## LIST OF ABBREVIATIONS:

AQP4= aquaporin-4,  $cR^2$ = conditional  $R^2$ , EDSS= expanded disability status scale, GCIPL= ganglion cell-inner plexiform layer, LETM= longitudinal extensive transverse myelitis, LGN=lateral geniculate nucleus, logMAR= logarithm of the minimum angle of resolution,  $mR^2$ = marginal  $R^2$ , MAGeT= Multiple Automatically Generated Templates, MRI= magnetic resonance imaging, NMO-NON: patients with NMOSD and no prior optic neuritis, NMO-ON: patients with NMOSD and prior optic neuritis, NMOSD= neuromyelitis optica spectrum disorders, ON= optic neuritis, OR= optic radiations, pRNFL= peripapillary retinal nerve fiber layer, SE= standard error, VPN= ventral posterior nucleus

## ABSTRACT

**OBJECTIVES:** In neuromyelitis optica spectrum disorders (NMOSD) thalamic damage is controversial, but thalamic nuclei were never studied separately. We aimed at assessing volume loss of thalamic nuclei in NMOSD. We hypothesized that only specific nuclei are damaged, by attacks affecting structures from which they receive afferences: the lateral geniculate nucleus (LGN), due to optic neuritis (ON) and the ventral posterior nucleus (VPN), due to myelitis.

**METHODS:** Thirty-nine patients with aquaporin 4-IgG seropositive NMOSD (age:  $50.1 \pm 14.1$  years, 36 women, 25 with prior ON, 36 with prior myelitis) and 37 healthy controls (age:  $47.8 \pm 12$  years, 32 women) were included in this cross-sectional study. Thalamic nuclei were assessed in magnetic resonance images, using a multi-atlas-based approach of automated segmentation. Retinal optical coherence tomography was also performed.

**RESULTS:** Patients with ON showed smaller LGN volumes ( $181.6 \pm 44.2 \text{ mm}^3$ ) compared to controls ( $198.3 \pm 49.4 \text{ mm}^3$ ;  $B = -16.97$ ,  $p = 0.004$ ) and to patients without ON ( $206.1 \pm 50 \text{ mm}^3$ ;  $B = -23.74$ ,  $p = 0.001$ ). LGN volume was associated with number of ON episodes ( $\text{Rho} = -0.536$ ,  $p < 0.001$ ), peripapillary retinal nerve fiber layer thickness ( $B = 0.70$ ,  $p < 0.001$ ) and visual function ( $B = -0.01$ ,  $p < 0.001$ ). Although VPN was not smaller in patients with myelitis ( $674.3 \pm 67.5 \text{ mm}^3$ ) than controls ( $679.7 \pm 68.33$ ;  $B = -7.36$ ,  $p = 0.594$ ), we found reduced volumes in five patients with combined myelitis and brainstem attacks ( $B = -76.18$ ,  $p = 0.017$ ). Volumes of entire thalamus and other nuclei were not smaller in patients than controls.

1  
2  
3  
4 **CONCLUSION:** These findings suggest attack-related anterograde degeneration rather  
5  
6 than diffuse thalamic damage in NMOSD. They also support a potential role of LGN  
7  
8 volume as an imaging marker of structural brain damage in these patients.  
9  
10

## 11 12 13 14 **INTRODUCTION**

15  
16 Neuromyelitis optica spectrum disorders (NMOSD) are chronic, relapsing inflammatory  
17  
18 disorders of the central nervous system, defined by pathogenic IgG antibodies against  
19  
20 astrocytic aquaporin-4 (AQP4-IgG) in the majority of cases[1]. The most typical clinical  
21  
22 manifestations are optic neuritis (ON) and acute myelitis, usually occurring as  
23  
24 longitudinally extensive transverse myelitis[1,2]. Other clinical core characteristics  
25  
26 include area postrema and acute brainstem syndromes[1].  
27  
28

29  
30 Patients with NMOSD very rarely show a secondary progressive phase[3], and the  
31  
32 mechanisms leading to neurological disability are thought to be mainly attack-related[3–  
33  
34 5]. However, recent findings suggested retinal neuronal loss independent of ON attacks in  
35  
36 NMOSD[6]. Moreover, some imaging[7,8] and histopathological studies in  
37  
38 NMOSD[9,10] showed abnormalities and neuronal loss in non-lesional cortical grey  
39  
40 matter. Less is known regarding deep grey matter changes in NMOSD, particularly the  
41  
42 affection of the thalamus is controversial[11–16].  
43  
44  
45

46  
47 Our aim was to assess volume loss in thalamic nuclei in NMOSD. Our hypothesis was  
48  
49 that lesions in i) the optic nerve due to ON and ii) the spinal cord due to myelitis may  
50  
51 cause anterograde degeneration only to specific nuclei, with which these structures are  
52  
53 connected. We hypothesized that the lateral geniculate nucleus (LGN), which receives  
54  
55 afferences from the optic nerve, is affected due to ON and the ventral posterior nucleus  
56  
57 (VPN), which receives afferences from the dorsal column-medial lemniscal pathway and  
58  
59 the spinothalamic tract, due to myelitis (Fig. 1). Thus, we assessed LGN and VPN  
60

volumes in NMOSD, and studied whether they are associated to clinical attacks (ON, myelitis), attack-related structural damage (in retina and spinal cord) and clinical deficits (visual and sensory dysfunction). Our secondary, exploratory objective was to investigate whether there is occult volume loss in other thalamic nuclei in NMOSD.

## METHODS

### Study participants

We screened 78 patients with NMOSD from a prospective observational cohort study at the NeuroCure Clinical Research Center at the Charité-Universitätsmedizin Berlin (recruited from May 2013 to January 2018). The inclusion criteria were: i) age  $\geq 18$  years and ii) AQP4-IgG seropositive NMOSD, according to the 2015 International Consensus Diagnostic Criteria[1]. AQP4-IgG were determined by a cell-based assay (Euroimmun, Lübeck, Germany). Patients that were AQP4-IgG seronegative (n=25), had incomplete clinical data and/or unknown AQP4-IgG-status (n=10), no MRI data (n=3) or an attack within three months prior to baseline (n=1) were excluded.

We included 39 AQP4-IgG seropositive NMOSD patients. Data from 37 healthy controls with age  $\geq 18$  years, without history of neurological or ophthalmological diseases were also included. Healthy controls were chosen from the institute's research database, to be as well matched as possible regarding age and sex to the patients. The characteristics of the study participants are presented in table 1.

**Table 1: Characteristics of the NMOSD patients and controls included in the study**

|  | NMOSD Patients<br>(n=39) | Controls (n=37) |
|--|--------------------------|-----------------|
|  |                          |                 |

|  |                 |                  |
|--|-----------------|------------------|
| Aquaporin 4 IgG antibodies<br>(seropositive, %)      | 39 (100%)       | -                |
| Age, years (mean $\pm$ SD)                           | 50.1 $\pm$ 14.1 | 47.8 $\pm$ 12.5  |
| Sex, female/male (female %)                          | 36/3<br>(92.3%) | 32/5<br>(86.5%)  |
| Handedness (right/left)                              | 34/4            | 33/2             |
| Race (White/Black/Asian)                             | 37/1/1          | 37/0/0           |
| Disease duration, years (mean $\pm$ SD)              | 8.8 $\pm$ 8     | -                |
| Total number of previous attacks<br>(median, range)  | 3 (1-22)        | -                |
| Patients with ON (n, %)                              | 25 (64.1%)      | -                |
| Number of ON episodes per patient<br>(median, range) | 1 (0-12)        | -                |
| Time since fist ON episode, years<br>(mean $\pm$ SD) | 9.6 $\pm$ 7.5   | -                |
| Time since last ON episode, years<br>(mean $\pm$ SD) | 5.4 $\pm$ 3.7   | -                |
| Visual acuity, logMAR (mean $\pm$ SD)                | 0.24 $\pm$ 0.71 | -0.01 $\pm$ 0.22 |
| pRNFL thickness, $\mu$ m (mean $\pm$ SD)             | 79.1 $\pm$ 21.2 | 96.0 $\pm$ 9.2   |
| GCIPL volume, mm <sup>3</sup> (mean $\pm$ SD)        | 1.6 $\pm$ 0.3   | 1.9 $\pm$ 0.2    |
| Patients with myelitis (n, %)                        | 36 (92.3%)      | -                |

|  |               |   |
|--|---------------|---|
| Number of myelitis episodes per patient (median, range)          | 1 (0-15)      | - |
| Time since first myelitis episode, years (mean $\pm$ SD)         | 7.4 $\pm$ 6.7 | - |
| Time since last myelitis episode, years (mean $\pm$ SD)          | 4.3 $\pm$ 3.4 | - |
| Patients with LETM in MRI at study baseline (n, %)               | 22 (56.4%)    | - |
| Sensory Functional System Score (median, range)                  | 2 (0-4)       | - |
| Patients with brainstem attacks (n, %)                           | 5 (12.8%)     | - |
| EDSS (median, range)   | 4 (0-7)       | - |
| Patients with other autoimmune diseases (n, %)                   | 13 (33.3%)    | - |
| Patients on immunosuppressive treatment at study baseline (n, %) | 34 (87.2%)    | - |
| Patients on daily corticosteroids at study baseline (n, %).      | 7 (17.9%)     | - |

Note that there were 25 patients with previous ON; from them, 22 had both ON- and myelitis history, while 3 had only ON history, without myelitis.

Visual acuity was tested monocularly and thus the mean logMAR refers to the mean of both eyes.

1  
2  
3  
4 The presence of LETM (defined as spinal cord lesions extending over at least 3  
5  
6 vertebrae) was evaluated at study baseline, i.e. months or years after the myelitis  
7  
8 episodes.  
9

10  
11 Note that from the five patients that were not on immunosuppressive treatment at study  
12  
13 baseline, only two were permanently untreated, due to severe leucopenia and long-term  
14  
15 prednisone therapy, respectively. The other three were untreated at this time-point, due to  
16  
17 side effects of previous treatments, but received immunosuppression later. Note also that  
18  
19 seven patients were receiving daily oral steroids (prednisolone) at study baseline: one at a  
20  
21 dose of 2mg/day, five at 5mg/day and one at 50mg/day.  
22  
23

24  
25 Abbreviations: EDSS= Expanded Disability Status Scale, LETM= longitudinal extensive  
26  
27 transverse myelitis, logMAR= Logarithm of the Minimum Angle of Resolution, MRI=  
28  
29 magnetic resonance imaging, NMOSD= neuromyelitis optica spectrum disorders, ON=  
30  
31 optic neuritis, SD= standard deviation.  
32  
33  
34  
35

36  
37 This study was approved by the local ethics committee (Ethikkommission der Charité –  
38  
39 Universitätsmedizin Berlin; EA1/131/09) and conducted in accordance with the  
40  
41 declaration of Helsinki in its currently applicable version. All participants gave written  
42  
43 informed consent before inclusion in the study.  
44  
45

### 46 **Clinical assessment**

47  
48 Comprehensive neurological examinations were performed by raters, under supervision  
49  
50 of board certified neurologists, to assess the Expanded Disability Status Scale (EDSS),  
51  
52 including the functional system scores (FSS) according to the Neurostatus definitions.  
53  
54

55 Attack history was also recorded, using clinical criteria.  
56

57  
58 Visual acuity was tested monocularly under photopic conditions using retroilluminated  
59  
60 Early Treatment in Diabetes Retinopathy Study charts at a four-meter distance. The

1  
2  
3  
4 logarithm of the minimum angle of resolution (logMAR) was used as a measure of visual  
5  
6 function. We included the visual function measurement only from patients where best  
7  
8 correction was used (n=30).  
9

### 10 11 **Magnetic resonance imaging** 12

13  
14 Magnetic resonance imaging (MRI) was performed for all participants at 3T  
15  
16 (MAGNETOM Trio Siemens, Erlangen, Germany) on the same day as the clinical  
17  
18 examination, except for two participants, where there was an interval of one day. Details  
19  
20 regarding the MRI protocol and the assessment of thalamic- and optic radiation lesions  
21  
22 are given as supplementary material.  
23  
24

### 25 26 **Measurement of thalamic volume and thalamic nuclei volume** 27

28 The volumes of the entire thalamus and the thalamic nuclei were measured using the  
29  
30 Multiple Automatically Generated Templates (MAGeT) brain algorithm [17] on 3D T1-  
31  
32 weighted magnetization prepared rapid acquisition gradient echo (MPRAGE) images.  
33  
34 MAGeT uses an atlas derived from manually segmented serial histological data,  
35  
36 including delineation of the thalamic nuclei. It first customizes the atlas to a subset of  
37  
38 participants, representative of the study population, using nonlinear registration and uses  
39  
40 this newly segmented subset as a template library for the remaining participants. This has  
41  
42 the advantage of correcting for the neuroanatomical variability of the study population.  
43  
44 Details regarding the representative subset of the present study are given as  
45  
46 supplementary material.  
47  
48  
49

50  
51 The segmentation results were visually inspected by one experienced rater (L.G.), who  
52  
53 was blinded to the clinical data and no subjects had to be excluded. Last, all volumes  
54  
55 were extracted and normalised using the SIENAX V-scaling factor for head-size[18].  
56  
57 Figure 1 and Supplementary figures 1 and 2 show examples of the LGN and VPN as  
58  
59 segmented by MAGeT.  
60

## Mean upper cervical cord area

The mean upper cervical cord area (MUCCA) was used as a sensitive measure to assess spinal cord atrophy in patients with NMOSD[19]. Methodological details are given as supplementary material.

## Optical coherence tomography

Retinal imaging was performed using a Heidelberg Engineering Spectralis spectral domain optical coherence tomography (OCT; Heidelberg Engineering, Heidelberg, Germany). We report the OCT acquisition settings, scanning protocol and details regarding excluded scans as supplementary material.

The peripapillary retinal nerve fiber layer (pRNFL) thickness and the combined ganglion cell and inner plexiform layer (GCIPL) volume were used in the analysis.

## Statistical Analysis

Differences in age and sex-distribution between patients and controls were investigated using t-test and Fisher's exact test, respectively.

The associations of thalamic, LGN and VPN volumes with demographic characteristics were studied in controls using linear mixed effect models (LMM), with age, sex, handedness and brain side as fixed effects. If not stated otherwise, group comparisons, as well as structural-structural and structural-functional associations of thalamic nuclei were also performed using LMM, to account for intra-subject inter-side dependencies. Age and sex were always included as fixed effects in these models. The association of LGN volume with visual function was studied in LMM with monocular logMAR as dependent variable and LGN volume sum of both hemispheres as independent variable, since both LGN receive afferences from each eye. Relevant results were checked in additional LMM, adjusting for OR lesions and retinal damage (mean pRNFL thickness). We also performed analyses stratified for: i) ON (for LGN), ii) myelitis (for VPN), and iii)

1  
2  
3  
4 brainstem attacks (for VPN). We report effect sizes from the LMM as marginal  $R^2$  ( $mR^2$ ),  
5  
6 representing the variance explained by the fixed effects alone, and conditional  $R^2$  ( $cR^2$ ),  
7  
8 representing the variance explained by both fixed and random effects.  
9

10  
11 Associations between LGN and VPN volumes with number of attacks and FSS were  
12  
13 studied through Spearman correlation tests, due to the non-normal distribution of these  
14  
15 variables (analysis per patient, using the volume sum of both hemispheres). Bilateral ON  
16  
17 was counted as two episodes.  
18

19  
20 Last, we performed an exploratory analysis comparing all other thalamic nuclei between  
21  
22 patients and controls, using LMM. This analysis was corrected for multiple comparisons  
23  
24 using the Holm-Bonferroni method.  
25

26  
27 For all models, statistical significance was achieved at  $p < 0.05$ . All statistical analysis  
28  
29 was performed using R[20], version 3.4.3 with packages: pastecs, lme4, lmerTest,  
30  
31 MuMIn and ggplot2.  
32  
33

### 34 **Data availability statement**

35  
36 All anonymised data not published within this article can be shared upon reasonable  
37  
38 request from any qualified investigator.  
39

## 40 **RESULTS**

### 41 **Demographics, clinical and imaging characteristics of the study population**

42  
43 Patients with NMOSD and controls showed no difference regarding mean age ( $p=0.447$ ),  
44  
45 sex ( $p=0.475$ ) or handedness ( $p=0.494$ ; table 1).  
46  
47

48  
49 Twenty-five patients (64.1%) had a history of at least one ON (NMO-ON) and the rest  
50  
51 never had an ON (NMO-NON). Most patients (92.3%) had at least one myelitis, while  
52  
53 there were also five patients with a brainstem attack (table 1).  
54  
55

56  
57 A total of 17/39 (43.6%) patients had OR lesions, typically small, with nonspecific  
58  
59 morphology (median lesion number: 0, range: 0-18). There was a single patient with a  
60

1.

left thalamic lesion. Since the left LGN and VPN volumes of this patient were not outliers (147.7 mm<sup>3</sup> and 612.2 mm<sup>3</sup>, respectively) we did not exclude this patient from the analysis.

### Volume of the entire thalamus

In controls, thalamic volume was associated with age (B=-17.50, SE=8.45, p=0.047) and brain side, with the thalamus being larger on the right (7760.5 ± 602.3 mm<sup>3</sup>) compared to left (7185.7 ± 560.2 mm<sup>3</sup>; B=573.54, SE=34.26, p<0.001).

Total thalamic volume did not differ between NMOSD patients (7382.6 ± 668.7 mm<sup>3</sup>) and controls (7473.1 ± 646.1 mm<sup>3</sup>), when accounting for age and brain side (B=-68.49, SE=119.62, p=0.569).

### Volume of the LGN

In controls, LGN volume was also associated with brain side, with the LGN being larger on the right (240.3 ± 29.9 mm<sup>3</sup>) compared to left (156.3 ± 20.6 mm<sup>3</sup>; B=83.42, SE=3.53, p<0.001), but not with age, sex or handedness. Mean LGN volume did not differ between NMOSD patients and controls (table 2).

**Table 2: Volumes of the lateral geniculate nucleus and ventral posterior nucleus in NMOSD patients and controls**

|                                   | Controls<br>(n=37) | NMOSD<br>(n=39) | NMO-<br>ON<br>(n=25) | NMO-<br>NON<br>(n=14) | NMOSD<br>vs.<br>controls         | NMO-ON<br>vs.<br>controls                       | NMO-<br>NON vs.<br>controls     |

|--|----------------------------|-------------------------|---|---|-----------------------------------|---|
|  | <b>Controls<br/>(n=37)</b> | <b>NMOSD<br/>(n=39)</b> | <b>NMOSD<br/>with<br/>myelitis<br/>(n=36)</b> | <b>NMOSD<br/>without<br/>myelitis<br/>(n=3)</b> | <b>NMOSD vs.<br/>controls</b>     | <b>NMOSD with<br/>myelitis vs.<br/>controls</b> |
| VPN<br>volume,<br>mm <sup>3</sup><br>(mean $\pm$ SD) | 679.7 $\pm$ 68.3           | 676.5 $\pm$ 67.8        | 674.3 $\pm$ 67.5                              | 703.2 $\pm$ 71.7                                | B= -4.58<br>(SE=13.44)<br>p=0.734 | B= -7.36<br>(SE=13.75)<br>p=0.594               |

Legend: Note that due to the fact that there were only three NMOSD patients without myelitis, we did not compare VPN volume between patients with and without myelitis.

Abbreviations: LGN= lateral geniculate nucleus, NMOSD= neuromyelitis optica spectrum disorders, NMO-ON= patients with NMOSD and previous optic neuritis, NMO-NON= patients with NMOSD and negative history of previous ON, SE= standard error, VPN= ventral posterior nucleus mm<sup>3</sup>

LGN volume was lower in NMO-ON patients compared to NMO-NON patients (B=-23.74, SE= 6.76, p=0.001, mR<sup>2</sup>= 0.05, cR<sup>2</sup>=0.94; Fig. 2) and in NMO-ON patients vs. controls (table 2, Fig. 2). These results remained after exclusion of seven patients on daily prednisolone (data not shown). In contrast, there was no difference between NMO-NON patients and controls (table 2, Fig. 2).

For a separate analysis of the ipsi- and contralateral LGN volumes and their association to ON, see supplementary material.

### **Volume of the LGN, optic neuritis and OCT parameters**

In line with the smaller LGN found in NMO-ON, LGN volume inversely correlated with number of ON episodes in patients ( $Rho=-0.536$ ,  $p<0.001$ ; Fig. 2). When assuming a linear relationship, each ON episode led to, on average, an LGN volume loss of  $-3.09$   $\text{mm}^3$  ( $SE=1.16$ ,  $p=0.012$ ). We did not find an association between LGN volume and time since first ( $B=-0.16$ ,  $SE=0.67$ ,  $p=0.809$ ) or last ON episode ( $B= 1.28$ ,  $SE= 1.29$ ,  $p=0.33$ ). In patients, LGN volume was associated with mean pRNFL thickness ( $B=0.70$ ,  $SE=0.14$ ,  $p<0.001$ ,  $mR^2=0.07$ ,  $cR^2=0.94$ ) and mean GCIPL volume of both eyes ( $B=51.82$ ,  $SE=11$ ,  $p<0.001$ ,  $mR^2=0.06$ ,  $cR^2=0.94$ ) (Fig. 2). The results were similar in models adjusted for OR lesions (pRNFL:  $B=0.71$ ,  $SE=0.15$ ,  $p<0.001$ ; GCIPL:  $B=51.86$ ,  $SE=11.10$ ,  $p<0.001$ ). In controls, there were no associations of pRNFL and GCIPL with LGN volume (data not shown).

When looking at NMO-NON and NMO-ON patients separately, the associations of LGN volume with pRNFL thickness and GCIPL volume remained only in the NMO-ON subgroup (pRNFL:  $B=0.64$ ,  $SE=0.21$ ,  $p=0.007$ ,  $mR^2=0.05$ ,  $cR^2=0.93$ ; GCIPL:  $B=40.18$ ,  $SE=16.18$ ,  $p=0.023$ ,  $mR^2=0.04$ ,  $cR^2=0.93$ ), but not in NMO-NON patients (pRNFL:  $B=0.19$ ,  $SE=0.55$ ,  $p=0.741$ ; GCIPL:  $B=40.51$ ,  $SE=39.09$ ,  $p=0.322$ ).

### **Volume of the LGN and lesions in the optic radiations**

Presence of OR lesions was not associated with ipsilateral LGN volume ( $B=-0.52$ ,  $SE= 6.35$ ,  $p=0.935$ ) and OR lesion number did not correlate with LGN volume ( $Rho=0.026$ ,  $p=0.877$ ). Moreover, LGN volume remained smaller in NMO-ON than in NMO-NON, when accounting for OR lesions ( $B=-23.74$ ,  $SE= 6.82$ ,  $p=0.001$ ,  $mR^2= 0.05$ ,  $cR^2=0.94$ ).

### **Volume of the LGN and visual function**

LGN volume (sum of both hemispheres) was associated with visual function measured as logMAR (B=-0.01, SE=0.002, p=0.002, mR<sup>2</sup>=0.22, cR<sup>2</sup>=0.27). This effect did not remain significant after inclusion of pRNFL thickness in the model (LGN: B=0.001, SE=0.002, p=0.613; pRNFL: B=-0.02, SE=0.003, p<0.001, mR<sup>2</sup>=0.52, cR<sup>2</sup>=0.52).

### **Volume of the VPN**

In controls, VPN volume was associated with brain side, with the VPN being larger on the left (706.7 ± 65.8 mm<sup>3</sup>) compared to right (652.8 ± 60.4 mm<sup>3</sup>; B=-54.44, SE= 6.54, p<0.001), but not with age, sex or handedness.

Mean VPN volume was not different between NMOSD patients and controls (B=-4.58, SE=13.4, p=0.730; table 2 and Fig. 3).

### **Volume of the VPN and myelitis**

There was no difference in VPN volume between patients with myelitis and controls (table 2). This remained after exclusion of seven patients on daily prednisolone (data not shown). Moreover, we found no correlation between VPN volume and number of myelitis episodes (Rho=-0.155, p=0.346; Fig. 3), time since first (B=-1.09, SE=1.48, p=0.466), or last myelitis (B=-4.32, SE= 2.78, p=0.131).

To study associations between VPN and myelitis-related spinal cord damage, we used the mean upper cervical cord area (MUCCA; mean in patients: 68.3 ± 7.0 mm<sup>2</sup> vs. 74.8 ± 6.4 mm<sup>2</sup> in controls). MUCCA was neither associated with VPN volume in NMOSD patients (B=-1.52, SE=1.33, p=0.261; Fig. 3) nor in the subgroup of patients with myelitis (B=-2.45, SE=1.37, p=0.084). Similar results were seen in controls (data not shown).

Moreover, there was no correlation between VPN volume and sensory FSS (Rho=-0.282, p=0.091).

### **Volume of the VPN and brainstem attacks**

Due to the unexpected lack of association between VPN and myelitis, and since the VPN segmented in the present study included the ventral posterolateral nucleus, which receives afferences from the brainstem (trigeminothalamic tract), we performed a subgroup analysis in patients that had both myelitis and brainstem attacks (n=5; see table 3).

**Table 3: Patients with myelitis and brainstem attacks**

| Patient | First attack   | Further attacks before study-baseline   | Time since last brainstem attack                        | MRI at study-baseline   |
|---------|--|---|---|---|
| 1       | Combined brainstem syndrome (double vision, nystagmus, tinnitus, headache, neck pain) and cervical myelitis (left hemiparesis)       | Six episodes of myelitis (incl. cervical myelitis), no further brainstem attacks                                    | 20.9 years (last brainstem attack was the first attack) | LETM including the medulla and cervical spinal cord (to level C5) |
| 2       | Combined brainstem/area postrema syndrome (double vision, nausea, vomiting, hiccups, dizziness) and cervical myelitis (sensory loss) | One further attack: combined brainstem syndrome (dizziness, double vision, nystagmus) and cervical myelitis (right) | 3.66 years  | LETM including the medulla and cervical spinal cord (to level C6) |

|   |  |   |   |   |
|---|--|---|---|---|
|   | and dysaesthesias on the left)   | hemiparesis and hemiataxia)   |   |   |
| 3 | Combined cervical myelitis (paresthesias on the left hemibody and spastic tetraparesis) with brainstem syndrome („brainstem encephalitis“; no further details available) | One further attack with nausea/vomiting and fatigue (probably brainstem/area postrema syndrome) | 14.11 years   | Lesions in the medulla and in the cervical spinal cord (level C5) |
| 4 | Combined brainstem syndrome (dizziness, nystagmus, balance problems, headache and neck pain) and cervical myelitis (sensory loss in four extremities and trunk)          | Five episodes of optic neuritis and two of myelitis, no further brainstem attacks               | 6.66 years (last brainstem attack was the first attack) | LETM including the medulla and cervical spinal cord (to level C7) |
| 5 | Brainstem syndrome/area postrema (double vision, nausea, vomiting, dizziness)  | One myelitis (one month after first attack), no further brainstem attacks                       | 1.26 years (last brainstem attack was the first attack) | Multiple lesions in the medulla and cervical spinal cord, LETM in |

|  |  |  |  |                                     |
|--|--|--|--|-------------------------------------|
|  |  |  |  | thoracic<br>spinal cord<br>(Th4-10) |
|--|--|--|--|-------------------------------------|

Legend: The lesions in the medulla and spinal cord of these patients were identified by two raters: a board-certified neurologist with experience in neuroimaging (A.P.) and a board-certified radiologist (M.S.), on sagittal T2-weighted spinal cord MR images (repetition time (TR) = 3500 ms, echo time (TE) = 101 ms, in-plane resolution = 0.91 mm × 0.91 mm, slice thickness = 2 mm). Abbreviations: C= cervical, LETM=longitudinal extensive transverse myelitis, Th= thoracic

Indeed, we found lower VPN volumes in these patients ( $613.6 \pm 71.8 \text{ mm}^3$ ) vs. controls ( $679.7 \pm 68.33$ ;  $B=-76.18$ ,  $SE=30.52$ ,  $p=0.017$ ,  $mR^2=0.12$ ,  $cR^2=0.85$ ; Fig. 4). Since two of these patients were on daily prednisolone, we also performed this analysis including prednisolone treatment as random effect and the result remained ( $B=-70.84$ ,  $SE=31.83$ ,  $p=0.048$ ). There was also a correlation between VPN volume and number of brainstem attacks ( $Rho=-0.378$ ,  $p=0.018$ ), but no significant correlation with brainstem FSS ( $Rho=-0.314$ ,  $p=0.058$ ).

### Volumes of the other thalamic nuclei

In an exploratory analysis, we investigated whether other thalamic nuclei were different in NMOSD patients vs. controls. Among nine nuclei, we found only the lateral posterior nucleus to be smaller in patients (table 4). When corrected for multiple comparisons, this effect became non-significant (corrected  $p=0.180$ ).

**Table 4: Volumes of the remaining thalamic nuclei in NMOSD patients and controls**

| <b>Volume of thalamic nuclei</b>                        | <b>NMOSD</b>   | <b>Controls</b> | <b>Comparison</b>               |
|---|----------------|-----------------|---------------------------------|
| Medial geniculate nucleus (mm <sup>3</sup> ), mean ± SD | 233.6 ± 34.1   | 233.2 ± 37.5    | B=-0.49 (SE=5.18),<br>p=0.925   |

| Ventral anterior nucleus (mm <sup>3</sup> ), mean ± SD  | 647.7 ± 95.4   | 670.6 ± 111.2   | B=-22.32 (SE=14.19),<br>p=0.120 |

|   |                    |                   |                                 |
|---|--------------------|-------------------|---------------------------------|
| Ventral lateral nucleus (mm <sup>3</sup> ), mean $\pm$ SD | 1007.2 $\pm$ 114.5 | 1022.4 $\pm$ 97.7 | B=-13.93 (SE=16.92),<br>p=0.413 |
|---|--------------------|-------------------|---------------------------------|

Legend: Note that all volumes are normalised using the SIENAX V-scaling factor and that the p-values given are uncorrected for multiple comparisons. After correction for multiple comparisons, the lateral posterior nucleus was not smaller in NMOSD than controls (corrected p=0.180). Abbreviations: SE= standard error.

## DISCUSSION

In this study that assessed all thalamic nuclei in patients with NMOSD, we hypothesized that attack-related damage would be measurable as volume loss only in specific nuclei (LGN due to ON and VPN due to myelitis).

Indeed, LGN volume was reduced in NMOSD patients with ON history compared to controls, and also compared to patients without prior ON. Moreover, LGN volume was associated with number of ON episodes, retinal damage and visual function. These results strongly suggest anterograde degeneration in the afferent visual pathway of NMO-ON patients. Moreover, they support the use of LGN volume as an imaging marker of attack-related brain structural damage in NMOSD, with also functional relevance.

Anterograde degeneration in the visual pathway is well established in multiple sclerosis (MS) [21,22], while even in radiologically isolated syndrome there seems to be an association between retinal and thalamic volume loss[23]. In NMOSD, previous studies investigated transsynaptic degeneration in the visual pathway by analysing changes in the OR[15,24–27]. Several studies using diffusion tensor imaging [15,24,27,28] reported decreased OR fractional anisotropy, indicating microstructural OR-changes in NMO-ON patients vs. controls. A further study[25] showed reduced myelin water fraction,

1  
2  
3  
4 suggesting reduced myelin density, in the OR of NMOSD patients (80% with prior ON)  
5  
6 compared to controls. The interpretation of these findings was, that axonal loss in the  
7  
8 optic nerve after ON can cause OR changes, by a propagation of damage through the  
9  
10 LGN-synapses (anterograde transsynaptic degeneration).  
11

12  
13 However, reported microstructural damage in the OR of NMOSD patients *without* prior  
14  
15 ON [26,27] suggests that white matter in this region might also be prone to direct  
16  
17 changes due to NMOSD-related astrocytopathy. Thus, the specific assessment of the  
18  
19 LGN, the grey matter structure where the actual synapses occur, is crucial to confirm  
20  
21 transsynaptic degeneration and measure attack-related structural damage in the visual  
22  
23 pathway in NMOSD. Moreover, LGN volume as assessed in our study has the advantage  
24  
25 of using a broadly available MRI sequence (3D T1-weighted). This is important, since  
26  
27 standardized diffusion tensor imaging for the OR-assessment is often hampered in  
28  
29 clinical routine.  
30  
31

32  
33 The lack of data on LGN volume in NMOSD is probably due to the small LGN size,  
34  
35 which makes its measurement technically challenging[22]. A single previous study[27]  
36  
37 reported, in line with our results, reduced LGN volume in NMOSD patients with ON  
38  
39 compared to controls and to patients without ON. In this previous study however, LGN  
40  
41 volume was measured manually, which is prone to bias, especially for such a small  
42  
43 structure[29]. In the present study, we used a multi-atlas-based tool of automated  
44  
45 segmentation, the MAGeT Brain algorithm[17]. This algorithm is based on histological  
46  
47 data, was validated against manual segmentations[30,31] and intraoperative  
48  
49 recordings[31] and was previously used to investigate deep grey matter volume in  
50  
51 patients with MS[29].  
52  
53

54  
55 Next to this methodological strength, the present study included a –given the rarity of  
56  
57 NMOSD in Europe[32]- relatively large (n=39) number of AQP4-IgG seropositive

NMOSD patients, compared to the heterogeneous population of Tian et al.[27], who analysed AQP4-IgG seropositive and seronegative patients together, and to the smaller sampler sizes of previous studies investigating the visual pathway of AQP4-IgG seropositive NMOSD[15,24–26].

Although previous work showed GCIPL volume reduction[6] and microstructural OR changes[26] in AQP4-IgG seropositive NMO-NON patients, our current results do not support a subclinical LGN volume loss in the absence of ON, since NMO-NON patients had normal LGN volumes. The reasons for this are not clear. It could be that neurodegenerative processes are different in the retina than the brain and in the white- than the grey matter in NMOSD. However, it cannot be ruled out that in this cross-sectional study we had insufficient power to detect subtle subclinical volume loss at the LGN level.

The LGN volume was not associated with OR lesions in our study. This is in contrast to what was shown in MS[33], where findings suggest retrograde degeneration from OR lesions towards the retina[34]. The reason for this could be, that the typically small, nonspecific lesions observed in the OR of NMOSD patients are less destructive than demyelinating OR lesions in MS. This would be in line with the nonspecific morphology and asymptomatic nature of most white matter brain lesions in NMOSD[35–37].

In contrast to the LGN findings, VPN volume was not smaller in NMOSD patients with myelitis vs. controls and did not correlate with number of myelitis episodes. One possible explanation for these negative findings is, that compared to the small LGN, which receives afferences almost exclusively from the retina/optic nerve, the VPN is a larger nuclear complex receiving afferences from several regions [38]. Moreover, the VPN as segmented in the present study included not only the ventral posterolateral subnucleus (receiving afferences from the spinal cord), but also the ventral intermediate nucleus and

1  
2  
3  
4 the ventral posteromedial subnucleus. The latter receives afferences from the  
5  
6 trigeminothalamic tract in the brainstem[39]. Accordingly, we found reduced VPN  
7  
8 volumes in five patients who suffered brainstem relapses. Four of these patients had  
9  
10 attacks with brainstem or area postrema syndromes and cervical myelitis, with MRI  
11  
12 lesions extending from the brainstem into the cervical spinal cord. We speculate that a  
13  
14 lesion located in the most cranial part of the spinal cord (i.e. a shorter distance from the  
15  
16 VPN) and the brainstem (i.e. close to the spinal tract of the trigeminal nerve and/or the  
17  
18 trigeminothalamic tract) might be associated with the VPN volume loss seen in these  
19  
20 patients.  
21  
22  
23  
24

25 Another possible explanation for the lack of association between VPN and myelitis is the  
26  
27 heterogeneous population of patients, with different degrees of sensory involvement, as  
28  
29 well as spinal cord lesions with different lengths and locations. Last, it should be  
30  
31 emphasized that lack of volume loss in the VPN does not necessarily mean lack of  
32  
33 damage. Microstructural changes that do not necessarily result in a volume reduction or  
34  
35 functional, adaptive changes could be present in the grey matter, despite “normal”  
36  
37 volume.  
38  
39  
40

41 The volume of the entire thalamus was not reduced in our NMOSD patients compared to  
42  
43 controls, which is in line with three previous European studies[13–15] with AQP4-IgG  
44  
45 seropositive patients. However, three other Asian studies[11,12,16] reported reduced  
46  
47 thalamic volumes compared to controls. In one of these studies[12], seven thalamic  
48  
49 subregions (not corresponding to specific subnuclei) were also examined separately and  
50  
51 almost all showed reduced volumes in NMOSD. These overall conflicting findings may  
52  
53 be due to the genetically different NMOSD populations in Europe and Asia[40] and due  
54  
55 to variability in antibody-status of the patients, with the Asian studies including also 10-  
56  
57 30% AQP4-IgG seronegative patients[11,12,16].  
58  
59  
60

1  
2  
3  
4 A limitation of our study is the use of volume changes as the only measure of thalamic  
5  
6 damage. Quantitative imaging methods, such as diffusion tensor imaging of thalamic  
7  
8 nuclei, or even functional MRI might contribute to our understanding of microstructural  
9  
10 and functional changes in NMOSD that do not necessarily result in volume loss, although  
11  
12 their application in such small structures as the thalamic nuclei would be technically  
13  
14 challenging. Moreover, the cross-sectional nature of the present study is a drawback.  
15  
16 Longitudinal studies following changes in thalamic nuclei in patients with NMOSD after  
17  
18 an acute (ideally the first) attack would be warranted in the future.  
19  
20  
21

22  
23 To conclude, we found structural damage of the LGN due to ON in AQP-IgG  
24  
25 seropositive NMOSD patients. Our results support the role of this thalamic nucleus as an  
26  
27 imaging marker of attack-related neurodegenerative damage in the brain of these patients,  
28  
29 also with functional relevance (association with visual function). Similar results were not  
30  
31 observed for VPN and myelitis, although we saw an association with brainstem attacks,  
32  
33 which needs confirmation in larger studies. Our findings suggest selective, attack-related  
34  
35 rather than diffuse damage to thalamic nuclei in NMOSD.  
36  
37

## 38 **ACKNOWLEDGMENTS**

39  
40  
41 We thank all patients and controls that participated in this study, Charlotte Bereuter for  
42  
43 performing the visual assessment and optical coherence tomography, as well as Susan  
44  
45 Pikol and Cynthia Kraut for performing the magnetic resonance imaging.  
46  
47  
48  
49

## 50 **FUNDING**

51  
52  
53 This study was supported by the “Deutsche Forschungsgemeinschaft” (grant DFG Exc.  
54  
55 257) and the German Federal Ministry for Education and Research (BMBF; grant N2-  
56  
57 ADVISIMS: 16GW0079) to F.P. and A.U.B. and by the Swiss National Science  
58  
59 Foundation (project number P300PB\_174480) to A.P.  
60

## COMPETING INTERESTS

Athina Papadopoulou has received speaker-fee from Sanofi-Genzyme and travel support from Bayer AG, Teva and Hoffmann-La Roche. Her research was supported by the University of Basel, the Swiss Multiple Sclerosis Society and the “Stiftung zur Förderung der gastroenterologischen und allgemeinen klinischen Forschung sowie der medizinischen Bildauswertung”. The current research work was supported by the Swiss National Science Foundation (Project number: P300PB\_174480).

Frederike Cosima Oertel was employee of Nocturne UG, not in context of this work.

Laura Gaetano was a temporary employee of Novartis AG and is currently an employee of Hoffmann-La Roche; her contribution to this work was prior to her employment in Hoffmann-La Roche.

Joseph Kuchling received conference registration fees from Biogen and financial research support from Krankheitsbezogenes Kompetenznetzwerk Multiple Sklerose (KKNMS).

Hanna Zimmermann received research grants from Novartis and speaker fees from Teva.

Claudia Chien has nothing to disclose.

Nadja Siebert has nothing to disclose.

Susanna E. Asseyer has nothing to disclose.

Judith Bellmann-Strobl has received travel grants and speaking fees from Bayer Healthcare, Biogen Idec, Merck Serono, Sanofi-Aventis/Genzyme, Teva Pharmaceuticals, and Novartis.

Klemens Ruprecht served on the scientific advisory board for Sanofi-Aventis/Genzyme, Novartis, and Roche; received travel funding and/or speaker honoraria from Bayer Healthcare, Biogen Idec, Merck Serono, Sanofi-Aventis/Genzyme, Teva Pharmaceuticals, Novartis, and Guthy Jackson Charitable Foundation; is an academic

1  
2  
3  
4 editor for PLoS ONE; receives publishing royalties from Elsevier; and received research  
5  
6 support from Novartis and German Ministry of Education and Research.

7  
8  
9 Mallar M. Chakravarty has nothing to disclose.

10  
11 Michael Scheel has nothing to disclose.

12  
13 Stefano Magon has received research support from Swiss MS Society, Swiss National  
14  
15 Science Foundation, University of Basel and Stiftung zur Förderung der  
16  
17 gastroenterologischen und allgemeinen klinischen Forschung sowie der medizinischen  
18  
19 Bildauswertung University Hospital Basel. He also received travel support from Biogen  
20  
21 and Genzyme.

22  
23  
24  
25 Jens Wuerfel is CEO of MIAC AG Basel, Switzerland. He served on scientific advisory  
26  
27 boards of Actelion, Biogen, Genzyme-Sanofi, Novartis, and Roche. He is or was  
28  
29 supported by grants of the EU (Horizon2020), German Federal Ministries of Education  
30  
31 and Research (BMBF) and of Economic Affairs and Energy (BMWI).

32  
33  
34 Friedemann Paul serves on the scientific advisory board for Novartis; received speaker  
35  
36 honoraria and travel funding from Bayer, Novartis, Biogen Idec, Teva, Sanofi-  
37  
38 Aventis/Genzyme, Merck Serono, Alexion, Chugai, MedImmune, and Shire; is an  
39  
40 academic editor for PLoS ONE; is an associate editor for Neurology® Neuroimmunology  
41  
42 & Neuroinflammation; consulted for SanofiGenzyme, Biogen Idec, MedImmune, Shire,  
43  
44 and Alexion; and received research support from Bayer, Novartis, Biogen Idec, Teva,  
45  
46 Sanofi-Aventis/Genzyme, Alexion, Merck Serono, German Research Council, Werth

Volume of the ventral posterior nucleus in NMOSD and its relationship with myelitis and spinal cord damage.

159x294mm (300 x 300 DPI)

Volume of the ventral posterior nucleus in patients with myelitis and brainstem involvement.

159x108mm (300 x 300 DPI)

## SUPPLEMENTARY MATERIAL

### METHODS

#### Magnetic resonance imaging protocol

Magnetic resonance imaging (MRI) was performed for all subjects at 3T (MAGNETOM Trio Siemens, Erlangen, Germany). The protocol included a 3D T1-weighted magnetization prepared rapid acquisition gradient echo (MPRAGE) sequence (repetition time (TR) =1900 ms, echo time (TE) =3.03 ms, isotropic resolution 1x1x1 mm), and a 3D T2-weighted fluid-attenuated inversion recovery (FLAIR) sequence (TR = 6000 ms, TE = 388 ms, isotropic resolution 1x1x1 mm) of the brain.

#### Measurement of thalamic volume and thalamic nuclei volume using the MAGEt brain algorithm

The Multiple Automatically Generated Templates (MAGEt) brain algorithm [1,2] was used to segment the entire thalami and the different thalamic nuclei on MPRAGE MR images.

MAGEt uses an atlas derived from manually segmented serial histological data, containing delineation of the thalamic nuclei, as per Hirai and Jones [3]. It first customizes the atlas to a subset of participants, representative of the entire study population, using a nonlinear registration scheme.

In our study, this representative subset was chosen in a manner consistent with best practices for the algorithm [4], according to age, sex and - for patients - number and type of attacks. It consisted of eleven NMOSD patients (ten women, mean age:  $50 \pm 15.1$  years, median number of attacks 3 (range 1-11), 10/11 with myelitis and 7/11 with ON) and ten controls (9 women, mean age:  $47.4 \pm 12$  years). This newly segmented subset acted as a template library for the remaining participants, to correct for the neuroanatomical variability of our study population and to average different sources of random error prior to the final segmentation [5].

## Lesions in the thalamus and the optic radiations

The 3D T2-weighted fluid-attenuated inversion recovery (FLAIR) images of patients were assessed and verified for thalamic- and optic radiations (OR) lesions in consensus by a board-certified neurologist (A.P.) and a board-certified radiologist (M.S.), to assess whether lesions in these strategic locations may influence our results.

## Mean upper cervical cord area

The mean upper cervical cord area (MUCCA) was used as a sensitive measure to assess spinal cord atrophy in patients with NMOSD[6]. MUCCA was measured in 3D MPRAGE images using an active surface model[7] by averaging the cross-sectional areas from five consecutive slices at the C2/C3 intervertebral space level, as described previously[6,8].

## Optical coherence tomography: excluded scans and scanning protocol

Retinal imaging was performed using a Heidelberg Engineering Spectralis spectral domain optical coherence tomography (OCT; Heidelberg Engineering, Heidelberg, Germany), with ART (automatic real-time) function for image averaging. We did not use pupil dilation. All patients had the OCT on the same day as the MRI and clinical examination, except for two, where there was an interval of one day. For the controls there was often an interval of few days between OCT and MRI/clinical assessment (on average:  $7.4 \pm 11.7$  days, range 0-50 days).

A total of ten eyes from eight patients had to be excluded from the analysis: six eyes due to incidental findings, three due to lack of OCT data, and one due to quality reasons, according to the OSCAR-IB criteria. For two additional eyes, only the macular scan had to be excluded, due to quality reasons[9].

The OCT acquisition settings and scanning protocol are reported below, according to the APOSTEL recommendations [10]:

1  
2  
3 The peripapillary retinal nerve fiber layer (pRNFL) was measured using 3.4-mm ring scans  
4 around the optic nerve head ( $12^\circ$ , 1536 A-scans,  $9 \leq \text{ART} \leq 100$ ). The combined ganglion cell  
5 and inner plexiform layer (GCIPL) volume was measured using a 6-mm diameter cylinder  
6 around the fovea from a macular volume scan ( $25^\circ \times 30^\circ$ , 61 vertical B-scans, 768 A-scans per  
7 B-scan,  $\text{ART}=15$ ). Segmentation of the pRNFL and the intraretinal layers in the macular scan  
8 was performed semi-automatically using software provided by the optical coherence  
9 tomography manufacturer (Eye Explorer 1.9.10.0 with viewing module 6.0.9.0; Heidelberg  
10 Engineering). All measurements were checked for segmentation errors and corrected if  
11 necessary, by one experienced rater (F.C.O.).

## 25 RESULTS

### 26 **Volume of the LGN: differences between ipsilateral and contralateral side to** 27 **optic neuritis (ON)** 28 29 30

31 Since the LGN of both hemispheres receive afferences from each optic nerve, both LGN  
32 were expected to be affected similarly after a unilateral ON episode.  
33  
34

35 To confirm this, we performed an additional analysis comparing the LGN volume between  
36 patients with ON (NMO-ON) and without ON (NMO-NON) separately for unilateral LGN to  
37 ON and contralateral LGN to ON. From this analysis, 12 NMO-ON patients with bilateral  
38 ON were excluded. From the included NMO-ON patients ( $n=13$ ), 6 patients had ON on the  
39 left eye and 7 patients on the right eye. The NMO-NON patients were 14.  
40  
41  
42  
43  
44  
45  
46  
47

48 This analysis was performed using linear mixed effect models (LMM), with LGN volume  
49 being the dependent variable, ON history fixed effect, next to age and sex, and subject and  
50 side random effects.  
51  
52  
53

54 Although the volume of ipsilateral to ON LGN was smaller than the LGN volume of NMO-  
55 NON patients ( $B=-21.10$ ,  $SE= 8.69$ ,  $p= 0.023$ ,  $mR^2= 0.05$ ,  $cR^2= 0.94$ ), this was not the case  
56 for contralateral LGN to ON ( $B= -16.29$ ,  $SE= 7.99$ ,  $p= 0.052$ ,  $mR^2= 0.02$ ,  $cR^2=0.95$ ).  
57  
58  
59  
60

1  
2  
3 However, the latter was a borderline not significant result, the p value being 0.052, and could  
4  
5 be also due to the lower power of this subgroup analysis, which included a total of 41 LGN.  
6

**SUPPLEMENTARY FIGURES**

Supplementary Figure 1: LGN segmentation by MAGeT

Legend: The figure shows an example of the lateral geniculate nucleus (LGN) segmentation in a control subject, as performed by the MAGeT brain algorithm[1,2]. The LGN is shown in red at: A) axial, B) coronal and C) sagittal view, on a 3D T1-weighted magnetization prepared rapid acquisition gradient echo (MPRAGE) sequence.

Supplementary Figure 2: VPN Segmentation by MAGeT

Legend: The figure shows an example of the ventral posterior nucleus (VPN) segmentation in a control subject, as performed by the MAGeT brain algorithm[1,2]. The VPN is shown in turquoise at: A) axial, B) coronal and C) sagittal view, on a 3D T1-weighted magnetization prepared rapid acquisition gradient echo (MPRAGE) sequence.
