Abstract

Advanced prostate cancer displays conspicuous chromosomal instability and rampant copy number aberrations, yet the identity of functional drivers resident in many amplicons remain elusive. Here, we implemented a functional genomics approach to identify new oncogenes involved in prostate cancer progression. Through integrated analyses of focal amplicons in large prostate cancer genomic and transcriptomic datasets as well as genes upregulated in metastasis,

Conflicts of interest disclosure: The authors declare no potential conflicts of interest.

276 putative oncogenes were enlisted into an *in vivo* gain-of-function tumorigenesis screen. Among the top positive hits, we conducted an in-depth functional analysis on Pygopus family PHD finger 2 (*PYGO2*), located in the amplicon at 1q21.3. *PYGO2* overexpression enhances primary tumor growth and local invasion to draining lymph nodes. Conversely, *PYGO2* depletion inhibits prostate cancer cell invasion *in vitro* and progression of primary tumor and metastasis *in vivo*. In clinical samples, *PYGO2* upregulation associated with higher Gleason score and metastasis to lymph nodes and bone. Silencing *PYGO2* expression in patient-derived xenograft models impairs tumor progression. Lastly, *PYGO2* is necessary to enhance the transcriptional activation in response to ligand-induced Wnt/ β -catenin signaling. Together, our results indicate that *PYGO2* functions as a driver oncogene in the 1q21.3 amplicon and may serve as a potential prognostic biomarker and therapeutic target for metastatic prostate cancer.

Prostate cancer; *in vivo* ORF screen; *PYGO2*; bone metastasis; patient-derived xenograft model

Introduction

Prostate cancer (PCa) is the most commonly diagnosed noncutaneous malignancy and the third leading cause of cancer mortality for men in the United States (1). Bone is the most frequent site for distant metastasis of PCa, which inflicts significant morbidity and mortality (2). Genomic profiling of PCa (3–7) has revealed overall lower mutation frequency compared with most solid cancer types (8), yet advanced disease is characterized by rampant genomic rearrangements and somatic copy number alterations (SCNAs) (3–7). SCNAs affect a larger fraction of the cancer genome than any other type of genetic alterations in cancer (9), underscoring the potential role of SCNAs in driving the malignant nature of PCa. Functional driver genes residing within recurrent amplifications include key PCa oncogenes such as *EZH2* on 7q36.1, *MYC* on 8q23–24, *NCOA2* on 8q13.3, and *AR* on Xq12 (3). Gain-of-function screens of resident genes within amplicons is a proven approach in the identification of novel oncogenes.

In this study, our screen identified *PYGO2* as a putative driver of PCa progression. *PYGO2* is an essential transcription co-activator with β -catenin/TCF complex for the Wnt signaling pathway in *Drosophila* (10). With a highly conserved plant homeodomain (PHD) in its C-terminus, *PYGO2* binds to H3K4me and activates β -catenin-dependent transcriptional regulation (11). Evidence suggests that *PYGO2* modulates gene transcription through both Wnt-dependent and Wnt-independent mechanisms (11). Emerging data indicate its pivotal role in multiple cancers including glioma (12), breast cancer (13), hepatic carcinoma (14), and intestinal tumors (15). Recently, *PYGO2* expression was identified as a potential risk stratification marker for PSA progression in PCa following radical prostatectomy (16). *PYGO2* is recruited by *PCGEM1*, a long non-coding RNA, to enhance AR-bound enhancer activity (17). Nevertheless, the functional contribution of *PYGO2* to PCa progression, particularly bone metastasis, is not known, prompting us to explore its role in PCa biology.

Materials and Methods

Cell culture and patient-derived xenograft models

The LHMK cell line was a generous gift from William Hahn (18). LHMK and 293T (obtained from ATCC) were maintained in DMEM, 10% FBS. Prostate cancer cell lines PC-3, LNCaP, C4, C4-2, DU145 and 22Rv1 were obtained from ATCC and maintained in RPMI640, 10% FBS. L cells and L Wnt-3A cells were obtained from ATCC and maintained in DMEM, 10% FBS (for L Wnt-3A cells, 0.4 mg/ml G-418 was supplemented). ATCC provides the Human STR Profiling Cell Authentication Service to authenticate these cell lines. All cells were routinely verified as being free of mycoplasma using MycoAlert Mycoplasma Detection Kit (Lonza). Patient-derived xenograft (PDX) models were previously published and generous gifts from Dr. Nora Navone (19,20). The scramble control shRNA and PYGO2-targeting shRNA were ordered from Sigma, with sequences listed in Supplementary Table S1.

Generation of LHMK sublines for screening

The ORF lentiviral vectors in the Precision LentiORF collection were obtained from the Functional Genomics Facility at MD Anderson Cancer Center. In 96-well plates, we packaged 288 ORF lentiviruses individually and infected low-passage LHMK cells. Stable sublines were generated by blasticidin selection, with each sub-line individually expanded for the *in vivo* screen.

In vivo ORF screen

To evaluate the tumorigenicity of the parental cell line, LHMK cells were injected subcutaneously with 10^6 viable cells in a mixture of PBS:Matrigel (BD Biosciences) in NCr nude mice (Taconic), which did not form tumors 6 months post implantation. Expecting a small fraction of the candidate genes to promote tumorigenesis, we designed a multi-site subcutaneous inoculation method to reduce the number of mice needed for the screen. For each LHMK-ORF sub-line, 10^6 viable cells, resuspended in 50 μ L mixture of PBS:Matrigel, were injected subcutaneously into pre-labeled flank positions of mice (5 sites on each side of flank, so total 10 sites per mouse). The experiment was designed so that each subline was evaluated in 10 different mice, and each mouse received injections from 10 different sublines. Mice were monitored for tumor formation via caliper measurement for 8 months. We did not observe formation of more than two subcutaneous tumors on any mice in the screen. All animal experimental protocols were approved by the IACUC at MD Anderson Cancer Center.

Tissue specimens, histology and western blot

A prostate cancer tissue microarray with 80 cases and Gleason grade information was purchased (PR803b, US Biomax). Archived prostate cancer FFPE specimens of adjacent normal, primary tumor and metastasis (total n = 49) were requested from MD Anderson Cancer Center Prostate Cancer SPORE program (Specialized Programs of Research Excellence) under approved IRB protocol at MD Anderson Cancer Center. For all clinical samples, written informed consent was obtained from the patients. The studies were

conducted in accordance with recognized ethical guidelines (Declaration of Helsinki, CIOMS, Belmont Report, U.S. Common Rule). H&E stain, immunohistochemical (IHC) and western blot were performed as previously described (21). Primary antibodies used include PYGO2 (HPA023689, Sigma, for IHC; GTX119726, GeneTex, for western blot), KRAS (sc-30, Santa Cruz), FGFR1, β -Catenin, c-Myc, Met, H3K4me2, H3K4me3, H3 (9740, 8480, 5605, 8198, 9725, 9751 and 4499, Cell Signaling Technology), β -actin (A2228, Sigma).

Cell proliferation and soft agar assay

For 2D proliferation, cells were seeded to 24-well plates with confluence tracked by IncuCyte (Essen BioScience) for 3 days. For soft agar assay, DMEM with 1% FBS, 0.6% LE Agarose (Lonza) was used as base layer while cells were seeded in 2×10^4 cells/mL in DMEM with 1% FBS, 0.3% SeaPlaque Agarose as top layer (Lonza). After incubated at 37°C for 3 weeks, the colonies were stained by crystal violet and quantified.

Migration and invasion assay

Cells were first starved in DMEM with 1% FBS overnight and then seeded in serum-free DMEM at 5×10^5 cells/200 μ L to the chamber inserts (BD Falcon) for migration or BioCoat Matrigel Invasion Chamber (BD Falcon) for invasion. DMEM with 10% FBS were placed at the bottom as chemoattractant. Migrated or invaded cells on the membrane were stained with crystal violet for quantification.

Quantitative RT-PCR

RNA was isolated by RNeasy Kit (Qiagen) and reversed transcribed using Superscript III cDNA synthesis Kit (Life Technology). Quantitative PCR was performed using SYBR-GreenER Kit (Life Technology). Primers are listed in Supplementary Table S1.

Functional validation using animal models

Experimental bone metastasis assay using intracardiac injection and noninvasive imaging was performed as previously reported (22). PDX models were passaged in the flank of C.B-17 SCID (Taconic) mice as previously reported (19,20). The tumors were measured by caliper and treated by intratumoral injection of 10 μ g siRNA targeting PYGO2 (Sigma-Aldrich, SASI_HS01_00059018, or 1:1 ratio of SASI_Hs01_00059021 and SASI_Hs02_00363399) or control siRNA (Sigma-Aldrich, SIC001) twice a week, using MaxSuppressor In Vivo RNA-LANCER II (Bioo Scientific) following the manufacturer's protocol and our recent report (23).

Luciferase reporter assay

TCF/LEF reporter plasmids, M50 Super 8x TOPFlash and M51 Super 8x FOPFlash (TOPFlash mutant), were gifts from Randall Moon (24) (Addgene plasmid # 12456, 12457). Activation of Wnt/ β -catenin signaling was achieved by using conditioned medium from Wnt3A-secreting L cells and control L cells (25). PC3 sublines were transfected with Lipofectamine LTX Reagent (Life Technologies) following manufacturer's protocol and the reporter assay was performed as described (26).

Statistical Analysis

Unless otherwise indicated, data represent mean \pm s.d., with Student's t-test assuming two-tailed distributions used to calculate statistical significance between groups. $P < 0.05$ was considered statistically significant (annotation: * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$, # $P > 0.05$). To display *PYGO2* expression from four Oncomine transcriptomic datasets containing primary and metastatic PCa samples (3,4,27,28), log₂ median-centered ratio of *PYGO2* probe data were drawn as Box plot with whiskers displaying 10–90 percentile using GraphPad Prism.

Results

***In vivo* ORF screen identified putative genes involved in prostate cancer progression**

To enlist genes with putative function in promoting PCa progression, we performed an integrated oncogenomic analysis to enrich for cancer-relevant genes and cull passenger genes. First, genes with focal copy number gains were identified using GISTIC2 (29) from 4 PCa genomic datasets: Taylor et al, Grasso et al, Barbieri et al, and TCGA (3–6) (Fig. 1). This analysis resulted in 6909 genes which were further selected based on two filters: genes with copy number correlated expression in at least 1 of the 4 datasets ($P < 0.01$) and genes with higher expression in metastasis compared with primary tumor ($P < 0.05$) in at least 3 out of 8 Oncomine transcriptomic datasets (3,4,27,30–34). The gene expression data for these 8 datasets were directly queried from Oncomine (35). After applying the filters, 394 genes remained (Fig. 1). Second, to enrich for genes potentially contributing to metastasis, 363 genes upregulated in metastasis compared with primary tumor were identified in at least 6 out of 8 Oncomine datasets. Third, 77 amplified genes were identified from integrated analysis of our previous telomerase reactivation PCa mouse model and human PCa genomics (36). From these diverse datasets and experimental systems, a total of 741 putative metastasis-promoting genes were identified (Supplementary Table S2), among which 288 ORFs (corresponding to 276 unique genes) were available at the time of experimentation from the Precision LentiORF Collection for lentiviral overexpression and ORF screening (Supplementary Table S3).

We employed LHMK cells for the *in vivo* screen, which were derived from primary human prostate epithelial cells after immortalization with SV40 LT and hTERT followed by transformation with MYC and PI3K (18). LHMK cells exhibit very limited tumorigenic capability when inoculated orthotopically or subcutaneously in nude mice (18), providing a suitable system to identify putative oncogenes through a gain-of-function approach. ORF-encoded lentivirus was packaged in 96-well plates and used to transduce LHMK cells, followed by blasticidin selection, to establish 288 individual ORF-expressing sublines (Fig. 2A). Overexpression of Red Fluorescent Protein (RFP) in the same LentiORF backbone was used as negative control (Fig. 2B). ORFs encoding KRAS and FGFR1 were used as positive controls (Fig. 2C), the choice of which was justified given the PCa-promoting role of RAS/MAPK (3,37) or FGF/FGFR1 signaling, respectively (38). ORF-driven overexpression was validated for a number of randomly selected genes using quantitative RT-PCR (Supplementary Fig. S1A) which all showed various levels of overexpression of the putative targets. In the screen, the 288 sublines and RFP control subline were inoculated into mice

subcutaneously (n=10 for each ORF). Mice were monitored for tumor development for 8 months. While no tumor growth was detected for the RFP control (total 30 sites were tested), the positive controls KRAS and FGFR1 generated 100% and 30% incidence of tumors, respectively (Supplementary Table S4). Importantly, 38 genes were identified as positive hits based on a 10–50% tumor incidence rate (Supplementary Table S4), among which 10 genes produced more than 2 tumors out of the 10 tested sites (Fig. 2D, Supplementary Fig. S1B). The top 10 hits include EZH2, known to be frequently upregulated in advanced PCa and to promote metastasis, and CCNE2 which is overexpressed in metastatic PCa and critical for cell cycle G1/S transition (39). Notably, the presence of known PCa-promoting genes among the top hits suggests the possibility that the other genes may represent *bona fide* oncogenes involved in PCa progression. To rule out the possibility that the negative hits were merely due to failure of LentiORF-driven gene overexpression, we randomly selected 26 negative hits from the lenti-ORF infected cells and showed that 23 out of 26 genes were upregulated more than 2-fold (Supplementary Fig. S1C).

Reasoning that *in vitro* assays could complement the *in vivo* result to illuminate biological effects, we performed proliferation, migration and invasion assays for the sublines of the top hits. While meager differences were observed in the two-dimensional (2D) growth curve assay (Fig. 3A), soft-agar assay showed that sublines overexpressing genes like *KRAS*, *PYGO2*, *MOS*, *CCNE2* and *MTBP* could form significantly more colonies than RFP control (Fig. 3B). The gain of colony formation potential by genes such as *PYGO2*, *MOS* and *MTBP* (with functions in PCa uncharacterized) was accompanied by their effect on increased migration and invasion (Fig. 3C,D). Together, the robustness of *PYGO2* in the *in vivo* ORF screen coupled with strong effect in the 3D colony assay (second only to *KRAS*) (Fig. 3B) prompted further functional investigation of this putative PCa promoting gene. Overexpression of *BOP1* (block of proliferation 1) led to strongest enhancement of migration and invasion (Fig. 3C,D). Located at 8q24.3, *BOP1* is close to *MYC* at 8q24.21. These two genes tend to co-amplified in the broad amplification peak at 8q24 (Supplementary Fig. S1D), which is commonly attributed to the oncogenic function of *MYC*. Therefore, we reasoned that the amplification of *BOP1* might be, at least partly, a passenger effect from *MYC* amplification, which would make a study on *BOP1* less significant in terms of finding independent biomarker and/or therapeutic target for PCa. *TOMM40L* overexpression led to higher tumor incidence rate and shorter onset day than *PYGO2* (Fig. 2D). The function of *TOMM40L* was not studied before. The commercially available reagents for *TOMM40L* are limited, making it difficult to perform clinical characterization of its expression and related functional studies.

PYGO2 expression is correlated with higher Gleason score and bone metastasis

PYGO2 resides on cytoband 1q21.3, a region amplified in advanced PCa (3,40,41) but containing no known definitive PCa oncogenes. When surveyed through PCa databases in cBioPortal, the status of *PYGO2* copy number was retrieved from 7 studies (3,4,6,7,42–44) and showed higher gain or amplification in primary CRPC (53.6–76.9%) or metastasis CRPC (33.3–67.7%) compared with treatment-naïve primary PCa (2.7–8.7%, Fig. 4A). In the TCGA dataset, *PYGO2* gain/amplification is associated with higher Gleason score in

treatment-naïve primary PCa (Fig. 4B), as well as shorter disease-free survival and shorter biochemical recurrence (Fig. 4C). Copy number correlated expression of *PYGO2* is evident across several datasets (Supplementary Fig. S2A). Regarding metastasis, *PYGO2* is significantly upregulated at the transcriptional level in metastatic PCa compared with primary tumors (Fig. 4D). At the protein level, tissue microarray (TMA) analysis showed that, while *PYGO2* expression was not detectable in normal prostate, stronger *PYGO2* expression was correlated with higher Gleason score (Fig. 4E). Furthermore, from an archived clinical PCa sample cohort at MD Anderson Cancer Center which includes normal, primary tumors, lymph node metastases and bone metastases, IHC analysis showed that *PYGO2* expression was highly upregulated in metastases (Fig. 4F). The clinical expression analysis, in addition to the *in vivo* functional screen and *in vitro* functional validation, strongly support a direct role of *PYGO2* in promoting PCa progression.

PYGO2 overexpression promotes prostate tumor growth and invasion to lymph nodes

To determine if *PYGO2* upregulation enhances PCa progression, we first re-tested the LHMK sublines expressing RFP or *PYGO2* by subcutaneous inoculation in NSG mice. The LHMK-*PYGO2* subline formed significantly larger tumors as compared to RFP controls (Fig. 5A, Supplementary Fig. S2B). To test the pro-tumor function of *PYGO2* in a different PCa cell line, we overexpressed *PYGO2* in LNCaP, which also has a low endogenous level of *PYGO2* (Fig. 5B). Compared with GFP control, *PYGO2* overexpression led to significant increase of subcutaneous tumor weight (Fig. 5B). Based on the IRES-GFP cassette in the overexpression vector, we identified GFP⁺ tumor cells in draining lymph nodes in 3 out of 10 mice inoculated with LNCaP-*PYGO2* cells (Fig. 5C, Supplementary Fig. S2C). Thus, *PYGO2* overexpression promotes both primary tumor growth and regional lymph node invasion.

PYGO2 depletion inhibits prostate cancer metastasis and PDX tumor growth

To determine whether *PYGO2* is required for PCa progression, we used two independent *PYGO2* shRNA vectors to deplete *PYGO2* levels in the aggressive PCa cell line PC3 (45) (Fig. 6A). *PYGO2* knockdown resulted in modest decrease in cell proliferation *in vitro* (Supplementary Fig. S3A) but significant reduction of cell invasion (Supplementary Fig. S3B). When inoculated subcutaneously in mice, *PYGO2* knockdown cells showed reduced tumorigenic potential (Fig. 6B). To evaluate whether *PYGO2* knockdown affects spontaneous metastasis of PC3 to lung, we removed the subcutaneous tumors at Day 50 post-inoculation and assessed metastasis formation in lung 2 months later by gross inspection and histology. While 60% of mice previously inoculated with the PC3-shControl subline developed spontaneous lung metastasis nodules, less than 20% of mice inoculated with the sh*PYGO2* sublines of PC3 developed lung metastasis nodules (Fig. 6C, Supplementary Fig. S3C). Expression of *PYGO2* in PC3 cells remains pronounced in lung metastasis (Supplementary Fig. S3D).

As bone is the most frequent site of distant metastasis of PCa, we performed intracardiac injection to compare the bone colonization capability of shControl and sh*PYGO2* sublines of PC3 after labeling PC3 with a triple reporter (TR) containing firefly luciferase, GFP and thymidine kinase (46). Noninvasive bioluminescence imaging revealed that *PYGO2*

knockdown impaired the ability of PC3-TR cells to colonize the bone and form osteolytic lesions (Fig. 6D–F). PYGO2 is also expressed by a few other PCa cell lines, including 22Rv1, C4 and C4–2 (Supplementary Fig. S3E).

As PDX models more closely resemble the clinical disease, we examined the effect of targeting PYGO2 in two PDX models: MDA-PCa-180 (derived from primary CRPC) (19) and MDA-PCa-118b (derived from bone metastatic CRPC) (20). We first performed IHC for PYGO2 and detected high PYGO2 expression in both models (Fig. 7A). Through intratumoral infusion of siRNA (either scramble control or PYGO2-targeting), we were able to significantly attenuate PYGO2 protein level (Fig. 7B). In both models, PYGO2-targeting siRNA treatment inhibited subcutaneous PDX tumor growth (Fig. 7C). For MDA-PCa-180, we also demonstrated the anti-tumor effect by an independent siRNA mixture (Supplementary Fig. S3F). Spontaneous metastasis to lung or bone from the PDX tumors was not detected based on histological evaluation, and metastasis was not reported to occur in these two models previously (19,20). These results support PYGO2 as a therapeutic target for PCa.

To explore the function of PYGO2 as a co-activator of the Wnt/ β -catenin pathway in the context of PCa, we compared the ability of PC3-shControl and PC3-shPYGO2 sublines to activate the Wnt/ β -catenin reporter TOPFlash (24) under conditioned medium from L Wnt-3A cells (25). As control, FOPFlash and conditioned medium from L cells were used. Interestingly, PYGO2 knockdown significantly reduced the Wnt-3A-induced TOPFlash activity (Fig. 7D). At the protein level, PYGO2 knockdown moderately decreased expression of β -catenin and Wnt/ β -catenin targets c-Myc and Met (Fig. 7E). PYGO2 knockdown affected little on H3K4me2 and H3K4me3 levels (Fig. 7E). Our results on the connection of PYGO2 with Wnt signaling was supported by the gene set enrichment analysis (GSEA) showing that Wnt pathway is enriched in both localized PCa and CRPC samples with high PYGO2 expression phenotype (Fig. 7F).

Discussion

In summary, through functional screen and analysis of recurrently amplified genes in PCa, we identified *PYGO2* as a PCa-promoting gene capable of driving disease progression and metastasis. Another candidate PCa gene located on 1q21.3, *CREB3L4* (a.k.a. AIBZIP, an androgen-regulated gene), has been reported as highly expressed in PCa (47). However, *CREB3L4* is distinct in that its expression is neither correlated with copy number gain (3) nor upregulated in metastatic PCa when we surveyed the 8 Oncomine datasets ($P > 0.5$ for all datasets). In fact, *CREB3L4* was not among the 60 of 178 genes located in 1q21.2-q22 with transcript levels correlated with copy number gain (3). From the 60 genes in 1q21.2-q22, 13 genes passed our gene selection filters and 6 genes (*ENSA*, *LYSMD1*, *RPRD2*, *FLAD1*, *KRTCAP2*, and *PYGO2*) were screened with available lentiviral ORFs. Only PYGO2 emerged as a functional hit in our tumor models. Our results indicate that PYGO2 promotes primary tumor growth, lymph node invasion and bone metastasis. Together, we conclude that PYGO2 is a key driver gene of 1q21.3 that is targeted for increased expression via copy number gain in PCa.

Hyperactivated Wnt signaling pathway has been increasingly identified to play important roles in promoting advanced prostate cancer, including the metastatic process and development of castration-resistant prostate cancer (48). Therefore, the implication of PYGO2 in Wnt pathway has significant clinical relevance. Future studies to investigate the molecular mechanism of PYGO2 in PCa progression will provide new opportunities to target lethal PCa. We envision at least two potential approaches to target PYGO2. First, the PHD finger in PYGO2 is responsible for binding to di- and trimethylated lysine 4 of histone H3 (H3K4me2/3). Therefore, small molecule inhibitors blocking the PHD finger (49) may serve as useful agents for PYGO2-overexpressed lethal PCa. Second, siRNAs that effectively downregulate PYGO2 *in vivo* may provide another avenue. siRNA or shRNA as therapeutics is being actively developed, although challenges remain in the delivery of these agents. That said, recent progress using exosomes to deliver siRNA or shRNA *in vivo* (50) marks a new direction for moving this idea forward.

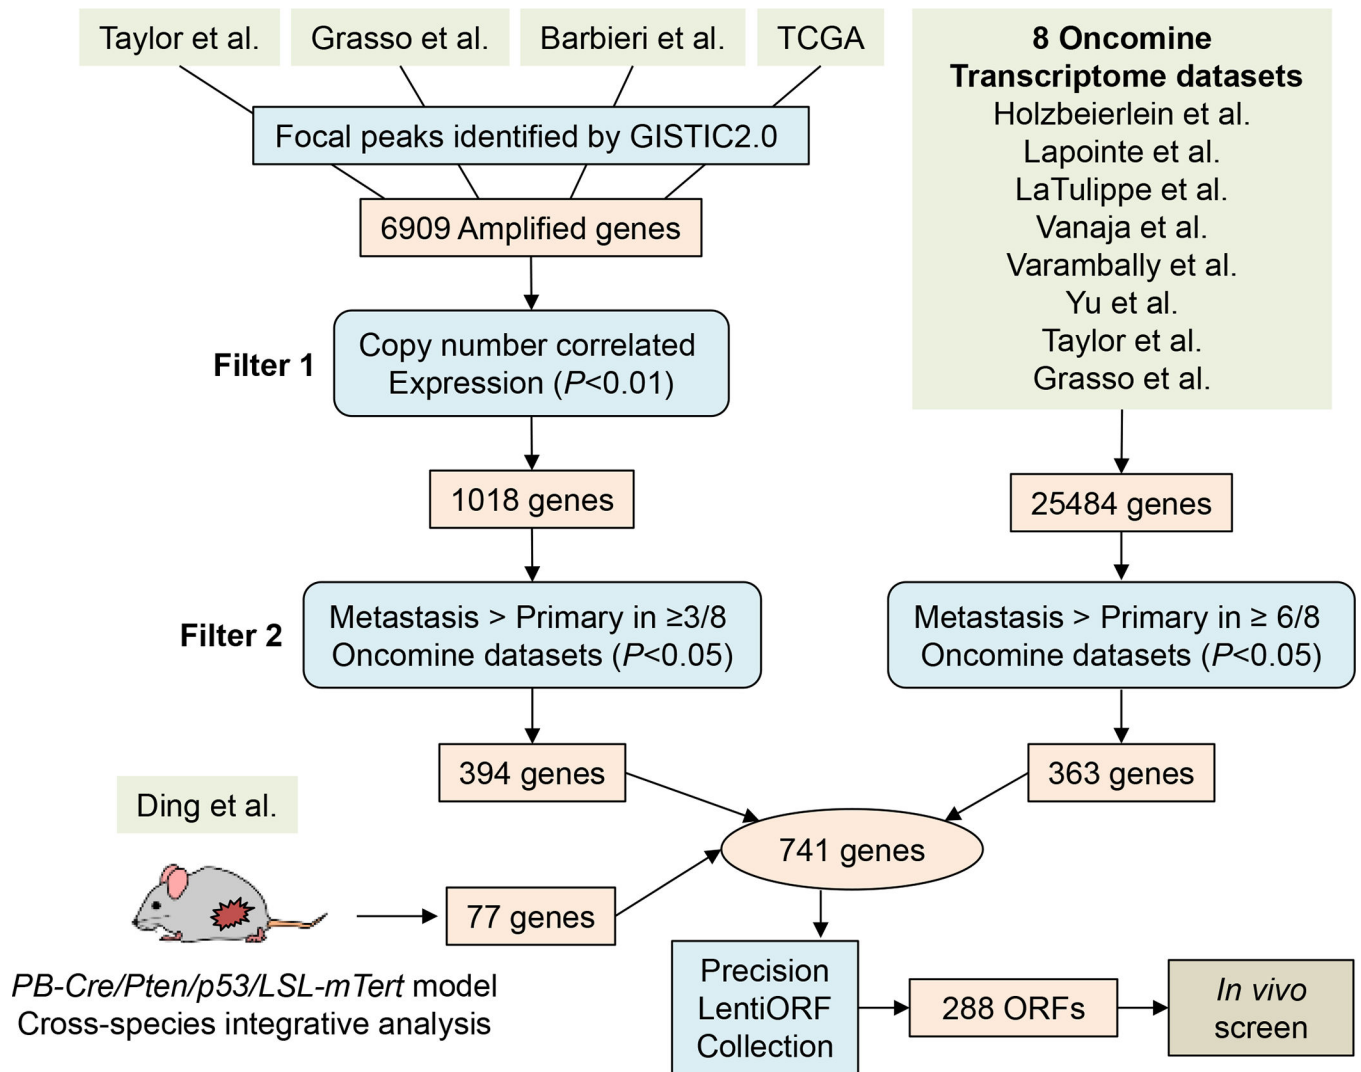

Figure 1. Oncogenomics-informed *in vivo* ORF screen.

Three sources of candidate PCa genes are integrated: 394 genes located in focal amplicons (4 genomics datasets) and expressed in correlation with copy number gain and metastasis phenotype (3/8 transcriptomic datasets); 363 genes upregulated in metastasis (6/8 transcriptomic datasets), and 77 genes from our published cross-species PCa genome analysis (36). Among the total 741 candidate genes, 288 ORFs corresponding to 276 genes were available for screening.

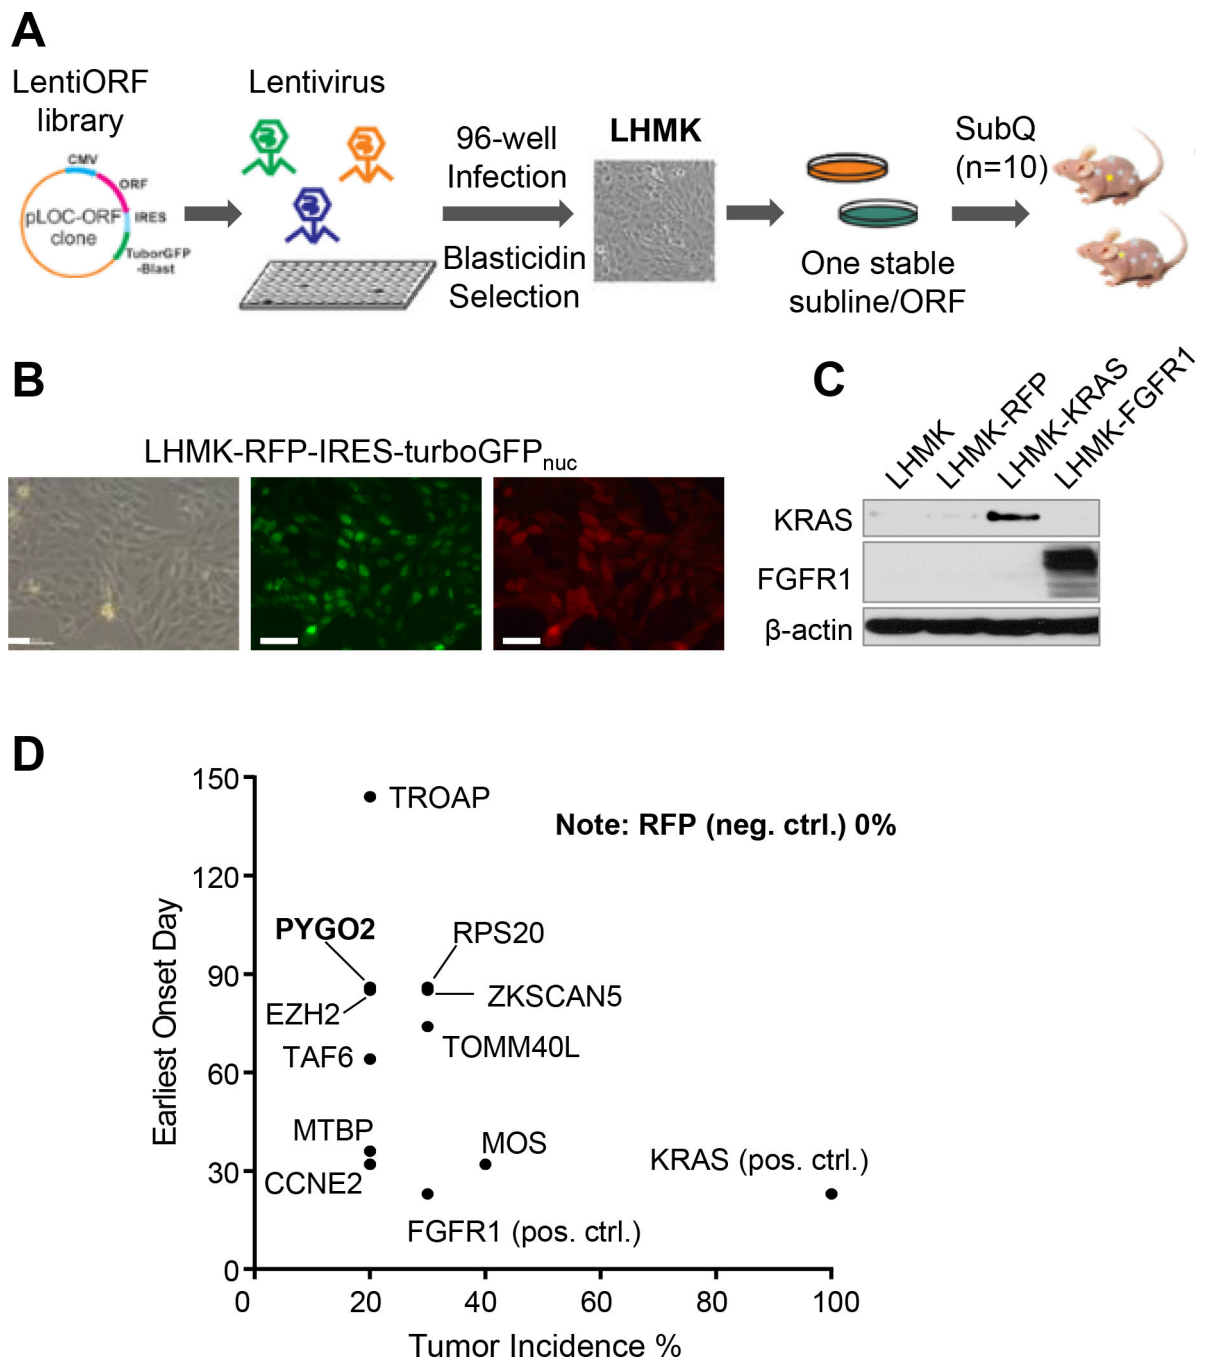

Figure 2. *In vivo* ORF screen identified genes promoting prostate tumorigenesis.

A, Procedure for lentivirus packaging, ORF stable overexpression in LHMK and *in vivo* tumorigenesis screen. **B**, Images of LHMK overexpressing the control vector RFP-IRES-turboGFP_{nuc}. Scale bar, 50 μ m. **C**, ORF-driven KRAS or FGFR1 overexpression in LHMK, confirmed with western blot. **D**, Top hits with 20% or higher incidence rate from the *in vivo* screen.

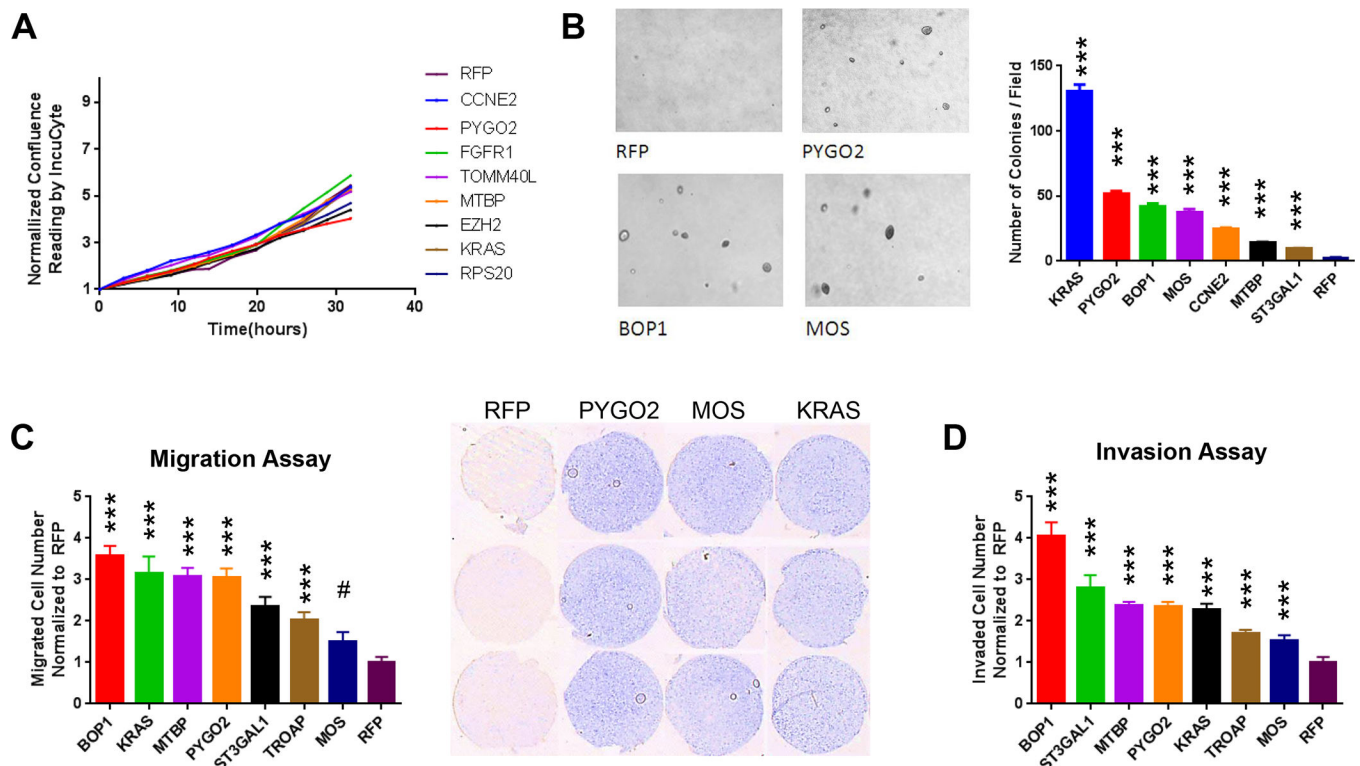

Figure 3. Candidate PCa genes promote soft agar colony formation, migration and invasion.

A, Normalized confluence curves on 2D culture for selected top hit genes showing modest change of cell proliferation. **B**, Significant increase of colony formation on soft agar by selected top hit genes compared with RFP control. **C**, Significant increase of cell migration by selected top hit genes compared with RFP control. **D**, Significant increase of cell invasion by selected top hit genes compared with RFP control. Representative images of invaded cells are shown.

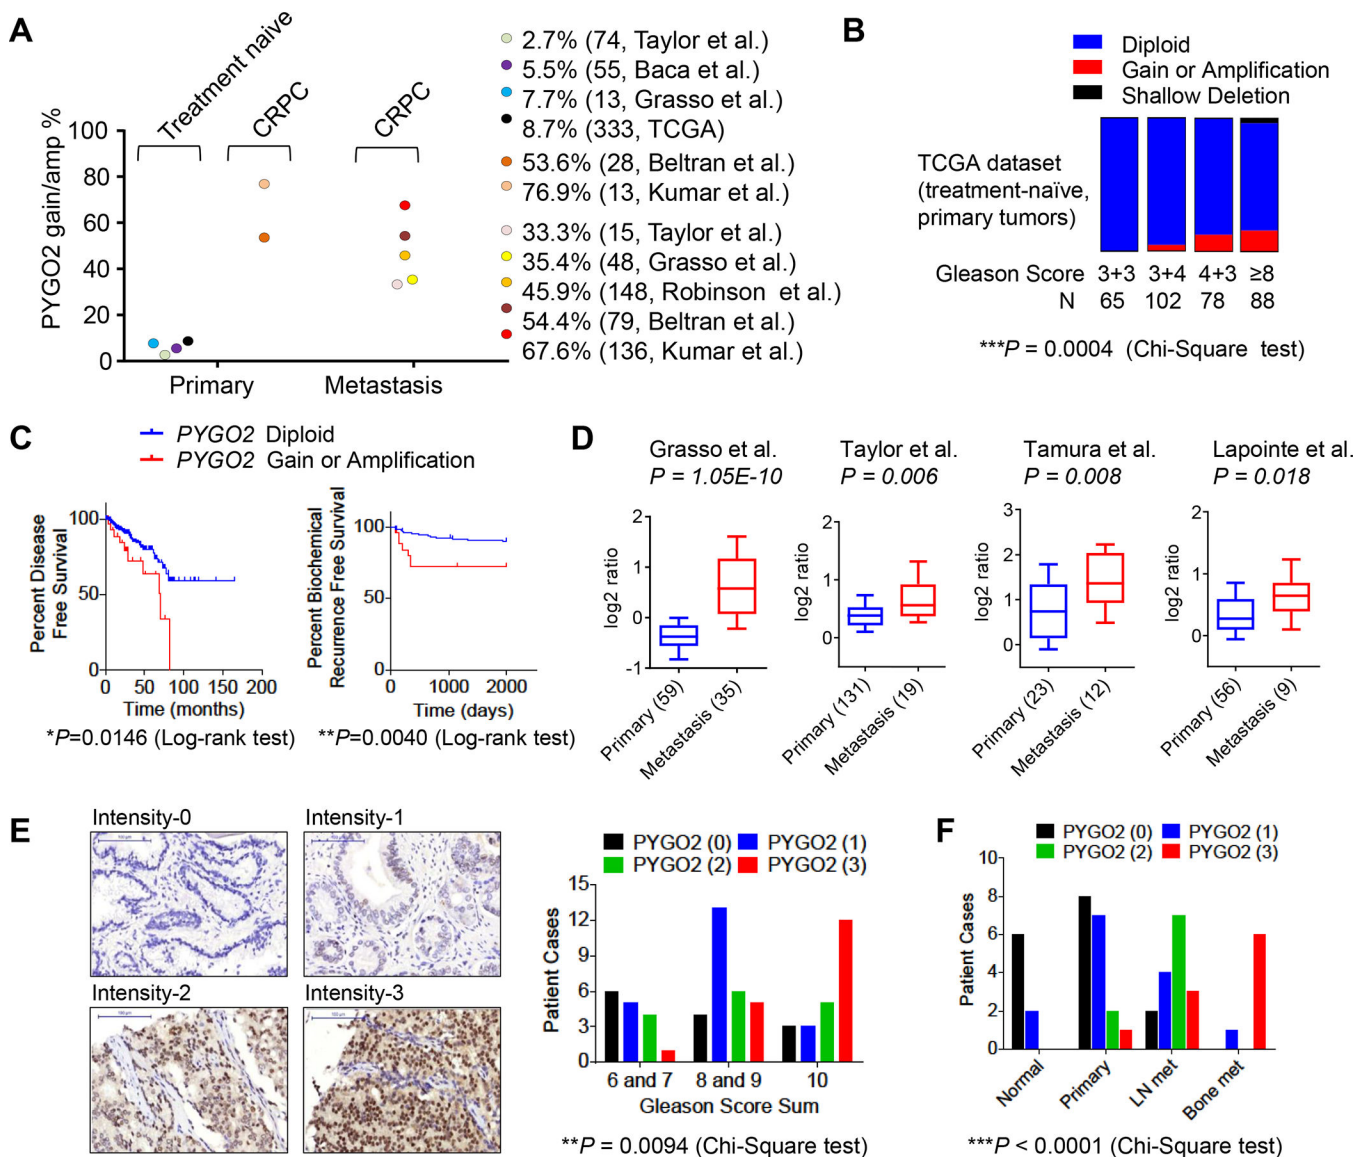

Figure 4. PYGO2 is amplified in PCa and correlates with higher Gleason score and metastasis.

A, Frequency of *PYGO2* copy number gain and amplification in a variety of PCa genomics datasets categorized by disease site and treatment. **B**, Fraction of *PYGO2* copy number status in different Gleason score categories in the TCGA dataset. **C**, Correlation of *PYGO2* copy number status with disease-free survival (n=329) or biochemical recurrence (n=281) in the TCGA dataset. **D**, *PYGO2* mRNA expression level in primary tumor and metastasis in 4 PCa studies with data compiled from Oncomine. **E**, In the TMA, *PYGO2* expression as measured by immunohistochemistry and plotted against Gleason grade categories. **F**, In an archived PCa clinical cohort from MD Anderson Cancer Center, *PYGO2* expression plotted against categories as normal prostate, primary prostate tumor, lymph node (LN) metastases and bone metastases.

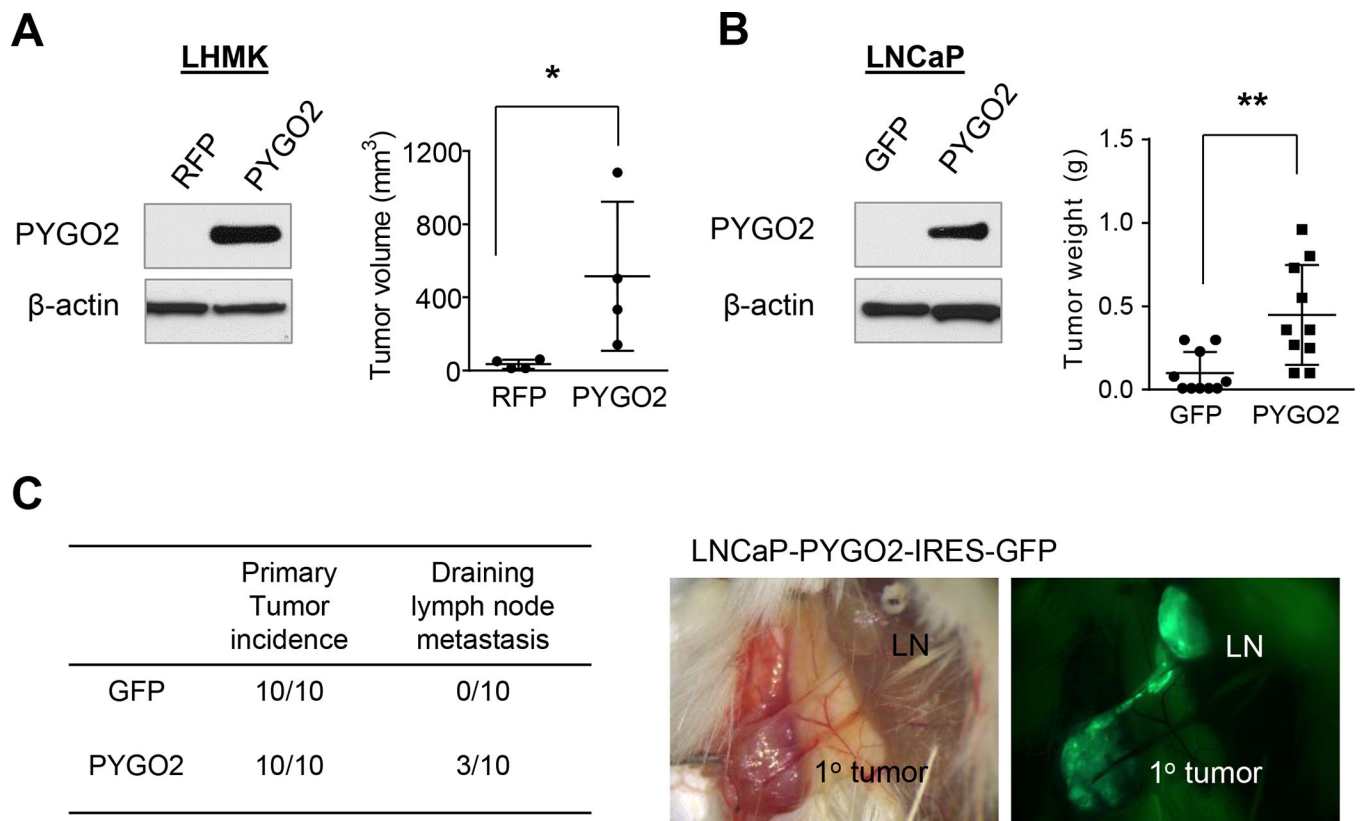

Figure 5. PYGO2 overexpression promotes PCa tumor growth and invasion to draining lymph nodes.

A, PYGO2 overexpression in LHMK cells significantly increased subcutaneous tumor growth in mice (n=4). **B**, PYGO2 overexpression in LNCaP significantly increased subcutaneous tumor growth in mice (n=10). **C**, Summary of tumor incidence by LNCaP sublines and fluorescence imaging showing the invasion of LNCaP-PYGO2-IRES-GFP from subcutaneous tumor to local draining lymph node. In (A) and (B), *P < 0.05, **P < 0.01, Mann-Whitney test.

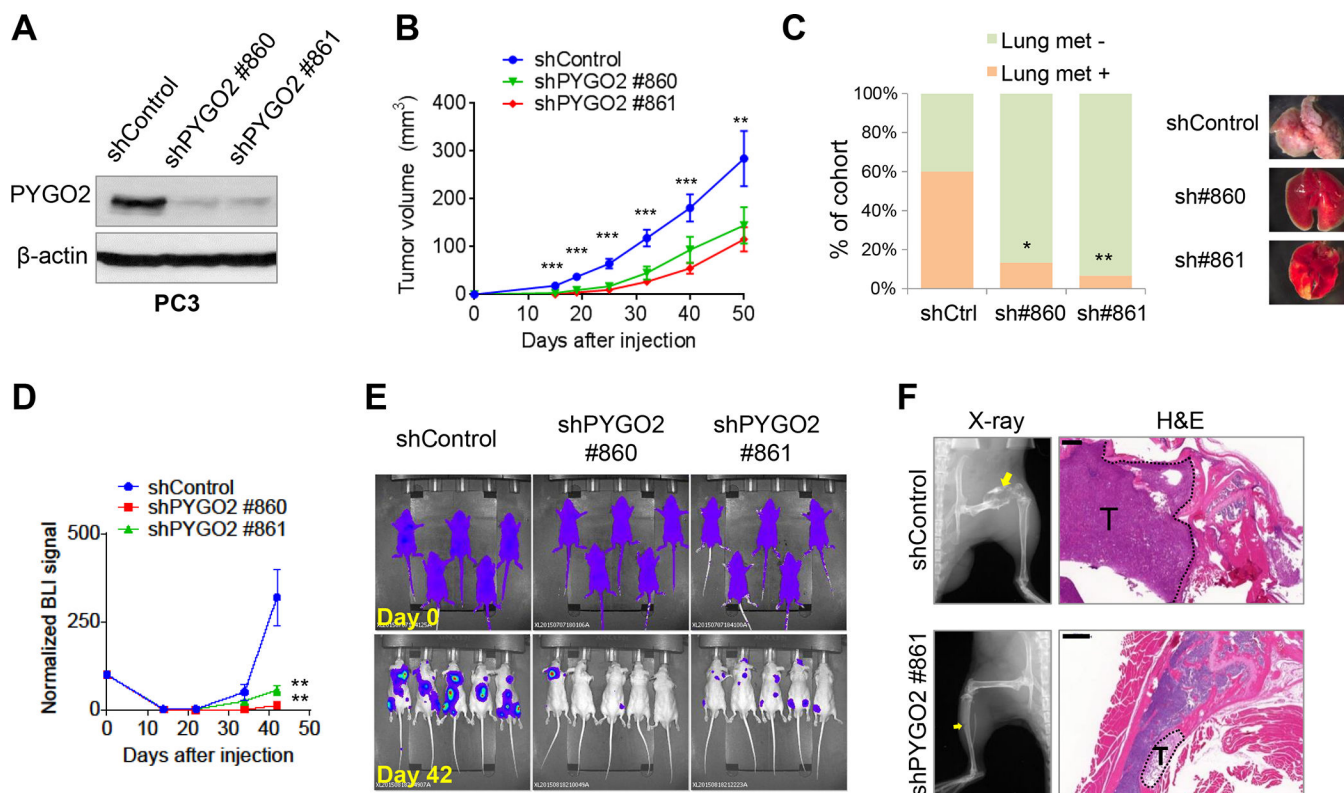

Figure 6. PYGO2 silencing reduces primary tumorigenicity and metastatic potential of PC3 cells. **A**, PYGO2 knockdown by two independent shRNA clones in PC3 shown by western blot. **B**, Significant decrease of subcutaneous tumor size by PYGO2 knockdown in PC3 (n=25 for each group). Data represent mean \pm SEM. **C**, Incidence of spontaneous lung metastasis from subcutaneous tumors formed by PC3 sublines (n=15 for each group). *P < 0.05, **P < 0.01, Fisher's exact test. **D,E**, Weakened bone colonization ability by PYGO2 knockdown in PC3-TR cells, shown by both bioluminescence signals (**D**, normalized to Day 0) and representative images (**E**, n=7 for each group). Data represent mean \pm SEM. **F**, Osteolysis in the long bones induced by PC3-TR sublines, shown by X-ray radiographs and H&E staining. Scale bar, 500 μ m.

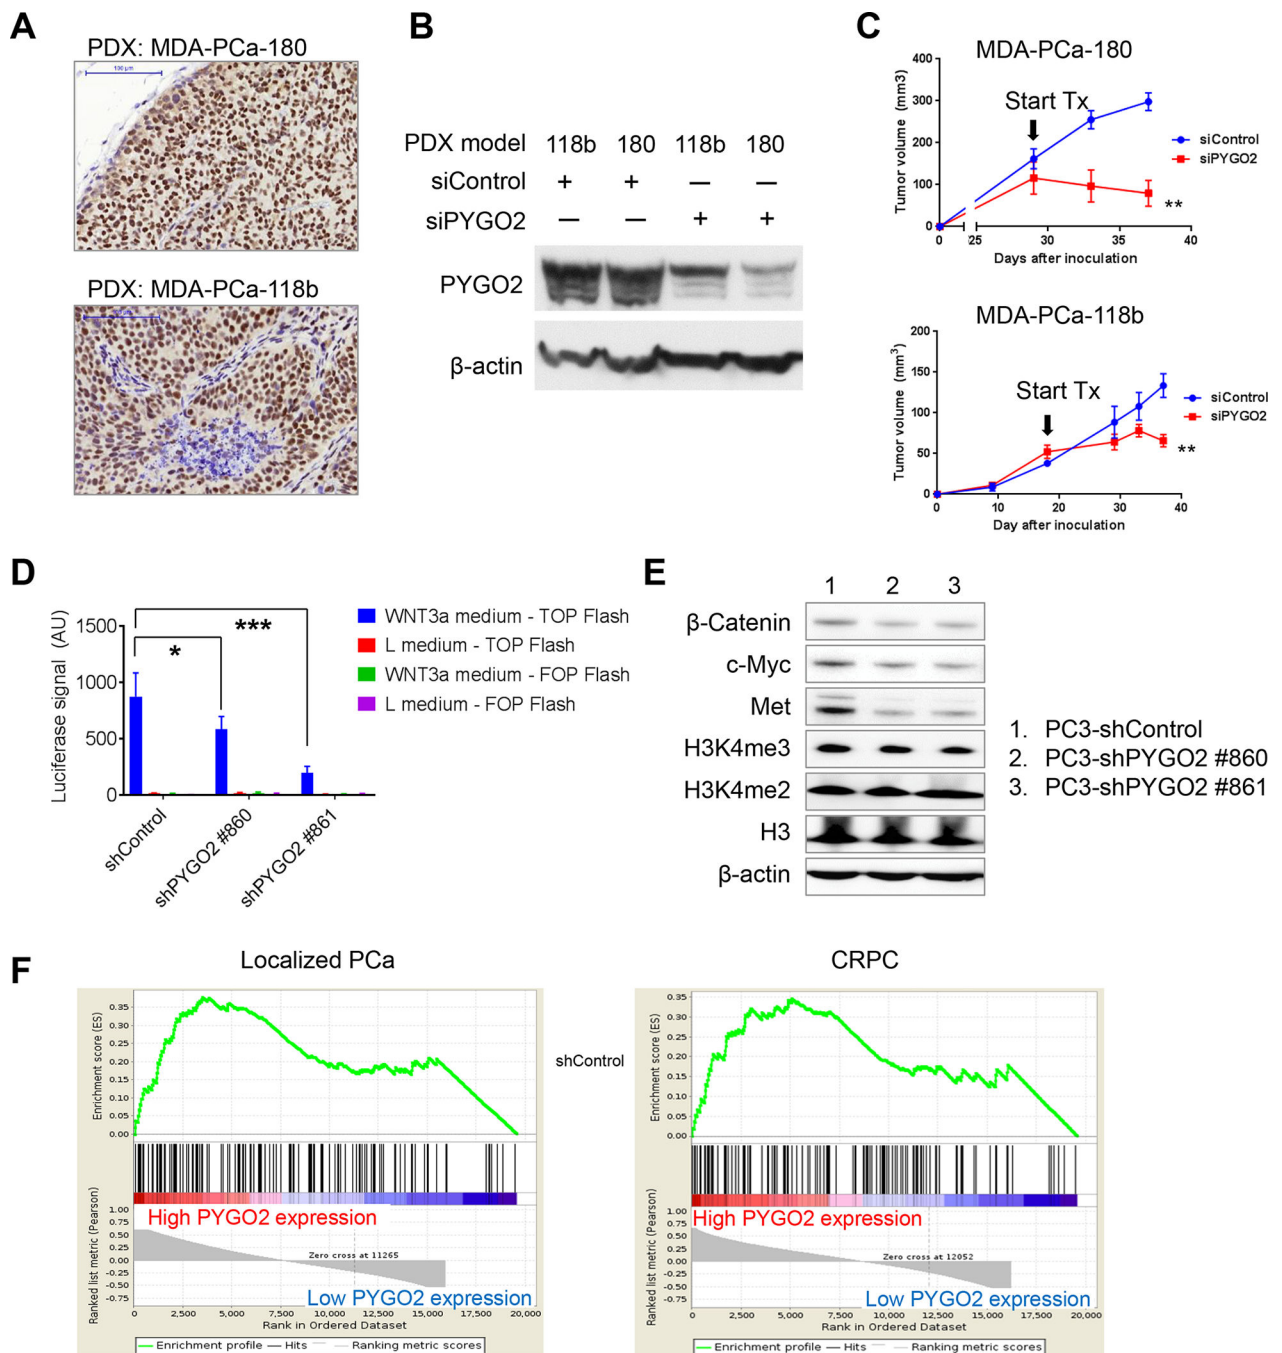

Figure 7. Intratumoral infusion of PYGO2 siRNA blocks prostate tumor growth in PDX models.

A, Strong nuclear expression of PYGO2 in two PDX models of CRPC, detected by IHC. Scale bar, 100µm. **B**, Reduction of PYGO2 level in two PDX models by PYGO2-targeting siRNA, detected by western blot. **C**, PYGO2-targeting siRNA (Sigma-Aldrich, SASI_HS01_00059018) impaired PDX tumor growth. Arrows indicate the start day for intratumoral siRNA infusion. **D**, Luciferase assay measuring effect of PYGO2 knockdown in PC3 on the response to Wnt-3A-mediated TOPFlash reporter activity. **E**, Effect of PYGO2 knockdown in PC3 on the expression of indicated proteins, detected by western

blot. **F**, GSEA analysis for transcriptomic samples. Samples from Grasso et al. (4), dichotomized by normalized expression level of the *PYGO2* probe A_23_P411953. KEGG Wnt pathway with 138 genes was the gene set for the analysis. Localized PCa and CRPC samples were analyzed separately, with FDR q-value being 0.051 and 0.070, respectively. Both FDR q-values are <0.25 , the recommended FDR cutoff value by the GSEA User Guide.
