Blockchain Applications in Supply Chains, Transport and Logistics: A Systematic Review of the Literature

This paper presents current academic and industrial frontiers on blockchain application in supply chain, logistics and transport management. We conduct a systematic review of the literature and find four main clusters in the co-citation analysis, namely Technology, Trust, Trade, and Traceability/Transparency. For each cluster, and based on the pool of articles included in it, we apply an inductive method of reasoning and discuss the emerging themes and applications of blockchains for supply chains, logistics and transport. We conclude by discussing the main themes for future research on blockchain technology and its application in industry and services.

Keywords: blockchain, supply chain, logistics, transport, systematic review

1. Introduction

Since the invention of blockchain and the introduction of Bitcoin in 2008 by Nakamoto (Nakamoto 2008), this decentralised and trustless peer-to-peer (P2P) technology has become one of the major transformative forces in business and is expected to be widely adopted by various industry and service sectors (Iansiti 2017). Recent surveys of industry experts and supply chain and logistics managers show an inclination to adopt blockchain technology, especially in the context of supply chains (Pawczuk, Massey, and Schatsky 2018) and transport and logistics (Carter and Koh 2018); however, we are still in the early stages of unlocking the true potential of blockchain technology in global supply chains, and logistics and transport operations. While there is still some hype surrounding the application of blockchains, and while we might be some years away from the actual commercialisation of blockchains, the future for this technology looks promising (Moore 2018).

Academic papers on the topic of blockchains in supply chain, logistics and transport

1
2
3 journals remain scarce. However, with increasing interest in the topic, it is very likely that in the
4
5 coming years we will witness a spike in the quantity of blockchain publications offering various
6
7 applications of this technology for supply chains, logistics and transport. This movement has
8
9 already begun, as evidenced by a number of papers published recently that provide a holistic
10
11 view on the future of blockchain technology for supply chain management. For example, Kshetri
12
13 (2018) uses a multiple case study method to investigate the impact of the blockchain on various
14
15 objectives of supply chain management by providing successful industry cases as examples for
16
17 each objective. Saberi et al. (2018) explore the main barriers to adopting blockchains and
18
19 especially smart contracts to fulfil sustainable supply chain management goals. Finally, Babich
20
21 and Hilary (2018) provide a comprehensive review of blockchain studies in operations and
22
23 supply chain management and the potential application of blockchains in this field, including
24
25 inventory management, data aggregation, contracting, supply chain risk management and
26
27 sustainable supply chain management, to name a few. In addition to the aforementioned
28
29 academic publications, industry and thought leadership papers published by top-tier consulting
30
31 firms such as McKinsey (McKinsey 2017), Deloitte (Gindner and Jain 2017; Pawczuk, Massey,
32
33 and Schatsky 2018) and Ernst and Young (Brody 2017) are paving the way for academics and
34
35 professionals into the world of blockchains.
36
37
38
39
40
41
42

43
44 Blockchains and other advanced technologies such as the Internet of Things (IoT) and
45
46 artificial intelligence are predicted to rapidly transform supply chains, transport and logistics by
47
48 2023 (Maguire et al. 2018; Xu, Xu, and Li 2018; Gunasekaran et al. 2018). While there are a
49
50 number of use cases already existing in the industry that reveal the hidden transformative powers
51
52 of blockchain technology such as increased supply chain transparency, freight tracking, carrier
53
54 onboarding and Mobility as a Service (Carter and Koh 2018; Babich and Hilary 2018; Casey and
55
56
57

1
2
3 Wong 2017), this paper aims to contribute to these attempts by reviewing the latest academic
4 debates, industry use cases and possible future trends that might emerge in this domain.
5
6

7 To achieve this objective, **we have made an attempt to answer the following research**
8 **questions: (i) What is the latest progress made by the scientific literature to examine the adoption**
9 **and implementation of blockchain technology in supply chains, logistics and transport**
10 **operations? (ii) What are some of the key knowledge areas in supply chain, logistics and**
11 **transport studies that blockchains can contribute to? (iii) What are some of the key research**
12 **questions to be addressed in each knowledge area? (iv) Which future applications and research**
13 **streams can be envisaged for blockchains in supply chains and logistics aside from the current**
14 **use cases?**
15

24
25
26

27 The present paper is organised as follows. First, we provide an overview of blockchain
28 technology and its main features. Next, we discuss the method we used to identify relevant
29 academic publications that discuss the application of blockchains in supply chains, transport or
30 logistics. We use an inductive approach to reveal the main research streams (Tranfield, Denyer,
31 and Smart 2003; Seuring and Gold 2012; Webster and Watson 2002), take an iterative approach
32 to categorise the main research clusters arising from our analyses, and elaborate on them by
33 accessing additional relevant resources and use cases. To identify the main clusters in our
34 identified pool of articles, we conduct co-citation network analysis and, using the clusters of
35 articles appearing from the co-citation analysis, we discuss the main themes in each cluster and
36 their relevance to the literature and future research in this domain. We conclude by providing
37 implications for future research and applications of blockchains in supply chains, logistics and
38 transport.

2. How Do Blockchains Work?

2.1. Blockchains: Key features

Blockchains are associated with Bitcoin and other cryptocurrencies such as Ethereum and Ripple. However, it should be emphasised that cryptocurrencies are a by-product of blockchains and blockchains are able to exist independently of any cryptocurrencies (Greenspan 2015). There are numerous sources that explain how blockchains work in simple technical language (see among, Swan 2015; Hutt 2016; Iansiti 2017). Here we explain the technology behind blockchains and the main features of blockchains as a basis for assessing applications in supply chains, logistics and transport.

Blockchains are ledgers that record transactions in a trustless environment and are protected by the science of cryptography. A finite set of transactions is placed on each block, which is protected by digital signatures and cryptographic hash functions. Using the hash of the immediate preceding block, the next block makes a link with this preceding block. With blockchain technology there is no need for a third party to verify the transactions; indeed, this verification is decentralised and performed by the nodes connected to each block. A node is a client on the blockchain that has a copy of the same blockchain and can add data to the blockchain. To create a valid digital signature for each user on blockchain that cannot be forged, each user is given a public key and a private key. Christidis and Devetsikiotis (2016) provide further details on how users of blockchains interact and reach consensus. Some of the main features of blockchains are that they are immutable, transparent, secure, decentralised, irreversible and based on consensus (Babich and Hilary 2018). These features provide a range of advantages and some disadvantages for the application of blockchains, which we will discuss in

1
2
3 the following sections.
4
5

6
7 In addition to the above, blockchains offer a number of unique opportunities such as the
8
9 use of smart contracts and tokenisation of assets. Smart contracts were first proposed in 1994
10
11 (Szabo 1996, 1994) and later became popular as a built-in feature on the NXT and Ethereum
12
13 blockchains. The Ethereum blockchain specifically provides the means to develop customised
14
15 and smart contracts and is by far the most commonly used platform for smart contracts. Smart
16
17 contracts are protocols on blockchain that are executed automatically by machine if the terms of
18
19 the contract are met (Dannen 2017). Smart contracts could be the most promising feature of
20
21 blockchains as they automate transfers and payments of currency and other assets (Iansiti 2017)
22
23 and on paper they can replace any kind of financial agreement (Orcutt 2018). Nevertheless, smart
24
25 contracts have their share of inadequacies and weaknesses, including the need for an
26
27 intermediary in the real world for external validation (Babich and Hilary 2018) and security
28
29 issues and theft (Orcutt 2018) that make them a high-risk choice. One specific application of
30
31 smart contracts is tokens that represent tokenised assets or utilities that can be traded on
32
33 blockchains. For decentralised apps (DAPPs) on a blockchain like Ethereum, tokens bought by
34
35 Ether (the cryptocurrency of the Ethereum blockchain) can be the means for the owner of those
36
37 tokens to access a certain type of service or asset such as rights to the production or warehousing
38
39 capacity of a supplier for a given period of time. More information on this can be found in Manoj
40
41 (2018).

1
2
3 or agents who have access to this decentralised ledger (Beck, Müller-Bloch, and King 2018). A
4 full list of IT blockchain artifacts (e.g., distributed ledgers, consensus mechanisms, encryption
5 mechanisms, smart contracts and immutable audit trails) and their descriptions are included in
6
7 Du et al. (2018). The literature on the actual implementation of blockchain technology in
8 industry and its implications/limitations is still scarce (Du et al. 2018; Beck et al. 2017). Thus,
9 insights from the success and failure of blockchain implementation projects are limited.
10
11 However, it should be noted that, so far, reported failure rates of such projects are high and in
12 2016, out of 26,000 blockchain projects, only 8% were reported to be successful (Browne 2017).
13
14
15
16
17
18
19
20
21

22
23 Blockchain technology has so far been envisaged to be implemented in machine-to-
24 machine coordination through IoT (e.g., Christidis and Devetsikiotis 2016) or to create
25 decentralised electronic marketplaces (e.g., Subramanian 2018), to name a few applications.
26
27 Some of the proposed advantages of implementing blockchain technology in organisations and
28 supply networks include increased speed of data and financial transactions, improved security of
29 shared data, digitised assets and a reduced number of intermediaries mainly due to enablers such
30 as smart contracts. Smart contracts specifically make execution of pieces of software on the
31 blockchain network possible once the conditions mentioned on the software are met (Buterin
32 2014). Thus, smart contracts enable autonomous transactions and the trade of digital assets or
33 rights to a tangible or intangible asset in the form of tokens, implemented through autonomous
34 contracts (Szabo 1994).

45
46
47
48

49 Considering the advantages of implementing blockchain projects, including automating
50 transactions and contracts and reducing intermediaries, global supply networks and the logistics
51 operations with multiple agents within them are deemed to be the best use case of blockchains
52 (Du et al. 2018; Pawczuk, Massey, and Schatsky 2018). Du et al. (2018) suggest a number of
53
54
55
56
57

1
2
3 decision rules that should be considered before implementing blockchain projects. These are: (i)
4 considering incremental changes rather than radical disruptions to operations by implementation
5 teams; (ii) avoiding use cases with large amounts of data and transactions as this will slow down
6 the blockchain and reduce its efficiency; and (iii) building a sandbox for pilot implementing and
7 understanding the risks of blockchain projects.
8
9
10
11
12
13

14 15 16 *2.2.2. Values and impact*

17
18 Blockchains impede data and transaction frauds since all transactions on a block are
19 continuously validated. In addition, the use of smart contracts with no centralised entity (e.g.,
20 banks or logistics service providers) to control operations, increases the transparency of
21 transactions and therefore trust among agents on the blockchain network (Constantinides,
22 Henfridsson, and Parker 2018). Blockchains can help protect both digital and information assets
23 from being copied, stolen or infringed, thereby adding to the trust levels among agents on the
24 blockchain (Beck et al. 2017; Steininger 2019). The increased transparency and traceability
25 enabled by implementing blockchains can help resolve disputes by following the audit trail of
26 transactions or by ensuring that terms mentioned in contracts are fully implemented once all the
27 conditions on smart contracts have been met (Tate, Johnstone, and Fiel 2017; Shafiei Gol, Stein,
28 and Avital 2019).

34
35
36
37
38
39
40
41
42
43

44
45 Use of blockchains promises improved regulatory compliance, increased speed in
46 transactions and local and international exchanges, and digitised assets for ease of trade,
47 especially in global supply networks (Tapscott and Tapscott 2016). Furthermore, the by-product
48 of blockchains, cryptocurrencies, creates opportunities to facilitate P2P transactions and money
49 transfer in a global trade environment (Constantinides, Henfridsson, and Parker 2018). The

60

1
2
3 combination of asset digitisation, smart contracts and cryptocurrencies creates a trade
4 environment free of intermediaries with full transparency and trust among any group of
5 stakeholders involved in the trade.
6
7
8
9
10
11
12

13 **3. Method**

14
15 We leveraged an inductive approach (Tranfield, Denyer, and Smart 2003; Seuring and Gold
16 2012; Webster and Watson 2002) to conduct a systematic literature review of the publications in
17 blockchain and supply chain logistics and transport. Seuring and Gold (2012) suggest a two-step
18 approach where the basic categories (or clusters) are developed based on theory and then each
19 category is discussed and refined inductively. Since the studies surrounding the topic of the
20 current literature review are in their early stages and there are no existing theories to categorise
21 the literature based on them, we used the clusters emerging from co-citation analysis of the
22 literature to conduct our inductive elaboration on each emerging cluster from the literature.
23
24
25
26
27
28
29
30
31
32
33
34

35 Thus, we conducted the systematic literature review by following these steps (Bryman
36 2012; Hart 1998): (1) source identification, (2) source selection, (3) source evaluation and (4)
37 data analysis. The main reason we opted for a systematic literature review was to minimise the
38 selection bias in reviewing the pertinent literature to the subject matter, which benefits from a
39 recursive and iterative process of selecting and refining keywords and the searched academic
40 resources to be incorporated within the review process (Saunders, Lewis, and Thornhill 2009). It
41 should be noted that in the case of blockchain publications on supply chain logistics and
42 transport, the keyword selection and filtering was less complicated than in more developed
43 knowledge areas in supply chain logistics and transport (e.g., see Davarzani et al. 2016;
44 Fahimnia et al. 2015). Using the systematic literature review framework, we explain below how
45
46
47
48

60

1
2
3 the keyword selection and source evaluation and analysis were conducted.
4
5

6 7 **3.1. Source identification and selection** 8

9
10 Given the scarcity of the literature and our intention to achieve maximum coverage of the current
11 academic publications on the topic, we initially opted for both Scopus and ISI Web of
12 Knowledge to search for relevant journal publications. To conduct the source search, we used an
13
14 advanced search tool and two-level keywords with level one consisting of *blockchain*,
15
16 *distributed ledger* and *smart contract*, while level two included *supply chain*, *logistics* and
17
18 *transport*. The search continued until the end of October 2018.
19
20
21
22
23

24
25 The Web of Knowledge *title* search resulted in 61 records (38 journal articles) and the
26
27 *topic* search resulted in 20 records (14 journal articles) with 10 out of 14 journal articles already
28
29 appearing in the *title* search. The *title*, *abstract* and *keywords* search on Scopus resulted in 132
30
31 records (48 journal articles). A comparison of the results of the two search engines enabled us to
32
33 conclude that the Scopus search results completely covered the Web of Knowledge search
34
35 outcomes and introduced more academic resources. Therefore, we used the Scopus search results
36
37 to conduct our bibliometric and network analysis.
38
39
40

41
42 Next we refined the 132 results and only chose journal articles that included *article*,
43
44 *article in press* and *review articles* (a total of 48 journal articles). To ensure the relevance of the
45
46 48 articles to the blockchain and supply chain, logistics and transport studies, each of the co-
47
48 authors independently reviewed the articles to filter out irrelevant articles. **Figure 1 shows the**
49
50 **word cloud extracted from the index keywords of the 48 articles.**
51
52
53
54
55
56
57

Figure 1. Word cloud of the most frequent keywords used in the pool of 48 papers

3.2. Source evaluation: Bibliometric analysis

The initial bibliometric analysis of the 48 articles showed that the publication frequency was distributed between 2016 (two articles), 2017 (25 articles) and (October) 2018 (21 articles), a significant increase in the frequency of publications and interest in this topic since 2017. The authors with the highest number of publications were Angappa Gunasekaran (Kamble, Gunasekaran, and Arha 2018; Gunasekaran et al. 2018), Joseph Sarkis (Kouhizadeh and Sarkis 2018; Saberi et al. 2018), Mahtab Kouhizadeh (Kouhizadeh and Sarkis 2018; Saberi et al. 2018) and Nil Kshetri (Kshetri 2018, 2017b, 2017a). The other authors had only one publication each in this area and could not be classified as prolific. The United States (15 articles) and China (10

1
2
3 articles) have the highest rate of publication so far with South Korea and the United Kingdom
4
5 following with four publications each. The three most cited articles were Hofmann and Rüsç
6
7 (2017), Kshetri (2017b) and Sharma, Moon, and Park (2017). The *International Journal of*
8
9 *Production Research* with five publications contained the highest number of publications. The
10
11 remaining journals with two or more publications included *Intelligent Systems in Accounting,*
12
13 *Finance and Management* (three articles), *IEEE Access* (two articles), *IEEE Communications*
14
15 *Magazine* (two articles) and *International Journal of Environmental Research and Public Health*
16
17 (two articles). While the bibliometric data and their frequency are not as significant as more
18
19 established fields of research in supply chains, logistics and transport, by conducting co-citation
20
21 analysis we aim to shine some light on the main themes and topics that were covered in the 48
22
23 articles.
24
25
26
27
28
29

30 **3.3. Source analysis: Co-citation analysis**

31
32 There are multiple ways of assessing similarities and extracting themes in scholarly literature,
33
34 and each has its advantages and disadvantages (Yan and Ding 2012; Boyack and Klavans 2010).
35
36 Some of the main tools adopted by operations and supply chain management scholars to this end
37
38 include citation analysis, co-citation analysis and bibliographic coupling. Co-citation analysis in
39
40 particular has become the preferred and most common method for scholarly network analysis
41
42 (e.g., Ben-Daya, Hassini, and Bahroun 2017; Fahimnia et al. 2019; Fahimnia, Sarkis, and
43
44 Davarzani 2015; Khorram Niaki and Nonino 2017; Xu et al. 2018). Moreover, it has been found
45
46 that co-citation analysis provides a better coverage of the literature for clustering analysis, and in
47
48 terms of accuracy of outcomes, is very close to bibliographic coupling (Boyack and Klavans
49
50 2010). In fact, it has been shown that bibliographic and co-citation networks are very similar
51
52 (Yan and Ding 2012). Thus, given the caveats of citation analysis (Pilkington and Meredith
53
54
55
56
57
58
59
60

2009) and its diminishing application in the academic literature, we opted for co-citation analysis to identify the main themes appearing in the field of blockchains and supply chains, transport and logistics. Two articles are co-cited if they are referenced by the same article (Small 1973). The main idea behind co-citation analysis is that as the frequency of the citations of the same two articles increases in a pool of pre-selected articles, the likelihood of the similarity in their topics increases as well (Batistič, Černe, and Vogel 2017). If two articles are co-cited more frequently in a pool of articles, it is more likely that they will end up in the same cluster due to a stronger link between them (Clauset, Newman, and Moore 2004; Leydesdorff 2011). Thus, each cluster represents a set of articles that has a strong two-by-two connection with each other and weaker connections with articles from other clusters.

To conduct the co-citation analysis, we used the Sci² Tool (Sci2 2009) and Gephi 0.9.1¹ software packages for graph network analysis and visualisation of the co-citation network. We first exported the CSV format of the 48 articles we found from Scopus to Sci² Tool and conducted the co-citation analysis. The co-citation network was strongly connected and had 1,327 nodes, which represents the total number of references for all 48 articles. The network also had 34,004 edges which represent the number of times any two articles were co-cited. Next, we used Gephi to visualise the co-citation network. To develop meaningful clusters that correspond to a specific theme in the co-citation network, we first had to filter the network and limit the in-degree feature of the network to a minimum threshold to eliminate isolated nodes (i.e., references that were not co-cited) or weakly connected nodes (i.e., references that were weakly connected to the network due to low co-citation frequency). Next we conducted a modularity analysis to assign the nodes to clusters. The modularity index can take any number between -1 and +1

¹ <https://gephi.org/>

1
2
3 which represents the strength of links within and between clusters (see Fahimnia et al. 2015;
4 Fahimnia, Sarkis, and Davarzani 2015). The modularity index of our co-citation network was
5
6 0.649, which indicates a strong connection between nodes within clusters but not a strong
7
8 connection between each cluster. Thus, the modularity index implies distinguishable themes in
9
10 each cluster. Four main clusters emerged from our co-citation and modularity analysis. By using
11
12 the Gelphi layout options we sorted and colour-coded the four clusters. Figure 2 shows the whole
13
14 co-citation network and each cluster, respectively. To assign a theme to each cluster, each co-
15
16 author independently reviewed the articles within each cluster and suggested a theme. Usually
17
18 each cluster has a variety of themes, but one theme is dominant and determines the overall
19
20 direction of the cluster. Thus, after several discussions, the authors agreed on the dominant
21
22 themes for each cluster as follows: *Technology* (n = 164 resources), *Trust* (n = 91 resources),
23
24 *Trade* (n = 85 resources) and *Traceability/Transparency* (n = 85 resources), which we named
25
26 ‘the 4Ts’ for brevity. The proposed sequence of the clusters is based on the frequency of
27
28 resources in each cluster. Most resources in the first cluster use keywords such as *IoT* or *RFID* as
29
30 well as *blockchain* or *supply chain* in their title or index keywords (if the resource is a journal
31
32 article). Since IoT and RFID imply the use of sensors technology, we labelled this cluster
33
34 *Technology*. Most resources in the second cluster use keywords such as *cyber attacks*, *cyber*
35
36 *threats*, *cyber security* and *trust*. Since cyber security issues can adversely impact trust levels in
37
38 supply chain and logistics networks, and blockchains can help alleviate this issue, we labelled
39
40 this cluster *Trust*. Most resources in the third cluster use keywords such as *trade*, *Bitcoin*,
41
42 *cryptocurrency* and *smart contracts*. After a closer examination of the main theme of the
43
44 resources in this cluster, we labelled it *Trade*. The main theme of the fourth cluster is
45
46 sustainability and transparency in supply networks. Looking closely at the resources included in
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 this cluster, there are many discussions revolving around blockchains ensuring the sustainable
4 procurement of goods by increasing traceability of inventory data. This, in turn, increases the
5
6 procurement of goods by increasing traceability of inventory data. This, in turn, increases the
7
8 transparency of operations for both supply chain partners as well as end customers. Therefore,
9
10 we labelled this cluster *Traceability/Transparency*. Section 4 provides more in-depth discussions
11
12 on each cluster and their implications for blockchain applications in supply chain, logistics and
13
14 transport operations.
15

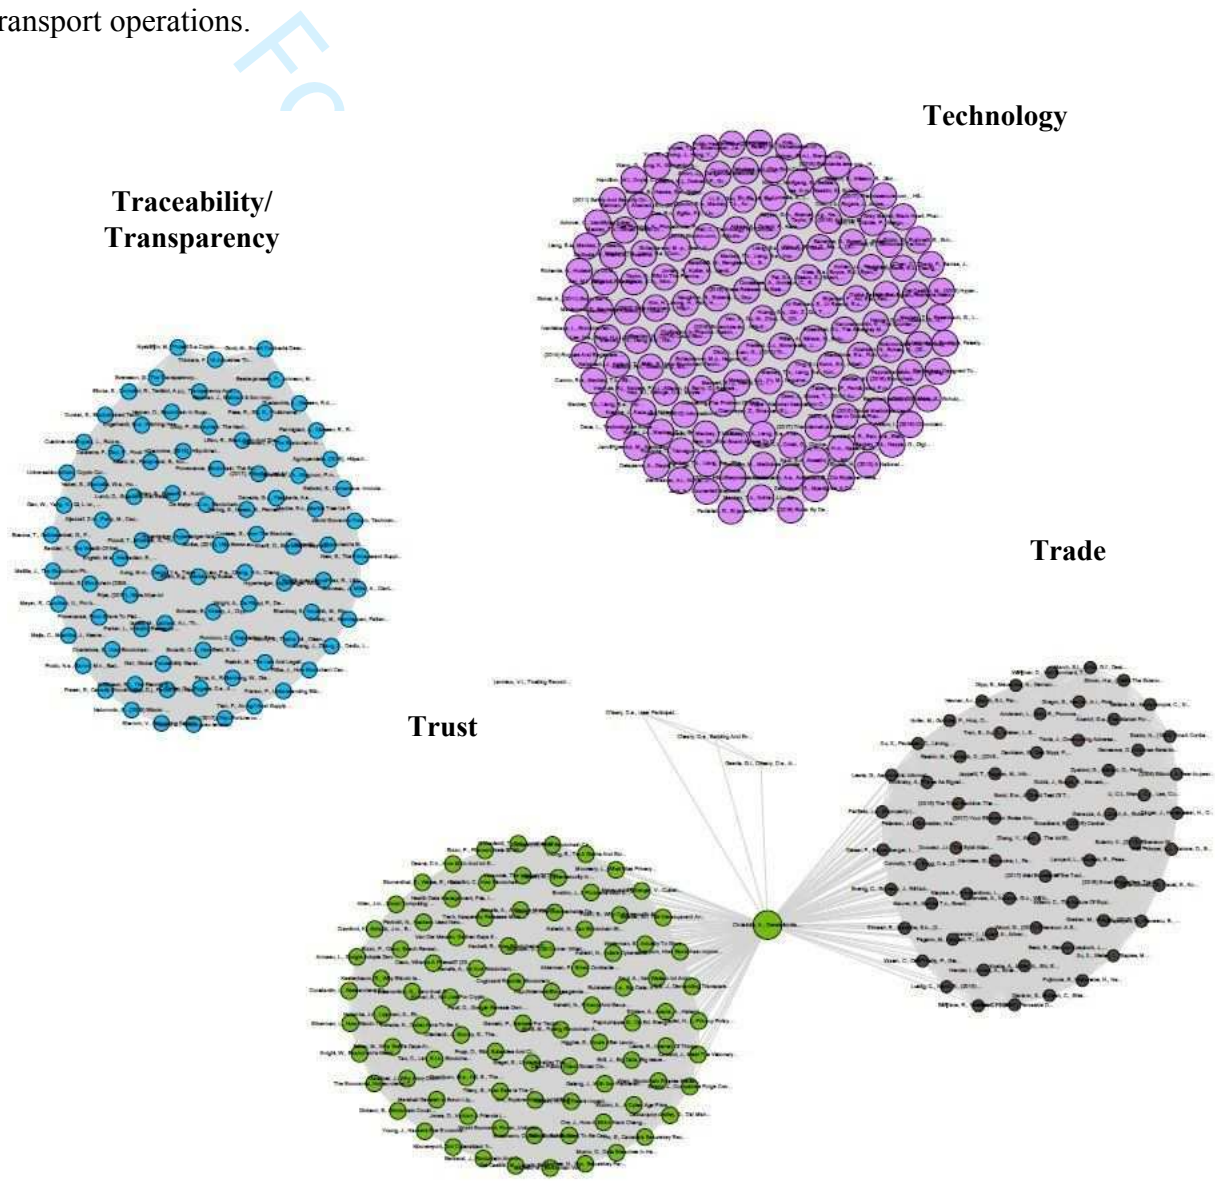

Figure 2. Four clusters emerging from co-citation analysis of 48 articles

4. Blockchain Applications in Supply Chains, Logistics and Transport: The 4Ts

The 4Ts of blockchain are interconnected concepts rooted in the nature of blockchains and are inherently designed for non-trusting members doing business with each other. Despite this, each component of the 4Ts has a cluster of scientific articles behind it that offer various applications for supply chains. Table 1 presents the most popular and prestigious academic resources for the topic of each cluster. **In order to choose the most prestigious papers in a cluster that contains hundreds of papers, we needed a measure that simultaneously considered the *importance* (i.e., the global citation count of the paper) as well as the *connectedness* of the paper within the cluster (i.e., the number of citations by paper in the cluster). A paper might be well connected within a cluster but it is not necessarily an important paper, which might reduce its prestige.** To select papers for each cluster we used PageRank analysis, as originally proposed by Brin and Page (1998), to analyse the connectivity of web pages. The adoption of PageRank analysis for co-citation analysis is increasing and widespread among researchers in the field of supply chain, logistics and transport management (Fahimnia et al. 2015; Fahimnia, Sarkis, and Davarzani 2015; Xu et al. 2018; Davarzani et al. 2016). In the context of co-citation analysis, PageRank prioritises **publications that have a higher global citation count as well as papers that are cited by these publications with high citation counts (Ding et al. 2009).** Since PageRank is a probability distribution, it yields a number between zero and one to rank papers in each cluster with larger numbers showing a higher degree of importance for any cited paper. To select the top five papers for each cluster we first sorted them according to their PageRank scores. Considering that most of these articles were published recently, their PageRank scores were very small. However, using PageRank was helpful in selecting the top five articles in each cluster. Additionally, given that PageRank scores do not have any inherent value and are only used comparatively, we did not

include them in Table 1 but they are available upon request. We also filtered out the articles that did not have any particular relevance to blockchain, supply chain or transport/logistics topics. For example, if an article only discussed the topic of counterfeit medicine with no implications for associated supply chains, logistics or transport, or if it did not include the role of blockchain in identifying or eliminating counterfeit medicine, it was not included in Table 1. Moreover, as can be seen in Table 1, there can be overlaps between the clusters where the same article has been included in two or more clusters (e.g., Christidis and Devetsikiotis (2016) is included in both clusters 1 and 2). This type of overlap is a common occurrence in network analysis (Ball, Karrer, and Newman 2011; Palla et al. 2005) and it shows that the aforementioned articles have been commonly referred to in multiple research areas.

Table 1. Most notable journal articles per cluster identified by co-citation analysis

Cluster 1: Technology	Cluster 2: Trust	Cluster 3: Trade	Cluster 4: Traceability/ Transparency
Banafa (2017)	Casey and Wong (2017)	Aitzhan and Svetinovic (2018)	Gualandris et al. (2015)
Ben-Daya, Hassini, and Bahroun (2017)	Christidis and Devetsikiotis (2016)	Böhme et al. (2015)	Kshetri (2018)
Catallini (2017)	Kshetri (2017b)	Davidson, De Filippi, and Potts (2016)	Kouhizadeh and Sarkis (2018)
Christidis and Devetsikiotis (2016)	Mainelli (2017)	Kang et al. (2017)	Mol (2015)
Mackey and Nayyar (2017)	Meng et al. (2018)	Mengelkamp et al. (2018)	Saberi et al. (2018)

Note: Articles are organised alphabetically by author.

In the *Technology* cluster there are a number of articles that focus on IoT–blockchain (Banafa 2017; Catallini 2017; Christidis and Devetsikiotis 2016), IoT–supply chain (Ben-Daya, Hassini, and Bahroun 2017) or IoT–blockchain–supply chain in the context of the pharmaceutical industry (Mackey and Nayyar 2017). In the *Trust* cluster, the articles presented in Table 1 represent supply chain–trust or blockchain–trust topics. The main themes in these

1
2
3 articles are trust and accountability in supply chains (i.e., supply chain–trust) (Casey and Wong
4
5 2017), the application of blockchains in a trustless context (i.e., blockchain–trust) (Christidis and
6
7 Devetsikiotis 2016), avoiding cyber attacks using blockchains (i.e., blockchain–trust) (Kshetri
8
9 2017b; Meng et al. 2018) and addressing the trust issue by using blockchains for proof of
10
11 identity (blockchain–trust) (Mainelli 2017). Overall in this cluster, we could not find an article
12
13 that directly examined how the use of distributed ledger technology can affect the issue of trust
14
15 in supply chains. The articles in the *Trade* cluster in Table 1 mainly discuss energy trade in
16
17 utilities supply networks using blockchains (Aitzhan and Svetinovic 2018; Mengelkamp et al.
18
19 2018; Kang et al. 2017) and the use of cryptocurrency and Bitcoin in trade and economics
20
21 (Böhme et al. 2015; Davidson, De Filippi, and Potts 2016). While Gualandris et al. (2015) and
22
23 Mol (2015) focus on supply chain sustainability through accountability and transparency in the
24
25 *Traceability/Transparency* cluster, Kouhizadeh and Sarkis (2018), Saberi et al. (2018) and
26
27 Kshetri (2018) specifically investigate the role of blockchains in ensuring sustainability and
28
29 increasing transparency in supply chains.
30

32
33
34
35

36 Below we elaborate on the discussion of the 4Ts and their current and future applications
37
38 in supply chains, logistics and transport. Considering that academic studies of blockchain
39
40 applications in these areas are still scarce, most resources cited in the discussion of the 4Ts are
41
42 media pieces, industry and thought leadership papers, and industrial blogposts, which are not
43
44 included in Table 1; however, we use them for elaboration. In discussing each cluster, we have
45
46 incorporated two sub-categories where we specifically elaborate on the relevance of the cluster
47
48 to either supply chain management or transport and logistics management.

4.1. Technology

4.1.1. Relevance to supply chain management

One of the most important aspects of blockchain application is their interface with the physical world, which requires the right tools and technology such as IoT (Christidis and Devetsikiotis 2016; Catallini 2017). IoT is a term that is used to describe interconnected sensing devices that can share information on a common platform, enabling innovative applications (Gubbi et al. 2013). Some of the main enabling technologies behind IoT are RFID tags, Wireless Sensor Networks, and data analysis and visualisation platforms (for more information on IoT elements see Gubbi et al. 2013).

Despite the wide applications of IoT devices in supply chains (Fan et al. 2015; Rong et al. 2015; Ben-Daya, Hassini, and Bahroun 2017), the high costs of maintaining centralised IoT systems in supply chains (Christidis and Devetsikiotis 2016) and the security concerns surrounding IoT devices such as RFID-enabled products (Yao et al. 2016) that could easily breach the critical manufacturing information of supply chains or the personal information of users, there is a perfect case for the application of trustless and P2P blockchain networks.

Blockchains arguably help with the connectivity and capacity issues of IoT systems by facilitating new devices that identify and authenticate each other so that the network is able to extend to billions of devices without any intermediary servers becoming a bottleneck in the process (Dickson 2016). In addition, blockchains are considered to record IoT devices' configurations by storing their cryptographic hashes (Kumar 2017). An example of the application of blockchains for IoT systems is delivering messages between devices on a blockchain where each message is treated similarly to a transaction (Banafa 2017). Smart

1
2
3 contracts are used in this instance to verify and allow actions by the devices, and any out of the
4
5 ordinary message will not activate the functions of the smart contract, thereby increasing the
6
7 security of the IoT platform.
8
9

10
11 One commonly applied aspect of pairing IoT devices on blockchain networks is the
12
13 identification and elimination of counterfeit medicine using a mix of RFID, analytics and
14
15 blockchains (Mackey and Nayyar 2017). According to the World Health Organization (WHO),
16
17 in 2017 alone, counterfeit drugs had a significant 10% share of the pharmaceutical market in
18
19 low- and middle-income countries (WHO 2018). The importance of eliminating the counterfeit
20
21 drug supply chain is a matter of controlling the adverse effects of these drugs on patients' non-
22
23 treatment, resistance to drugs and death (Mackey and Liang 2011).
24
25
26
27
28

29 *4.1.2. Relevance to logistics and transport management*

30
31 One way of using tracking tools and blockchains in transport and logistics is to couple them with
32
33 smart contracts that can facilitate payments to suppliers or 3PLs once they fulfil their tasks such
34
35 as delivering goods to a warehouse or to a port in a predefined specification (e.g., quality and
36
37 quantity). For instance, the RFID tracking device at a buyer's warehouse is directly connected to
38
39 the blockchain and once it receives the cargo from the supplier, it checks if the agreed quantity is
40
41 delivered, and if there are no other conditions to be met (e.g., deliveries undergoing quality
42
43 assessments and approved by the buyer), the smart contract can automatically release the
44
45 payment to the supplier.
46
47
48
49

50
51 Another implication of coupling IoT with blockchain technology is better control of
52
53 physical environment characteristics (e.g., temperature and pressure) provided by the fleet for
54
55 perishable food products or biopharmaceutical products, which has been given the term 'cold
56
57

1
2
3 chain'. A successful case of such technology use is IBM's Hyperledger Fabric blockchain for the
4 vaccine cold chain to connect all stakeholders in the vaccine supply chain including
5
6 manufacturers, public health hosting organisations and authorities, and audit and regulatory
7
8 organisations that can gain instant access to the location, status and conditions under which
9
10 vaccines have been prepared and distributed (Fish and Barnard 2018). Smart contracts can be
11
12 used across this cold chain to ensure that desirable conditions are maintained during
13
14 manufacturing and transportation as well as issuing warning signs in case the sensors report any
15
16 abnormalities in handling vaccines across the cold chain. Similarly, in 2017, Walmart filed a
17
18 patent for drones using blockchains for last mile delivery. The main idea behind this technology
19
20 is a *blockchain identifier* associated with a delivery box and an encrypted key that can
21
22 authenticate an approaching drone, automatically unlock the box and accept the package from
23
24 the drone (Hackett 2017). The same principle could be used to make last mile delivery more
25
26 flexible and customised to consumer needs such as deliveries to houses or cars or designated
27
28 boxes for consumers using a blockchain identifier and encrypted key.
29
30
31
32
33
34
35

36 Using IoT technology in transportation fleet and inter-vehicle communications usually
37
38 exposes the fleet to a range of security risks, such as the recent hack of Jeep Cherokee digital
39
40 systems where the central system of the car was remotely controlled by hackers, jeopardising 1.4
41
42 million similar products from this manufacturer (Greenberg 2016). Blockchain technology can
43
44 provide a secure and decentralised system to secure the privacy of users as well the security of
45
46 inter-vehicle communications (for more details, see Dorri et al. 2017).

4.2. Trust

4.2.1. Relevance to supply chain management

Trust and trustworthiness in supply chains affect information sharing and forecasting accuracy (Özer, Zheng, and Ren 2014; Özer, Zheng, and Chen 2011), which in turn play a pivotal role in matching supply and demand in supply chains. One issue that can decrease the level of trust in supply chains is the cybersecurity of supply chain members. Cybersecurity has become one of the biggest challenges for global supply chains in recent years (Massimino, Gray, and Lan 2018; Kache and Seuring 2017). In the most recent *Global Risk Report* by the World Economic Forum (WEF) (Collins 2018), cyber attacks along with extreme weather are categorised as the most disruptive risk categories threatening societies and global businesses. The WEF also estimates that the prevalence and negative financial impacts of cyber attacks are increasing rapidly. Blockchain technology can contribute to strengthening the security of supply chain data flows and the IoT data generated in the end-to-end supply chain. The latter can be achieved by decentralising the currently centralised cloud network that is used to manage the operations of IoT devices and controlling the types of data that are shared on blockchain and between supply chain tiers. One major issue with having a centralised cloud system for all IoT devices within a supply chain is its susceptibility to cyber attacks that can make supply chain services unavailable until the cyber issue is eliminated. Using blockchain technology, the transactions between IoT devices are protected by cryptography and are verified to ensure the originator of the message is not a malware or external intermediary (Kshetri 2017b; Kumar 2017). Other ways of increasing trust in multi-tier supply chains include providing proof of identity and enabling supply chain members to record, validate and track transactions in their supply chain. The function behind this is called Mutual Distributed Ledgers (MDLs), which are ‘multiorganizational databases with a

1
2
3 super audit trail' (Mainelli 2017, 4). MDLs in supply chains will ultimately make the storage and
4
5 transfer of signed documents secure, thereby increasing trust among all members in the
6
7 blockchain. Another example of using blockchains to create trusted identity networks is a
8
9 company called Securekey who collaborated with IBM in 2017 to create a secure digital identity-
10
11 sharing platform on IBM's blockchain that enables customers to share their trusted credentials
12
13 with their chosen organisations, which saves on time and the costs of identity verification (Kirk-
14
15 Douglas and Haswell 2017).
16
17
18
19

20
21 Conflicting objectives or a lack of aligned goals in supply chains, especially between
22
23 buyers and suppliers, is another factor that deteriorates trust in supply chains (Sinha, Whitman,
24
25 and Malzahn 2004; Nyaga, Whipple, and Lynch 2010). Using blockchains to record supply chain
26
27 data free of errors would hold relevant supply chain members accountable and resolve disclosure
28
29 issues, minimising the impact of conflicting objectives and increasing trust in supply chains.
30
31
32

33 34 *4.2.2. Relevance to logistics and transport management*

35
36 One of the ideal applications of blockchain technology is in complex extended transportation
37
38 networks where there are multiple modes of transportation (e.g., road, rail, air) and multiple
39
40 transport intermediaries (e.g., 3PLs, freight forwarders, insurance providers). Such a
41
42 transportation network includes multiple players that do not necessarily trust or even know each
43
44 other and in most cases do not have a standardised method of sharing the transport data to
45
46 facilitate the transport processes. Using a customised blockchain that connects these parties
47
48 would ensure sharing the required transaction and shipment data, which are both secure and
49
50 reliable given the inherent features of the blockchain (Forbes 2018).
51
52
53
54
55
56
57
58
59
60

4.3. Trade

4.3.1. Relevance to supply chain management

In reviewing the articles in the third cluster, two groups of cited articles provide notable discussions on the trade aspect of blockchain application in supply chain, logistics and transport management. The first group of papers discusses P2P trade and especially energy trade using blockchain technology (Kang et al. 2017; Aitzhan and Svetinovic 2018). Most of the models provided for P2P energy trading are based on the notion of smart contracts (Szabo 1994), which make bidirectional and decentralised energy trading on blockchains secure. The implications of such applications to facilitate P2P energy (especially green energy) trading among supply chain tiers not only contributes to sustainable energy consumption in supply chains but also saves on energy and utility costs across supply chains (Saberli et al. 2018). The second group of papers in this cluster builds on the concept of crypto trading, cryptocurrencies such as Bitcoin and the economics of blockchain technology to facilitate the transfer of funds within a network (Böhme et al. 2015; Davidson, De Filippi, and Potts 2016), which can be applied to supply chain networks for various payment purposes (e.g., overseas payment) including supply chain finance (for more details, see Babich and Hilary 2018).

4.3.2. Relevance to logistics and transport management

With the rise of China's One Belt One Road (OBOR) initiative and considering the many countries in Eurasia, Africa and Oceania involved in the project, applying a trustless and immutable distributed ledger technology for streamlining logistics and transport operations has already been considered by the Chinese Government. The Belt and Road Blockchain

1
2
3 Consortium, launched in 2016 in Hong Kong², primarily uses blockchain technology to provide
4 Shariah-compliant provenance and to ensure the greening of OBOR. Another critical aspect of
5
6 the successful implementation of the OBOR project is funding construction projects across more
7
8 than 56 countries. With the Asian Infrastructure Investment Bank being a major sponsor of such
9
10 projects across the OBOR region, there will need to be a fast and efficient way of transferring
11
12 funds across borders for various construction projects. With the successful implementation of
13
14 blockchain technology to transfer funds across borders in significantly less time and with lower
15
16 costs compared to traditional methods (such as the Interbank Information Network project by JP
17
18 Morgan Chase (Morgan 2017)), blockchain technology sounds like a viable option for funding
19
20 projects across OBOR. Another aspect of blockchain technology that can facilitate trade across
21
22 OBOR is the use of a unified currency such as a cryptocurrency to reduce transaction costs and
23
24 create a single trade market for OBOR countries (Tam 2017).
25
26
27
28
29
30
31

32 **4.4. Traceability/Transparency**

33 34 35 *4.4.1. Relevance to supply chain management*

36
37
38 The traceability of inventory and information transparency are the main themes of the fourth
39
40 identified cluster in our co-citation analysis. While traceability aims to answer the
41
42 ‘what/when/where’ questions of inventory transfer in supply chains, transparency attempts to
43
44 shed light on the ‘how’ aspect, for example, how a product is sourced, how it is processed by
45
46 suppliers and how it is handled while being transported (IBM 2017). With the ever-increasing
47
48 rate of globalisation and the expansion of supply chains all over the world, developing
49
50 transparent operations is pivotal to ensuring environmental sustainability and social
51
52
53
54

55
56 ² <https://www.beltandroadblockchain.org/>

1
2
3 responsibility (Mol 2015; Garcia-Torres et al. 2019). Transparency is at the core of developing
4 sustainable supply chains (Carter and Rogers 2008) and can be achieved if the right tools and
5
6 measures are applied to end-to-end sustainable supply chain management (Beske-Janssen,
7
8 Johnson, and Schaltegger 2015). Early use of RFID tags and online verification codes in supply
9
10 chains has been argued to help with transparency and sustainability in supply chains.
11
12

13
14 Nevertheless, the validity and security of this data cannot be ensured unless the cryptographic
15
16 features of blockchains are put to use. In this way, blockchains will be the core facilitating
17
18 technology ensuring traceability and thus transparency in supply chains by tracking the social
19
20 and environmental conditions across supply chain tiers (Adams, Kewell, and Parry 2018). Saberi
21
22 et al. (2018) argue that in order to ensure sustainability and ethical business conduct in supply
23
24 chains, blockchains can help increase traceability of inventory and transparency through, among
25
26 other means, coupling blockchains with RFID, maintaining the accountability of supply chain
27
28 partners towards their social and environmental responsibilities and helping trace the carbon
29
30 footprint of supply chains accurately.
31
32
33
34
35

36 Another aspect of achieving traceability in supply chains is the traceability of inventory,
37
38 especially food traceability, across supply chains using blockchains. When it comes to food
39
40 safety and traceability, the WHO estimated in 2015 that, globally, one in 10 people contract
41
42 foodborne diseases, which results in 420,000 deaths every year (WHO 2015). One of the main
43
44 reasons behind food contamination is the lack of traceability and transparency in the food supply
45
46 chain, which makes it prone to manipulation of food sources for profit maximisation or results in
47
48 a lack of standards for handling and storing food (Crossey 2018). A recent success story where
49
50 blockchains were used to identify contaminated food is Walmart employing IBM's Blockchain
51
52 Platform, where information on the food source is collected at the farm, and in the packing
53
54
55
56
57

1
2
3 houses and transportation systems using smart IoT devices, and then stored on blockchain
4
5 (Ivanov, Dolgui, and Sokolov 2018). By scanning a code on the final food package that is
6
7 handed over to customers, there is access to all this information in the IBM Blockchain Platform,
8
9 which ensures food safety and quality (IBM 2017; Alexandre 2018). Moreover, by using
10
11 blockchain technology, permanent records kept on the blockchain can be traced back to the main
12
13 contaminators in the supply chain, thereby eliminating the contaminating sources from the
14
15 supply chain (Charlebois 2017).
16
17
18
19
20

21 *4.4.2. Relevance to logistics and transport management*

22
23 A major implication of using blockchain technology for tracking cargo is the faster processing of
24
25 insurance claims in cases where cargo has been lost or damaged. Considering that the tracking
26
27 data on blockchains are trustworthy and traceable to the origin of loss, insurance companies can
28
29 process the causes of the incident, the carrier involved, the type of cargo and the validity of the
30
31 claims faster and easier. A very recent example of such an application is the world's first marine
32
33 insurance platform on blockchain called Insurwave, which leverages blockchain technology, the
34
35 Microsoft Azure analytics platform using ACORD data standards (EY 2018). Insurwave is
36
37 designed to support half a million transactions and manage the risk of shipping for more than
38
39 1,000 commercial vessels by connecting all stakeholders in the insuring process including third
40
41 parties, clients, insurers and brokers. Table 2 provides a summary of the 4Ts and their
42
43 implications for supply chains, logistics and management by enumerating the main themes and
44
45 using cases for each cell in the table.
46
47
48
49
50
51

52 Table 2. Summary of 4T applications in supply chain, logistics and transport management
53
54
55
56
57

	Cluster 1: Technology	Cluster 2: Trust	Cluster 3: Trade	Cluster 4: Traceability/ Transparency
Supply chain management	Addressing IoT connectivity and security issues (e.g., elimination of counterfeit drugs)	Decentralising supply chain data using cloud technology and blockchain Providing proof of identity for supply chain transactions (e.g., Securekey and IBM blockchain)	P2P energy trade across supply chain partners and increasing energy consumption efficiency Using cryptocurrencies to facilitate financial transactions and supply chain finance	Ensuring sustainable and ethical supply chain operations Inventory traceability and safety (e.g., IBM and Walmart food tracking blockchain)
Transport and logistics management	Increased synchronisation across transport and logistics entities (e.g., instant payments to 3PLs upon delivery of goods) Controlling characteristics of physical environment during transport using IoT and smart contracts (e.g., cold chain of vaccines) Securing inter-vehicle communications	Increased trust between multiple transport intermediaries by sharing secure and customised transport data	<i>Blockchain applications for trade in OBOR:</i> - Sharih-compliant provenance and greening of OBOR - Financing construction projects across OBOR - Cross-border transactions for transport and logistics processes through OBOR blockchain cryptocurrency	Insuring cargo across the transportation network (e.g., Insurwave by Microsoft, EY)

4.5. Limitations of blockchain technology

Despite current and future applications of blockchain technology in supply chains, logistics and transport, this technology still has caveats that limit its widespread commercialisation. Most blockchains today have transactional throughput (volume of transactions), latency (time required to add data to the blockchain) and size (bytes per transaction) constraints that make them less

1
2
3 agile than their centralised or decentralised counterparts such as Visa or Mastercard. While credit
4
5 cards can handle on average 5,000 transactions per second, a single Bitcoin transaction might
6
7 take a few minutes or sometimes a few days depending on the traffic in the network (Vlastelica
8
9 2017). In addition, blockchains such as Bitcoin were primarily created to facilitate high-value
10
11 transactions rather than high-volume transactions (Carter and Koh 2018), and in the context of
12
13 supply chains and transport, where the volume of transactions is high, the inability of
14
15 blockchains to fulfil such high volumes is troubling.
16
17
18
19

20
21 While this paper does not provide an in-depth analysis of the technical aspects of
22
23 blockchains, it does consider the integration of blockchain systems with current data
24
25 management systems in supply chain logistics and transport systems such as ERP, WMS, CRM
26
27 and SRM to be a turning point in the wide adoption of blockchains. This technical knowledge
28
29 should help clarify how various companies' blockchains within a supply chain can be connected
30
31 or merged to develop a unified blockchain system. Currently, lack of communication between
32
33 blockchains hinders them from interoperability and therefore mass adoption to form a higher-
34
35 order and more capable data storage and analysis mechanism (Little 2018; Treat et al. 2018).
36
37
38
39

40
41 Another constraint of blockchains is their immutability, which might hinder erasing
42
43 erroneous data on blockchains, making the data entry to blockchains irreversible (Bloomberg
44
45 2017; Lumb 2016). Consider, for instance, a buyer who reports that a certain product in their
46
47 inventory is low, and when these data are entered into the blockchain a smart contract
48
49 automatically places a purchase order for the supplier(s). If the data entered are for any reason
50
51 incorrect, and the purchase order needs to be cancelled, erasing the ordering data from the
52
53 blockchain is not easy and might require extra time and effort to fix the error. Moreover, there is
54
55 always a risk that the private key of a node on the blockchain (in this context a node represents a
56
57
58
59
60

1
2
3 supply chain tier or a transport intermediary) gets lost or damaged and renders the blockchain
4 unusable (Frauenfelder 2016). Eventually, the high costs of implementing blockchain
5 technology, in addition to issues surrounding data privacy and governance, make this technology
6 challenging to adopt (Kamble, Gunasekaran, and Arha 2018). Saberi et al. (2018) provide a
7 conceptual framework of barriers to adopting blockchain in sustainable supply chains by
8 categorising these barriers into inter-organisational barriers, systems-related barriers, intra-
9 organisational barriers and external barriers.

21 **5. Discussion**

22 **5.1 Contribution**

23
24 This paper is an attempt to collect and elaborate on the existing academic and industrial
25 knowledge base regarding the applications of blockchains in supply chains, logistics and
26 transportation. Recent attempts have been made to set the future research agenda on blockchain
27 technology's applications in supply chain management. For instance, Babich and Hilary (2018)
28 investigated the research opportunities that could be further explored with regard to this topic in
29 various aspects of operations management such as *production, procurement, inventory*
30 *management, contracting, supply chain risk management* and *sustainable supply chain*
31 *management*, to name a few. Saberi et al. (2018) set a research agenda for post-adoption of
32 blockchain technology and its theoretical implications for supply chain management. They
33 covered supply chain topics such as *opportunism, trust in the buyer-supplier relationship, supply*
34 *chain governance, sustainable supply chain management* and *supply chain risk management*, and
35 investigated the contributions of blockchain studies to further understanding of these topics and
36 their supporting theoretical frameworks.

1
2
3 While this paper acknowledges the invaluable attempts that have initiated the dialogue on the
4 application of blockchains in supply chain studies, we have systematised and elaborated on these
5 discussions using the proposed 4T structure and its implications for the supply chain, logistics
6 and transport literature. By identifying the four main clusters (the 4Ts – technology, trust, trade,
7 traceability/transparency) emerging from our co-citation analysis of the academic publications on
8 this topic, we were able to expound on the implications of each of these clusters for supply chain
9 and transportation networks. This condenses the (thus far) scattered literature on blockchain
10 applications in logistics and supply chain management beyond the single arguments being made
11 in the aforementioned review papers.

25 **5.2 Limitations**

26
27
28 The theoretical limitations derive from the more inductively driven analysis allowed by the
29 bibliometric cluster analysis. While four clusters emerging from the citation analysis is quite
30 straightforward, the labels given are based on the interpretation of the research team. This might
31 be questioned, while the 4Ts are justified against the explanatory power elaborated in the
32 findings section.
33
34
35
36
37
38
39
40

41 This immediately links into the strengths and weaknesses of the method. Given that the
42 application of distributed ledger technologies in logistics and supply chain management is an
43 emerging topic, a method that is geared more towards exploring the field seems well justified.
44 The documentation of its application ensures reliability, while the cluster analysis guarantees a
45 high degree of internal validity. The typical shortcoming of such a method is that it only partly
46 links to existing theoretical framings, for example, the application of IoT in logistics and supply
47 chain management. This might open up directions for future research, which are discussed next.

5.3. Implications for research

By leveraging the 4T framework that we extracted from the co-citation analysis of the existing literature, we systematise the future research agenda in supply chain, logistics and transport management through the lens of the 4Ts of blockchains.

- *Technology*: Supply chain, logistics and transport operations across all industries are experiencing a rapid transformation in their use of disruptive technologies (Ivanov, Dolgui, and Sokolov 2018). While blockchains and advanced analytics and big data platforms (Tan et al. 2017) are at the heart of this transformation, the development and adoption of hardware technologies such as IoT (Ben-Daya, Hassini, and Bahroun 2017) and RFID (Ngai et al. 2010) feed the required data into these platforms (e.g., Zhong et al. 2015; Hopkins and Hawking 2018). Despite the increased interest in these topics in the academic literature, frameworks surrounding the adoption, integration and implementation of the combination of these technologies remain scarce. Case study research (Seuring 2008; Barratt, Choi, and Li 2011) is recommended to investigate the integration of hardware and software technologies into supply chain, logistics and transport operations.
- *Trust*: The study of trust in supply chains and logistics, and especially trust in sharing information in supply chains, is a well-established area of research (e.g., Kaipia et al. 2017; Cai, Jun, and Yang 2010; Firouzi, Jaber, and Baglieri 2016; Han and Dong 2015). One of the main ideas behind this stream of research is how to ensure that the *right* and *accurate* information is shared among supply chain partners in a timely manner. Since

1
2
3 blockchains have been developed to perform in a *trustless* environment, it is expected
4 that when a supply chain is using a blockchain platform to share data among supply chain
5 partners, all the relevant supply chain partners have access to the same sets of data
6 required to extract insights. The latter will have theoretical implications so researchers
7 should consider first whether blockchains will eliminate the need for trust in supply and
8 transport networks and second how the dynamics in the buyer–supplier relationship
9 might change when there is not a dire need to build trust between supply chain partners.

- 10
11
12
13
14
15
16
17
18
19
20 • *Trade*: Blockchains can have significant implications for trade in global supply chains.
21 First, by facilitating payments through cryptocurrencies, supply chain partners can use
22 instant money transfers with lower commissions to pay for goods and services. Second,
23 product ownership and transfer and the contractual arrangements for them can be
24 facilitated by smart contracts (Saber et al. 2018) so that the contract terms will be
25 executed instantly after they are met. This will save on the time and costs (e.g.,
26 intermediaries, paperwork) required to execute contracts and carry out the terms by both
27 parties. The latter, as well as changes in information sharing (Shen, Choi, and Minner
28 2018; Xie et al. 2014; Shou, Zheng, and Zhu 2016), can initiate a debate in the current
29 state of our knowledge on supply chain contracting and how distributed ledger
30 technology can affect contracting and coordination mechanisms in supply chains.
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47 • *Traceability/Transparency*: The increased transparency and traceability of inventory in
48 supply chains using blockchains can have multiple implications for research. First, the
49 use of blockchains in inventory and capacity management can help mitigate the bullwhip
50 effect (Lee 1997; De La Fuente and Lozano 2007) by sharing inventory information with
51 supply chain partners that place orders across the supply chain (Babich and Hilary 2018).
52
53
54
55
56
57

1
2
3 The application of advanced analytics (Baryannis et al. 2018) to the data provided by
4 blockchains can lead to better predictions of the impending risks in the supply chain and
5 transport networks, and the ability to devise better customised plans to manage potential
6 disruptions to these networks. Furthermore, and as mentioned earlier, one of the most
7 anticipated applications of blockchains is in sustainable supply chain and transport
8 operations where the data collected on blockchains can report on the environmental and
9 social sustainability of supply chain partners (Saberli et al. 2018).

10
11
12
13
14
15
16
17
18
19
20 Finally, we would like to encourage future research to empirically investigate the 4T structure
21 and the links between the 4T constructs that emerge from the application of blockchain
22 technology in supply chain, logistics or transport networks. **Our proposed framework is based on**
23 **our discussion in sub-section 2.2 (Blockchain: Implementation, values and impact), where**
24 ***implementation* represents the technological aspect of blockchains, *values* indicates traceability,**
25 **transparency and trust as the main advantages arising from the implementation of blockchains,**
26 **and *impact* refers to the effects on trade operations which contain all aspects of trade in supply**
27 **networks that can benefit from implementing blockchain technology. *Impact***
28 **(*Traceability/Transparency and Trust*) follows effective *implementation (Technology)* and**
29 ***implementation* is also a prerequisite for extracting *value (Trade)* from investments in blockchain**
30 **technology (Du, Pan, Leidner, and Ying 2018). We therefore propose a hypothetical structural**
31 **model in Figure 3, in which we assume that *Technology* is an independent variable that increases**
32 ***Traceability/Transparency* in supply chain and transport networks, which in turn facilitates**
33 ***Trade* within these networks. We also assume a moderating role for *Trust* to better regulate the**
34 **relationship between increased *Traceability/Transparency* and *Trade*.**

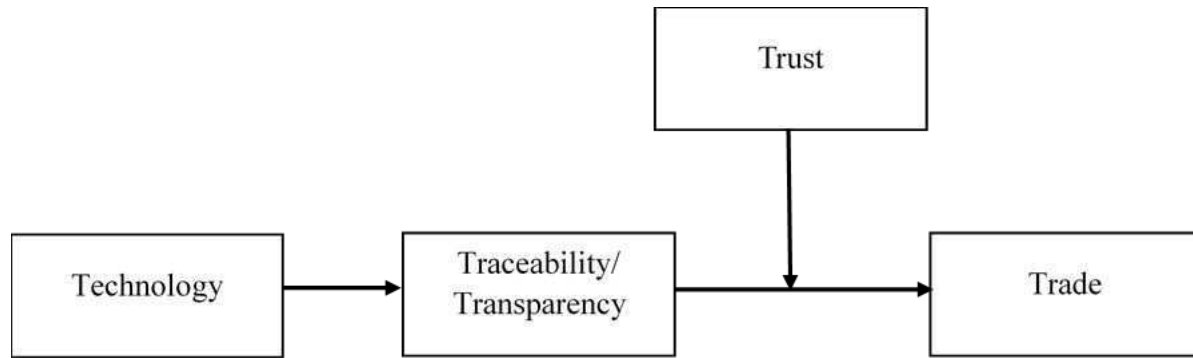

Figure 3. Proposed structural model for blockchain application in supply chain, logistics and transport networks

6. Conclusion

Blockchain technology is still in the early stages of commercialisation and while there are many industry experts who believe there is a promising future for the application of this technology across industry, many others believe there is an inflated expectation from blockchains, which might in fact exacerbate the effect of the failed adoption of blockchains in industry. However, while there have been many failed attempts to use blockchain technology, there have also been many successful business cases, such as those mentioned in this paper. The latter render a rather optimistic view that as more progress is made in addressing the limitations of blockchains, like many other emerging technologies, blockchains will find their place in practice and become widely accepted.
