 similarly applied to resource efficiency. This using the scalable properties of exergy.

571 **5.3 Driving industrial decarbonisation**

572 Evidence suggests that the decarbonisation potential of resource efficiency measures is vast
573 (Allwood et al., 2010, Circle Economy, 2019). For the energy-intensive industry sectors alone,
574 the potential contribution of material efficiency is predicted to provide 10-12% of the carbon
575 emission savings required to prevent 1.5° average temperature rise (IEA, 2017). To unlock
576 this potential, however, current energy efficiency and ME metrics must be reconciled into a
577 single production performance metric.

578 It is commonly understood that reducing energy use results in emissions savings, for fossil-
579 fuel-based energy supplies. However, less obvious is the emissions savings resulting from
580 improving material efficiency. Neglecting the impact of material use in emission mitigation
581 efforts gives only partial insight into the emission savings. Furthermore, energy efficiency and
582 material efficiency interventions should be assessed together to avoid trading one against the
583 other. Energy-intensive industries must therefore be equipped with actionable metrics that
584 allow the leveraging of the full gamut of RE options.

585 While tracking emissions is essential for understanding measuring progress against targets
586 and holding actors to account, they provide only limited insight into the most effective actions
587 required to decarbonise industrial production systems. Emission-based metrics—such as total
588 annual GHG emissions, GHG per unit of gross domestic product (GDP) or production—
589 indicate how well an economy, sector or plant is doing, but fail to reveal which actions have
590 influenced the results or where to focus next. The linking of exergy efficiency metrics to
591 carbon emissions, can reveal the potential impact of interventions which aim at improving
592 resource efficiency, thus closing this missing gap in understanding.

593 Our belief is that focused RE metrics are more effective at catalysing change for multiple
594 reasons. They can:

- 595 • Help producers understand opportunities for action in a language that they are more
596 comfortable with;
- 597 • Reframe the decarbonisation challenge positively, as an opportunity to be seized as
598 opposed to a burden to be carried;
- 599 • Drive sector transformation in a more targeted manner and in doing so, provide
600 producers and policy makers with increased confidence that targets can be achieved.
- 601 • Provide deeper insight into the underlying drivers of change and can track interventions
602 with long-term as well as short-term impacts.

603 Tracking exergy efficiency allows the impacts of changes in energy use, on material inputs
604 and material by-products to be quantified, and vice-versa for the impact material changes
605 have on energy use. Furthermore, exergy can still be compared as ratios to other economic
606 or impact variables, such as resource cost or carbon emissions, but halves the number of
607 indicators required to do so. This opens up hitherto neglected opportunities to reduce overall
608 energy use and emissions.

609 **5.4 Improving accessibility and uptake**

610 There is little doubt that exergy metrics can be made more accessible to non-expert audiences
611 (Sousa et al., 2017). Once a metric has been mainstreamed, people are comfortable using
612 it even if they do not understand the intricacies behind it. The metrics of gross domestic
613 product (GDP) or internal rate of return (IRR) are just two examples where metrics have
614 been widely adopted despite the limited understanding of how they are calculated.

615 One option for improving the accessibility of exergy analysis and efficiency to non-expert
616 audiences is the use of Sankey diagrams. Presenting mass-flow, energy-flow and exergy-flow
617 diagrams for the same process system, helps show how exergy is calculated and interpreted in
618 practice. Recent efforts to translate the principles of exergy analysis into software solutions,
619 with databases of exergy conversion factors and Sankey visualisation tools, shows much
620 promise (Gonzalez Hernandez, Lupton, Williams and Cullen, 2018, Gonzalez Hernandez,

621 Paoli and Cullen, 2018). These have the potential to extract large quantities of data
622 from industrial process control systems and produce real-time resource flow maps for plant
623 managers. Automation of data collection and analysis could soon make integrated exergy
624 analyses a feasible practice in industry firms. If combined with appropriate resource efficiency
625 methodologies, the access to more and higher-quality, bottom-up data has the potential
626 to help companies and governments make better-informed decisions about how to reduce
627 industrial resource use.

628 Other pursuits that would facilitate the socialisation of exergy metrics in industry and
629 policy-making practices include: (1) the development of internal training programmes for
630 engineers, plant managers and industry practitioners in general, so that they are comfortable
631 with implementing exergy methodologies and interpreting exergy metrics; (2) the development
632 of a standard exergy efficiency and exergy auditing methodology for industry practitioners
633 endorsed by international standardisation bodies, so that there is a universal language among
634 practitioners (like with LCA today); (3) the support (and endorsement) from industry
635 trade associations (such as worldsteel or worldaluminium) and other influential international
636 organisations such as the International Energy Agency.

637 Academic papers on their own do not make a metric popular. For an exergy-based Resource
638 Efficiency metric to be socialised, a broader consensus across policy makers, scientific experts
639 and industrial communities is necessary. However, making an informed proposal which
640 champions the RE metric is a prerequisite to achieve such consensus. This is especially
641 important at a time where it is increasingly urgent to develop more appropriate RE tools to
642 support decarbonisation strategies.

643 **6 Conclusions**

644 Providing industry firms with the necessary tools to measure and improve resource efficiency is
645 crucial. This paper provides a review and evaluation of metrics that might be used to measure
646 resource efficiency and drive industrial decarbonisation. Results suggest that an exergy-based
647 metric can offer a more complete and universal measure of resource efficiency.

648 We find Exergy Efficiency to be: *holistic*, because it covers entire systems; *flexible*, because
649 it can be applied at any system level; *integrated*, because exergy consolidates energy and
650 materials into a single framework, capturing the interactions between these; *transparent*,
651 because all physical resources are included, thereby preventing burden-shifting. Furthermore,
652 Exergy Efficiency provides a basis for incentivising the reduction of raw-material inputs and
653 the recovery of material by-products, neither of which is captured in conventional energy
654 metrics. It is also useful for driving industrial decarbonisation, as the efficient use of energy
655 and materials directly impacts carbon emissions.

656 What is clear from the results, is that Exergy Efficiency requires further advocacy if it is to be
657 accepted as a mainstream measure of resource efficiency. The metric, in our view, is no more

658 complex to calculate that many common industrial and financial KPIs (Key Performance
659 Indicators). However, more work is required to provide simple guides, training and software
660 tools, to facilitate wider use of Exergy Efficiency. We hope that this paper, is a first step
661 towards demystifying Exergy Efficiency and will spur further discussion about the use of
662 Exergy Efficiency metrics for measuring Resource Efficiency.
