Identifying playing talent in professional football using artificial neural networks

--Manuscript Draft--

Full Title:	Identifying playing talent in professional football using artificial neural networks
Manuscript Number:	RJSP-2019-0277R2
Article Type:	Special Issue
Keywords:	soccer; talent identification; Premier League; Championship; Artificial Intelligence
Abstract:	<p>The aim of the current study was to objectively identify position-specific key performance indicators in professional football that predict out-field players league status. The sample consisted of 966 out-field players from 2 seasons in the Football League Championship. Players were assigned to one of three categories (0, 1 and 2) based on where they completed most of their match time in the following season, and then split based into five positions. 340 performance, biographical and esteem variables were analysed using a Stepwise Artificial Neural Network approach. A Monte Carlo cross-validation procedure was used to avoid over-fitting and the neural network modelling involved a multi-layer perceptron architecture with a feed-forward back-propagation algorithm. The models correctly predicted between 72.7% and 100% of test cases (Mean prediction of models = 85.9%), the test error ranged from 1.0% to 9.8% (Mean test error of models = 6.3%). Variables related to passing, shooting, regaining possession and international appearances were key factors in the predictive models. This is highly significant as objective position-specific predictors of players league status could be used to aid the identification and comparison of transfer targets as part of the due diligence process in professional football.</p>

Response to Reviewers:	<p>Response to Reviewers – Journal of Sports Sciences</p> <p>Reviewer #4: I suggest highlighting in the discussion that the network does not merely predict the subjective scouting decisions, as you've explained in your response. Otherwise, I am satisfied with the revised version.</p> <p>Response</p> <p>The text in the discussion has been updated to answer your query around merely predicting subjective scouting decisions. Please provide feedback if you feel this is not sufficient or needs revision.</p> <p>Discussion</p> <p>The aim of the current study was to develop objective models that identified position-specific key performance indicators that predict out-field players league status. The artificial neural network created fifteen position-specific models to predict out-field players league status. The artificial neural network's ability to correctly classify more than 75% of the players league status for fourteen different position comparisons is a key result. The models were able to accurately predict the league status of players being transferred between different levels of competition and those who were promoted or demoted with their team. Therefore, they did not simply predict subjective scouting decisions.</p>

7 **Abstract**
8

9 The aim of the current study was to objectively identify position-specific key performance
10 indicators in professional football that predict out-field players league status. The sample
11 consisted of 966 out-field players who completed the full 90 minutes in a match during the
12 2008/09 or 2009/10 season in the Football League Championship. Players were assigned to
13 one of three categories (group 0, 1 and 2) based on where they completed most of their match
14 time in the following season, and then split based on five positions including full backs (n =
15 205), centre backs (n = 193), centre midfielders (n = 205), wide midfielders (n = 168) and
16 forwards (n = 195). 340 performance, biographical and esteem variables were analysed using
17 a Stepwise Artificial Neural Network approach. The models correctly predicted between 72.7%
18 and 100% of test cases (Mean prediction of models = 85.9%), the test error ranged from 1.0%
19 to 9.8% (Mean test error of models = 6.3%). Variables related to passing, shooting, regaining
20 possession and international appearances were key factors in the predictive models. This is
21 highly significant as objective position-specific predictors of players league status have not
22 previously been published. The method could be used to aid the identification and comparison
23 of transfer targets as part of the due diligence process in professional football.

38 **Introduction**
39

40 Coaches and decision makers in professional football have traditionally used subjective
41 observations to assess the performance of their team, to review the strengths and weaknesses
42 of future opponents and to identify potential signings (Carling, Williams and Reilly, 2005).
43 Match analysis research into the individual's performance in football has focused heavily on
44 the physical demands of the sport (Carling, 2013). Research led by sport scientists with a heavy
45 focus upon the physical aspects of performance in football has not managed to identify key
46 predictors of match outcome or team success (Bradley et al., 2016; Carling, 2013).

However, studies investigating physical performance during matches have also incorporated technical elements and provided some insights into the successful performance of players and teams (Bradley et al., 2013; Bradley et al., 2016; Dellal et al., 2010; Dellal et al., 2011). Technical factors have been identified that are prominent predictors of team success and match outcome. Shots, shots on target and ball possession are the most commonly reported predictors (Castellano, Casamachina and Lago, 2012; Lagos-Penas, Lago-Ballesteros, Dellal and Gomez, 2010; Liu, Gomez, Lago-Penas and Sampaio, 2015). There has been a heavy emphasis on the attacking aspects of play linked to success and more detailed analysis is required into the defensive aspects of play to gain a greater understanding of the game.

Following on from the research into team success and physical profiles, there has been an increasing interest in the technical profiles of players. Studies have found positional differences in Ligue 1 in France, the Premier League in England and in Spain's La Liga (Dellal, Wong, Moalla and Chamari 2010; Dellal et al., 2011). The development of advanced computer systems has supported a greater understanding of position profiles in football. However, most of the research to date has used subjective methods to select variables for analysis (Taylor, Mellalieu and James, 2004) or they have replicated indicators used in other studies (Andrzejewski, Konefal, Chmura, Kowalczyk and Chmura, 2016). Using subjective criteria selection rather than exploring a broad spectrum of the data points has meant that many variables have yet to be assessed. Therefore, the impact of these variables upon playing success and career progression is unknown.

A broader analysis of player performance and career progression has been provided by using artificial neural networks to assess a wide range of variables (Barron, Ball, Robins and Sunderland, 2018). Artificial neural networks have been shown to be better at identifying

1
2
3
4
5
6
7 patterns in complex non-linear data sets than forms of regression analysis and they are capable
8 of generalizing results to solve real world problems (Basheer and Hajmeer, 2000; Lancashire,
9 Lemetre and Ball, 2009; Tu, 1996). In a football context, artificial neural networks have been
10 shown to be capable of creating models that can differentiate between specific groups and
11 identify key variables that predict career progression (Barron et al, 2018). Previous studies
12 though have been limited by assessing players regardless of position and their accuracy could
13 be improved by making assessments of each position and the creation of position-specific
14 career progression models.

23
24 To the authors' knowledge there has not been an objective study carried out to develop a
25 position-specific predictive model that could support the scouting and recruitment process in
26 professional football. The efficient and effective identification and assessment of transfer
27 targets is a key aspect of any professional football club and requires a thorough due diligence
28 process. Therefore, the aim of the current study was to develop an objective model to identify
29 position-specific key performance indicators in professional football that predict out-field
30 players league status using an artificial neural network.

38 **Methods**

39 **Players and Match Data**

40
41
42 The basis of the current study followed Barron *et al's* (2018) method but looked to build on it
43 and focus on position-specific assessments of players. The sample consisted of 966 out-field
44 players (mean \pm SD age and height: 25 \pm 4 yr, 1.81 \pm 0.06 m) who had completed a full 90
45 minutes in the English Football League Championship during the 2008/09 and 2009/10 seasons
46 (Table 1). Technical performance data and biographical data was collected using ProZone's
47 MatchViewer software (ProZone Sports Ltd., Leeds, UK), the official Football League website

3
4
5
6
7 (www.efl.com) and Scout7 Ltd's (Birmingham, UK) site. The Prozone MatchViewer system
8
9 was used to collect performance data due to its accurate inter-observer agreement for the
10
11 number and type of events (Bradley, O'Donoghue, Wooster and Tordoff, 2007). The data
12
13 collected from the Prozone MatchViewer software was made available by STATS LLC
14
15 (Chicago, USA). Institutional ethical approval was attained from the Non-Invasive Human
16
17 Ethics Committee at Nottingham Trent University.

18
19
20 In total, 536 variables were collected in including the total number, accuracy (% success),
21
22 means, medians and upper and lower quartiles of passes, tackles, possessions regained,
23
24 clearances and shots. Additional data on total appearances, playing percentage, total goals and
25
26 assists, international appearances and heights was also collected. The data set originally
27
28 included 536 variables but low variance statistics were removed. After removing low variance
29
30 data points, the data set included 340 variables for comparison. Each player's data was
31
32 converted into mean 90-minute performance data before they were assigned to one of three
33
34 categories (group 0, group 1 and group 2).

35 36 **Player Grouping**

37
38
39 Players were allocated to one of five positions (full back, centre back, wide midfielder, central
40
41 midfielder or attacker) based on where they spent most of their playing time during the season
42
43 (See Table 1). They were then assigned to one of three categories (group 0, group 1 and group
44
45 2) based on where they went on to complete most of their match time during the following
46
47 season. The first category (group 0) included the players who completed most of their match
48
49 time in a lower league during the following season. The second group (group 1) included those
50
51 players who completed most their match time in the English Football League Championship
52
53 during the following season and the final category (group 2) contained the players who

7 progressed to complete most their match time in the English Premier League during the
8 following season.
9

10
11
12 Sample sizes for each comparison were balanced to have an equal number of cases using a
13 random number selector (i.e. 24 full backs were selected from group 0 to have an equal number
14 of cases for comparisons to group 2). Players who played on loan during the 2008/09 and
15 2009/10 seasons were included in the study but players who moved to a club outside England
16 were excluded due to the complications in assessing the merits of foreign competitions against
17 those in England. The five positions for each category of playing status were subsequently
18 analysed using a Stepwise Artificial Neural Network approach to identify the optimal
19 collection of variables for predicting playing status.

25
26

27 28 29 **Artificial Neural Network Model** 30

31
32 The artificial neural network modelling was based on the approach previously used in gene
33 profiling with breast cancer data (Lancashire et al., 2009) and used in assessing player
34 performances in the Football League Championship (Barron et al., 2018). It used in house code
35 written in Microsoft visual basic 6 to call Statistica 10.0 (Statsoft Inc., Tulsa, USA) artificial
36 neural network model at each loop of the stepwise procedure and output the results in a text
37 format.
38
39
40
41
42
43

44 Before training the artificial neural network, the data was randomly split (60% for training
45 purposes, 20% for validation and 20% blind test cases). A Monte-Carlo cross validation
46 procedure was used to avoid over-fitting of the data. The artificial neural network modelling
47 involved a multi-layer perceptron architecture with a feed-forward back-propagation
48 algorithm. This algorithm used a sigmoidal transfer function and weights were updated by

7 feedback from errors. Results were provided for the average test performance and the average
8 test error. The average test performance indicates the percentage of test cases that are correctly
9 predicted. The average test error is the root mean square error for the test data set, this indicates
10 the difference between the values predicted by the model and the actual values of the test data
11 set (Salkind, 2010). Further information on the artificial neural network model can be viewed
12 in the supplementary information.

19

20 **Results**

21
22 Analysis using the artificial neural network created fifteen position-specific models to predict
23 out-field player's league status. The models correctly predicted between 72.7% and 100% of
24 test cases (Mean prediction of models = 85.9%), the test error ranged from 1.0% to 9.8% (Mean
25 test error of models = 6.3%). Fourteen models correctly predicted 75% or more of the test
26 players league status with an error of 9.6% or less (Table 2). The fifteen models, created in
27 total, contained between five and twenty variables to predict the players league status with 134
28 variables in total being required to make the position models. The most prominent set of
29 variables were those related to the players passing ability, with 48 of the 134 variables (35.8%)
30 being passing statistics. The next most prominent type of variable was related to players
31 shooting. In total, twenty variables (14.9%) related to shooting were selected in the models.
32 Statistics related to regaining possession accounted for eleven of the variables (8.2%) selected.
33 Variables related to international appearances were selected nine times (6.7%). A full outline
34 of the categories of variables selected can be viewed in full (Table 3).

48 **Full Back Models**

49
50 The performance of the full back models as a group were the lowest of the five positions
51 (Average test performance = 78.4% ± 8.0% and average test error = 8.6% ± 1.7%) (Table 4).

2
3
4
5
6
7 The group 0 v1 comparison had the lowest average test performance and highest test error out
8 of all the models created (Average test performance = 72.7% and average test error = 9.8%).
9
10 Total appearances and mean percentage of backwards passes successful were key variables in
11 the model (Table 5). The group 1 v 2 comparison had an average test performance of 75% and
12 a test error of 9.3%. The percentage of sideways passes successful (upper quartile) and median
13 total shots were the most prominent variables in the model (Table 6). The best full back model
14 was for group 0 v 2 which had an average test performance of 87.5% and a test error of 6.6%.
15
16 The mean goals scored and minimum headers were the two most prominent factors in the model
17 (Table 7).
18
19
20
21
22
23
24
25

26 **Centre Back Models**

27 The performance of the centre back models as a group had an average test performance of
28 94.4% \pm 5.1% and an average test error of 3.5% \pm 2.3%. The group 0 v 1 model had an average
29 test performance of 93.3% and an average test error of 4.1% using twenty variables. The
30 percentage of successful passes in the opposition half (upper quartile) and shooting accuracy
31 (upper quartile) were the most prominent variables in the model (Table 8). The group 1 v 2
32 model had the lowest average test performance and highest test error of the three centre back
33 models (average test performance = 90.0% and average test error = 5.5%). Backwards passes
34 (lower quartile) and maximum short passes were the top two factors in the model (Table 9).
35
36 The group 0 v 2 model had the highest average test performance of any model and the lowest
37 test error of any model (average test performance = 100% and test error = 1.0%). The group 0
38 v 2 centre back model contained eighteen variables with 0-6 assists mean (group 0 = 0.1 \pm 0.1,
39 group 2 = 0.2 \pm 0.1), mean shots on target inside the box (group 0 = 0.2 \pm 0.2, group 2 = 0.3 \pm
40 0.2) and minimum penalty area entries (Group 0 = 0.2 \pm 0.4, Group 2 = 0 \pm 0) being key
41 variables (Table 10).

7 **Wide Midfielder Models**
8

9 The wide midfield models group average test performance was $84.8\% \pm 13.2\%$ with an average
10 test error of $6.3\% \pm 2.5\%$. The group 0 v 1 model had an average test performance of 79.4%
11 and a test error of 8.2%. The maximum percentage of unsuccessful headers and forward passes
12 successful (upper quartile) were the biggest predictors in the model (Table 11). The group 1 v
13 2 model had an average test performance of 77.8% and a test error of 7.4%. U21 international
14 caps and median forward passes unsuccessful were the most prominent factors in the model
15 (Table 12). The group 0 v 2 model had the second highest average test performance and third
16 lowest test error of all the models created (average test performance = 100% and a test error of
17 3.4%). The group 0 v 2 wide midfielder model contained six variables including: total goals
18 (group 0 = 1.4 ± 1.9 , group 2 = 5.5 ± 3.8), passes attempted opposition half upper quartile
19 (group 0 = 16.2 ± 6.3 , group 2 = 21.4 ± 5.8), fouls in the defensive third mean (group 0 = 0.2
20 ± 0.2 , group 2 = 0.3 ± 0.3), total shots on target (excluding blocked) maximum (group 0 = 1.0
21 ± 0.8 , group 2 = 2.6 ± 1.1), % forward passes successful mean (group 0 = $53.4\% \pm 14.8\%$,
22 group 2 = $55.2\% \pm 9.7\%$) and forward passes successful median (group 0 = 5.0 ± 3.2 , group 2
23 = 6.1 ± 2.2) (Table 13).

33
34
35
36
37

38 **Centre Midfielder Models**
39

40 The best overall average was for the centre midfielder's models as a group (Average test
41 performance = $86.1\% \pm 6.6$ and average test error = $6.8\% \pm 2.5$). The group 0 v 1 model had
42 the lowest average test performance of the centre midfield models and had the second highest
43 test error across all models (Average test performance = 78.6% and average test error = 9.6%).
44 Fouls and maximum first time passes were the most prominent variables in the model (Table
45 14). The group 1 v 2 model had an average test performance of 88.9% and a test error of 5.9%.
46 Successful passes (lower quartile) and penalty area entries (lower quartile) were two key

6
7 variables in the model (Table 15). The group 0 v 2 model had an average test performance of
8 90.9% and a test error of 4.8%. The number of starts and maximum shots on target outside the
9 box were the highest predictors in the model (Table 16).
10
11

12 **Attacker Models**

13
14 The performance of the attacker models as a group had an average test performance of 84.7%
15 $\pm 6.6\%$ and an average test error of $6.2\% \pm 3.2\%$. The group 0 v 1 model had an average test
16 performance of 80% and an average test error of 8.7%. The most prominent variables in the
17 model were international caps and the number of touches (lower quartile) (Table 17). The group
18 1 v 2 model had an average test performance of 81.8% and a test error of 7.2%. U21
19 international caps and international caps were the two most important factors in the model
20 (Table 18). The best average test performance for an attacker model was recorded for the group
21 0 v 2 model and it had the lowest overall test error of all models (average test performance =
22 92.3% and test error = 2.6%). The group 0 v 2 attacker model contained ten variables with total
23 goals (group 0 = 2.7 ± 3.0 , group 2 = 10.0 ± 6.2), blocks upper quartile (group 0 = 1.0 ± 0.5 ,
24 group 2 = 1.5 ± 0.7) and short passes minimum (group 0 = 4.9 ± 2.5 , group 2 = 4.3 ± 2.4) being
25 key variables (Table 19).

40 **Model Comparisons**

41
42 The models produced comparing positions for group 0 v 1 had the lowest overall average test
43 performance and highest test error (mean test performance = $80.8\% \pm 7.6\%$ and average test
44 error = $8.1\% \pm 2.3\%$). The overall average test performance across all five positions for group
45 1 v 2 comparisons was $82.7\% \pm 6.6\%$ and the average test error was $7.1\% \pm 1.5$. The highest
46 overall average test performance across the five positions was for group 0 v 2 (mean test
47 performance = $94.1\% \pm 5.6\%$ and average test error = $3.7\% \pm 2.1\%$) (Table 20). The top three

17 **Discussion**

18
19 The aim of the current study was to develop objective models that identified position-specific
20 key performance indicators that predict out-field players league status. The artificial neural
21 network created fifteen position-specific models to predict out-field players league status. The
22 artificial neural network's ability to correctly classify more than 75% of the players league
23 status for fourteen different position comparisons is a key result. The models were able to
24 accurately predict the league status of players being transferred between different levels of
25 competition and those who were promoted or demoted with their team. Therefore, they did not
26 simply predict subjective scouting decisions.
27
28
29
30
31
32
33
34
35

36
37 The results surpass the previous prediction rates reported using artificial neural networks in
38 other team sports, such as those undertaken in cricket (Iyer and Sharda, 2009; Saikia,
39 Bhattacharjee and Lemmer, 2012). Their studies could predict classification of batsmen and
40 bowlers with accuracy levels ranging from 49% to 77%. In individual sports, artificial neural
41 networks have been able to predict 80.2% of gymnast's future classifications based on a multi-
42 dimensional testing process (Pion, Hohmann, Liu, Lenoir and Segers, 2017). Therefore, the
43 current artificial neural network prediction rates are among the highest reported to date in an
44 athlete classification study.

Passing Variables

The most prominent set of variables were those related to the players passing ability, with 48 of the 134 total variables included in models (35.8%) being passing statistics. Many passing variables have been highlighted previously as key indicators when differentiating between players of various playing levels and linked to team success (Bradley et al., 2013; Rampinini, Impellizzerie, Castagna, Coutts and Wisloff, 2009). Comparisons between players within the English football pyramid showed that players in the Premier League performed a greater number of total passes, successful passes and forward passes (Bradley et al., 2013). Out of the 48 passing variables identified in the models, 29 were related to the success of the passing variables. The passing variables related to their success were a mixture of 27 different statistics accounting for the direction (forwards, sideways and backwards) of the pass, the origin of the pass (own half or opposition half) and the mean, median, minimum, maximum and upper and lower quartile figure for different variables.

In further agreement with Bradley and colleagues (2013) findings, thirteen of the passing variables were related to forward passing. Forward passes have been shown to have the lowest chance of success when compared to sideways or backwards passes (Szczepanski and McHale, 2016). Yet, to create scoring opportunities and in turn score goals players are required to progress the play with forward passing. Variables relating to forward passes appeared in models for full backs (group 0 v 1 and group 0 v 2), centre backs (group 0 v 1), wide midfield (group 0 v 1, group 1 v 2 and group 0 v 2), centre midfield (group 0 v 1 and group 0 v 2) but did not feature prominently in any models for attackers. This would appear logical as attackers play in more advanced areas and have fewer opportunities to perform forward passes. The prevalence of forward passing variables for a number of positions and different comparisons highlights its importance in playing success.

1
2
3
4
5
6
7 The current study also highlighted two variables related to short passing with the maximum
8 and minimum variables being selected in two models (group 1 v 2 centre back and group 0 v 2
9 attacker). Research into factors that distinguish between top four and bottom four English
10 Premier League teams highlighted short passes as a key variable (Adams, Morgans,
11 Sacramento, Morgan and Williams, 2013). Specifically, the mean frequency of successful short
12 passes played by centre backs and full backs was the biggest factor differentiating between the
13 two groups.
14
15
16
17
18
19
20
21

22 Using the artificial neural network methodology has highlighted some overlap between factors
23 previously identified by research articles. The current study has also identified novel findings
24 for variables that have not previously been analysed or identified as key variables. Eight
25 passing variables were related to those in the opposition half and they appeared in six different
26 position models (group 0 v 1 centre back, group 0 v 1 and 0 v 2 centre midfield, group 0 v 1
27 and 0 v 2 wide midfield and 0 v 2 attacker models). Six of the variables were also related to
28 first time passes played and they appeared in the group 0 v 1 and 0 v 2 centre back, group 1 v
29 2 full back, group 0 v 1 and 1 v 2 centre midfield and group 0 v 1 attacker models. Passes in
30 the opposition half indicate possession taking place in more offensive pitch locations and could
31 indicate the involvement of players in attacking moves. The ability to pass the ball accurately
32 over a range of distances and directions is a key factor in performance and for differentiating
33 between players of varying ability. This is accepted knowledge amongst coaches but the
34 models have accurately identified specific key variables and provided an objective assessment
35 of their impact on league status.

65

Shooting Variables

The next most prominent type of variable was related to players shooting ability. In total, twenty variables (14.9%) related to shooting were selected in the models. This agrees with previous research into team success in football, with total shots and shooting accuracy being the most commonly reported predictors in matches (Castellano et al., 2012; Lagos-Penas et al., 2010; Liu et al., 2015). Surprisingly, all positions except attacker included shooting variables in the models created in the current study. However, one of the attacker models (group 0 v 2) did include total goals as a key variable. Many teams now prefer to play with one lone attacker in their line-up that spreads the need for scoring goals throughout the team and the requirements of the centre forward position could be changing as a result (Adams et al., 2013).

Attacking Entries

Other attacking variables selected as part of the models were related to crossing and entries into the final third and penalty area. Final third and penalty area entries were selected three times and in three different models. Crosses are a factor that have been repeatedly identified as being key to differentiating between successful and unsuccessful teams (Lagos-Penas *et al.*, 2010; Lagos-Penas *et al.*, 2011). They have not been identified as key when differentiating between players of different performance levels previously, they were only selected twice in the current study meaning they did not play a prominent role in the position models. The mean number of crosses were selected in the group 0 v 2 attacker model (crosses mean group 0 1.0 \pm 0.8, group 2 1.75 \pm 1.23). The inclusion of the number of crosses in the attacker model and the higher values reported for group 2 may offer more evidence for the evolving role of the attacker.

1
2
3
4
5
6
7 As well as crosses, final third and penalty area entries were selected three times and in three
8 different models. Previous research has indicated that penalty area entries differentiate between
9 winning and losing teams (Ruiz-Ruiz, Fradua, Fernandez-Garcia and Zubillaga, 2013).
10
11 However, in the current study they were selected in one model for centre backs (group 0 v 2),
12
13 the centre backs from players dropping down to a lower playing level reported higher values
14
15 (minimum penalty area entries group 0 0.2 ± 0.4 , group 2 0.0 ± 0.0). The identification of
16
17 minimum penalty area entries in the centre back model and group 0 having a higher value is a
18
19 novel finding. It may appear counter intuitive but centre backs who drop down to a lower level
20
21 may play in teams who use a more direct style of play and play longer passes from their centre
22
23 backs as opposed to building the play with shorter passing combinations.
24
25

26 27 **Defensive Variables**

28
29 The models also highlighted several defensive variables as key predictors of league status.
30
31 Statistics related to regaining possession accounted for eleven of the variables (8.2%). Previous
32
33 research into match outcomes and players technical and tactical ability has heavily focused on
34
35 the attacking aspects of play (Mackenzie and Cushion, 2013), passing (Adams et al., 2013;
36
37 Szczepanski and McHale, 2016) and possession (Castellano et al., 2012; Collett, 2013; Lagos-
38
39 Penas et al., 2010; Liu et al., 2015). A limited number of defensive variables have been
40
41 researched or identified that are linked to success. A balanced defensive shape (Tenga, Holme,
42
43 Ronglan and Bahr, 2010), defensive reaction after losing possession (Vogelbein, Nopp and
44
45 Hokelmann, 2014) and regaining possession in the final third have been identified previously
46
47 (Almeida, Ferreira and Volossovitch, 2014).
48

49
50 The current study highlighted possession won based on the minimum, median, maximum and
51
52 upper quartile variables as being key predictors of league status. Possession gained upper
53
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4
5
6
7 quartile and interceptions median and maximum were also selected as key variables in models.
8
9 The defensive variables were not selected as part of any of the full back models. They were
10 commonly selected as part of the wide midfield (group 0 v 1 and group 1 v 2) and attacker
11 models (group 1 v 2 and group 0 v 2). This may appear counter intuitive and these factors
12 would not normally be assessed when profiling more attacking positions within the team.
13
14 Modern playing philosophies valuing high pressing tactics from forward players to regain
15 possession in more advanced areas of the pitch, this may explain the importance of these factors
16 in wide midfield and attacker models within the current study (Perarnau, 2014).
17
18
19
20
21
22

23 **International Recognition**

24
25 Other key variables selected throughout several models relate to international appearances,
26 international caps and U21 international caps were selected nine times (6.7%) in total. This is
27 a novel finding as previous assessments of player's performances have limited themselves to
28 match performance and season totals of performance data. Previous research into international
29 recognition and team or playing success has not been undertaken to the author's knowledge.
30
31 However, international recognition has been found to be linked with player salary allocation,
32 particularly at the higher levels of the game (Frick, 2011).
33
34
35
36
37
38
39

40 **Position-Specific Models**

41
42 The current study created a number of strong predictive models for player's league status, there
43 were also some key findings relating to the prediction rates of specific positions. Three of the
44 five positions had very similar levels of classification accuracy (centre midfield 86.1%, wide
45 midfield 85.7% and attacker 84.7%) but the full back position's overall accuracy was only
46
47 78.4% and the centre back position's overall accuracy was 94.4%. The full back results are still
48
49 an important finding but below the levels reported for other positions. The group 0 v 1 full back
50
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4
5
6
7 model had the lowest classification accuracy of all the models and the group 1 v 2 full back
8
9 model had the second lowest classification accuracy. The full back position is one that requires
10
11 a complex set of technical and tactical skills as it requires a wide array of attacking and
12
13 defensive qualities (Bush, Archer, Hogg and Bradley, 2015).
14
15

16 Recent evaluations of the changes within performance data for playing positions has shown
17
18 extensive changes over time in the Premier League (Bush et al., 2015). Pronounced increases
19
20 were found for the levels of high-speed running and the distances covered while sprinting, with
21
22 full backs showing the largest increases between 2006-07 and 2012-13 (Bush et al., 2015).
23
24 Therefore, the full back position may be influenced more by the physical aspects of
25
26 performance. This could explain the lower prediction rates for full backs due to the lack of
27
28 physical tracking data being available.
29
30

31 **Study Limitations**

32
33 Strong models were identified for fourteen out of the fifteen position comparisons assessed but
34
35 there are some limitations to the present study that should be addressed in future research. The
36
37 match running performance data for players was not available for the current study. There is
38
39 an acceptance amongst the sports science community that running performance is not a
40
41 predictor of team success or match outcome (Bradley et al., 2016; Carling, 2013). However,
42
43 including match running performance data could provide a higher level of classification
44
45 accuracy for some of the positions assessed. Another limitation of the study is the lack of
46
47 contextual data available and the inability of the data to provide a detailed assessment for off
48
49 the ball parameters. The final limitation of the study relates to the sample size for players
50
51 progressing to play in the Premier League. The samples for the players progressing from the
52
53 five positions to play in the Premier League were the smallest of all the groupings. Statistical

5
6
7 power tests on similar sample sizes have reached the required levels (Lancashire et al., 2009).
8
9 However, future studies should look to increase the sample available to increase confidence
10
11 that the results are repeatable to new cases.
12
13

14 **Conclusions**

15
16
17 The current study has shown that artificial neural networks are a valid and highly effective tool
18
19 to classify and predict players league status. Fourteen models across all five positions were
20
21 created that provided strong prediction accuracy levels for players league status. This is an
22
23 important result as it outlines an objective methodology that can aid the scouting and
24
25 recruitment process in professional football. The process of identifying and recruiting players
26
27 in professional football has largely been a subjective process in the past. Further research
28
29 should look to combine assessments of physical and technical performance data to provide a
30
31 more accurate prediction of league status. Studies should also look to create models to predict
32
33 the career progression of players from multiple leagues to provide a better practical tool for
34
35 scouting and recruitment purposes. The combination of subjective assessments and more
36
37 objective tools could lead to a more effective overall process in the highly competitive football
38
39 transfer market.
40

Table 1. Biographical data represented as means and standard deviations for player groupings.

Group	Players (n)	Age (years)	Height (cm)	90 Minute Appearances	Total Minutes
Group 0 Full Back	56	24.2 ± 4.3	180.5 ± 4.4	10.1 ± 10.7	1112 ± 1040
Group 1 Full Back	125	24.9 ± 4.2	180.2 ± 4.3	20.0 ± 12.1	2603 ± 1107
Group 2 Full Back	24	25.4 ± 3.3	179.7 ± 3.6	18.5 ± 12.5	1919 ± 1200
Group 0 Centre Back	37	27.5 ± 5.1	187.2 ± 5.1	15.9 ± 10.9	15901 ± 1023
Group 1 Centre Back	131	25.6 ± 3.7	186.7 ± 4.2	22.5 ± 12.4	2186 ± 1116
Group 2 Centre Back	25	25.6 ± 3.4	187.4 ± 3.7	22.8 ± 12.0	2173 ± 1141
Group 0 Wide Midfield	42	24.4 ± 4.3	179.1 ± 5.5	6.6 ± 7.0	1119 ± 858
Group 1 Wide Midfield	103	24.6 ± 3.7	177.2 ± 5.6	12.6 ± 9.6	1840 ± 1000
Group 2 Wide Midfield	23	24.8 ± 3.7	179.2 ± 4.8	19.4 ± 11.5	2425 ± 1109
Group 0 Centre Midfield	36	25.6 ± 4.8	179.7 ± 5.1	12.4 ± 11.9	1505 ± 1147
Group 1 Centre Midfield	148	25.6 ± 3.9	178.8 ± 5.8	19.5 ± 11.1	2238 ± 1006
Group 2 Centre Midfield	21	26.3 ± 4.5	178.5 ± 4.5	25.6 ± 13.6	2693 ± 1253
Group 0 Attacker	38	26.6 ± 4.8	182.2 ± 6.5	6.2 ± 6.9	1096 ± 920
Group 1 Attacker	130	26.0 ± 3.9	181.6 ± 5.9	11.8 ± 9.3	1845 ± 931
Group 2 Attacker	27	26.2 ± 4.5	181.7 ± 5.8	13.2 ± 9.3	2081 ± 930

Table 2. Results for all models with balanced data sets. The best average test performance = 100.0% and the best average test error = 1.0% (Using a combination of eighteen variables) – Centre Back Group 0 v 2. The worst average test performance = 72.7% and the worst average test error = 9.8% (Using a combination of five variables) – Full Back Group 0 v 1.

Position	Groups	Average Test Performance (%)	Average Test Error (%)	Number of Variables
Full Back	0 v 1	72.7	9.8	5
Full Back	0 v 2	87.5	6.5	10
Full Back	1 v 2	75	9.3	6
Centre Back	0 v 1	93.3	4.1	20
Centre Back	0 v 2	100	1.0	18
Centre Back	1 v 2	90	5.5	6
Wide Midfield	0 v 1	76.5	8	10
Wide Midfield	0 v 2	100	3.4	6
Wide Midfield	1 v 2	77.8	7.4	9
Centre Midfield	0 v 1	78.6	9.6	9
Centre Midfield	0 v 2	90.9	4.8	10
Centre Midfield	1 v 2	88.9	5.9	5
Attacker	0 v 1	80	8.7	5
Attacker	0 v 2	92.3	2.6	10
Attacker	1 v 2	81.8	7.2	6
Average	NA	85.7	6.3	9.0

Table 3. Summary of the variables in all position models by grouping.

Variable Grouping	Times Selected	Selected (%)
Passing	48	35.8
Shooting	20	14.9
Regains	11	8.2
International Appearances	9	6.7
Heading	8	6.0
Fouls	5	3.7
Goals	5	3.7
Appearances	4	3.0
Entries	3	2.2
Possession Lost	4	3.0
Tackled	3	2.2
Time in Possession	3	2.2
Assists	2	1.5
Blocks	2	1.5
Clearances	2	1.5
Crossing	2	1.5
Touches	2	1.5
Balls Received	1	0.7
Possessions	1	0.7

Table 4. Comparison of overall average test performance scores from position models as means and standard deviations.

Position Comparison	Overall Average Test Performance (%)	Overall Average Test Error (%)
Full Back	78.4 ± 8.0	8.6 ± 1.7
Centre Back	94.5 ± 5.1	3.5 ± 2.3
Wide Midfield	84.8 ± 13.2	6.3 ± 2.5
Centre Midfield	86.1 ± 6.6	6.8 ± 2.5
Attacker	84.7 ± 6.6	6.2 ± 3.2

Table 5. Results for Group 0 v Group 1 Full Back balanced data set comparison. The best average test performance = 72.7% and the best average test error = 9.8% (Using a combination of five variables).

Rank	Variable	Average Test Performance (%)	Average Test Error (%)
61	Total Appearances	63.6	11.2
282	% Backwards Passes Successful (Mean)	72.7	10.6
293	Total Minutes	72.7	9.8
314	% Forwards Passes Successful (Mean)	72.7	9.8
325	Forwards Passes (Maximum)	72.7	9.8
346	Blocks (Mean)	70.5	9.9
357	% Unsuccessful Headers (Median)	68.2	10.0
378	Forward Passes Successful (Median)	68.2	10.0
389	% Passes Successful Own Half (Mean)	72.7	9.9
4010	Passes Own Half 25% (Lower Quartile)	72.7	10.0

Table 6. Results for Group 1 v Group 2 Full Back balanced data set comparison. The best average test performance = 75.0% and the best average test error = 9.3% (Using a combination of six variables).

Rank	Variable	Average Test Performance (%)	Average Test Error (%)
1	% Sideways Passes Successful 75% (Upper Quartile)	60.0	11.3
2	Total Shots (Median)	60.0	10.9
3	International Caps	70.0	9.7
4	Tackled (Mean)	70.0	9.3
5	First Time Passes (Maximum)	70.0	9.1
6	Number of Possessions (Median)	75.0	9.3
7	Tackled (Minimum)	70.0	9.4
8	% Sideways Passes Successful 25% (Lower Quartile)	70.0	9.4
9	Total Assists	70.0	9.8
10	% First Time Passes Unsuccessful 25% (Lower Quartile)	70.0	9.8

Table 7. Results for Group 0 v Group 2 Full Back balanced data set comparison. The best average test performance = 87.5% and the best average test error = 6.6% (Using a combination of ten variables).

Rank	Variable	Average Test Performance (%)	Average Test Error (%)
1	Goals (Mean)	75.0	9.1
2	Headers (Minimum)	75.0	8.6
3	% Forward Passes Unsuccessful (Mean)	81.3	8.2
4	Shots Off Target (Exc. Blocked) (Maximum)	78.1	8.1
5	% Forward Passes Unsuccessful 75% (Upper Quartile)	75.0	8.2
6	U21 Caps	75.0	8.0
7	Shots Inside the Box (Mean)	81.3	7.7
8	Possession Lost (Mean)	81.3	7.0
9	Shots On Tgt Outside the Box (Maximum)	81.3	7.2
10	Total Assists	87.5	6.6

Table 8. Results for Group 0 v Group 1 Centre Back balanced data set comparison. The best average test performance = 93.3% and the best average test error = 4.1% (Using a combination of twenty variables).

Rank	Variable	Average Test Performance (%)	Average Test Error (%)
1	% Passes Successful Opp Half 75% (Upper Quartile)	66.7	10.9
2	Shooting Accuracy 75% (Upper Quartile)	73.3	9.3
3	% Successful Headers 75% (Upper Quartile)	80.0	7.6
4	Balls Received 75% (Upper Quartile)	80.0	7.6
5	Crosses (Median)	80.0	7.9
6	% First Time Passes Successful 25% (Lower Quartile)	80.0	6.8
7	Total Shots on Target (Mean)	86.7	6.4
8	Passes Successful Opp Half (Minimum)	86.7	6.0
9	U21 Caps	86.7	6.1
10	Shooting Accuracy 25% (Lower Quartile)	86.7	5.2
11	Medium Passes (Mean)	86.7	5.2
12	Forward Passes Successful (Minimum)	93.3	4.5
13	Total Shots on Tgt (Excluding Blocked) (Mean)	86.7	5.0
14	Goals (Mean)	86.7	4.5
15	% Unsuccessful Headers 25% (Lower Quartile)	90.0	4.7
16	Long Passes (Median)	93.3	4.5
17	% Passes Successful Opp Half (Minimum)	93.3	4.2
18	Avg Time in Possession (Mean)	86.7	4.8
19	% Forwards Passes Successful (Minimum)	86.7	4.7
20	Shooting Accuracy (Median)	93.3	4.1

Possession Gained 75% (Upper Quartile)	34.2 ± 5.5	36.7 ± 5.7
Avg Time in Possession (Median)	2.4 ± 2.2	2.6 ± 0.3
Clearances (Maximum)	10.9 ± 3.2	11.4 ± 3.2
Shots Outside the Box (Median)	0.0 ± 0.2	0.0 ± 0.0
First Time Passes (Mean)	6.5 ± 1.9	7.0 ± 1.2
Unsuccessful Passes (Minimum)	1.4 ± 1.8	1.0 ± 1.2
Interceptions 75% (Upper Quartile)	29.9 ± 4.2	31.1 ± 5.3
Possession Gained (Minimum)	21.1 ± 4.9	18.5 ± 6.3
Shots Inside the Box 25% (Lower Quartile)	0.1 ± 0.4	0.0 ± 0.1
Total Shots on Target (Mean)	0.2 ± 0.2	0.3 ± 0.2
Tackled (Minimum)	0.2 ± 0.7	0.0 ± 0.2

Table 22. Group 0 v 2 Wide Midfield model variables represented as means and standard deviations for all player groupings.

Variables	Group 0 Wide Midfield	Group 2 Wide Midfield
Total Goals	1.4 ± 1.9	5.5 ± 3.8
Passes Attempted Opp Half 75% (Upper Quartile)	16.2 ± 6.3	21.4 ± 5.8
Fouls in Defensive 3rd (Mean)	0.2 ± 0.2	0.3 ± 0.3
Total Shots on Tgt (Excluding Blocked) (Maximum)	1.0 ± 0.8	2.6 ± 1.1
% Forwards Passes Successful (Mean)	53.4 ± 14.8	55.2 ± 9.7
Forward Passes Successful (Median)	5.0 ± 3.2	6.1 ± 2.2
Total Goals	1.4 ± 1.9	5.5 ± 3.8
Passes Attempted Opp Half 75% (Upper Quartile)	16.2 ± 6.3	21.4 ± 5.8
Fouls in Defensive 3rd (Mean)	0.2 ± 0.2	0.3 ± 0.3
Total Shots on Tgt (Excluding Blocked) (Maximum)	1.0 ± 0.8	2.6 ± 1.1

Table 23. Group 0 v 1 Centre Back model variables represented as means and standard deviations for all player groupings.

Variables	Group 0 Centre Back	Group 1 Centre Back
% Passes Successful Opp Half 75% (Upper Quartile)	81.2 ± 22.3	92.4 ± 13.5
Shooting Accuracy 75% (Upper Quartile)	23.5 ± 35.6	20.1 ± 33.8
% Successful Headers 75% (Upper Quartile)	51.0 ± 8.7	52.7 ± 6.6
Balls Received 75% (Upper Quartile)	16.9 ± 5.8	20.6 ± 8.9
Crosses (Median)	0.1 ± 0.3	0.1 ± 0.3
% First Time Passes Successful 25% (Lower Quartile)	59.3 ± 13.0	59.9 ± 12.7
Total Shots on Target (Mean)	0.2 ± 0.2	0.3 ± 0.3
Passes Successful Opp Half (Minimum)	0.2 ± 0.5	0.3 ± 1.0
U21 Caps	0.3 ± 0.9	1.3 ± 3.2
Shooting Accuracy 25% (Lower Quartile)	0.0 ± 0.0	1.9 ± 11.4
Medium Passes (Mean)	7.9 ± 2.9	9.6 ± 5.1
Forward Passes Successful (Minimum)	1.5 ± 1.3	1.6 ± 2.5
Total Shots on Tgt (Excluding Blocked) (Mean)	0.1 ± 0.1	0.2 ± 0.2
Goals (Mean)	0.0 ± 0.1	0.1 ± 0.1
% Unsuccessful Headers 25% (Lower Quartile)	49.0 ± 8.7	47.2 ± 6.7
Long Passes (Median)	5.5 ± 2.1	6.3 ± 2.5

7 **Supplementary Information**
8

9 The learning rate (the rate at which weights are updated as a proportion of the error) was set at
10 0.1 while the momentum (the proportion of the previous change in weights applied back to the
11 current change in weights) was 0.5 and two hidden nodes (feature detectors) were used as part
12 of the artificial neural network architecture in a single hidden layer. The maximum number of
13 epochs (updates of the network) used was three hundred while the maximum number of epochs
14 without improvement on the test was one hundred. This was used to prevent over fitting of the
15 model.

Identifying playing talent in professional football using artificial neural networks

Keywords: Soccer, Talent Identification, Premier League, Championship, Artificial Intelligence

Abstract

The aim of the current study was to objectively identify position-specific key performance indicators in professional football that predict out-field players league status. The sample consisted of 966 out-field players who completed the full 90 minutes in a match during the 2008/09 or 2009/10 season in the Football League Championship. Players were assigned to one of three categories (group 0, 1 and 2) based on where they completed most of their match time in the following season, and then split based on five positions including full backs (n = 205), centre backs (n = 193), centre midfielders (n = 205), wide midfielders (n = 168) and forwards (n = 195). 340 performance, biographical and esteem variables were analysed using a Stepwise Artificial Neural Network approach. The models correctly predicted between 72.7% and 100% of test cases (Mean prediction of models = 85.9%), the test error ranged from 1.0% to 9.8% (Mean test error of models = 6.3%). Variables related to passing, shooting, regaining possession and international appearances were key factors in the predictive models. This is highly significant as objective position-specific predictors of players league status have not previously been published. The method could be used to aid the identification and comparison of transfer targets as part of the due diligence process in professional football.

Introduction

Coaches and decision makers in professional football have traditionally used subjective observations to assess the performance of their team, to review the strengths and weaknesses

of future opponents and to identify potential signings (Carling, Williams and Reilly, 2005). Match analysis research into the individual's performance in football has focused heavily on the physical demands of the sport (Carling, 2013). Research led by sport scientists with a heavy focus upon the physical aspects of performance in football has not managed to identify key predictors of match outcome or team success (Bradley et al., 2016; Carling, 2013).

However, studies investigating physical performance during matches have also incorporated technical elements and provided some insights into the successful performance of players and teams (Bradley et al., 2013; Bradley et al., 2016; Dellal et al., 2010; Dellal et al., 2011). Technical factors have been identified that are prominent predictors of team success and match outcome. Shots, shots on target and ball possession are the most commonly reported predictors (Castellano, Casamachina and Lago, 2012; Lagos-Penas, Lago-Ballesteros, Dellal and Gomez, 2010; Liu, Gomez, Lago-Penas and Sampaio, 2015). There has been a heavy emphasis on the attacking aspects of play linked to success and more detailed analysis is required into the defensive aspects of play to gain a greater understanding of the game.

Following on from the research into team success and physical profiles, there has been an increasing interest in the technical profiles of players. Studies have found positional differences in Ligue 1 in France, the Premier League in England and in Spain's La Liga (Dellal, Wong, Moalla and Chamari 2010; Dellal et al., 2011). The development of advanced computer systems has supported a greater understanding of position profiles in football. However, most of the research to date has used subjective methods to select variables for analysis (Taylor, Mellalieu and James, 2004) or they have replicated indicators used in other studies (Andrzejewski, Konefal, Chmura, Kowalczyk and Chmura, 2016). Using subjective criteria selection rather than exploring a broad spectrum of the data points has meant that many

variables have yet to be assessed. Therefore, the impact of these variables upon playing success and career progression is unknown.

A broader analysis of player performance and career progression has been provided by using artificial neural networks to assess a wide range of variables (Barron, Ball, Robins and Sunderland, 2018). Artificial neural networks have been shown to be better at identifying patterns in complex non-linear data sets than forms of regression analysis and they are capable of generalizing results to solve real world problems (Basheer and Hajmeer, 2000; Lancashire, Lemetre and Ball, 2009; Tu, 1996). In a football context, artificial neural networks have been shown to be capable of creating models that can differentiate between specific groups and identify key variables that predict career progression (Barron et al, 2018). Previous studies though have been limited by assessing players regardless of position and their accuracy could be improved by making assessments of each position and the creation of position-specific career progression models.

To the authors' knowledge there has not been an objective study carried out to develop a position-specific predictive model that could support the scouting and recruitment process in professional football. The efficient and effective identification and assessment of transfer targets is a key aspect of any professional football club and requires a thorough due diligence process. Therefore, the aim of the current study was to develop an objective model to identify position-specific key performance indicators in professional football that predict out-field players league status using an artificial neural network.

Methods

Players and Match Data

The basis of the current study followed Barron *et al's* (2018) method but looked to build on it and focus on position-specific assessments of players. The sample consisted of 966 out-field players (mean \pm SD age and height: 25 \pm 4 yr, 1.81 \pm 0.06 m) who had completed a full 90 minutes in the English Football League Championship during the 2008/09 and 2009/10 seasons (Table 1). Technical performance data and biographical data was collected using ProZone's MatchViewer software (ProZone Sports Ltd., Leeds, UK), the official Football League website (www.efl.com) and Scout7 Ltd's (Birmingham, UK) site. The Prozone MatchViewer system was used to collect performance data due to its accurate inter-observer agreement for the number and type of events (Bradley, O'Donoghue, Wooster and Tordoff, 2007). The data collected from the Prozone MatchViewer software was made available by STATS LLC (Chicago, USA). Institutional ethical approval was attained from the Non-Invasive Human Ethics Committee at Nottingham Trent University.

In total, 536 variables were collected in including the total number, accuracy (% success), means, medians and upper and lower quartiles of passes, tackles, possessions regained, clearances and shots. Additional data on total appearances, playing percentage, total goals and assists, international appearances and heights was also collected. The data set originally included 536 variables but low variance statistics were removed. After removing low variance data points, the data set included 340 variables for comparison. Each player's data was converted into mean 90-minute performance data before they were assigned to one of three categories (group 0, group 1 and group 2).

Player Grouping

Players were allocated to one of five positions (full back, centre back, wide midfielder, central midfielder or attacker) based on where they spent most of their playing time during the season (See Table 1). They were then assigned to one of three categories (group 0, group 1 and group 2) based on where they went on to complete most of their match time during the following season. The first category (group 0) included the players who completed most of their match time in a lower league during the following season. The second group (group 1) included those players who completed most their match time in the English Football League Championship during the following season and the final category (group 2) contained the players who progressed to complete most their match time in the English Premier League during the following season.

Sample sizes for each comparison were balanced to have an equal number of cases using a random number selector (i.e. 24 full backs were selected from group 0 to have an equal number of cases for comparisons to group 2). Players who played on loan during the 2008/09 and 2009/10 seasons were included in the study but players who moved to a club outside England were excluded due to the complications in assessing the merits of foreign competitions against those in England. The five positions for each category of playing status were subsequently analysed using a Stepwise Artificial Neural Network approach to identify the optimal collection of variables for predicting playing status.

Artificial Neural Network Model

The artificial neural network modelling was based on the approach previously used in gene profiling with breast cancer data (Lancashire et al., 2009) and used in assessing player performances in the Football League Championship (Barron et al., 2018). It used in house code

written in Microsoft visual basic 6 to call Statistica 10.0 (Statsoft Inc., Tulsa, USA) artificial neural network model at each loop of the stepwise procedure and output the results in a text format.

Before training the artificial neural network, the data was randomly split (60% for training purposes, 20% for validation and 20% blind test cases). A Monte-Carlo cross validation procedure was used to avoid over-fitting of the data. The artificial neural network modelling involved a multi-layer perceptron architecture with a feed-forward back-propagation algorithm. This algorithm used a sigmoidal transfer function and weights were updated by feedback from errors. Results were provided for the average test performance and the average test error. The average test performance indicates the percentage of test cases that are correctly predicted. The average test error is the root mean square error for the test data set, this indicates the difference between the values predicted by the model and the actual values of the test data set (Salkind, 2010). Further information on the artificial neural network model can be viewed in the supplementary information.

Results

Analysis using the artificial neural network created fifteen position-specific models to predict out-field player's league status. The models correctly predicted between 72.7% and 100% of test cases (Mean prediction of models = 85.9%), the test error ranged from 1.0% to 9.8% (Mean test error of models = 6.3%). Fourteen models correctly predicted 75% or more of the test players league status with an error of 9.6% or less (Table 2). The fifteen models, created in total, contained between five and twenty variables to predict the players league status with 134 variables in total being required to make the position models. The most prominent set of variables were those related to the players passing ability, with 48 of the 134 variables (35.8%)

being passing statistics. The next most prominent type of variable was related to players shooting. In total, twenty variables (14.9%) related to shooting were selected in the models. Statistics related to regaining possession accounted for eleven of the variables (8.2%) selected. Variables related to international appearances were selected nine times (6.7%). A full outline of the categories of variables selected can be viewed in full (Table 3).

Full Back Models

The performance of the full back models as a group were the lowest of the five positions (Average test performance = $78.4\% \pm 8.0\%$ and average test error = $8.6\% \pm 1.7\%$) (Table 4). The group 0 v 1 comparison had the lowest average test performance and highest test error out of all the models created (Average test performance = 72.7% and average test error = 9.8%). Total appearances and mean percentage of backwards passes successful were key variables in the model (Table 5). The group 1 v 2 comparison had an average test performance of 75% and a test error of 9.3% . The percentage of sideways passes successful (upper quartile) and median total shots were the most prominent variables in the model (Table 6). The best full back model was for group 0 v 2 which had an average test performance of 87.5% and a test error of 6.6% . The mean goals scored and minimum headers were the two most prominent factors in the model (Table 7).

Centre Back Models

The performance of the centre back models as a group had an average test performance of $94.4\% \pm 5.1\%$ and an average test error of $3.5\% \pm 2.3\%$. The group 0 v 1 model had an average test performance of 93.3% and an average test error of 4.1% using twenty variables. The percentage of successful passes in the opposition half (upper quartile) and shooting accuracy (upper quartile) were the most prominent variables in the model (Table 8). The group 1 v 2

model had the lowest average test performance and highest test error of the three centre back models (average test performance = 90.0% and average test error = 5.5%). Backwards passes (lower quartile) and maximum short passes were the top two factors in the model (Table 9). The group 0 v 2 model had the highest average test performance of any model and the lowest test error of any model (average test performance = 100% and test error = 1.0%). The group 0 v 2 centre back model contained eighteen variables with 0-6 assists mean (group 0 = 0.1 ± 0.1 , group 2 = 0.2 ± 0.1), mean shots on target inside the box (group 0 = 0.2 ± 0.2 , group 2 = 0.3 ± 0.2) and minimum penalty area entries (Group 0 = 0.2 ± 0.4 , Group 2 = 0 ± 0) being key variables (Table 10).

Wide Midfielder Models

The wide midfielder models group average test performance was $84.8\% \pm 13.2\%$ with an average test error of $6.3\% \pm 2.5\%$. The group 0 v 1 model had an average test performance of 79.4% and a test error of 8.2%. The maximum percentage of unsuccessful headers and forward passes successful (upper quartile) were the biggest predictors in the model (Table 11). The group 1 v 2 model had an average test performance of 77.8% and a test error of 7.4%. U21 international caps and median forward passes unsuccessful were the most prominent factors in the model (Table 12). The group 0 v 2 model had the second highest average test performance and third lowest test error of all the models created (average test performance = 100% and a test error of 3.4%). The group 0 v 2 wide midfielder model contained six variables including: total goals (group 0 = 1.4 ± 1.9 , group 2 = 5.5 ± 3.8), passes attempted opposition half upper quartile (group 0 = 16.2 ± 6.3 , group 2 = 21.4 ± 5.8), fouls in the defensive third mean (group 0 = 0.2 ± 0.2 , group 2 = 0.3 ± 0.3), total shots on target (excluding blocked) maximum (group 0 = 1.0 ± 0.8 , group 2 = 2.6 ± 1.1), % forward passes successful mean (group 0 = $53.4\% \pm 14.8\%$,

group 2 = 55.2% \pm 9.7%) and forward passes successful median (group 0 = 5.0 \pm 3.2, group 2 = 6.1 \pm 2.2) (Table 13).

Centre Midfielder Models

The best overall average was for the centre midfielder's models as a group (Average test performance = 86.1% \pm 6.6 and average test error = 6.8% \pm 2.5). The group 0 v 1 model had the lowest average test performance of the centre midfield models and had the second highest test error across all models (Average test performance = 78.6% and average test error = 9.6%). Fouls and maximum first time passes were the most prominent variables in the model (Table 14). The group 1 v 2 model had an average test performance of 88.9% and a test error of 5.9%. Successful passes (lower quartile) and penalty area entries (lower quartile) were two key variables in the model (Table 15). The group 0 v 2 model had an average test performance of 90.9% and a test error of 4.8%. The number of starts and maximum shots on target outside the box were the highest predictors in the model (Table 16).

Attacker Models

The performance of the attacker models as a group had an average test performance of 84.7% \pm 6.6% and an average test error of 6.2% \pm 3.2%. The group 0 v 1 model had an average test performance of 80% and an average test error of 8.7%. The most prominent variables in the model were international caps and the number of touches (lower quartile) (Table 17). The group 1 v 2 model had an average test performance of 81.8% and a test error of 7.2%. U21 international caps and international caps were the two most important factors in the model (Table 18). The best average test performance for an attacker model was recorded for the group 0 v 2 model and it had the lowest overall test error of all models (average test performance = 92.3% and test error = 2.6%). The group 0 v 2 attacker model contained ten variables with total

goals (group 0 = 2.7 ± 3.0 , group 2 = 10.0 ± 6.2), blocks upper quartile (group 0 = 1.0 ± 0.5 , group 2 = 1.5 ± 0.7) and short passes minimum (group 0 = 4.9 ± 2.5 , group 2 = 4.3 ± 2.4) being key variables (Table 19).

Model Comparisons

The models produced comparing positions for group 0 v 1 had the lowest overall average test performance and highest test error (mean test performance = $80.8\% \pm 7.6\%$ and average test error = $8.1\% \pm 2.3\%$). The overall average test performance across all five positions for group 1 v 2 comparisons was $82.7\% \pm 6.6\%$ and the average test error was $7.1\% \pm 1.5$. The highest overall average test performance across the five positions was for group 0 v 2 (mean test performance = $94.1\% \pm 5.6\%$ and average test error = $3.7\% \pm 2.1\%$) (Table 20). The top three models produced by the neural network were for 0 v 2 centre back (average test performance 100% and 1.0% test error), group 0 v 2 wide midfielder (average test performance 100% and 3.4% test error) and group 0 v 1 centre back (average test performance 93.3% and 4.1% test error). The means and standard deviations for key variables for the top three models can be reviewed in full (Tables 21-23).

Discussion

The aim of the current study was to develop objective models that identified position-specific key performance indicators that predict out-field players league status. The artificial neural network created fifteen position-specific models to predict out-field players league status. The artificial neural network's ability to correctly classify more than 75% of the players league status for fourteen different position comparisons is a key result. The models were able to accurately predict the league status of players being transferred between different levels of

competition and those who were promoted or demoted with their team. Therefore, they did not simply predict subjective scouting decisions.

The results surpass the previous prediction rates reported using artificial neural networks in other team sports, such as those undertaken in cricket (Iyer and Sharda, 2009; Saikia, Bhattacharjee and Lemmer, 2012). Their studies could predict classification of batsmen and bowlers with accuracy levels ranging from 49% to 77%. In individual sports, artificial neural networks have been able to predict 80.2% of gymnast's future classifications based on a multi-dimensional testing process (Pion, Hohmann, Liu, Lenoir and Segers, 2017). Therefore, the current artificial neural network prediction rates are among the highest reported to date in an athlete classification study.

Passing Variables

The most prominent set of variables were those related to the players passing ability, with 48 of the 134 total variables included in models (35.8%) being passing statistics. Many passing variables have been highlighted previously as key indicators when differentiating between players of various playing levels and linked to team success (Bradley et al., 2013; Rampinini, Impellizzerie, Castagna, Coutts and Wisloff, 2009). Comparisons between players within the English football pyramid showed that players in the Premier League performed a greater number of total passes, successful passes and forward passes (Bradley et al., 2013). Out of the 48 passing variables identified in the models, 29 were related to the success of the passing variables. The passing variables related to their success were a mixture of 27 different statistics accounting for the direction (forwards, sideways and backwards) of the pass, the origin of the pass (own half or opposition half) and the mean, median, minimum, maximum and upper and lower quartile figure for different variables.

In further agreement with Bradley and colleagues (2013) findings, thirteen of the passing variables were related to forward passing. Forward passes have been shown to have the lowest chance of success when compared to sideways or backwards passes (Szczepanski and McHale, 2016). Yet, to create scoring opportunities and in turn score goals players are required to progress the play with forward passing. Variables relating to forward passes appeared in models for full backs (group 0 v 1 and group 0 v 2), centre backs (group 0 v 1), wide midfield (group 0 v 1, group 1 v 2 and group 0 v 2), centre midfield (group 0 v 1 and group 0 v 2) but did not feature prominently in any models for attackers. This would appear logical as attackers play in more advanced areas and have fewer opportunities to perform forward passes. The prevalence of forward passing variables for a number of positions and different comparisons highlights its importance in playing success.

The current study also highlighted two variables related to short passing with the maximum and minimum variables being selected in two models (group 1 v 2 centre back and group 0 v 2 attacker). Research into factors that distinguish between top four and bottom four English Premier League teams highlighted short passes as a key variable (Adams, Morgans, Sacramento, Morgan and Williams, 2013). Specifically, the mean frequency of successful short passes played by centre backs and full backs was the biggest factor differentiating between the two groups.

Using the artificial neural network methodology has highlighted some overlap between factors previously identified by research articles. The current study has also identified novel findings for variables that have not previously been analysed or identified as key variables. Eight passing variables were related to those in the opposition half and they appeared in six different position models (group 0 v 1 centre back, group 0 v 1 and 0 v 2 centre midfield, group 0 v 1

and 0 v 2 wide midfield and 0 v 2 attacker models). Six of the variables were also related to first time passes played and they appeared in the group 0 v 1 and 0 v 2 centre back, group 1 v 2 full back, group 0 v 1 and 1 v 2 centre midfield and group 0 v 1 attacker models. Passes in the opposition half indicate possession taking place in more offensive pitch locations and could indicate the involvement of players in attacking moves. The ability to pass the ball accurately over a range of distances and directions is a key factor in performance and for differentiating between players of varying ability. This is accepted knowledge amongst coaches but the models have accurately identified specific key variables and provided an objective assessment of their impact on league status.

Shooting Variables

The next most prominent type of variable was related to players shooting ability. In total, twenty variables (14.9%) related to shooting were selected in the models. This agrees with previous research into team success in football, with total shots and shooting accuracy being the most commonly reported predictors in matches (Castellano et al., 2012; Lagos-Penas et al., 2010; Liu et al., 2015). Surprisingly, all positions except attacker included shooting variables in the models created in the current study. However, one of the attacker models (group 0 v 2) did include total goals as a key variable. Many teams now prefer to play with one lone attacker in their line-up that spreads the need for scoring goals throughout the team and the requirements of the centre forward position could be changing as a result (Adams et al., 2013).

Attacking Entries

Other attacking variables selected as part of the models were related to crossing and entries into the final third and penalty area. Final third and penalty area entries were selected three times and in three different models. Crosses are a factor that have been repeatedly identified as

being key to differentiating between successful and unsuccessful teams (Lagos-Penas *et al.*, 2010; Lagos-Penas *et al.*, 2011). They have not been identified as key when differentiating between players of different performance levels previously, they were only selected twice in the current study meaning they did not play a prominent role in the position models. The mean number of crosses were selected in the group 0 v 2 attacker model (crosses mean group 0 1.0 ± 0.8 , group 2 1.75 ± 1.23). The inclusion of the number of crosses in the attacker model and the higher values reported for group 2 may offer more evidence for the evolving role of the attacker.

As well as crosses, final third and penalty area entries were selected three times and in three different models. Previous research has indicated that penalty area entries differentiate between winning and losing teams (Ruiz-Ruiz, Fradua, Fernandez-Garcia and Zubillaga, 2013). However, in the current study they were selected in one model for centre backs (group 0 v 2), the centre backs from players dropping down to a lower playing level reported higher values (minimum penalty area entries group 0 0.2 ± 0.4 , group 2 0.0 ± 0.0). The identification of minimum penalty area entries in the centre back model and group 0 having a higher value is a novel finding. It may appear counter intuitive but centre backs who drop down to a lower level may play in teams who use a more direct style of play and play longer passes from their centre backs as opposed to building the play with shorter passing combinations.

Defensive Variables

The models also highlighted several defensive variables as key predictors of league status. Statistics related to regaining possession accounted for eleven of the variables (8.2%). Previous research into match outcomes and players technical and tactical ability has heavily focused on the attacking aspects of play (Mackenzie and Cushion, 2013), passing (Adams *et al.*, 2013;

Szczepanski and McHale, 2016) and possession (Castellano et al., 2012; Collett, 2013; Lagos-Penas et al., 2010; Liu et al., 2015). A limited number of defensive variables have been researched or identified that are linked to success. A balanced defensive shape (Tenga, Holme, Ronglan and Bahr, 2010), defensive reaction after losing possession (Vogelbein, Nopp and Hokelmann, 2014) and regaining possession in the final third have been identified previously (Almeida, Ferreira and Volossovitch, 2014).

The current study highlighted possession won based on the minimum, median, maximum and upper quartile variables as being key predictors of league status. Possession gained upper quartile and interceptions median and maximum were also selected as key variables in models. The defensive variables were not selected as part of any of the full back models. They were commonly selected as part of the wide midfield (group 0 v 1 and group 1 v 2) and attacker models (group 1 v 2 and group 0 v 2). This may appear counter intuitive and these factors would not normally be assessed when profiling more attacking positions within the team. Modern playing philosophies valuing high pressing tactics from forward players to regain possession in more advanced areas of the pitch, this may explain the importance of these factors in wide midfield and attacker models within the current study (Perarnau, 2014).

International Recognition

Other key variables selected throughout several models relate to international appearances, international caps and U21 international caps were selected nine times (6.7%) in total. This is a novel finding as previous assessments of player's performances have limited themselves to match performance and season totals of performance data. Previous research into international recognition and team or playing success has not been undertaken to the author's knowledge.

However, international recognition has been found to be linked with player salary allocation, particularly at the higher levels of the game (Frick, 2011).

Position-Specific Models

The current study created a number of strong predictive models for player's league status, there were also some key findings relating to the prediction rates of specific positions. Three of the five positions had very similar levels of classification accuracy (centre midfield 86.1%, wide midfield 85.7% and attacker 84.7%) but the full back position's overall accuracy was only 78.4% and the centre back position's overall accuracy was 94.4%. The full back results are still an important finding but below the levels reported for other positions. The group 0 v 1 full back model had the lowest classification accuracy of all the models and the group 1 v 2 full back model had the second lowest classification accuracy. The full back position is one that requires a complex set of technical and tactical skills as it requires a wide array of attacking and defensive qualities (Bush, Archer, Hogg and Bradley, 2015).

Recent evaluations of the changes within performance data for playing positions has shown extensive changes over time in the Premier League (Bush et al., 2015). Pronounced increases were found for the levels of high-speed running and the distances covered while sprinting, with full backs showing the largest increases between 2006-07 and 2012-13 (Bush et al., 2015). Therefore, the full back position may be influenced more by the physical aspects of performance. This could explain the lower prediction rates for full backs due to the lack of physical tracking data being available.

Study Limitations

Strong models were identified for fourteen out of the fifteen position comparisons assessed but there are some limitations to the present study that should be addressed in future research. The match running performance data for players was not available for the current study. There is an acceptance amongst the sports science community that running performance is not a predictor of team success or match outcome (Bradley et al., 2016; Carling, 2013). However, including match running performance data could provide a higher level of classification accuracy for some of the positions assessed. Another limitation of the study is the lack of contextual data available and the inability of the data to provide a detailed assessment for off the ball parameters. The final limitation of the study relates to the sample size for players progressing to play in the Premier League. The samples for the players progressing from the five positions to play in the Premier League were the smallest of all the groupings. Statistical power tests on similar sample sizes have reached the required levels (Lancashire et al., 2009). However, future studies should look to increase the sample available to increase confidence that the results are repeatable to new cases.

Conclusions

The current study has shown that artificial neural networks are a valid and highly effective tool to classify and predict players league status. Fourteen models across all five positions were created that provided strong prediction accuracy levels for players league status. This is an important result as it outlines an objective methodology that can aid the scouting and recruitment process in professional football. The process of identifying and recruiting players in professional football has largely been a subjective process in the past. Further research should look to combine assessments of physical and technical performance data to provide a more accurate prediction of league status. Studies should also look to create models to predict

the career progression of players from multiple leagues to provide a better practical tool for scouting and recruitment purposes. The combination of subjective assessments and more objective tools could lead to a more effective overall process in the highly competitive football transfer market.

U21 Caps	0.3 ± 0.9	1.3 ± 3.2
Shooting Accuracy 25% (Lower Quartile)	0.0 ± 0.0	1.9 ± 11.4
Medium Passes (Mean)	7.9 ± 2.9	9.6 ± 5.1
Forward Passes Successful (Minimum)	1.5 ± 1.3	1.6 ± 2.5
Total Shots on Tgt (Excluding Blocked) (Mean)	0.1 ± 0.1	0.2 ± 0.2
Goals (Mean)	0.0 ± 0.1	0.1 ± 0.1
% Unsuccessful Headers 25% (Lower Quartile)	49.0 ± 8.7	47.2 ± 6.7
Long Passes (Median)	5.5 ± 2.1	6.3 ± 2.5

Supplementary Information

The learning rate (the rate at which weights are updated as a proportion of the error) was set at 0.1 while the momentum (the proportion of the previous change in weights applied back to the current change in weights) was 0.5 and two hidden nodes (feature detectors) were used as part of the artificial neural network architecture in a single hidden layer. The maximum number of epochs (updates of the network) used was three hundred while the maximum number of epochs without improvement on the test was one hundred. This was used to prevent over fitting of the model.

List of Initial 340 Variables Included in the Study

Number	Variable
1	% Backwards Passes Successful Lower Quartile
2	% Backwards Passes Successful Mean
3	% Backwards Passes Successful Min

List of 196 Variables Excluded from the Study

Number	Variable
1	% Backwards Passes Successful Max
2	% Backwards Passes Successful Median
3	% Backwards Passes Successful Upper Quartile
4	% Backwards Passes Unsuccessful Lower Quartile
5	% Backwards Passes Unsuccessful Median
6	% Backwards Passes Unsuccessful Min
7	% Backwards Passes Unsuccessful Upper Quartile
8	% First Time Passes Successful Max
9	% First Time Passes Unsuccessful Min
10	% Passes Successful Opp Half Max
11	% Sideways Passes Successful Max
12	% Sideways Passes Unsuccessful Min
13	0-6 Assists Lower Quartile
14	0-6 Assists Max

15	0-6 Assists Median
16	0-6 Assists Min
17	0-6 Assists Upper Quartile
18	1st Assist Lower Quartile
19	1st Assist Max
20	1st Assist Mean
21	1st Assist Median
22	1st Assist Min
23	1st Assist Upper Quartile
24	2nd Assist Lower Quartile
25	2nd Assist Max
26	2nd Assist Mean
27	2nd Assist Median
28	2nd Assist Min
29	2nd Assist Upper Quartile
30	3rd Assist Lower Quartile
31	3rd Assist Max
32	3rd Assist Mean
33	3rd Assist Median
34	3rd Assist Min
35	3rd Assist Upper Quartile
36	4th Assist Lower Quartile
37	4th Assist Max
38	4th Assist Mean
39	4th Assist Median
40	4th Assist Min
41	4th Assist Upper Quartile
42	5th Assist Lower Quartile
43	5th Assist Max
44	5th Assist Mean
45	5th Assist Median
46	5th Assist Min
47	5th Assist Upper Quartile
48	6th Assist Lower Quartile
49	6th Assist Max
50	6th Assist Mean
51	6th Assist Median
52	6th Assist Min
53	6th Assist Upper Quartile
54	Avg Touches Lower Quartile
55	Avg Touches Mean
56	Avg Touches Median

57	Avg Touches Min
58	Avg Touches Upper Quartile
59	Backwards Passes Unsuccessful Lower Quartile
60	Backwards Passes Unsuccessful Median
61	Backwards Passes Unsuccessful Min
62	Backwards Passes Unsuccessful Upper Quartile
63	Blocks Lower Quartile
64	Blocks Min
65	Clearances Min
66	Corners Conceded Lower Quartile
67	Corners Conceded Median
68	Corners Conceded Min
69	Corners Conceded Upper Quartile
70	Corners from LEFT Lower Quartile
71	Corners from LEFT Max
72	Corners from LEFT Mean
73	Corners from LEFT Median
74	Corners from LEFT Min
75	Corners from LEFT Upper Quartile
76	Corners from RIGHT Lower Quartile
77	Corners from RIGHT Max
78	Corners from RIGHT Mean
79	Corners from RIGHT Median
80	Corners from RIGHT Min
81	Corners from RIGHT Upper Quartile
82	Corners Taken Lower Quartile
83	Corners Taken Max
84	Corners Taken Mean
85	Corners Taken Median
86	Corners Taken Min
87	Corners Taken Upper Quartile
88	Crosses from LEFT Lower Quartile
89	Crosses from LEFT Max
90	Crosses from LEFT Mean
91	Crosses from LEFT Median
92	Crosses from LEFT Min
93	Crosses from LEFT Upper Quartile
94	Crosses from RIGHT Lower Quartile
95	Crosses from RIGHT Max
96	Crosses from RIGHT Mean
97	Crosses from RIGHT Median
98	Crosses from RIGHT Min

99	Crosses from RIGHT Upper Quartile
100	Crosses Min
101	Dribbles Lower Quartile
102	Dribbles Median
103	Dribbles Min
104	First Time Passes Unsuccessful Lower Quartile
105	First Time Passes Unsuccessful Median
106	First Time Passes Unsuccessful Min
107	Fouled Lower Quartile
108	Fouled Median
109	Fouled Min
110	Fouls in Defensive 3rd Lower Quartile
111	Fouls in Defensive 3rd Max
112	Fouls in Defensive 3rd Median
113	Fouls in Defensive 3rd Min
114	Fouls in Defensive 3rd Upper Quartile
115	Fouls Lower Quartile
116	Fouls Median
117	Fouls Min
118	Fouls Upper Quartile
119	Free Kicks Taken Lower Quartile
120	Free Kicks Taken Max
121	Free Kicks Taken Mean
122	Free Kicks Taken Median
123	Free Kicks Taken Min
124	Free Kicks Taken Upper Quartile
125	Goals Lower Quartile
126	Goals Max
127	Goals Median
128	Goals Min
129	Goals Upper Quartile
130	Offsides Lower Quartile
131	Offsides Max
132	Offsides Median
133	Offsides Min
134	Offsides Upper Quartile
