## INTRODUCTION

Cognitive accessibility involves removing barriers to inclusion caused by a mismatch between contextual demands and individuals' perceptual, attentional, memory, problem-solving, social skills, and styles. Context needs to be adapted to respond to these skills and styles. For example, changes have been introduced in urban environments and transport through the use of pictograms or pictures. Texts are written in an Easy-to-Read style. Usability of web pages is increased by adapting formal aspects and content.

There are specific guidelines and recommendations for the adaptation of physical contexts and of written materials. However, many of these recommendations have originated in the field of intellectual disabilities and learning disorders and are non-specific to autism. Also, it is unclear how much evidence supports their impact on the inclusion of persons with autism.

In our study we aimed to carry out a systematic review that: 1) Determined the specificity of recommendations of cognitive accessibility for persons with autism, and 2) the level of empirical evidence which supports different recommendations.

## What do studies on cognitive accessibility specifically recommend for persons with autism?

Recommendations Domain **Findings** Eraslan, Yaneva, Accessible web People with autism: less success in searching tasks which there is a limited time, a tendency to look at ATTENTION TO CONTENT OF WEB PAGES! Yesilada & more elements on the web pages, more transitions between the elements, and shorter but more The differences in web page search patterns between neurotypical people and **Harper**, 2019 frequent fixations on elements which are not directly related to a given search task. people with autism should be taken into account in order to adapt the content of web pages correctly for people with autism. Images did not have an effect on comprehension and memorisation as measured through objective ATTENTION TO IMAGES! **Yaneva**, 2016 Easy-to-read measures, but autistic participants felt that images did help them comprehend and memorise the text Insertion of images (e.g. insertion of images relevant to the meaning of the texts on the paragraph), types of images (e.g. do not insert logos), positioning of images (e.g. better. web preferably image above the word or on the right-hand side of the word).

### **CONCLUSIONS**

- > There are few studies found on cognitive accessibility in autism and they are carried out by the same research team. Most studies are oriented to adapt the content of web pages.
- > The recommendations are similar to those shown in the European recommendations' guidelines.
- > No studies showed the characteristics of the interventionist, participants were not assigned to conditions using a random assignment procedure, and the raters were not blind. Furthermore, most of the studies did not report effect sizes or they were low, and none fulfilled the condition of social validity. Consequently, most of the studies presented an adequate level of empirical evidence.
