The Impact of 3D Printing Implementation on Stock Returns: A Contingent Dynamic Capabilities Perspective

Abstract

Purpose – The purpose of this paper is to theoretically hypothesize and empirically test the impact of 3D printing (3DP) implementation on stock returns. It further explores how the stock returns due to 3DP implementation vary across different industry environments.

Design/methodology/approach – This paper integrates the dynamic capabilities view with contingency theory to provide a contingent dynamic capabilities (CDC) perspective on 3DP implementation. It argues that implementing 3DP enables firms to enhance their manufacturing capabilities and gain a competitive advantage, but the extent to which the competitive advantage can be realized is contingent on the fit between 3DP-enhanced manufacturing capabilities and firms' operating environments. Those arguments are tested based on an event study of 232 announcements of 3DP implementation made by U.S. publicly listed firms between 2010 and 2017.

Findings – The event study results show that firms implementing 3DP gain higher stock returns compared with their non-implementation industry peers over two years after the implementation. Such stock returns due to 3DP implementation are more pronounced for firms operating in more munificent, more dynamic, and less competitive industry environments. Those findings are consistent with our CDC perspective.

Originality/value – This is the first research empirically examining the impact of 3DP implementation on stock returns. It provides important implications for managers to implement 3DP to enhance firms' manufacturing capabilities and for researchers to study 3DP implementation from the CDC perspective.

Keywords – 3D printing, Additive manufacturing, Event study, Stock returns, Dynamic capabilities, Contingency theory

1. Introduction

Investment in appropriate manufacturing technology has been a critical managerial decision, not only because it usually involves substantial resource commitments, but also due to its potential in creating competitive advantage (Grant *et al.*, 1991). In today's rapidly-evolving business world, companies are making continuous efforts to identify innovative technologies that suit their market environments and support strategic goals (Grant *et al.*, 1991). 3D printing (3DP), also known as additive manufacturing, has caught noticeable attention from the business community in recent years (Ernst & Young, 2016; d'Aveni, 2015). Former U.S. President Obama highlighted the strategic importance of 3DP by saying that "3DP has the potential to revolutionize the way we make almost everything" (Gross, 2013). An Ernst & Young (2016) global survey shows that 36% of the firms have already implemented or are considering the implementation of 3DP. Originally adopted as a prototyping technology about thirty years ago, 3DP has evolved to be a direct manufacturing technology for the production of components, parts and even end-use products in different industries (Atzeni and Salmi, 2012; Ernst & Young, 2016). For example, GE aviation used 3DP to build the Advanced Turboprop, the components of which were reduced from 855 to only 12. The simplified design reduced the weight of the engine by 5%, ultimately saving 20% of fuel and achieving 10% more power than its competitors (Van Dusen, 2017). The transformation grows with a more astonishing speed in the U.S. hearing aid industry, which converted to 100% additive manufacturing in less than 500 days (d'Aveni, 2015).

Despite the great progress of 3DP within the past few years, little empirical evidence has been provided of its impact on firm performance. Most previous research of 3DP concentrates on its technological features and industrial applications (Lam *et al.*, 2002; Ventola, 2014; Williams *et al.*, 2010). Recently, the business implications of 3DP have received greater attention, though the majority of the studies only provide qualitative discussions of its benefits,

1
2
3 limitations, and socio-economic impact (Huang *et al.*, 2012; Petrick and Simpson, 2013; Weller
4 *et al.*, 2015; Ford and Despeisse, 2016; Shukla *et al.*, 2018; Eyers *et al.*, 2018). For example,
5
6 prospective economic benefits of 3DP implementation discussed in the literature include
7
8 improved resource efficiency, production flexibility, and enhanced mass-customization
9
10 (Huang *et al.*, 2012; Shukla *et al.*, 2018). Moreover, sustainability benefits such as reduced
11
12 waste during manufacturing, less energy consumption, and extended product life are also
13
14 identified by researchers (Ford and Despeisse, 2016). In recent years, quantitative empirical
15
16 investigations of 3DP implementation start to emerge. While some researchers have examined
17
18 the antecedents of 3DP adoption using surveys (Schniederjans, 2017) or investigated the
19
20 business models enabled by 3DP using computer modeling and simulation (Jia *et al.*, 2016),
21
22 there is a lack of empirical research investigating the performance impact of 3DP
23
24 implementation at the firm level.
25
26
27
28
29

30
31 Our study fills this important gap in the literature by providing an empirical
32
33 investigation of the impact of 3DP implementation on stock returns, which are regarded as a
34
35 proxy for overall firm value and more likely to capture the full performance impact due to 3DP
36
37 implementation (Joshi and Hanssens, 2010; Sorescu *et al.*, 2017). Specifically, we conducted
38
39 an event study based on 232 announcements of 3DP implementation made by U.S. publicly
40
41 listed firms between 2010 and 2017. Our event study results suggest that firms implementing
42
43 3DP gain higher stock returns compared with their non-implementation industry peers over
44
45 two years after the implementation. This finding is consistent with our dynamic capabilities
46
47 view (Barreto, 2010; Schilke *et al.*, 2018) which argues that 3DP implementation enables firms
48
49 to enhance their manufacturing capabilities and gain a competitive advantage, resulting in
50
51 positive stock returns.
52
53
54

55
56 However, it is less likely that firms operating in different environments will gain the
57
58 same benefits from their 3DP implementation. For example, while implementing 3DP may
59
60

1
2
3 enable firms operating in dynamic environments with changing customer preferences and
4
5 fluctuating market demands to gain a competitive advantage due to its ability to enhance firms'
6
7 manufacturing capabilities to satisfy the requirements emerging from such environments
8
9 (Jansen *et al.*, 2006), firms operating in less munificent environments without sufficient
10
11 resources and support available may encounter difficulty in implementing 3DP to enhance their
12
13 manufacturing capabilities, thus preventing them from reaping the benefits of 3DP innovation
14
15 (Park and Mezias, 2005). Therefore, our research further considers how the stock returns due
16
17 to 3DP implementation vary across firms operating in different environments. In particular, we
18
19 deploy contingency theory (Reinking, 2012; Sousa and Voss, 2008) to hypothesize how
20
21 external contingent factors in terms of industry munificence, dynamism, and competition affect
22
23 the extent to which firms benefit from 3DP implementation. Consistent with the contingency
24
25 perspective, our cross-sectional regression analysis shows that the stock returns due to 3DP
26
27 implementation are more pronounced for firms operating in more munificent, more dynamic,
28
29 and less competitive industry environments. These findings highlight the importance of the fit
30
31 between 3DP-enhanced manufacturing capabilities and firms' operating environments.
32
33
34
35
36

37
38 Our study makes several important contributions. First, this is one of the first research
39
40 efforts that empirically examine the impact of 3DP implementation on firm performance in
41
42 terms of stock returns. The positive stock returns documented in our research provide empirical
43
44 support for firms to implement 3DP. Moreover, our research further shows the moderating role
45
46 of operating environments in the 3DP implementation-stock returns relationship, urging firms
47
48 to take account of their operating environments in order to reap more benefits from 3DP
49
50 implementation. On the other hand, we integrate the dynamic capabilities view with
51
52 contingency theory to offer a more comprehensive and complementary explanation of the 3DP
53
54 implementation-stock returns relationship. Our theoretical perspective helps explain not only
55
56 how 3DP implementation enables firms to gain a competitive advantage through enhancing
57
58
59
60

1
2
3 manufacturing capabilities but also how the competitive advantage can be realized depends on
4
5 the fit between 3DP-enhanced manufacturing capabilities and firms' operating environments.
6
7 This perspective can serve as a useful theoretical foundation for future 3DP research. It also
8
9 extends the research on manufacturing capabilities beyond the structure-conduct-performance
10
11 framework (Terjesen *et al.*, 2011) as we view environmental conditions as a moderator, rather
12
13 than a driver, in the manufacturing capabilities-firm performance relationship.
14
15
16
17
18

19 **2. Hypotheses development**

20 *2.1 Literature review*

21
22
23
24 The extant research about 3DP has primarily focused on its technological advancements
25
26 and industrial applications (Lam *et al.*, 2002; Ventola, 2014; Williams *et al.*, 2010). Although
27
28 the manufacturing process of 3DP may use different printer technologies or printing materials,
29
30 the basic steps remain the same: (1) A computerized 3D model of the object to be manufactured
31
32 is developed in a computer-aided design (CAD) file. (2) The printer follows the instructions of
33
34 the CAD file to build a foundation of the object by moving the printhead along the x - y plane.
35
36 (3) The printhead then moves along the z -axis to add materials layer by layer. The additive
37
38 manufacturing process differs from conventional manufacturing techniques which subtract
39
40 materials from a larger piece (Ventola, 2014). 3DP has been adopted by manufacturers as a
41
42 complementary technology for rapid prototyping since 1980s (Huang *et al.*, 2012). About thirty
43
44 years into its development, 3DP has revealed great potential as a direct manufacturing
45
46 technique in various contexts including repairing existing products, manufacturing tools and
47
48 machine parts, and manufacturing end-use components and products (Atzeni and Salmi, 2012;
49
50 Thomas-Seale *et al.*, 2018).
51
52
53
54
55

56 Studies seeking to understand the implications of 3DP implementation have started to
57
58 emerge in recent years (Dong *et al.*, 2017; Ford and Despeisse, 2016; Holmström *et al.*, 2016;
59
60

1
2
3 Huang *et al.*, 2012; Petrick and Simpson, 2013; Weller *et al.*, 2015; Shukla *et al.*, 2018; Eysers
4
5 *et al.*, 2018; Jia *et al.*, 2016). On the one hand, these studies provided preliminary discussions
6
7 about the advantages of 3DP such as accelerating product development, offering customized
8
9 products, and increasing production flexibility. For instance, Huang *et al.* (2012) claimed that
10
11 3DP by nature eliminates the need for tooling, molding, warehousing, transportation, and
12
13 packaging. The simplified supply chain leads to improved material efficiency, resource
14
15 efficiency, part flexibility, and production flexibility, thus enabling on-demand manufacturing.
16
17 Shukla *et al.* (2018) discussed the impact of 3DP implementation on mass-customization and
18
19 proposed that 3DP facilitates four key practices in mass-customization including agility,
20
21 customer involvement, postponement (i.e. “print-to-order”), and modularization. Dong *et al.*
22
23 (2017) conducted one of the few analytical studies about the optimal manufacturing strategy
24
25 under traditional flexible technology and 3DP. They proved that, compared with traditional
26
27 flexible technology, 3DP excels in enhancing product diversity by allowing firms to choose a
28
29 large product assortment with little profit loss.
30
31
32
33
34

35
36 On the other hand, previous studies also indicated that 3DP has not been accepted as a
37
38 standard production technology due to limitations including technological constraints,
39
40 investment costs, and business challenges (Attaran, 2017; Shukla *et al.*, 2018; Thomas-Seale
41
42 *et al.*, 2018; Weller *et al.*, 2015). First, compared with conventional subtractive manufacturing,
43
44 3DP lacks economy of scale. Different from conventional injection molding, the production
45
46 throughput speed of the additive manufacturing process is rather low, so 3DP is mostly adopted
47
48 and advantageous in multi-variant and low-volume production (Petrick and Simpson, 2013).
49
50 Second, the limitations of printing materials, colors, and surface finishes could impede broader
51
52 applications of 3DP (Petrick and Simpson, 2013; Weller *et al.*, 2015). For example, at current
53
54 stage, additive manufacturing still cannot compete with the subtractive manufacturing in terms
55
56 of precision (Shukla *et al.*, 2018). As a result, significant efforts are required for the polishing
57
58
59
60

1
2
3 and finishing surfaces afterwards. Third, the purchasing costs for 3D printers are unneglectable,
4
5 not to mention additional costs including supporting machinery, printing materials, and highly
6
7 skilled personnel (Huang *et al.*, 2012; Shukla *et al.*, 2018). Last but not least, “soft barriers”
8
9 such as the lack of technological know-how (Thomas-Seale *et al.*, 2018), CAD software
10
11 complexity (Shukla *et al.*, 2018), and unestablished global quality and test standards (Weller
12
13 *et al.*, 2015) may also hinder the implementation of 3DP.
14
15

16
17 Taken together, although previous research has adopted various research methods such
18
19 as case studies and analytical modeling to explore the opportunities and challenges of 3DP
20
21 implementation (Dong *et al.*, 2017; Eyers *et al.*, 2018; Shukla *et al.*, 2018), the question
22
23 remains whether, and to what extent, 3DP implementation affects firm performance. Our study
24
25 complements the literature by theoretically hypothesizing and empirically testing the impact of
26
27 3DP implementation on firm performance in terms of stock returns.
28
29
30
31
32

33 *2.2 A contingent dynamic capabilities perspective on 3DP implementation*

34

35 We integrate the dynamic capabilities view with contingency theory to provide a
36
37 contingent dynamic capabilities (CDC) perspective on the 3DP implementation-stock returns
38
39 relationship, for several reasons. First, different from the static resource-based view of the firm
40
41 that is focused on a firm’s existing resource base, the dynamic capabilities view stresses a
42
43 firm’s capacity to “purposefully create, extend, or modify its resource base” (Helfat *et al.*, 2007,
44
45 p. 1). This conceptualization enables us to adopt the dynamic capabilities view to theorize how
46
47 firms implement 3DP to renew their resource base and enhance manufacturing capabilities.
48
49 Moreover, the dynamic capabilities literature has commonly linked firms’ dynamic capabilities
50
51 to competitive advantage (Barreto, 2010; Schilke *et al.*, 2018), consistent with our research
52
53 objective which is to investigate the impact of 3DP implementation on firm performance in
54
55 general and stock returns in particular. However, although the dynamic capabilities view is
56
57
58
59
60

concerned with the “rapidly changing environments” (Teece *et al.*, 1997, p. 516) or dynamic environments, it pays less attention to other dimensions of the environments such as environmental munificence. We thus adopt contingency theory to further explore how the impact of 3DP implementation is contingent on different dimensions of firms’ operating environments. Contingency theory suits our research well as it focuses on the fit between firms’ internal endogenous processes or practices (e.g., 3DP implementation) and external exogenous contexts (e.g., operating environments) (Chavez *et al.*, 2013; Wong *et al.*, 2011). Also, consistent with the dynamic capabilities view, firm performance is a typical dependent variable investigated in the contingency literature (Sousa and Voss, 2008). Therefore, a combination of the dynamic capabilities view and contingency theory provides a complementary and comprehensive perspective on not only the direct relationship between 3DP implementation and stock returns but also the indirect moderating role of firms’ operating environments. In what follows, we first deploy the dynamic capabilities view to theorize how 3DP implementation enables firms to broaden their operational scopes without cost penalties, thus enhancing manufacturing capabilities and gaining a competitive advantage. We also explain how the competitive advantage can be quantified as stock returns. We then adopt contingency theory to explore the fit between 3DP-enhanced manufacturing capabilities and industry environments in terms of industry munificence, dynamism, and competition, thus moderating the 3DP implementation-stock returns relationship. Our research model is shown in Figure 1.

(Insert Figure 1 about here)

Previous studies have identified operational scope as a multi-dimensional concept, comprised of product/service scope, geographic scope, and process scope (Clark and Huckman, 2011; Hitt *et al.*, 1997; Kovach *et al.*, 2015). Product/service scope is the breadth of the product/service portfolio offered by a firm (Clark and Huckman, 2011). Geographic scope is the breath of expansion into different geographic locations or markets (Hitt *et al.*, 1997).

1
2
3 Process scope is the level of flexibility to cope with the change in output (Anand and Ward,
4
5 2009). A consensus has been reached concerning the trade-off between operational scope and
6
7 efficiency in existing research (Clark and Huckman, 2011). It has been well acknowledged that
8
9 diversification is not free, and expanding operational scope almost inevitably increases
10
11 operational complexity and inflates costs (Hitt *et al.*, 1997; Ramdas, 2009).
12
13

14
15 3DP potentially challenges this conventional wisdom as it implies increased operational
16
17 scope without cost penalties, thus renewing firms' resource base and enhancing their
18
19 manufacturing capabilities (Petrick and Simpson, 2013; Schniederjans, 2017; Weller *et al.*,
20
21 2015). Specifically, first, 3DP expands product scope through cost-effective and time-efficient
22
23 product innovation, customization and intricacy (Shukla *et al.*, 2018; Weller *et al.*, 2015).
24
25 Traditionally, offering a diverse product portfolio incurs additional operational costs such as
26
27 tooling and variety-related inventory holding costs (Kovach *et al.*, 2015). However, as there
28
29 are no tooling requirements nor minimum batch size pressure in the one-step additive
30
31 manufacturing process, diversified product design can be achieved without additional tooling
32
33 costs or inventory holding of a large variety of products (Weller *et al.*, 2015). Moreover, 3DP
34
35 enhances new product development by removing the restrictions of innovation. 3DP can be
36
37 used to manufacture any sophisticated parts that can be imaged without the need to compromise
38
39 on the functionality for the ease of manufacturing (Attaran, 2017). Beyond manufacturing
40
41 settings, 3DP has also been adopted to provide services of producing 3D-printed items for
42
43 customers, mostly in healthcare, retailing, logistics and transportation industries (Ernst &
44
45 Young, 2016). For example, Henry Schein, a worldwide dental supplier, provided 3D-printed
46
47 mouth guards for their customers using intra-oral scanners (Bloomberg, 2017). UPS, aside
48
49 from package delivery service, has expanded its service scope to provide 3DP services in UPS
50
51 stores since 2013 (Carey, 2016).
52
53
54
55
56

57
58 Second, 3DP expands the geographic locations where firms produce and sell products
59
60

1
2
3 through decentralized manufacturing (Attaran, 2017). With a 3D printer, customers are allowed
4
5 to download digital models from websites, and then additively manufacture the parts in need
6
7 by themselves at almost any locations. Manufacturing at the point of use is expected to reduce
8
9 the requirement of extensive physical inventory and large-volume logistics and transportations.
10
11 For instance, Ford launched an online 3DP store to provide 3DP services that allow customers
12
13 to “print” the scale automotive models with the digital models downloaded from their website
14
15
16 (McCue, 2015).
17
18

19
20 Third, 3DP achieves broad process scope with increased production flexibility. Process
21
22 scope is associated with both mix flexibility and volume flexibility (Kovach *et al.*, 2015). 3DP
23
24 increases mix flexibility in the manufacturing process as any changes of design are allowed by
25
26 simply modifying the 3D model stored in the CAD file. Moreover, 3DP enables direct
27
28 manufacturing without the need for tools or molds, so the design changes can be easily
29
30 transferred into production (Ernst & Young, 2016). In addition, 3DP substantially reduces
31
32 manufacturing steps by removing the processes of casting, molding, machining, and assembly,
33
34 thus reducing manufacturing costs. The negligible changeover costs and simplified
35
36 manufacturing steps contribute to the increased flexibility of adjusting production according to
37
38 varying designs, sequences, or volumes (Weller *et al.*, 2015).
39
40
41

42
43 The above discussion suggests that 3DP implementation helps firms broaden their
44
45 operational scopes (i.e., product/service scope, geographic scope, and process scope) and
46
47 mitigate operational complexities and costs, thus enhancing manufacturing capabilities. The
48
49 dynamic capabilities literature has commonly agreed that improved firm capabilities enable the
50
51 focal firm to gain an advantage over its competitors (Barreto, 2010; Schilke *et al.*, 2018).
52
53 Empirically, the operations management literature has well documented the positive
54
55 relationship between enhancing manufacturing capabilities and various dimensions of firm
56
57 performance such as sales growth, cost reduction, and profitability improvement (White, 1996;
58
59
60

1
2
3 Terjesen *et al.*, 2011; Corbett and Claridge, 2002). We thus expect 3DP implementation to
4
5 foster a competitive advantage for firms through enhancing their manufacturing capabilities.
6
7 While prior dynamic capabilities research has used different performance measures such as
8
9 profitability, growth, and survival to indicate a firm's competitive advantage (Schilke *et al.*,
10
11 2018; Shamsie *et al.*, 2009), we quantify it in terms of abnormal stock returns in this research.
12
13 This is because abnormal stock returns, as measured based on the event study method discussed
14
15 in Section 3, are the difference in stock returns between firms implementing 3DP and their
16
17 industry peers without 3DP implementation, which is more in line with the concept of
18
19 competitive advantage discussed in the literature. Moreover, such "abnormal" stock returns are
20
21 consistent with the "above average returns" or "abnormal rents" emphasized in prior research
22
23 on dynamic capabilities (Jiang *et al.*, 2015; Oliver and Holzinger, 2008). Therefore, we
24
25 hypothesize that:
26
27
28
29

30
31 *H1: Firms' 3DP implementation has a positive impact on their stock returns.*
32
33

34 35 2.3 The contingent role of industry environments 36 37

38
39 Contingency theory submits that there is no one best way of organizing or one-size-
40
41 fits-all strategy (Chavez *et al.*, 2013; Zhang *et al.*, 2012). Instead, the contingency literature
42
43 has commonly agreed that firms do not operate in a vacuum and better firm performance is a
44
45 consequence of the proper alignment of firms' internal characteristics with external contextual
46
47 factors (Sousa and Voss, 2008; Wong *et al.*, 2011). Put into our research context, it is possible
48
49 that the extent to which the competitive advantage due to 3DP implementation can be realized
50
51 depends on the alignment of the 3DP-enhanced manufacturing capabilities with firms'
52
53 operating environments. For example, if firms' operating environments do not provide
54
55 sufficient resources and support for firms to implement 3DP, it may be difficult for the firms
56
57 to reap the benefits of 3DP innovation. Similarly, if firms' operating environments do not
58
59
60

1
2
3 present the need for more advanced manufacturing capabilities, the manufacturing capabilities
4 enhanced by 3DP implementation may not help firms to gain a competitive advantage.
5
6

7
8 In fact, although the positive relationship between manufacturing capabilities and
9 competitive advantage has been well documented in the literature, some prior studies have
10 shown non-significant or even negative relationships under certain circumstances. For instance,
11 a meta-analysis conducted by White (1996) suggested that the manufacturing capabilities-
12 business performance relationships as documented in the literature range from positive to non-
13 significant, while Corbett and Claridge (2002) showed that such relationships could be negative
14 in some industries. Kim and Arnold (1993) also questioned whether manufacturing capabilities
15 matter in all industries or they matter more in some specific industries. Informed by the findings
16 of those prior studies and through the lens of contingency theory, we consider how industry
17 environments moderate the impact of 3DP implementation on stock returns. In particular, we
18 focus on three industry characteristics, namely munificence, dynamism, and competition
19 (Jansen *et al.*, 2006; Park and Mezias, 2005) in this research because they represent different
20 levels of environmental support and environmental requirement for 3DP implementation, as
21 discussed below.
22
23
24
25
26
27
28
29
30
31
32
33
34
35
36
37
38
39

40 *Industry munificence* refers to the level of resources available to support the sustained
41 growth of the firms in the industry (Dess and Beard, 1984; Park and Mezias, 2005). It is
42 primarily determined by the rate of sales growth in the industry (Dess and Beard, 1984). In an
43 industry with high level of munificence, firms are more likely to accumulate slack resources
44 such as venture capital, government funds, labor markets, and suppliers (Dess and Beard, 1984;
45 Park and Mezias, 2005). Dess and Beard (1984) indicated that these slack resources not only
46 function as buffer during times of scarcity, but also facilitate organizational innovation. Firms
47 implementing 3DP in munificent industries are more likely to gain benefits because the
48 effectiveness of 3DP depends on the availability of several critical resources such as qualified
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 experts, software vendors, and investment capitals (Huang *et al.*, 2012; Shukla *et al.*, 2018;
4
5 Thomas-Seale *et al.*, 2018). On the contrary, firms in the industry with low level of munificence
6
7 could encounter several obstacles preventing them from accessing the resources for
8
9 development. These obstacles may include tax burdens, fragile infrastructure, inaccessible
10
11 technology support from educational institutions, and lack of qualified labor (Chen *et al.*, 2014).
12
13 In general, 3DP implementation is more likely to be effective when firms are operating in more
14
15 munificent industries (Chen *et al.*, 2014; Terjesen *et al.*, 2011). Thus we hypothesize that:
16
17

18
19 *H2: The impact of 3DP implementation on stock returns will be higher for firms*
20
21 *operating in more munificent industries.*
22
23

24
25
26 *Industry dynamism* refers to the instability of the environment (Dess and Beard, 1984;
27
28 Jansen *et al.*, 2006). Dess and Beard (1984) further emphasized that dynamism should be
29
30 restricted to the changes which are unpredictable. Dynamic industries are characterized by
31
32 changeable customer preferences, unpredictable technology development, fluctuated market
33
34 demand, and inconstant government regulations (Anand and Ward, 2009; Stoel and Muhanna,
35
36 2009). Anand and Ward (2009) indicated that in order to cope with a large number of
37
38 unpredictable scenarios, firms are required to broaden process scope by maintaining diverse
39
40 capabilities and building up excess capacity, which inevitably leads to higher costs. As a result,
41
42 manufacturing capabilities play a significant role in gaining competitive advantage in dynamic
43
44 industries. Firms investing in 3DP are allowed to move between different product designs and
45
46 production volumes with less incurring time and cost penalties, and thus are likely to gain
47
48 greater advantages. Similar to Stoel and Muhanna's (2009) argument about externally-oriented
49
50 IT, we believe that the effectiveness of 3DP is more pronounced in dynamic environments in
51
52 that it enables firms to better sense the market through customization and timely respond to the
53
54 fluctuations in customer and supplier demand. Overall, we expect the 3DP-enhanced
55
56
57
58
59
60

1
2
3 manufacturing capabilities to enable firms to better meet the requirements induced in more
4
5 dynamic industries and gain a competitive advantage. Therefore, we hypothesize that:

6
7
8 *H3: The impact of 3DP implementation on stock returns will be higher for firms*
9
10 *operating in more dynamic industries.*

11
12
13
14
15 *Industry competition* refers to intensity of competition in an industry, often reflected in
16
17 the number of competitors and the concentration of market shares (Jansen *et al.*, 2006; Melville
18
19 *et al.*, 2004). Low level of concentration represents a competitive market with market shares
20
21 almost evenly distributed among a large number of competitors, while high level of
22
23 concentration depicts a monopoly or oligopoly industry with a small number of competitors
24
25 dominating the market (Azadegan *et al.*, 2013). While industry munificence and industry
26
27 dynamism indicate the levels of environmental support and environmental requirement,
28
29 respectively, for 3DP implementation, industry competition implies a more complicated
30
31 situation. First, similar to industry dynamism, industry competition can represent the level of
32
33 environmental requirement for 3DP implementation. For example, in highly competitive
34
35 industries, firms are motivated to break out the price war by differentiating themselves from
36
37 their competitors who are providing homogeneous products or services (Chen *et al.*, 2014). In
38
39 particular, through product innovation, new market exploration, and enhanced tailoring of
40
41 products or services, firms are able to gain an advantage over their competitors (Jansen *et al.*,
42
43 2006). The implementation of 3DP can help firms achieve such differentiations and satisfy the
44
45 requirements arising from the competitive markets. Specifically, 3DP facilitates product
46
47 innovation by eliminating the iteration costs and manufacturing limitations in the product
48
49 design process (Weller *et al.*, 2015). 3DP also allows customization without cost penalties,
50
51 consequently increasing customers' perceived values and willingness to pay (Shukla *et al.*,
52
53 2018). Therefore, it is possible that 3DP implementation will be more valuable for firms in
54
55
56
57
58
59
60

1
2
3 industries with high level of competition. As a result, industry competition is expected to have
4
5 a positive moderating effect on the 3DP implementation-stock returns relationship such that
6
7 the impact of 3DP implementation on stock returns will be higher for firms operating in more
8
9 competitive industries.
10

11
12 However, industry competition can also be related to the level of environmental support
13
14 for 3DP implementation. This is because in highly competitive industries with a large number
15
16 of competitors, resources are relatively scarce as firms compete not only for customers and
17
18 market shares but also for inputs into the production processes such as qualified labors and
19
20 investment capitals (Prajogo and Oke, 2016). Moreover, due to low entry barriers and intensive
21
22 competition in such industries, the adoption of new innovation such as 3DP will be
23
24 aggressively matched by competitors, reducing the adopters' first-mover advantage and the
25
26 power to generate abnormal rents from the innovation adoption (Jansen *et al.*, 2006; Melville
27
28 *et al.*, 2004). As a result, competitive industries exhibit a low level of environmental support
29
30 for firms to implement 3DP. By contrast, in monopoly or oligopoly industries with a small
31
32 number of competitors, resources are readily available to a few dominant players to support
33
34 their 3DP implementation. Due to low competition, they have strong power to charge a price
35
36 premium for the products and services offered by them. Weller *et al.* also suggested that "in a
37
38 monopoly, the adoption of AM [Additive manufacturing] allows a firm to increase profits by
39
40 capturing consumer surplus when flexibly producing customized products" (2015, p. 43).
41
42 Therefore, from the environmental support perspective, industry competition will have a
43
44 negative, rather than positive, moderating effect on the 3DP implementation-stock returns
45
46 relationship such that the impact of 3DP implementation on stock returns will be higher for
47
48 firms operating in less competitive industries.
49
50
51
52
53
54

55
56 The above discussion suggests two opposite moderating roles for industry competition.
57
58 In fact, past empirical studies have also documented mixed results regarding the role of
59
60

1
2
3 competition (Prajogo and Oke, 2016; Wilden *et al.*, 2013). For example, Wilden *et al.* (2013)
4
5 found that the performance impact of dynamic capabilities improves in competitive
6
7 environments, whereas Prajogo and Oke (2016) showed that competitive environments weaken
8
9 the relationship between service innovation advantage and business performance. Informed by
10
11 the findings of those past studies and based on the above discussion, we propose two competing
12
13 hypotheses for the role of industry competition:
14
15

16
17 *H4a: The impact of 3DP implementation on stock returns will be higher for firms*
18
19 *operating in more competitive industries.*

20
21 *H4b: The impact of 3DP implementation on stock returns will be higher for firms*
22
23 *operating in less competitive industries.*
24
25

26 27 28 **3. Methods**

29 30 *3.1 Sample*

31
32 We attempt to identify the population of U.S. publicly listed firms that announced the
33
34 implementation of 3DP. Consistent with prior studies (Ding *et al.*, 2018; Sorescu *et al.*, 2017),
35
36 we conducted a comprehensive search in the Factiva news database with 3DP related keywords
37
38 to collect firm announcements of 3DP implementation across all industries between 2010 and
39
40 2017. The keywords used in this study are (NASDAQ or NYSE or AMEX) and (3D print* or
41
42 three-dimensional print* or additive manufactur* or rapid manufactur* or rapid prototyp*). We
43
44 reviewed all the announcements collected from Factiva to ascertain that they meet the
45
46 following criteria. (1) The announcement should be related to applying 3DP technology to the
47
48 firm's business practices such as product design and development, rapid prototyping,
49
50 specialized manufacturing, service providing and other related activities. Announcements only
51
52 informationally associated with 3DP without applications were excluded. For example, the
53
54 announcement about Staples becoming the first U.S. retailer to sell 3D printers was eliminated.
55
56
57
58
59
60

(2) For the same type of 3DP implemented by a firm, only the earliest announcement was included (Ding *et al.*, 2018). However, announcements made by the same firm reporting different types of 3DP implementation were included. For example, the announcement about Ford using 3DP to produce prototype parts and the announcement about Ford launching an online 3DP store to provide scale model printing services for customers were both included.

(3) Announcements made by private firms or firms not listed on NYSE, AMEX, or NASDAQ were excluded. The process resulted in 242 announcements made by 132 firms. For further matching process, we excluded 7 firms without data in Compustat and 3 firms with negative book to market ratios. The final sample consists of 232 announcements made by 122 firms.

Some examples of the announcements are shown below.

- Under Armour's 3D-printed shoes bring computer designer to heel.
- Ford begins large-scale 3D printing trial.
- Amazon offers 3D printing to customize earrings, bobble head toys.
- UPS store makes 3D printing accessible to start-ups and small business owners.

A key challenge of relying on announcements for this kind of research is the issue of "decoupling", meaning that firms may not actually implement 3DP after they make the announcements. To verify the consistency of words and deeds, we further searched in Google to check whether firms implemented the announced 3DP based on information from various sources. For each of the 232 announcements, our search included the type of 3DP mentioned in the announcement and the name of the announcing firm. We were able to identify 207 announcements with information related to the implementation of the 3DP announced, representing about 89% of the 232 announcements used in our research. As most announcements have been verified, we believe the decoupling issue is not a major concern in our research.

(Insert Table 1 about here)

1
2
3 Table 1 presents the distributions of the announcements across years and industries and
4 the descriptive characteristics of the announcing firms. It shows that the majority (81%) of the
5
6 the descriptive characteristics of the announcing firms. It shows that the majority (81%) of the
7
8 announcements were made in the recent four years from 2014 to 2017, indicating soaring
9
10 adoption rates. Most of the announcements (66%) are from manufacturing industries, while the
11
12 remaining are from service industries or others¹. The average market value of the announcing
13
14 firms is 72160.8 million U.S. dollars, suggesting that the announcements are mostly from large-
15
16 scale firms.
17
18
19
20
21

22 3.2 Long-term event study method

23
24 We employ the long-term event study method to quantify the performance impact of
25
26 3DP implementation in terms of stock returns (Kothari and Warner, 2007). We choose to focus
27
28 on stock returns rather than accounting-based operating performance indicators such as sales
29
30 growth and cost reduction (De Jong *et al.*, 2014; Orzes *et al.*, 2017) for several reasons. First,
31
32 the implementation of 3DP varies greatly across industries such as healthcare, automotive
33
34 manufacturing, fashion, consumer products, and aerospace, so it is difficult to determine
35
36 appropriate operating performance measures that fit in all the contexts of different types of
37
38 implementation. Moreover, operating performance indicators such as sales and costs focus on
39
40 a firm's tangible value, which may fail to account for the impact of 3DP implementation on
41
42 the firm's intangible value. Stock returns, on the other hand, represent a firm's overall value,
43
44 taking both tangible and intangible components into account (Joshi and Hanssens, 2010;
45
46
47
48
49

50
51 ¹ To verify whether our sample is representative in terms of industry distribution, we included the
52
53 keyword "service" and "manufacturing", and searched the announcements of 3DP implementation
54
55 made by both publicly listed and private firms in Factiva between 2010 and 2017. About 68% of the
56
57 announcements were found when the keyword "manufacturing" was included, corresponding with our
58
59 sample distribution.
60

1
2
3 Sorescu *et al.*, 2017) and thus more likely to capture the overall performance impact due to
4
5 3DP implementation. In addition, accounting-based performance indicators are lagging
6
7 measures, representing a firm's performance over a specific period (e.g., a fiscal year). This
8
9 suggests that it may take a relatively long time period for the impact of a firm's strategy to be
10
11 reflected in the accounting-based performance measures, especially when technology
12
13 implementation is involved. For example, Hendricks *et al.* (2007) examined the impact of the
14
15 implementation of enterprise systems on accounting-based performance measures over a five-
16
17 year period. Such an approach is not feasible for our research as 63% of the 3DP
18
19 implementation were announced in 2015 to 2017, suggesting that our sample size will drop
20
21 drastically if a five-year investigation period is applied. On the other hand, stock returns are a
22
23 forward-looking measure (Sorescu *et al.*, 2017), which indicates investors' expectation of a
24
25 firm's future performance and better suits our research context.

26
27
28
29
30 We prefer quantifying the impact of 3DP implementation in terms of long-term rather
31
32 than short-term stock returns (Ding *et al.*, 2018) as stock markets may fail to reveal the true
33
34 intrinsic value of 3DP implementation within a short time period. Specifically, immediately
35
36 after the announcements are made, investors possibly over-react to the 3DP implementation
37
38 due to over-optimism and limited knowledge. In an investigation of e-commerce, Ferguson *et*
39
40 *al.* (2010) argued that stock market may overprice the added value of technologies which are
41
42 regarded as innovative, exciting, and glamorous. Similarly, we believe that there could also be
43
44 an upward bias in investors' valuation of 3DP, which is perceived as a groundbreaking
45
46 technology to disrupt conventional manufacturing. As Hendricks and Singhal (2001) indicated
47
48 in a study of TQM, the market may wait for more information to incrementally acquire
49
50 knowledge about new innovation and judge its effectiveness. Therefore, we adopt the long-
51
52 term event study method to examine the stock returns due to the implementation of 3DP which
53
54 is a pioneering technology with relatively little knowledge of its value.
55
56
57
58
59
60

1
2
3 For the long-term event study, we calculate the abnormal stock returns as the buy-and-
4 hold return (BHR) of the sample firms less the BHR of an appropriate benchmark (Barber and
5 Lyon, 1997; Lyon *et al.*, 1999). The buy-and-hold abnormal return (BHAR) is
6
7
8

$$9 \quad \text{BHAR} = \prod_{t=1}^T (1 + R_{it}) - \prod_{t=1}^T (1 + R_{bt}),$$

10
11
12 where R_{it} is the monthly stock return of the sample firm i in month t , R_{bt} is the monthly stock
13 return of the control firm paired with sample firm i in month t , and T is the length of the event
14 window. Monthly stock returns were retrieved from the Center for Research in Security Prices
15 (CRSP) database. In developing the benchmark, we follow the standard procedures proposed
16 in previous research (Barber and Lyon, 1997; Hendricks and Singhal, 2001) and match each
17 sample firm to a control firm based on different combinations of three widely-accepted
18 characteristics, namely industry, size, and market-to-book (MTB) ratio. The control firm
19 approach has advantages in eliminating new listing bias, rebalancing bias, and the skewness
20 problem compared with the portfolio approach (Barber and Lyon, 1997). As the maturity level
21 and magnitude of sustainability benefits of 3DP vary across industries (Thomas-Seale *et al.*,
22 2018), we emphasize industry as an important matching criteria to control for industry
23 heterogeneity (Hendricks and Singhal, 2001). We use all the NYSE, NASDAQ, and AMEX
24 listed firms without 3DP implementation announcements as the benchmark pool². Industry is
25 indicated by the firm's primary SIC code, size is measured as the market value of equity, and
26 MTB ratio is calculated as market value of equity divided by book value of equity. All the
27 accounting data are in the most recent fiscal year prior to the announcement year and were
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51

52
53 ² We further verified whether the matched control firms have implemented 3DP. Specifically, we
54 searched a combination of 3DP related keywords and the names of the matched control firms in Factiva
55 between 2010 and 2017. We could not identify any control firm that had implemented 3DP in this time
56 period, confirming the appropriateness of the control firms used in our research.
57
58
59
60

retrieved from the Compustat database. To enable us to check the sensitivity of our results, we take three different matching approaches to identify the control firm for each firm-year observation: (1) For the industry-size match, we first match a sample firm to control firms with the same four-digit SIC code, then the control firm closest in size is identified. If the control firm is not found, we match the sample firm to control firms with the same three-digit SIC code. The control firm must have at least same two-digit SIC code as the sample firm and is closest in size. (2) For industry-MTB match, we follow similar procedures as in the industry-size match, but the control firm closest in MTB ratio is identified. (3) For industry-size-MTB match, we follow similar procedures as in the industry-size match, but the control firm closest in the absolute percentage difference between size and MTB ratio is identified. As a robustness test, we adopt propensity score matching (PSM) as an alternative matching approach to control for other factors besides industry, size, and MTB ratio, as discussed in Section 4.

We set the calendar month when the announcement was made public as the event month 0. The month before and after the event month are denoted as month -1 and 1, respectively. In reality, it usually takes several months for firms to finish the implementation of 3DP, suggesting that the effectiveness of 3DP implementation may not manifest until a few months after the announcement month. However, as there is little guidance in the literature regarding the appropriate time period for 3DP implementation, we determine the length of implementation period based on the evidence provided in our sample announcements. For example, Mattel Inc. announced on April 20, 2016 that they start a collaboration with Autodesk Inc. to power the Mattel toy line with cutting-edge 3D printing technology. Ten months later, Mattel introduced their 3D printing eco-system named ThingMaker to enable consumers to design, create, and print their own toys (Business Wire, 2015). Based on the information in the announcements and previous long-term event studies (Hendricks and Singhal, 2001), we set month (1, 12) as the time period required for implementation. A long post-implementation

investigation period may capture the effect of 3DP implementations more extensively but also reduce our sample size substantially as most of our announcements were released between 2014 and 2017. To strike a balance, we set the post-implementation period as month (13, 24). We measure the effect of 3DP implementation over both implementation and post-implementation periods, i.e., month (1, 12) and month (1, 24), to fully capture the market reactions. Month (-24, -1) is set as the pre-implementation period. We conduct *t*-test, Wilcoxon-signed rank (WSR) test, and sign test to determine the significance of the BHARs over different periods but mainly focus on the non-parametric test results due to their better ability to account for possible extreme values of BHARs. Moreover, as the multiple event windows used in our research might increase the possibility of false positive results, we follow Orzes *et al.* (2017) and adopt the approach proposed by Benjamini and Hochberg (1995) to control the false discovery rate (FDR) and address the multiple testing concern.

3.3 Cross-sectional regression

(Insert Table 2 about here)

We construct a cross-sectional regression model as shown below to investigate the moderating role of environmental factors including industry munificence, dynamism, and competition. Table 2 presents the measures, data sources, and references of the variables in the regression analysis.

$$\begin{aligned}
 BHAR_i &= \beta_0 + \beta_1 Firm\ size_i + \beta_2 MTB\ ratio_i + \beta_3 R\&D\ intensity_i + \beta_4 \\
 &Prior\ performance_i + \beta_5 Capital\ structure_i + \beta_6 Momentum_i + \beta_7 \\
 &Velocity_i + \beta_8 Manufacturing_i + Year\ dummies + \beta_9 Munificence_i + \beta_{10} \\
 &Dynamism_i + \beta_{11} Competition_i + \varepsilon_i
 \end{aligned}$$

The dependent variable is the BHAR calculated for each sample firm over a specific event window. As to the independent variables, we control for several firm-specific, industry-specific and market-specific factors that have been commonly identified to potentially affect

1
2
3 firms' stock returns (Ding *et al.*, 2018; Lam, 2018; Hendricks and Singhal, 2001; Qian and
4
5 Zhu, 2017; Sorescu *et al.*, 2017). We also include year dummies to account for unobservable
6
7 time-specific effects (Jacobs *et al.*, 2015). We rely on β_9 , β_{10} , and β_{11} to determine the effects
8
9 of industry munificence, dynamism, and competition, respectively.
10
11
12
13
14

15 **4. Results**

16 *4.1 The stock returns of 3DP implementation*

17
18
19 (Insert Table 3 about here)
20

21
22 Table 3 presents the BHAR results based on three different matching approaches:
23 industry-size match, industry-MTB match, and industry-size-MTB match. To alleviate the
24 concern that other factors rather than 3DP implementation might affect firm performance, we
25 test the BHARs during pre-implementation periods (Yang *et al.*, 2019). If significant BHARs
26 are found even before 3DP is implemented, we might suspect that the significant BHARs, if
27 any, detected during the post-implementation period are driven by other factors rather than
28 3DP implementation. The BHARs over three multi-month periods (i.e., month (-24, -1), (-24,
29 -13), (-12, -1)) prior to 3DP implementation are not significant ($p > 0.1$) across the three
30 matching approaches, indicating that the sample and control firms are comparable in terms of
31 potential BHARs if the sample firms had not implemented 3DP.
32
33
34
35
36
37
38
39
40
41
42
43

44
45 We then look at the BHARs in the implementation periods within month (1, 12). In
46 different time periods within month (1, 12), the BHARs are generally non-significant ($p > 0.1$)
47 across the three matching approaches, except the BHAR over month (1, 12) with the industry-
48 size-matched control firms, which is significant at the 10% level based on sign test. Overall,
49 the non-significant test results confirm our expectation that it may take a few months for firms
50 to implement 3DP and the value of 3DP implementation cannot emerge immediately following
51 the announcement.
52
53
54
55
56
57
58
59
60

1
2
3 However, for longer time periods including the post-implementation periods of month
4 (13, 24), there are significant positive changes in BHARs ($p < 0.1$) across the three matching
5 approaches, especially when non-parametric tests are conducted. These positive results justify
6 our choice of the long-term event study method and show the importance of focusing on 3DP's
7 post-implementation periods. As we find significant positive BHARs after the implementation
8 of 3DP, H1 is supported.

19 4.2 *The moderating effect of environmental factors*

20
21
22 (Insert Table 4 about here)

23
24 Table 4 presents the correlations among variables to be included in the regression
25 analysis. For brevity in presenting and discussing our results, the regression analysis with the
26 dependent variable of BHAR over month (1, 18) calculated with the industry-size-matched
27 group is shown in Table 5. To check the sensitivity of the results, BHARs measured with
28 alternative event window (1, 24) and matching approaches (industry-MTB match and industry-
29 size-MTB match) are also tested and presented in Table 8.
30
31
32
33
34
35
36
37

38 (Insert Table 5 about here)

39
40 Model 1 is the basis model with a variety of control variables included. In Models 2-4,
41 industry munificence, dynamism, and competition are added gradually. The value of R -squared
42 increases with additional variables added to the regression, showing that each environmental
43 factor explains a significant amount of variation in the BHAR. Specifically, the coefficient of
44 industry munificence is positive and significant ($p < 0.01$) across Models 2-4, suggesting that
45 the stock returns of 3DP implementation is more positive for firms operating in more
46 munificent industries. H2 thus is supported. The coefficient of industry dynamism is positive
47 and significant ($p < 0.05$) in Models 3 and 4, indicating that the BHAR is higher for firms
48 operating in more dynamic industries. Therefore, H3 is supported. The coefficient of industry

54
55
56
57
58
59
60

1
2
3 competition is negative and significant ($p < 0.05$) in Model 4, showing that firms operating in
4 more competitive industries benefit less from 3DP implementation. As a result, H4a is rejected
5 but H4b is supported. The hypothesis test results based on both event study and regression
6 analysis are summarized in Figure 2.

13
14
15
16

17 4.3 Sensitivity analyses

18
19 We conduct several sensitivity analyses to check the robustness of our findings and to
20 account for alternative explanations.
21
22

23
24 *Propensity score matching (PSM)*. We employ the PSM approach to match each
25 sample firm with a control firm that had a similar probability or propensity as the sample firm
26 to implement 3DP but eventually did not implement 3DP. This matching approach enables us
27 to control for other factors that may influence 3DP implementation and address possible self-
28 selection bias (Austin, 2011; Ding *et al.*, 2018). To implement PSM, we first construct a logistic
29 regression model with 3DP implementation as the dependent variable while the independent
30 variables include industry dummies, firm size, MTB ratio, return on asset, R&D intensity,
31 industry velocity, industry munificence, industry dynamism, and industry competition. After
32 running the logistic regression, the firms in the benchmark pool with the closest propensity
33 scores to the sample firms are chosen as the control firms. The resulting BHARs based on the
34 PSM approach shown in Table 6 reveal a consistent pattern as that found in our main analyses.
35
36

42
43
44
45
46
47
48

49 (Insert Table 6 about here)
50

51
52 *Reduced sample size*. The results shown in Table 3 suggest that our sample size drops
53 significantly for longer event windows because about 45% of our announcements were made
54 in 2016 and 2017. To check whether the decrease in sample size leads to biased estimation, we
55 follow De Jong *et al.* (2014) and calculate the BHARs for the reduced sample across all the
56
57
58
59
60

1
2
3 event windows. We focus on the subgroup of firms that have monthly stock return data over
4
5 the longest time period of month (1, 24). The BHARs of this subsample generally follow a
6
7 similar pattern as those of the firms in the full sample, as shown in Table 7. Specifically, the
8
9 BHARs over three multi-month periods (i.e., month (-24, -1), (-24, -13), (-12, -1)) prior to the
10
11 implementation are not significant ($p > 0.1$). However, over the post-implementation periods,
12
13 especially for month (13, 18), (1, 18) and (1, 24), we find significant positive BHARs across
14
15 all three matching approaches. In addition, the results show that this subsample enjoys greater
16
17 gains in BHARs and earlier in time (e.g., month (7, 12), (1, 12)) compared with the full sample.
18
19 One possible explanation is that these firms are early 3DP adopters, thus achieving greater
20
21 benefits due to the first-mover advantage (Hendricks *et al.*, 2007).
22
23
24

25
26 (Insert Table 7 about here)
27

28
29 *Alternative dependent variable.* We also examine whether the results of regression
30
31 analysis are consistent if BHAR with alternative event window and benchmark is used as the
32
33 dependent variable. Table 8 presents the regression results with the BHAR calculated over
34
35 month (1, 24) and with industry-MTB-matched and industry-size-MTB-matched benchmark
36
37 groups. The coefficients of the three environmental factors are significant and consistent across
38
39 different regression models, demonstrating the robustness of our regression results.
40
41

42
43 (Insert Table 8 about here)
44
45
46

47 **5. Discussion and conclusions**

48
49 Based on 232 announcements of 3DP implementation made by U.S.-listed firms from
50
51 2010 to 2017, we employ the event study method to examine the stock returns of 3DP
52
53 implementation over two years after the announcements. The event study results show
54
55 significant higher BHARs of sample firms compared with their non-implementation industry
56
57 peers over the two-year post-implementation period. Our cross-sectional regression analysis
58
59
60

1
2
3 further suggests that the stock returns due to 3DP implementation are more pronounced for
4 firms operating in more munificent, more dynamic, and less competitive industry environments.
5
6 Those findings are consistent with our CDC perspective which integrates the dynamic
7 capabilities view with contingency theory. The empirical evidence documented and theoretical
8 perspective adopted in our study provide important implications for practice and research, as
9 discussed below.

17
18

19 *5.1 Managerial contribution*

20
21 Although 3DP has received extensive public attention in recent years, the current level
22 of adoption of the technology is still relatively low. Such a low adoption rate is partly due to
23 practitioners' lack of the knowledge of 3DP and difficulties to quantify its impact (Ernst &
24 Young, 2016). Our study represents one of the first research efforts examining the impact of
25 3DP implementation in terms of stock returns. We employ the event study method to provide
26 an objective documentation of the positive stock returns due to 3DP implementation, which
27 helps resolve the controversy over the business value of 3DP and encourage firms to implement
28 3DP to reap the financial benefits. The positive stock returns documented in our research also
29 enable firms to convince their shareholders or investors to support their 3DP implementation.
30
31 However, firms should realize that 3DP is not a "quick fix" solution as we cannot find
32 significant positive stock returns in the first few months following the announcements of 3DP
33 implementation. This can be attributed to the fact that 3DP implementation is a complex
34 process and it takes time for firms to overcome various barriers (e.g., technical issues, human
35 resources, quality concerns) in order to implement 3DP (Shukla *et al.*, 2018; Thomas-Seale *et*
36 *al.*, 2018). Instead, our research suggests that the positive stock returns become more
37 significant in the long run (about two years after the announcements of 3DP implementation).
38
39 Therefore, managers (and also investors) should be patient with 3DP implementation, allowing
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 3DP's value to emerge in the post-implementation periods.
4

5 While we encourage firms to implement 3DP based on the positive stock returns
6 documented in our research, we also urge them to pay attention to the industry environments
7 in which the 3DP is implemented. This is because our research shows that the stock returns
8 due to 3DP implementation vary across different industry environments. In particular, our
9 research suggests that firms can benefit more from 3DP implementation in munificent and
10 dynamic industries. Munificent industries are characterized by their sufficient resources to
11 support firms' growth, which are important to 3DP implementation. Various critical barriers
12 such as "education, cost, software, material, mechanical properties, validation and finishing"
13 (Thomas-Seale *et al.*, 2018, p. 108) have limited the broader applications of 3DP. The resources
14 available in munificent industries can help firms overcome those barriers and support the
15 effective implementation of 3DP. On the other hand, in dynamic industries with fluctuating
16 market demands and changing customer preferences, 3DP enables firms to gain a competitive
17 advantage due to its ability to help firms improve manufacturing flexibility and product variety
18 (Dong *et al.*, 2017; Shukla *et al.*, 2018). For example, in the highly dynamic apparel industry,
19 Nike was able to implement 3DP to slash the time required for manufacturing and testing and
20 better accommodate the ever-changing fashion (Jopson, 2013). Therefore, we urge firms
21 operating in munificent and dynamic industries to take advantage of their operating
22 environments to reap more benefits from 3DP implementation.
23
24
25
26
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45

46 However, our research suggests that firms operating in competitive industries with a
47 large number of competitors may not benefit from 3DP implementation. Although
48 implementing 3DP can enable a firm to differentiate itself from its competitors in competitive
49 industries, it is difficult for the firm to gain sufficient resources to support its 3DP
50 implementation due to the intensive competition for resources among firms in such industries.
51 Our research shows that the negative effect due to weak support for 3DP implementation
52
53
54
55
56
57
58
59
60

1
2
3 overweighs the positive effect arising from strong demand for 3DP implementation, resulting
4
5 in lower benefits gained from 3DP implementation in competitive industries. This finding
6
7 provides important implications for policy makers. In particular, for industries with strong
8
9 demand but weak support for 3DP implementation, governments can provide better financial
10
11 (e.g., tax incentives) and non-financial resources (e.g., education and trainings) to support 3DP
12
13 implementation, enabling 3DP adopters to gain competitive advantage in such industries.
14
15
16
17
18

19 *5.2 Theoretical contribution*

21
22 Our CDC perspective provides a comprehensive and complementary theoretical
23
24 explanation of the 3DP implementation-stock returns relationship. On the one hand, we deploy
25
26 the dynamic capabilities view (Barreto, 2010; Schilke *et al.*, 2018) to theorize how 3DP
27
28 implementation enhances firms' manufacturing capabilities through broadening their
29
30 operational scopes without cost penalties, ultimately leading to improved competitive
31
32 advantage and resulting in positive stock returns. This theorization enables us to link firms'
33
34 practices or strategies such as 3DP implementation to their performance in terms of stock
35
36 returns. On the other hand, we adopt contingency theory (Reinking, 2012; Sousa and Voss,
37
38 2008) to reject the one-size-fits-all assumption and explore the possible fit between 3DP-
39
40 enhanced manufacturing capabilities and firms' operating environments in terms of industry
41
42 munificence, dynamism, and competition. We theorize how these industry variables represent
43
44 different levels of environmental support and environmental requirement for 3DP
45
46 implementation, thus moderating the impact of 3DP implementation on stock returns. Taken
47
48 together, this CDC perspective advances our understanding of the 3DP implementation-stock
49
50 returns relationship as it considers not only the direct impact of 3DP implementation on stock
51
52 returns but also the indirect moderating role of firms' operating environments. We believe this
53
54 CDC perspective can serve as a useful theoretical foundation for future 3DP research. In
55
56
57
58
59
60

1
2
3 particular, it urges researchers to shift their focus from the discussion of 3DP's technological
4 features and industrial applications (Lam *et al.*, 2002; Ventola, 2014; Williams *et al.*, 2010) to
5 a more strategic view on 3DP implementation, exploring its ability to enhance firms'
6 manufacturing capabilities and its potential to contribute to firms' competitive advantage.
7 Moreover, it also reminds researchers about the importance of taking firms' operating
8 environments in which the 3DP is implemented into account. While our research is focused on
9 industry munificence, dynamism, and competition, future research can adopt the CDC logic to
10 further explore other environmental characteristics that may exhibit varying levels of alignment
11 with 3DP implementation and thus affect its performance impact.
12
13
14
15
16
17
18
19
20
21
22
23

24 Our research contributes to the literature on dynamic capabilities and contingency
25 theory in several ways. First, we extend the dynamic capabilities view to consider the role of
26 other dimensions of firms' operating environments beyond environmental dynamism. In
27 addition to confirming the dynamic capabilities view that stresses the importance of developing
28 dynamic capabilities to satisfy the requirements arising from "rapidly changing environments"
29 (Teece *et al.*, 1997, p. 516) or dynamic environments, our research suggests it is also crucial
30 for the environments to provide sufficient support for firms to develop such capabilities in
31 order to gain a competitive advantage. Specifically, our research shows that munificent
32 environments with sufficient resources and support available for firms to implement 3DP
33 enable them to gain higher stock returns. Moreover, our research on industry competition
34 further suggests that environmental support may be even more critical than environmental
35 requirement when there is a conflict between them. Specifically, although competitive
36 environments exhibit the requirement or demand for developing dynamic capabilities, such
37 environments with a large number of competitors may not possess sufficient resources to
38 support firms to develop the required dynamic capabilities, thus preventing them from gaining
39 competitive advantage in such environments. Therefore, our research highlights the limitations
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 of focusing only on environmental requirement in general and environmental dynamism in
4 particular and encourages future dynamic capabilities research to explore the roles of other
5 dimensions of firms' operating environments.
6
7
8
9

10 On the other hand, while the contingency literature has considered many different
11 environmental variables that may moderate the performance outcomes of firms' practices or
12 strategies, it has been criticized for relying too much on the "it all depends" notion without
13 more theoretical classifications of those external factors (Reinking, 2012). Our research helps
14 address this concern by characterizing firms' operating environments in terms of
15 environmental support and environmental requirement. We believe such classifications should
16 be beneficial to future contingency research for explaining the performance variation due to
17 the fit between other firm strategies beyond 3DP implementation and other environmental
18 variables beyond munificence, dynamism, and competition. In particular, researchers can adopt
19 our classifications to theorize whether the specific environmental variables considered in their
20 research indicate different levels of environmental support and/or environmental requirement
21 for the specific firm strategies concerned, thus affecting the extent to which such strategies
22 impact on firm performance.
23
24
25
26
27
28
29
30
31
32
33
34
35
36
37
38
39

40 Finally, our research sheds some light on the structure-conduct-performance
41 framework that has been frequently adopted in the operations management literature to study
42 manufacturing capabilities (Terjesen *et al.*, 2011). In particular, prior research has relied on
43 this framework to view environmental conditions as a driver of firms' manufacturing strategies
44 and capabilities, which in turns lead to firm performance (Mellor *et al.*, 2014; Ward and Duray,
45 2000). Although we do not reject this causal sequencing explanation, our CDC perspective
46 stresses the overlooked moderating role of environmental conditions in the manufacturing
47 capabilities-firm performance relationship. To put it another way, our research suggests that
48 structure can be viewed not only as a driver but also as a moderator in the conduct-performance
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 relationship. Our research thus enriches the structure-conduct-performance framework by
4
5 encouraging future research to consider the multiple roles that structure plays in the conduct-
6
7 performance relationship.
8
9

10 11 12 *5.3 Limitations and future research* 13

14
15 Our research suffers from several limitations which in turn create new opportunities for
16
17 future research. First, our research is focused on U.S. publicly listed firms, which may limit
18
19 the generalizability of our findings to private firms and firms located in other countries. Indeed,
20
21 private firms should possess less resources compared with publicly listed firms, which may
22
23 affect their 3DP implementation. Similarly, firms located in different countries may receive
24
25 different levels of environmental support to implement 3DP, thus reaping different benefits
26
27 from 3DP implementation. Therefore, it would be interesting for future research to examine
28
29 the benefits of 3DP implementation for other firms (e.g., private firms) and in different contexts
30
31 (e.g., developing countries).
32
33
34

35
36 Moreover, we study the impact of 3DP implementation in terms of stock returns.
37
38 Although stock returns represent overall firm value and better capture the full performance
39
40 impact due to 3DP implementation (Joshi and Hanssens, 2010; Sorescu *et al.*, 2017), it is
41
42 unclear whether 3DP implementation influences stock returns “through top-line impact,
43
44 bottom-line impact, or both” (De Jong *et al.*, 2014, p. 131). It thus is worth investigating how
45
46 3DP implementation may affect other dimensions of firm performance such as sales growth,
47
48 cost reduction, and profitability improvement (De Jong *et al.*, 2014; Orzes *et al.*, 2017) in order
49
50 to gain a more comprehensive understanding of the performance implications of 3DP
51
52 implementation. Such investigations can also help verify the conclusions drawn in our research
53
54 based on abnormal stock returns.
55
56
57

58
59 Finally, following contingency theory that emphasizes the fit between firm strategies
60

1
2
3 and external environments (Reinking, 2012; Sousa and Voss, 2008), our research considers the
4
5 moderating role of several factors at the industry level rather than at the firm or individual
6
7 level. However, firm-level and individual-level factors may also affect 3DP's implementation
8
9 and thus its performance impact. For example, firms with larger sizes may possess more
10
11 resources to implement 3DP while CEOs with technical backgrounds may be more likely to
12
13 support 3DP implementation, both of which may affect the effectiveness of 3DP
14
15 implementation. Therefore, future research on 3DP implementation can explore the moderating
16
17 role of other non-industry-level factors.

Table 1 Descriptive statistics

Panel A: Distribution of 3DP implementation announcements across years				
Year	Frequency		Percentage	
2010	4		2%	
2011	5		2%	
2012	9		4%	
2013	25		11%	
2014	42		18%	
2015	41		18%	
2016	61		26%	
2017	45		19%	
Total	232		100%	
Panel B: Distribution of 3DP implementation announcements across industries				
Industry	SIC	Frequency	Percentage	
Agriculture, Mining, Construction	0100-1999	5	2%	
Food, textiles, furniture, paper, and chemicals	2000-2999	34	15%	
Rubber, leather, stone, metals, machinery, and equipment	3000-3569, 3580-3659, 3800-3999	57	25%	
Computers, electronics, communications, and defense	3570-3579, 3660-3699, 3760-3789	37	16%	
Automobile, aircraft, and transportation manufacturing	3700-3759, 3790-3799	24	10%	
Transportation, communications, wholesaling and retailing	4000-5999	22	9%	
Services and non-classifiable	6000-9999	53	23%	
Total		232	100%	
Panel C: Characteristics of 3DP implementation announcing firms				
Firm characteristics	Mean	Standard deviation	Maximum	Minimum
Market value (\$ million)	72160.8	108860.4	647506.9	20.2
Total assets (\$ million)	34618.8	150870.0	751216	15.8
Sales (\$ million)	37442.5	46791.1	233715	0.38
Net Income (\$ million)	3235.9	6491.83	53394	-6127

Table 2 Measurement of variables

Variable Type	Variable Name	Measurement	Data Source	Reference
Dependent Variable	BHAR	Abnormal buy-and-hold stock return calculated with monthly return $BHAR = \prod_{t=1}^T (1 + R_{it}) - \prod_{t=1}^T (1 + R_{bt})$	CRSP	(Lyon <i>et al.</i> , 1999)
Explanatory variables	Industry munificence	Slope coefficient obtained by regressing sales over the time period of 2010-2017 / mean sales over the same time period	Compustat	(Jacobs <i>et al.</i> , 2015)
	Industry dynamism	Standard error of the slope coefficient obtained by regressing sales over the time period of 2010-2017 / mean sales over the same time period	Compustat	(Jacobs <i>et al.</i> , 2015)
	Industry competition	1-Herfindahl index = $1 - \sum_i^N \left(\frac{Sales_i}{Total\ Sales\ of\ firms\ in\ the\ same\ industry} \right)^2$	Compustat	(Xia <i>et al.</i> , 2016)
Control variables	Firm size	Natural logarithm of market value of equity in the most recent fiscal year before the announcement year	Compustat	(Hendricks and Singhal, 2001)
	MTB ratio	Market value of equity / Book value of equity in the most recent fiscal year before the announcement year	Compustat	(Lam, 2018)
	R&D intensity	R&D expenses / Sales in the most recent fiscal year before the announcement year	Compustat	(Jacobs <i>et al.</i> , 2015)
	Prior performance	Sample firm ROA – Median ROA of firms with the same 3-digit SIC code	Compustat	(Swink and Jacobs, 2012)
	Capital structure	Total liabilities / Sales in the most recent fiscal year before the announcement year	Compustat	(Chari <i>et al.</i> , 2007)
	Momentum	Buy-and-hold return of sample firms from 6 months to 1 month prior to the announcement month	CRSP	(Qian and Zhu, 2017)
	Velocity	Fast velocity industries (SIC = 284, 367, 737) = 1 Other industries = 0	Compustat	(Jacobs <i>et al.</i> , 2015)
	Manufacturing	Manufacturing industries = 1 Service and other industries = 0	Compustat/ Announcements	(Swink and Jacobs, 2012)
Year dummies	Years of 3DP implementation announcements	Announcements	(Lam, 2018)
