**Abstract.** The *even*-based approach to NPI licensing arose as a competitor to the traditional idea that NPIs are licensed by some monotone environments. The approach itself equates NPIs with *even* + existential quantification. As such, distributional differences between NPIs and the expression *even ONE* are undesirable. There are, however, a small number of known differences: (i) They behave differently in the restrictor of a universal quantifier, and (ii) questions containing *even ONE* are negatively biased, whereas questions with an NPI are not. Under our proposal, we decompose weak EVEN into two focus particles. One is identical to the original EVEN, whereas the other particle has a directly opposite scalar presupposition and an additional presupposition of exclusivity. In doing so, we can derive both problematic cases for the *even*-based approach in a straightforward fashion.

**Keywords:** negative polarity item, NPI, *even*, question bias, local accommodation, projection

## 1. Introduction

Accounting for the entire distribution of negative polarity items (NPI) has been an ongoing issue for linguists for nigh a century: Formally starting with the work of Jespersen (1917) and Klima (1964), we have yet to discover a model that is capable of accounting for the entire set of known empirical data. Traditionally, NPIs are analysed as being licensed by certain monotone environments (cf. Fauconnier, 1975; Ladusaw, 1979): Namely, NPIs are generally considered to be licensed by (Strawson) downward-monotone environments.

However, alternative models to NPI licensing have recently been on the rise (e.g. Krifka, 1995; Chierchia, 2013: and others). One of the major alternative NPI models would be the *even*-based approach to NPI licensing (cf. Lee and Horn, 1994; Lahiri, 1998; Crnić, 2011a). Essentially, this approach states that any NPI is covertly licensed by the focus particle *even* at logical form (LF). The NPI itself is equivalent to weak existential quantification (i.e. *any* would be equivalent to *even ONE*). With most of the objections to this approach (cf. Heim, 1984) having been defused by Crnić (2014a, b), only a few major obstacles remain: One of them is the difference in polar question bias between questions containing the expression *even ONE* (hereafter referred to as *even*-questions) and questions containing the unstressed NPI *any* (hereafter referred to as NPI-questions). Whereas the former type appears to be negatively biased (i.e. rhetorical by nature), the latter question type corresponds to normal information-seeking questions. A dissimilarity that is not predicted by equating both expressions, as is done in the *even*-based approach. Another difference in distribution is that *even ONE* and *any* behave differently within the restrictor of a universal quantifier.

This paper explores how the *even*-based approach may be reconciled with this set of empirical data. To achieve this, we propose (i) that EVEN be decomposed into the two focus parti-

---

<sup>1</sup>We would like to thank Maribel Romero and María Biezma for their continued guidance and valuable input. We would also like to thank Andreas Walker for his insightful comments.

cles  $\text{EVEN}_{\text{MIN}}$  and  $\text{EVEN}_{\text{MAX}}$  (cf. Crnič, 2012; Lahiri, 2010), (ii) that *any* is only licensed by  $\text{EVEN}_{\text{MIN}}$ , (iii) that overt *even* is licensed by the combination of  $\text{EVEN}_{\text{MIN}}$  and  $\text{EVEN}_{\text{MAX}}$ , (iv) that, crucially,  $\text{EVEN}_{\text{MAX}}$  carries an additional presupposition of exclusivity, (v) that the difference in the universal quantifier's restrictor is derivable via local accommodation of  $\text{EVEN}_{\text{MAX}}$ 's aforementioned presupposition, and (vi) that the difference in question bias is the result of the same projected presupposition of exclusivity from  $\text{EVEN}_{\text{MAX}}$ .

- (1) a. LF for *any*  
        $[\text{even}_{\text{MIN}} [\not\uparrow \dots [\uparrow \dots \text{one}_F \dots ]]]$   
   b. LF for *even ONE*  
        $[\text{even}_{\text{MIN}} [\not\uparrow \dots [\text{even}_{\text{MAX}} [\uparrow \dots \text{one}_F \dots ]]]]$

In §2 we go into how NPIs are traditionally viewed and how they are modelled under the *even*-based approach to NPIs (see §2.1). In §3 we go into how rhetorical questions can be derived (see §3.1), how polar questions are analysed according to Guerzoni and Sharvit's (2014) question model (see §3.2), and how these question models fail to handle the difference in question bias with a non-decomposed *EVEN*. In §4 we then decompose the NPI-licensing *EVEN* into the two focus sub-particles  $\text{EVEN}_{\text{MIN}}$  and  $\text{EVEN}_{\text{MAX}}$ . We then show in §4.2 how the difference in question bias is obtained with this decomposed model of weak *EVEN*.

## 2. NPI licensing

Accounting for NPIs is a complex issue in formal semantics. Any model that seeks to license them needs to have a unified analysis for a wide range of different licensing environments. See below for a (non-exhaustive) list of NPI-licensing and non-licensing constructions.

- (2) a. #John read any book.  
       b. John didn't read any book.  
       c. Exactly two students read any book.  
       d. Every student who read any book passed the exam.  
       e. Did John read any of the relevant books?

NPIs are not licensed within simple affirmative declarative sentences. They are licensed under negation, within the restrictor of universal quantification, under *only*, within the antecedent of a conditional, within questions, and within the scope of some non-monotone quantifiers.

The first workable model that covered a wide range of the known empirical data was put forth by Fauconnier (1975) and Ladusaw (1979). Their model of licensing was based upon the monotonicity of the environment containing the NPI in question: According to their model, an NPI is licensed iff it occurs within a downward-monotone environment. Later on, their model was improved upon by von Stechow (1999, 2001), who extended their account to cover more empirical data, by lessening the restrictions to Strawson downward-monotone environments (environments that are shown to be downward-monotone given the right circumstances). Together, they form the traditional mainstream line of thought concerning how NPIs are licensed. We refer to

their model, and other models like them, as the monotonicity-based approach to NPI licensing (or, alternatively, the Fauconnier-Ladusaw-Fintel approach).

Naturally, over the years, other models developed that diverged from these monotonicity-based models: Krifka (1995) and Chierchia (2013), to name two of the more substantive ones. However, recently one particular line of thought rose to greater prominence: the *even*-based approach to NPI licensing. Originally ruled out as a viable candidate by Heim (1984), the idea that NPIs are to be licensed by a (covert) EVEN at LF was nevertheless picked up by a number of authors over the years. Amongst them are Lee and Horn (1994), Lahiri (1998), and Crnič (2014a, b).

### 2.1. *Even*-based approach to NPI licensing

An alternative approach to NPI licensing is based upon the focus particle *even*. The essential idea behind this approach is that every NPI is covertly licensed by EVEN at LF. This notion was first considered by Heim (1984) as she noted the similarity in distribution between the expression *even ONE* and the NPI *any*. See below for the *even ONE* counterparts to (2).

- (3) a. #John read *even ONE* book.
- b. John didn't read *even ONE* book.
- c. Exactly two students read *even ONE* book.
- d. Every student who read *even ONE* book passed the exam.
- e. Did John read *even ONE* book?

As we can see, there is an exact match between the felicity distribution of *even ONE* and the NPI *any* (at least for this limited range of data). However, this approach was initially ruled out by Heim (1984) herself, after she encountered some differences that are not easily accounted for: First, that the felicity of *even ONE* in (3d) is context-dependent, as can be seen below, whereas its NPI counterpart is felicitous, regardless from contextual influences.

- (4) a. Every student who read *any* book wore blue jeans.
- b. #Every student who read *even ONE* book wore blue jeans.

Second, it was noted that questions containing the expression *even ONE* are negatively biased (i.e. the positive answer is strictly unexpected), whereas their NPI counterparts are not.

- (5) a. Did John read *any* book?
  - (i) Yes, he did.
  - (ii) No, he didn't.
- b. Did John read *even ONE* book?
  - (i) #Yes, he did.
  - (ii) No, he didn't.

As mentioned before, the *even*-based approach was nevertheless picked up by a number of authors. Prominent examples would be Lee and Horn (1994), who first proposed that NPIs are always composed of a covert EVEN and an existential quantifier; Lahiri (1998), who has shown that this approach is a natural selection for Hindi (its NPIs are transparently consist of an *even*-like particle and existential quantification); and Crnič (2014a, b), who has shown that this approach is able to account for the distributional difference in (4) and the licensing of NPIs in non-monotone environments such as in (2c). The approach also accounts for the infelicity of NPIs in upward-monotone environments and the felicity in downward-monotone ones.

Now that we have an overview over the empirical data, the history of the *even*-based approach, and what the approach is currently able to account for, we must consider *how* it accounts for them. To do this, we first list a number of assumptions most adherents to this approach typically make: (i) EVEN may move freely at LF (Karttunen and Peters, 1979); (ii) focus generates a set of possible alternatives to the focused element (Rooth, 1992); (iii) EVEN has no assertive contribution, but presupposes that its prejacent proposition is the least likely member of its set of focus alternatives (Karttunen and Peters, 1979; Kay, 1990); (iv) NPIs are semantically equivalent to indefinites (Lee and Horn, 1994; Lahiri, 1998); (v) NPIs also induce alternatives that are utilized by some alternative-sensitive operators (Krifka, 1995; Chierchia, 2013); (vi) NPI-licensing EVEN only associates with weak predicates (therefore also referred to as weak EVEN) (Crnič, 2011a, 2014a, b); and (viii) predicates are considered weak, iff they are the most probable member of their focus set (Crnič, 2011a, 2014a, b). See below for the formal definition of weak EVEN, where  $\triangleleft_c$  represents the function *less likely than*:

$$(6) \quad \llbracket \text{even} \rrbracket(C)(p)(w) = p(w) \text{ is defined iff } \forall q \in C[p \neq q \rightarrow p \triangleleft_c q]$$

Another important piece of formal machinery is Kolmogorov's (1933) third axiom of probability that says that any proposition  $\phi$  that entails any proposition  $\psi$  is at most as likely  $\psi$ :

$$(7) \quad \text{Kolmogorov's (1933) third axiom of probability} \\ \text{If } \phi \Rightarrow \psi, \text{ then } \phi \triangleleft_c \psi.$$

Equipped with these assumptions we may now review the current state of the literature on how the (in-)felicity of the different environments are derived. We review how the *even*-based approach handles upward-, downward-, and non-monotone environments. We furthermore review how the Crnič (2014a) accounts for the differences in the universal restrictor and how the difference in question bias can not be accounted for with the current model. We refer to the aforementioned literature on *even* and the *even*-based approach for details on those environments which we do not expand upon.

**UPWARD-MONOTONE ENVIRONMENTS** and their infelicity are easily accounted for under the *even*-based approach. For the sentence (8), we would derive the following presupposition:

$$(8) \quad \# \text{John read any/even ONE book.} \\ \text{a. even [ John read one}_F \text{ book ]} \\ \text{b. For } n > 1: \exists_1 x[\text{BOOK}(x) \wedge \text{READ}(j, x)] \triangleleft_c \exists_n x[\text{BOOK}(x) \wedge \text{READ}(j, x)]$$

In an upward-monotone environments, entailing relations are preserved. Ergo, the original prejacent entails all of its focus alternatives, as can be seen below.

- (9) John read at least  $n$  books  $\Rightarrow$  John read at least one book

Thereby, according to the axiom of probability in (7), it must be the most probable alternative. This is diametrically opposed to EVEN's felicity requirements, causing the sentence to crash.

**DOWNWARD-MONOTONE ENVIRONMENTS**, on the other hand, reverse entailing relations:

- (10) John didn't read at least one book  $\Rightarrow$  John didn't read at least  $n$  books

Therefore, the same principle of probability now enforces that *not at least one* is the least likely member of its focus set. Thus, there can never be a downward-monotone environment in which *even ONE* (and thereby NPIs) are infelicitous, explaining the NPIs perceived link to them.

- (11) John didn't read any/even ONE book.  
 a. even [ not [ John read one<sub>F</sub> book ] ]  
 b. For all  $n > 1$ :  $\neg \exists_1 x [\text{BOOK}(x) \wedge \text{READ}(j, x)] \triangleleft_c \neg \exists_n x [\text{BOOK}(x) \wedge \text{READ}(j, x)]$

**NON-MONOTONE ENVIRONMENTS** suspend all entailing relations. As such, Kolmogorov's (1933) third axiom of probability holds no influence over the felicity of such sentences. Therefore, it comes as no surprise that not all non-monotone environments license NPIs. Critically, Crnič (2011a, 2014b) noted that for sentences containing the expression *exactly n*, it appears that the varying number  $n$  is the most decisive factor for felicity. Consider this scenario:

- (12) Context: There is a lecture with 500 enrolled students. The professor announced ten relevant books before the start of the semester. The first class is now over. The professor relates her experience to one of her colleagues.  
 a. Exactly two students read any/even ONE book.  
 (i) even [ exactly two students read one<sub>F</sub> book ]  
 (ii) For all  $n > 1$ :  $\exists!_2 x [\text{STUDENT}(x) \wedge \exists_1 y [\text{BOOK}(y) \wedge \text{READ}(x, y)]]$   
 $\triangleleft_c \exists!_2 x [\text{STUDENT}(x) \wedge \exists_n y [\text{BOOK}(y) \wedge \text{READ}(x, y)]]$   
 b. #Exactly 250 students read any/even ONE book.  
 (i) even [ exactly 250 students read one<sub>F</sub> book ]  
 (ii) For all  $n > 1$ :  $\exists!_{250} x [\text{STUDENT}(x) \wedge \exists_1 y [\text{BOOK}(y) \wedge \text{READ}(x, y)]]$   
 $\triangleleft_c \exists!_{250} x [\text{STUDENT}(x) \wedge \exists_n y [\text{BOOK}(y) \wedge \text{READ}(x, y)]]$

It appears that the sentence is only felicitous, if  $n$  refers to a contextually low quantity. Crnič (2014b) advocates that the fulfillment of the scalar presupposition is determined by our expectations and general world knowledge, as there are no axioms of probability to guide us. In our example, our general expectations would have been (i) that most students read at least one book, (ii) some students read more than one book, and (iii) that very few students read all ten books. The further the number of students having read  $n$  books deviates from these assump-

tions, the more unexpected the respective proposition becomes. See figure 1 for a graph that represents our general expectations for this scenario.

Figure 1: Expectedness graph of (12) and its alternatives. The x-axis represents the number of students having read  $n$  books. The y-axis to the expectedness of the assertion.

By converting our expectations of the world into probabilities, we can see that the original assertion of (12a) scores the lowest available probability for its value of  $n$  (fulfilling the scalar presupposition of *EVEN*). The infelicitous sentence in (12b), however, does not.

**IN THE RESTRICTOR OF UNIVERSAL QUANTIFICATION**, we have a seeming difference in distribution between weak *even* and NPIs. Whilst NPIs are universally felicitous, its counterpart *even ONE* is not. Below is the expected LF and presupposition for the NPI sentence:

- (13) Every student who read any book passed the exam.
- [ even [ Every student who read one<sub>F</sub> book passed the exam ] ]
  - For all  $n > 1$ :  $\forall x[\text{STUDENT}(x) \wedge \exists_1 y[\text{BOOK}(y) \wedge \text{READ}(x, y)] \rightarrow \text{PASS}(x, \iota v[\text{EXAM}(v)])]$   
 $\triangleleft_c \forall x[\text{STUDENT}(x) \wedge \exists_n y[\text{BOOK}(y) \wedge \text{READ}(x, y)] \rightarrow \text{PASS}(x, \iota v[\text{EXAM}(v)])]$

Being (Strawson) downward-monotone, one can easily see that this scalar presupposition is fulfilled, regardless of any correlation between the restrictor of the quantifier and its verb phrase. As such, the general felicity of NPIs in this environment is derived. But how do we account for the context-sensitivity of *even ONE*? According to Crnič (2014a), the focus particle in (16) violates Crnič’s (2011b) principle of non-vacuity (see his paper for details on how):

- (14) *Principle of Non-Vacuity*  
 “The meaning of a lexical item used in the discourse must affect the meaning of its host sentence (either its truth-conditions or its presuppositions)” (Crnič, 2011b) or its presence must be required on structural grounds (Crnič, 2014a: p. 133).

As a means to rescue the use of *even*, he proposes that there is a covert exhaustifying operator EXH that asserts that all alternatives that are not entailed by the original are false. This operator is obligatorily used to ensure that the contribution of *EVEN* is non-vacuous.

- (15)  $\llbracket \text{Exh} \rrbracket = \forall q \in C[p \not\Rightarrow q \rightarrow q(w) = 0]$

- (16) Every student who read any book passed the exam.
- [ even [ Every student  $\text{wh}_x$  [  $\text{exh}(C) x$  read one<sub>F</sub> book ] passed the exam ] ]
  - For all  $n > 1$ :  $\forall x[\text{STUDENT}(x) \wedge \exists!_1 y[\text{BOOK}(y) \wedge \text{READ}(x, y)] \rightarrow \text{PASS}(x, \iota v[\text{EXAM}(v)])]$   
 $\triangleleft_c \forall x[\text{STUDENT}(x) \wedge \exists!_n y[\text{BOOK}(y) \wedge \text{READ}(x, y)] \rightarrow \text{PASS}(x, \iota v[\text{EXAM}(v)])]$

It accomplishes this purpose by changing the weak existential existential *at least one* into *exactly one*, since all higher-numbered alternatives are negated. This suspends the entailing relations that enforce the felicity of *even*. Since the axiom of probability in (7) no longer affects our judgment, we have to rate the asserted proposition against its alternatives based upon our world knowledge and expectations. As there is a correlation between reading (relevant) books and passing the exam, we would expect that the more books you read, the more likely you are to pass it. As such, our presupposition would be fulfilled. If we exchange our VP with *wore blue jeans* (see (4)), however, our world-knowledge should dictate an expected correlation between wearing blue jeans and the number of books read.

### 3. The issue of questions

Before we go on to see how the *even*-based approach has problems with deriving the (non-)bias of questions, we first give a sketch on how bias/rhetoricity is derivable. This is followed by an overview of Guerzoni and Sharvit's (2014) question model and the problems contemporary question models have with a non-decomposed version of EVEN (with respect to the *even*-based approach to NPI licensing).

#### 3.1. Rhetoricity

There are multiple theories concerning how rhetorical questions derive their rhetoricity. Not all of them are mutually exclusive. In this paper, we present two known ways to derive rhetoricity. The first was proposed by Guerzoni (2003), whereas the second theory was first proposed by van Rooy (2003) and Rohde (2006). Guerzoni (2003) proposes that a question must be considered rhetorical, if only one felicitous answer to the question is derived by the LF of the question form. The second approach is based upon the average informativity of the question (or rather, the lack thereof) and requires some general explanations.

The first approach to rhetoricity was designed by Guerzoni (2003), who focused entirely on the distribution of *even* in questions and how it can be used to derive its negative bias. In her semantics, there are two possible structures for questions containing a focus particle such as *even*. In either structure, however, the focus particle would scope above both answers to the polar question. The only possible difference is whether or not the particle scopes above or below the negation in the negative answer. For *even*, this would result in the following possible structures:

- (17) Did John read even ONE book?
- $\{\#[\text{even}](C)([\text{John read one}_F \text{ book}]), \#[\text{not}](\text{even } C [\text{John read one}_F \text{ book}])\}$
  - $\{\#[\text{even}](C)([\text{John read one}_F \text{ book}]), [\text{even}](C)([\text{not } [\text{John read one}_F \text{ book}]])\}$

In (17a), *EVEN* always associates with an upward-monotone environment. As such, as detailed in §2.1, both answers would be considered infelicitous, since the scalar presupposition is unfulfillable. In (17b) the affirmative answer is still infelicitous. However, the negative answer has *EVEN* associated with a downward-monotone environment, thereby fulfilling its scalar presupposition (as detailed before). Therefore, the only possible answer that fulfills the scalar presupposition would be the negative answer of the second LF. This renders the question itself rhetorical, as reasoned by Guerzoni (2003), since there is but one possible felicitous answer.

The second approach is based upon the informativity of a question and was mostly characterised by van Rooy (2003). The essential idea is, that you seek to gain the most information possible to the question you ask. Starting with very general questions, the more knowledge you already possess about the respective state of the world, the more specific your questions become. In his paper, he explains how we can derive the rhetoricity of minimizer questions:

(18) Did John (even) LIFT A FINGER to help?

The minimizer, which is licensed by *EVEN*, invokes a presuppositional scale of helpful contributions. It also presupposes that the value is known for all units of help except for two: one and zero. In essence, according to van Rooy (2003), the minimizer restricts the range of helpful contributions to the lowest part of the contextually relevant scale. The question whether he did the minimal amount of work or no work at all still remains uncertain. The rhetorical effect is then achieved, according to van Rooy (2003), as follows: Whilst either answer is equally probable, due to the fact that either answer reflects very negatively on John, the actual answer itself does not really matter. As such, the informativity of the question can be judged to be considerably lower than its minimizer-less alternative which does not restrict John's helpfulness to such a degree.

### 3.2. Environments in questions approach

The approach to polar questions by Guerzoni and Sharvit (2014) contrasts with traditional question models (cf. Karttunen, 1977) in that they encode all possible answers to the question within the syntax of the question's LF. They do this by arguing that polar questions are alternative yes-or-no questions containing an optionally silent *whether (or not)*. Instead of assuming that a question operator derives both answers from a single LF, they assume that both answers are present within the LF and linked via disjunction. One of them is pragmatically omitted, however, via ellipsis. They would argue that a question like *Did John kiss Mary(, or not)?* would have the following LF:

(19) [whether<sup>L</sup>] [ 7 ? [[John kissed Mary] (or<sub>7</sub> [not] [~~John kissed Mary~~]]]]

Within this structure, one of the options is elided by pragmatical omission. This can only be done when both answers share an identical structure, which is a necessity of any polar question (under the assumption that negation scopes over a proposition and is not analysed *in situ*).

$$\begin{aligned}
(20) \quad & \text{a. } \llbracket \text{whether}^L \rrbracket = [\lambda Q_{\langle \langle s, t \rangle, \langle \langle s, t \rangle, t \rangle \rangle} . [\lambda q_{\langle s, t \rangle} . \exists ! r_{\langle s, t \rangle} [Q(r)(q) = 1 \wedge q(w) = 1]]] \\
& \text{b. } \llbracket \text{or}_7 \rrbracket = [\lambda P_{\langle \sigma, t \rangle} . [\lambda Q_{\langle \sigma, t \rangle} . [\lambda z_{\sigma} . (g(7) = P \vee g(7) = Q) \wedge g(7)(z) = 1]]] \\
& \text{c. } \llbracket ? \rrbracket = [\lambda p_{\langle s, t \rangle} . [\lambda p_{\langle s, t \rangle} . p = q]]
\end{aligned}$$

(21)  $\llbracket \text{Did John kiss Mary?} \rrbracket = \{ \llbracket \text{John kissed Mary} \rrbracket, \llbracket \text{not [John kissed Mary]} \rrbracket \}$

The major difference to Guerzoni (2003) in relation to NPIs also lies with the expanded alternative structure of polar questions: If the negative clause is directly represented at LF, then the EVEN need not be applied to both sides simultaneously (cf. Guerzoni, 2003). In Crnič (2014a, b)’s adaptation of Guerzoni and Sharvit (2014)’s question model, we assume that NPI-licensing EVEN is only generated in the downward-monotone environment underneath the negation. The EVEN is then raised above the negating element, leaving the substructures of the affirmative and negative answer identical:

Since the constituents are equal to one another, the elision of the affirmative answer is licensed as a pragmatic omission. As such, we arrive at the following generalized structure for sentences containing an NPI-licensing *even*:

Which, in turn, derives the following Hamblin sets:

(24) a.  $\llbracket \text{Did John kiss even one}_F \text{ girl?} \rrbracket = \{ \llbracket \text{John kissed one girl} \rrbracket, \llbracket \text{even} \rrbracket(C)(\neg \llbracket \text{John kissed one}_F \text{ girl} \rrbracket) \}$   
 b.  $\llbracket \text{Did even CP?} \rrbracket = \{ \llbracket \text{CP} \rrbracket, \llbracket \text{even} \rrbracket(C)(\neg \llbracket \text{CP} \rrbracket) \}$

<sup>2</sup>A Heimian indefinite is a restricted variable bound by another operator further up in the LF. See Heim (1982) for further details on this topic.

Under the assumption of the simple *even* hypothesis, this would correctly predict the non-bias of questions containing NPIs. Therein also lies the problem: Since we do not make a distinction between *even ONE* and *any*, questions containing an overt *even ONE* are incorrectly predicted to be unbiased. So far, two attempts have been made to rectify this erroneous prediction: The first correction was attempted by Guerzoni and Sharvit (2014: p. 216, footnote 18) themselves. They proposed the following LF to derive negative bias for such questions:

$$(25) \quad [\text{whether}^L] [ \text{?} ? [\text{even C}] \text{CP}] (\text{or}_7 [\text{even C}] [\text{not} \text{CP}]] ] ]$$

This structure would correctly assign an infelicitous reading to the affirmative question. However, Crnič (2014a) correctly pointed out that such structures violate the constraint on ellipsis:

(26) *Constraint on Ellipsis*

A constituent  $\alpha$  may be elided if it is contained in a constituent  $\beta$  that contrasts with an antecedent constituent  $\beta'$  (where  $\beta$  contrasts with  $\beta'$  if and only if the meaning of  $\beta'$  is in the focus value of  $\beta$ ).

The second attempt to correct the erroneous prediction was carried out by Crnič (2014b). He had drawn parallels to the conundrum he faced with Strawson downward-monotone environments and suggested that the use of covert exhaustification might improve matters. As such, he considered the following LF structure:

$$(27) \quad [\text{whether}^L] [ \text{?} ? [\text{John kissed one girl} (\text{or}_7 [\text{even C}] [\text{not} \text{Exh John kissed one}_F \text{ girl}]] ] ] ]$$

Crnič (2014b: p. 206) reasons that the sentence's scalar presupposition entails that John is less likely to have kissed a high number of girls in contrast to having kissed fewer girls.

$$(28) \quad \llbracket \text{even} \rrbracket(C)(\neg \llbracket \text{Exh C [John kissed one}_F \text{ girl]} \rrbracket)) \text{ is defined iff for all } n > 1 : \\ \text{That } \textit{John did not kiss exactly one girl} \triangleleft_c \text{ that } \textit{John did not kiss exactly } n \text{ girls.}$$

Crnič (2014b) himself states that this presupposition is not an exact match to the negative bias observed. It might, however, be an additional presupposition that accompanies NPI questions anyway. But that is beside the point. So far, no solution has been found regarding the difference in bias between *even ONE* and unstressed NPI questions.

#### 4. Decomposing weak *even*

This still leaves us, however, with the problem of how to derive the presuppositions that induce the questions' rhetoricity. Having exhausted all possible configurations with Guerzoni and Sharvit's (2014 question model, we need to innovate to find an LF that might derive the question's negative bias. In line with Lahiri (2010) and Crnič's (2012) analyses of weak scalar particles, we therefore propose that *even* is morphologically complex. That is to say, *EVEN* decomposes into two separate focus particles. In Crnič's (2012) analysis, he proposes that some scalar particles decompose into  $\llbracket \text{even} \rrbracket$  and its antonym  $\llbracket \neg \text{even} \rrbracket$ .

- (29) a.  $\llbracket \text{even} \rrbracket(C)(p)(w) = p(w)$  is defined iff  $\forall q \in C[p \neq q \rightarrow p \triangleleft_c q]$   
 b.  $\llbracket \neg \text{even} \rrbracket(C)(p)(w) = p(w)$  is defined iff  $\forall q \in C[p \neq q \rightarrow q \triangleleft_c p]$

We propose that *EVEN* decomposes into two similar focus particles: *EVEN<sub>MIN</sub>* and *EVEN<sub>MAX</sub>*. The former is identical to standard weak *EVEN*, whereas the latter has no at-issue contribution but two separate presuppositions: First, that its prejacent is the most probable alternative, and second, that all alternatives that are not entailed by its original prejacent are false. In essence, we adopt Crnič's (2012) model, with the exception of an added presupposition of exclusivity.<sup>3</sup>

- (30) a.  $\llbracket \text{even}_{\text{MIN}} \rrbracket(C)(p)(w) = p(w)$  is defined iff  $\forall q \in C[p \neq q \rightarrow p \triangleleft_c q]$   
 b.  $\llbracket \text{even}_{\text{MAX}} \rrbracket(C)(p)(w) = p(w)$  is defined iff  $\forall q \in C[p \neq q \rightarrow q \triangleleft_c p]$ , and  
 $\forall q \in C[p \not\neq q \rightarrow q(w) = 0]$

We independently motivate this decomposition by two factors: (i) Some element is required to enforce weak *EVEN*'s pairing with weak predicates, and (ii) to account for the presupposition of exclusivity exuded by sentences of the same type as below:

- (31) a. John doesn't even know how to *START* a computer.  
 $\Rightarrow$  John doesn't know how to do any activity with a computer.<sup>4</sup>  
 b. Exactly two of her friends even know how to *START* a computer.  
 $\Rightarrow$  None of her friends know how to do anything else with a computer.

While the first sentence would be easily accounted for with an additive particle that might accompany *EVEN*, the latter would not be (Crnič, 2011a: p. 157). With our account, however, both of the above readings are derivable, as shown below.

- (32) John doesn't even know how to *START* a computer.  
 a.  $\llbracket \text{even}_{\text{MIN}} \llbracket \text{not} \llbracket \text{even}_{\text{MAX}} \llbracket \text{John knows how to start}_F \text{ a computer} \rrbracket \rrbracket \rrbracket$   
 b. Presupposition of *EVEN<sub>MIN</sub>*:  
 For all *R*: It is less likely that *John doesn't know how to start a computer* than *John doesn't know how to R a computer*.  
 c. Presupposition of *EVEN<sub>MAX</sub>*:  
 For all *R*  $\neq$   $\llbracket \text{start} \rrbracket$ : It is more likely that *John knows how to start a computer* than *John knows how to R a computer*, and John does not know how to *R* a computer.

The computation of the other sentence is less straightforward, as it contains an instance of presupposition projection. For the purposes of this paper, we assume that presuppositions under quantifiers project universally (cf. Heim, 1983).<sup>5</sup> Under this assumption, we derive the following presuppositions:

<sup>3</sup>It should be noted that adding a presupposition of exclusivity virtually renders *EVEN<sub>MAX</sub>* identical to Guerzoni's (2003) *only<sub>2</sub>* in her analysis of German scalar particle *auch nur*.

<sup>4</sup>Note that we intentionally do not use a predicate that is entailed by all of its alternatives. If the alternatives were entailed, then the negation itself would already result in the correct reading. Theoretically, people exist who might not know how to start a computer, but are perfectly able to use it for specific tasks (e.g. writing).

<sup>5</sup>This assumption, however, is not crucial, and existential projection leads to a weaker, but also tenable claim.

- (33) Exactly two of her friends even know how to START a computer.
- a.  $[ \text{even}_{\text{MIN}} [ \text{exactly two of her friends} [ 1 [ \text{even}_{\text{MAX}} [ t_1 \text{ knows how to start}_F \text{ a computer} ] ] ] ] ]$
  - b. Presupposition of  $\text{EVEN}_{\text{MIN}}$ :  
For all  $R$ : It is less likely that *Exactly two of her friends know how to start a computer* than *John doesn't even know how to R a computer*.
  - c. Presupposition of  $\text{EVEN}_{\text{MAX}}$ :  
For all  $R \neq \llbracket \text{start} \rrbracket$ : It is more likely for all of her friends to know how to start a computer, rather than how to  $R$  a computer (individually, not collectively), and all of her friends do not know how to  $R$  a computer.

Now that we have sufficiently motivated our decision to decompose *EVEN*, we proceed to show how this analysis would fare with the different kinds of environments we find it in (cf. §2). Note that this analysis simply adds additional presuppositions upon the already existing analysis. As such, any LF that was already ruled out by our previous non-decomposed approach, will also be ruled out under this approach, as their presuppositions will still remain unfulfilled. We therefore refrain from showing the presuppositions of  $\text{EVEN}_{\text{MAX}}$  under upward monotone environments. Also note that we propose that only overt *even* requires to be licensed by  $\text{EVEN}_{\text{MAX}}$ . As such, the analysis for sentences containing an NPI remains the same and is not reiterated here.

**DOWNWARD-MONOTONE ENVIRONMENTS** remain as straight-forward as they used to be under the original *even*-based account. In downward-monotone environments,  $\text{EVEN}_{\text{MAX}}$  moves to take scope over the upward-monotone expression, beneath the downward-monotone operator. As such, if the predicate is weak, the presupposition is an automatic success due to Kolmogorov's third axiom of probability.

- (34) John didn't read even ONE book.
- a.  $[ \text{even}_{\text{MIN}} [ \text{not} [ \text{even}_{\text{MAX}} [ \text{John read one}_F \text{ book} ] ] ] ]$
  - b. Assertion:  
 $\llbracket (34) \rrbracket = \neg \exists_1 x [\text{BOOK}(x) \wedge \text{READ}(j, x)]$
  - c. Presupposition of  $\text{EVEN}_{\text{MIN}}$ :  
For all  $n > 1$ :  $\neg \exists_1 x [\text{BOOK}(x) \wedge \text{READ}(j, x)] \triangleleft_c \neg \exists_n x [\text{BOOK}(x) \wedge \text{READ}(j, x)]$
  - d. Presupposition of  $\text{EVEN}_{\text{MAX}}$ :  
For all  $n > 1$ :  $\exists_n x [\text{BOOK}(x) \wedge \text{READ}(j, x)] \triangleleft_c \exists_1 x [\text{BOOK}(x) \wedge \text{READ}(j, x)]$ , and  
 $\neg \exists_n x [\text{BOOK}(x) \wedge \text{READ}(j, x)]$

The presupposition of exclusivity is also successful and precludes the possibility of John having read more than one book, which is entirely compatible with the sentence's asserted content.

**NON-MONOTONE ENVIRONMENTS** remain as context-sensitive as they used to be. The presupposition of  $\text{EVEN}_{\text{MIN}}$  remains responsible for the context-sensitivity of the expression.

- (35) Exactly three students read even ONE book.
- $[ \text{even}_{\text{MIN}} [ \text{exactly three students } [ 1 [ \text{even}_{\text{MAX}} [ t_1 \text{ read one}_F \text{ book } ] ] ] ] ]$
  - Assertion:  

$$\llbracket (35) \rrbracket = \exists!_3 x [\text{STUDENT}(x) \wedge \exists_1 y [\text{BOOK}(y) \wedge \text{READ}(x, y)]]$$
  - Presupposition of  $\text{EVEN}_{\text{MIN}}$ :  
For all  $n > 1$ :  $\exists!_3 x [\text{STUDENT}(x) \wedge \exists_1 y [\text{BOOK}(y) \wedge \text{READ}(x, y)]]$   
 $\triangleleft_c \exists!_3 x [\text{STUDENT}(x) \wedge \exists_n y [\text{BOOK}(y) \wedge \text{READ}(x, y)]]$
  - $\forall$ -projected presuppositions of  $\text{EVEN}_{\text{MAX}}$ :  
For all  $n > 1$ :  $\forall y [y \in \mathcal{P} \rightarrow \exists_n x [\text{BOOK}(x) \wedge \text{READ}(y, x)]]$   
 $\triangleleft_c \exists_1 x [\text{BOOK}(x) \wedge \text{READ}(y, x)]$ , and  
 $\forall y [y \in \mathcal{P} \rightarrow \neg \exists_n x [\text{BOOK}(x) \wedge \text{READ}(y, x)]]$

The presuppositions of  $\text{EVEN}_{\text{MAX}}$ , on the other hand, are a tad more complicated as they must be projected. The scalar presupposition remains trivial, as it still associates with an upward-monotone environment. The presupposition of exclusivity, however, projects in such a way that for all members of  $\mathcal{P}$  it is true that they did not read more than one book. The set  $\mathcal{P}$  represents the domain of the projection, which corresponds to the entire set of students (not only those three that have been mentioned). Coupled with the asserted content this entails that amongst all students, only the three students in question have read anything at all.

Having shown that the standard non-problematic environments are also accounted for by our extension of the original account, things are now ready to get interesting. We now go into how our account handles those cases that were considered problematic by Heim (1984). As demonstrated in the next two subsections, our account is able to explain the unwanted differences in a straightforward fashion and requires no added assumptions or mechanisms.

#### 4.1. Restrictor of universal quantification

In the restrictor of universal quantification, things turn more complicated and, by extension, more interesting. Let us review what the LF of a relevant NPI sentence looks like. Being downward-monotone, the felicity is fulfilled and not influenced by external factors.

- (36) Every student who read any book passed the exam.
- $[ \text{even} [ \text{Every student who read one}_F \text{ book passed the exam } ] ]$
  - For all  $n > 1$ :  $\forall x [\text{STUDENT}(x) \wedge \exists_1 y [\text{BOOK}(y) \wedge \text{READ}(x, y)] \rightarrow \text{PASS}(x, \iota v [\text{EXAM}(v)])]$   
 $\triangleleft_c \forall x [\text{STUDENT}(x) \wedge \exists_n y [\text{BOOK}(y) \wedge \text{READ}(x, y)] \rightarrow \text{PASS}(x, \iota v [\text{EXAM}(v)])]$

For the LF of the corresponding *even*-counterpart, we first need to decide what happens with the presupposition under quantification. Let us consider the following possible projections:

- (37) Every student who read even ONE book passed the exam.
- $[\text{even}_{\text{MIN}}[[\text{every}[\text{student that}[1[\text{even}_{\text{MAX}}[t_1 \text{ read one}_F \text{ book}]]]] [\text{passed the exam}]]]$
  - Unprojected presuppositions of  $\text{EVEN}_{\text{MAX}}$ :  
For all  $n > 1$ :  $\exists_n x[\text{BOOK}(x) \wedge \text{READ}(g(1), x)] \triangleleft_c \exists_1 x[\text{BOOK}(x) \wedge \text{READ}(g(1), x)]$ ,  
and  $\neg \exists_n x[\text{BOOK}(x) \wedge \text{READ}(g(1), x)]$
  - $\forall$ -projected presuppositions of  $\text{EVEN}_{\text{MAX}}$ :  
For all  $n > 1$ :  $\forall y[y \in \mathcal{P} \rightarrow \exists_n x[\text{BOOK}(x) \wedge \text{READ}(y, x)]$   
 $\triangleleft_c \exists_1 x[\text{BOOK}(x) \wedge \text{READ}(y, x)]$ , and  
 $\forall y[y \in \mathcal{P} \rightarrow \neg \exists_n x[\text{BOOK}(x) \wedge \text{READ}(y, x)]]$
  - $\exists$ -projected presuppositions of  $\text{EVEN}_{\text{MAX}}$ :  
For all  $n > 1$ :  $\exists y[y \in \mathcal{P} \wedge \exists_n x[\text{BOOK}(x) \wedge \text{READ}(y, x)]]$   
 $\triangleleft_c \exists_1 x[\text{BOOK}(x) \wedge \text{READ}(y, x)]$ , and  
 $\exists y[y \in \mathcal{P} \wedge \neg \exists_n x[\text{BOOK}(x) \wedge \text{READ}(y, x)]]$

For the universally projected presupposition of exclusivity, the reading we get would be far too strong for our intuitions. The sentence (37) does not give rise to the intuition that no student at all read more than one book. The existentially projected presupposition, too, does not match the intuitions that arise from this sentence: In this case, the exclusivity presupposition would presuppose that there is some student who has not read more than one book. Since the sentence is perfectly fine in a scenario where all students have read all the required books and it is taken to be a general statement, this also excludes the existentially projected presupposition. This leaves us with a third option: Shifting the presupposed content to the assertive level via local accommodation. And indeed, under the assumption that the presuppositions of  $\text{EVEN}_{\text{MAX}}$  are locally accommodated in the restrictor of the universal quantifier, we would derive the following assertion and presuppositions:<sup>6</sup>

- (38) Every student who read even ONE book passed the exam.
- $[\text{even}_{\text{MIN}}[[\text{every}[\text{student that}[1[\text{even}_{\text{MAX}}[t_1 \text{ read one}_F \text{ book}]]]] [\text{passed the exam}]]]$
  - Assertion with local accommodation of  $\text{EVEN}_{\text{MAX}}$ :  
 $[(37)] = \forall x[\text{STUDENT}(x) \wedge \exists!_1 y[\text{BOOK}(y) \wedge \text{READ}(x, y)]$   
 $\rightarrow \text{PASS}(x, \iota v[\text{EXAM}(v)])]$
  - Presupposition of  $\text{EVEN}_{\text{MIN}}$  with local accommodation of  $\text{EVEN}_{\text{MAX}}$ :  
For all  $n > 1$ :  $\forall x[\text{STUDENT}(x) \wedge \exists!_1 y[\text{BOOK}(y) \wedge \text{READ}(x, y)] \rightarrow \text{PASS}(x, \iota v[\text{EXAM}(v)])]$   
 $\triangleleft_c \forall x[\text{STUDENT}(x) \wedge \exists!_n y[\text{BOOK}(y) \wedge \text{READ}(x, y)] \rightarrow \text{PASS}(x, \iota v[\text{EXAM}(v)])]$

These assertive and presuppositional levels are nigh-equivalent to the ones derived by Crnić (2014a) in (16). As such, under the assumption of local accommodation, we derive the required context-sensitivity of *even* without resorting to the introduction of additional rescue operators (i.e. *Exh*). Under the assumption that NPIs were licensed by weak *EVEN* (i.e. by both of its sub-particles), we would also introduce context-sensitivity to (37)'s NPI counterpart. This is undesirable. To circumvent this problem, we proposed the following alteration to the original

<sup>6</sup>Note that we make no assertion on what happens to the scalarity presupposition of  $\text{EVEN}_{\text{MAX}}$ . There are two possible options. (i) The presupposition projects as usually, or (ii) the presupposition is also locally accommodated. However, this would lead to infelicitous propositions, and, as such, should be avoided as an option. Further research is required for how a presupposition trigger with multiple presuppositions projects with regard to its individual presuppositions.

*even*-based approach: Weak NPIs are licensed by covert  $\text{EVEN}_{\text{MIN}}$  at LF. Overt instances of weak *even* and strong NPIs (e.g. minimizers), on the other hand, are licensed by the combination of  $\text{EVEN}_{\text{MIN}}$  and  $\text{EVEN}_{\text{MAX}}$ . This means that we leave the existing analysis of weak NPIs under this approach entirely untouched: We only change the semantics of overt *even* and strong NPIs.

(39) *Summary of our proposal so far*

- a. Weak NPIs are licensed by  $\text{EVEN}_{\text{MIN}}$
- b. Strong NPIs and overt weak *even* are licensed by  $\text{EVEN}_{\text{MIN}}$  and  $\text{EVEN}_{\text{MAX}}$
- c.  $\text{EVEN}_{\text{MAX}}$  is locally accommodated in the restrictor of universal quantification, and thereby introduces the required context-sensitivity of weak *even*

Now that we have covered the environments that the *even*-based approach already accounted for, let us turn our eye to how questions are affected by our proposal.

#### 4.2. Decomposed *even* and English polar questions

Given that we now assume that NPIs are licensed only by  $\text{EVEN}_{\text{MIN}}$ , the analysis for NPI questions remains the same as presented in §3.2. That is, they do not derive any kind of question bias or feeling of rhetoricity. Concerning the LF of *even*-questions, on the other hand, we would derive the following structure and Hamblin set:

(40) Did John read *even* ONE book?

- a.  $[\text{whether}^L] [ \text{?} [ [\text{John read one}_F \text{ book}] (\text{or}_7$   
 $\quad \quad \quad \text{[even}_{\text{MIN}} [\text{not even}_{\text{MAX}} [\text{John read one}_F \text{ book}]]) ] ] ]$
- b.  $\llbracket \text{Did John read any book?} \rrbracket = \{ \llbracket \text{John read one}_F \text{ book} \rrbracket,$   
 $\quad \quad \quad \llbracket \text{even}_{\text{MIN}} \rrbracket (C') ( \llbracket \text{not [even}_{\text{MAX}} C [\text{John read focus}_F \text{ book}] ] \rrbracket ) \}$

The negative answer would have the following presuppositions:

(41) John didn't read *even* ONE book.

- a.  $[ \text{even}_{\text{MIN}} [ \text{not} [ \text{even}_{\text{MAX}} [ \text{John read one}_F \text{ book} ] ] ] ]$
- b. Presupposition of  $\text{EVEN}_{\text{MIN}}$ :  
 $\text{For all } n > 1: \neg \exists_1 x [\text{BOOK}(x) \wedge \text{READ}(j, x)] \triangleleft_c \neg \exists_n x [\text{BOOK}(x) \wedge \text{READ}(j, x)]$
- c. Presupposition of  $\text{EVEN}_{\text{MAX}}$ :  
 $\text{For all } n > 1: \exists_n x [\text{BOOK}(x) \wedge \text{READ}(j, x)] \triangleleft_c \exists_1 x [\text{BOOK}(x) \wedge \text{READ}(j, x)], \text{ and}$   
 $\neg \exists_n x [\text{BOOK}(x) \wedge \text{READ}(j, x)]$

Under the assumption that questions inherit the presuppositions of all of their possible answers (cf. Abrusán, 2014: p. 40, amongst others), this would entail that the question itself is only defined if we already preclude the possibility that John has read more than one book.<sup>7</sup> This

<sup>7</sup>Note that we can arrive at the same requirements, even if we do not assume that questions inherit all of their answer's presupposition. Under the assumption that questions only inherit presuppositions shared by all of their answers, we can simply maximize the ellipsis to ensure that  $\text{EVEN}_{\text{MAX}}$  is also contained by the affirmative answer:

would mean that the speaker has already settled for herself that John will not have read any great amount of books. In fact, she assumes that he could have read at most one book, if any, which she also communicates to the addressee via the question form itself. This situation is identical to van Rooy's (2003) analysis of minimizer questions. We simply derive the necessary conditions for his derivation of rhetoricity in a different fashion. In fact, under our assumptions, minimizer-questions would derive their rhetoricity through the very same process as above, since we assume that strong NPIs are also licensed by the combination of both types of *EVEN*.<sup>8</sup> One caveat, however: Since overt *even* does not always associate with ludicrously minimal amounts (in comparison to lifting a finger), the derivation of rhetoricity is dependent upon the judgment of the speaker/addressee. Is the difference between nothing and one relevant to the situation? If so, the question would still be information-seeking. If not, the question would be considered rhetorical. As such, our proposal makes the following prediction: Not all instances of *even*-questions are rhetorical in nature. This difference would be determined by context.

## 5. Conclusion

The aim of this paper was to consider how the *even*-based approach NPI licensing can be reconciled with the differences in distribution between NPIs and the expression *even ONE* with the general assumption that NPIs are also licensed by *EVEN*. We have achieved this in §4, §4.1 and §4.2, where we have altered the semantics of overt *even*, whilst we left the analysis of NPIs untouched. Under our account, the impression that *even ONE* and *any* are licensed by the same factors was fabricated due to the fact that they share one important licensing factor: *EVEN*<sub>MIN</sub>. In our account, however, overt *even* requires a second licensing *EVEN*<sub>MAX</sub> that is solely responsible for all of the distributional differences pointed out by Heim (1984).

We are aware that our approach may have problems with accounting for the correct reading of some sentences such as the ones below.

- (42) a. John regrets opening even ONE book.  
 b. John knows that asking out even ONE girl is a difficult task.  
 c. If John opens even ONE book, he will learn something new.

More precisely, our account is likely to make some predictions of exclusivity that are too strong to match our general intuitions for such sentences. A point for future research would be to examine how our account interacts with these environments and whether the presupposition of exclusivity might be dealt with in a similar fashion to the solution we provided for the universal quantifier's restrictor (or an entirely different approach for that matter). Another potential point for future research would be the empirical examination of our prediction concerning the

- (i) Did John read even ONE book?  
 a. [whether<sup>L</sup>] [ 7 ? [[*even*<sub>MAX</sub> John read one<sub>F</sub> book] (or<sub>7</sub> [*even*<sub>MIN</sub> [not] *even*<sub>MAX</sub> [John read one<sub>F</sub> book]]]]]

<sup>8</sup>It is interesting to note that minimizers and other strong NPIs are often considered to bear obligatory stress. The indefinite in *even ONE* also bears stress. A possibility for future research might be, whether an interaction with the stress itself somehow derives *EVEN*<sub>MAX</sub>, possibly explaining why *any* turns into a strong NPI once stressed.

contextually-determined rhetoricity of *even*-questions. Another important point for future research is to analyse the projection of multiple presuppositions triggered by the same focus particle and empirically test whether all of them obligatorily project in the same manner.

# Polarity reversals under sluicing<sup>1</sup>

Margaret KROLL — *University of California, Santa Cruz*

**Abstract.** This paper presents novel English sluicing data that challenge even the most successful existing theories of the relationship between antecedent and elided content in sluicing constructions. The data supply robust evidence for a previously unobserved phenomenon in which the elided content and the antecedent content in a sluiced construction contain opposite polarity. The phenomenon challenges current accounts of identity conditions on ellipsis by demonstrating that a greater mismatch between antecedent and elided content is possible than previously thought; specifically, the paper shows that the identity condition for sluicing must be sensitive to pragmatic as well as to semantic content. This observation motivates a proposal in which sluicing is treated as a pragmatics-sensitive phenomenon licensed by local contextual entailment.

**Keywords:** ellipsis, sluicing, dynamic semantics, formal pragmatics, polarity

## 1. Introduction

Sluicing, first noted by Ross (1969), is an ellipsis phenomenon in which the TP of an interrogative is elided under some identity condition, stranding an overt *wh*-phrase in the CP domain. An example is given in (1) below.

- (1) Bernie knows that someone in Iowa voted for Trump, but he doesn't know who<sub>i</sub>  
[TP ~~*t<sub>i</sub> in Iowa voted for Trump*~~].

This paper discusses the previously unobserved phenomenon of polarity reversals<sup>2</sup> under sluicing. The phenomenon I am calling *polarity reversal* is that in which the antecedent and elided material in a sluicing construction contain opposite polarity. For example, the antecedent content (A) in (2), *Trump will comply*, has positive polarity while the elided content (E), *Trump won't comply*, has negative polarity.

- (2) I don't think that [Trump<sub>i</sub> will comply]<sub>A</sub>, but I don't know why [TP ~~*he<sub>i</sub> won't comply*~~]<sub>E</sub>.<sup>3</sup>

---

<sup>1</sup>Thank you to Pranav Anand, Rachelle Boyson, and Jim McCloskey for bringing this phenomenon to my attention and for inspiring/providing much of the project's data. Thank you to Pranav Anand, Sandy Chung, Dan Hardt, Bill Ladusaw, Jim McCloskey, and Deniz Rudin for invaluable discussion of the ideas presented here, as well as audiences at UCSC, UC Berkeley, and SuB21. Finally, thank you to the undergraduate annotators of the Santa Cruz Ellipsis Project for their work in classifying the original corpus data. This project has in part been supported by a UC Santa Cruz Institute of Humanities Research cluster grant to the Santa Cruz Ellipsis Consortium, and by the National Science Foundation Grant No. 1451819: *The Implicit Content of Sluicing*.

<sup>2</sup>I use this label pre-theoretically and for convenience. As we will see, no actual "reversal" of polarity takes place between an antecedent and elision site.

<sup>3</sup>Note that there is a reading in which the antecedent includes the matrix clause, but this reading is pragmatically odd.

I show that data like (2) require a shift in current beliefs about the identity conditions that license sluicing constructions. I propose a theory of sluicing that builds on the advances made in previous accounts while allowing for greater mismatches between antecedent and elided content in order to accommodate the newly observed data.<sup>4</sup>

The paper proceeds as follows. Section 2 provides an overview of Merchant's (2001) theory of e-GIVENness and demonstrates that it fails to predict the polarity reversal data. Section 3 proposes an alternative theory and steps through its predictions for three polarity reversal examples. Section 4 addresses the concern of overgeneration that arises for pragmatic accounts of sluicing, and Section 5 concludes.

## 2. e-GIVENness

Numerous theories of sluicing have been proposed since the original syntactic isomorphy approach given in Ross (1969). The dominant semantics-based account of sluicing is Merchant's (2001) theory of e-GIVENness, which imposes a bidirectional semantic entailment identity condition on ellipsis. More recent theories have constrained the e-GIVENness account in various ways (Merchant 2005; Chung 2006, 2013; Barker 2013; AnderBois 2014). As these accounts are designed to be *more* restrictive than Merchant's original account, the objection outlined here that e-GIVENness undergenerates the polarity reversal data applies equally to these theories.<sup>5</sup>

### 2.1. Bidirectional semantic entailment

Merchant (2001) proposes that sluicing constructions are formed via wh-movement of a remnant constituent and subsequent deletion at PF of the remaining TP. e-GIVENness is a modification of Schwarzschild's (1999) GIVENness, which itself is a theory of focus and deaccenting. Schwarzschild proposes, drawing upon Rooth's (1985, 1992) theory of focus, that an expression can be deaccented if it is GIVEN, where GIVENness is defined as follows:

#### *Formal GIVENness Condition:*

An utterance B counts as GIVEN iff it has an antecedent A and:

$$\forall \langle w, g \rangle \in c \exists h [\text{ExClo}(\llbracket A \rrbracket^g)(w) \rightarrow \text{ExClo}(\llbracket B \rrbracket^{g,h})(w)]$$

Informally, GIVENness says that an expression can be deaccented if the existential focus closure of the expression is contextually entailed by the existential closure of an antecedent.<sup>6</sup>

<sup>4</sup>A methodological aside on the data used throughout: The corpus examples given here were identified by undergraduate annotators trained on the Santa Cruz Ellipsis Consortium. The properties of the sluices, including the provided pre-sluices, are those given by (at least) two independent annotators. After the annotation process, the judgments were verified by (an average of) ten trained linguists, including faculty and graduate students, in consultation with naïve speakers. Many of the examples presented here have more than one possible interpretation for the pre-sluice. The claim here is not that the pre-sluices provided for these examples are the *only* interpretation available for these examples, but merely that they are a felicitous, freely available interpretation in the context in which the sluice was found or constructed.

<sup>5</sup>Barros (2014) and Ginzburg and Sag (2001) take a different approach, combining syntactic and pragmatic constraints. See Kroll (in prep) for a discussion of these theories.

<sup>6</sup>Existential closure is a type-shifting operation that raises expressions to type  $\langle t \rangle$  by existentially binding unfilled arguments.

Because Schwarzschild was concerned with deaccenting, his theory does not discuss ellipsis. However, Merchant draws upon the idea from Rooth (1992) and Romero (1997) that the licensing conditions for deaccenting and ellipsis are related, the strong version of which is to say that ellipsis is just an extreme version of deaccenting. Merchant notes, though, that the theory of GIVENness runs into a problem if applied faithfully to cases of ellipsis. Specifically, it fails to rule out impossible sluices such as (3), in which the elided content is entailed by the labelled antecedent (assuming *calling x an idiot*  $\rightarrow$  *insulting x*), but is not judged to be a possible interpretation of the sluiced sentence.

- (3) [Abby called someone an idiot]<sub>A</sub>, but I don't know who [~~Abby insulted t~~]<sub>E</sub>.

Based on such examples, Merchant proposes that GIVENness alone is not strong enough to act as a licensing condition for ellipsis. Merchant therefore strengthens GIVENness by requiring that the entailment relationship between the antecedent and elided expression be bidirectional instead of unidirectional. The account is given as follows:

**Focus condition on TP-ellipsis:** A TP  $\alpha$  can be deleted only if  $\alpha$  is e-GIVEN.

**e-GIVENness:** An expression E counts as e-GIVEN iff E has a salient antecedent A and, modulo  $\exists$  type-shifting, i) A entails F-clo(E), and **ii) E entails F-clo(A)**.

Note that condition (ii) is the novel aspect of the theory. Note also that the entailment requirement here is that of semantic entailment and, unlike GIVENness, does not leave room for contextual entailment.

The bidirectional entailment requirement of e-GIVENness will correctly rule out the problematic example given in (3), repeated below, as the elided expression does not entail the F-closure of the antecedent expression.

- (3) [Abby called someone an idiot]<sub>A</sub>, but I don't know who [~~Abby insulted t~~]<sub>E</sub>.

A entails F-clo(E): Yes.

A =  $\exists x$ . Abby called x an idiot

F-Clo(E) =  $\exists x$ . Abby insulted x

E entails F-clo(A): No.

E =  $\exists x$ . Abby insulted x

F-Clo(A) =  $\exists x$ . Abby called x an idiot

## 2.2. e-GIVENness predictions

The semantic identity condition of e-GIVENness is permissive enough to allow for certain observed syntactic mismatches between sluiced clauses and their antecedents, such as tense (Merchant 2001); however, the bidirectional entailment requirement is too restrictive to allow for polarity mismatches. Let's look again at (2), repeated below as (4).

- (4) I don't think that [<sub>TP</sub> Trump<sub>i</sub> will comply]<sub>A</sub>, but I don't know why [<sub>TP</sub> ~~he<sub>i</sub> won't comply~~]<sub>E</sub>.

Applying e-GIVENness to A and E yields the following:

A entails F-clo(E): No.

A = **comply**(t)

F-Clo(E) =  $\neg$ **comply**(t)

E entails F-clo(A): No.

E =  $\neg$ **comply**(t)

F-Clo(A) = **comply**(t)

Neither the antecedent expression nor the elided expression in (4) entails the other. An alternate possibility is to include the matrix clause in the antecedent, thereby capturing its negation in the antecedent expression. This is given in (5).

- (5) [TP I don't think that Trump<sub>i</sub> will comply]<sub>A</sub>, but I don't know why [TP ~~he<sub>i</sub> won't comply~~]<sub>E</sub>.

A entails F-clo(E): No.

A =  $\neg \forall w [w \in W_{\text{dox}, s} \rightarrow \text{comply}(t)(w)]$

F-Clo(E) =  $\{w: \neg \text{comply}(t)(w)\}$

E entails F-clo(A): No.

E =  $\{w: \neg \text{comply}(t)(w)\}$

F-Clo(A) =  $\neg \forall w [w \in W_{\text{dox}, s} \rightarrow \text{comply}(t)(w)]$

As (5) shows, expanding the antecedent to include the matrix negation does not yield entailment in either direction. Indeed, my lacking a belief that Trump will comply does not semantically entail that Trump will not comply, as my lack of beliefs about an event does not entail any truth about the event itself. Notice that even if one argues that the stronger neg-raised interpretation of the antecedent, e.g. along the lines of Gajewski (2007) (see §3.1), counts as semantic content, we still do not have mutual entailment, as my thinking that Trump will not comply does not entail that he won't, as I can have false beliefs. Similarly, it will not work to take the matrix as antecedent, and the complement of *but* as the potential elided phrase,<sup>7</sup> as my thinking that Trump will not comply does not semantically entail my not knowing why he won't, as I may indeed know the reason he won't. I leave it to the reader to confirm the formal predictions here.

In summary, bidirectional semantic entailment accounts such as e-GIVENness are too restrictive and fail to predict the existence of polarity reversal data. The next section proposes an alternative account that builds off the insights of both GIVENness and e-GIVENness.

### 3. A modified account

This section presents a theory of sluicing that abandons semantic identity in favor of pragmatics-based entailment. The spirit of the proposal is indebted to those accounts already discussed and to the contextual entailment allowance that was included, though not given an exposition, in Schwarzschild's GIVENness. Informally, I propose that the TP of an interrogative can be elided if and only if the proposition expressed by the TP, modulo existential closure, is entailed by the context in which the proposition would be uttered. Formally, Local Givenness is expressed as follows:

<sup>7</sup>If one wanted to argue that, similar to focus licensing (Rooth 1985, 1992), one can have a larger expression license the deletion of a smaller contained expression.

**Local Givenness (Preliminary):** A TP  $\alpha$  can be deleted iff  $ExClo(\llbracket \alpha \rrbracket^g)$  expresses a proposition  $p$  such that  $c_L \subseteq p$ .

The relevant notion of context we are concerned with is the local context,  $c_L$ , in which  $p$  is expressed. The local context of a proposition  $p$  is more constrained and therefore not necessarily identical to the global context of the discourse in which  $p$  is uttered. For Stalnaker, the context set is updated as propositions are entered into the discourse and accepted by speakers as true for the purposes of the discourse (2002). However, propositions can be entered into local contexts without being entered into the context set, i.e. without being accepted as true of the actual world by the speakers of the discourse. Note that this means that, throughout a discourse,  $c_L$  is not a continually narrowing set of worlds. Instead,  $c_L$  is the set of worlds compatible with the presuppositions of the local proposition. While the account presented here is compatible with a range of dynamic theories, I assume the following basic formal reasoning (Kadmon 2001 and citations within):

*Context update:*

- a. If  $c_L$  entails the presuppositions of  $p$ , then  $c_L + p = \{c_L \cap p\}$
- b. If  $c_L$  does not entail the presuppositions of  $p$ , then either:
  - i. undefined, or
  - ii. the presuppositions of  $p$  are accommodated,  $c_L + p = \{(c_L \cap ps(p)) \cap p\}$

The following sections apply Local Givenness to three categories of polarity reversal sluices.<sup>8</sup>

### 3.1. Neg-raising polarity reversals

One class of polarity reversal sluices contains neg-raising verbs. For example, (2) is repeated below as (6):

(6) [I don't think that Trump<sub>i</sub> will comply]<sub>A</sub>, but I don't know why [TP ~~he<sub>i</sub> won't comply~~]<sub>E</sub>.

That neg-raising is the relevant property in (6) can be seen by swapping the neg-raising verb *think* with the non-neg raising verb *hope*, as in (7a). Example (7a) cannot receive the polarity reversal interpretation; the only available interpretation is that in which the matrix clause acts as antecedent, given in (7b).

- (7) a. Mary doesn't hope that Trump<sub>i</sub> will comply, and she can't explain why [~~# he<sub>i</sub> won't comply~~].
- b. Mary doesn't hope that Trump will comply, but she can't explain why [~~she<sub>i</sub> doesn't hope that Trump will comply~~].

Neg-raising verbs are clause-embedding verbs that when negated allow a reading in which matrix negation takes scope in an embedded clause. As it is arguably the dominant approach

<sup>8</sup>See Kroll (in prep) for derivations of polarity reversal examples containing *until*, *doubt*, and *say*.

in the literature, I use here the account of neg-raising given in Gajewski (2007).<sup>9</sup> Gajewski's account draws importantly on an idea from Bartsch (1973) that the inference from the literal interpretation of a neg-raising sentence like (6<sub>A</sub>), where negation takes matrix scope, to the neg-raised interpretation, where negation takes embedded scope, is a pragmatic inference. Specifically, Bartsch argues that neg-raising verbs license an excluded middle presupposition as a pragmatic inference. For a sentence like (6<sub>A</sub>) that contains the neg-raising verb *think*, the presupposition is that the subject either believes that the proposition expressed by the complement of the verb is true, or believes that it is false. The assertion of (6<sub>A</sub>) combined with this presupposition then pragmatically entails that the speaker in (6) has a belief that Trump will not comply. The pragmatic nature of the reasoning involved explains how negation comes to be interpreted low and also explains why the neg-raised reading is cancellable in context. The criticism leveled against Bartsch's original account is that no principled reason is given for why some verbs are neg-raising verbs and others are not (Horn 1978). For example, no explanation is given for why the verb *think* can neg-raise while the epistemically stronger verb *know* cannot, or why neg-raising verbs are idiosyncratically distributed across different languages.

Gajewski proposes to alleviate this objection by categorizing the excluded middle presupposition of neg-raising verbs as a soft-trigger presupposition in the sense of Abusch (2005). Abusch's soft-trigger presuppositions are presuppositions that are easily cancellable in context and as such are distinct from hard-trigger presuppositions, which are not. Soft-trigger presuppositions are carried by predicates that invoke lexically-stipulated alternatives as a matter of convention. The invocation of these alternatives triggers a pragmatic presupposition that one of the alternatives is true. In the case of neg-raising verbs, the alternatives invoked are the literal interpretation of the sentence and the neg-raised interpretation of the sentence.

To summarize this discussion, Gajewski proposes to treat neg-raising predicates as soft triggers that invoke a pragmatic excluded-middle presupposition. This captures the behavior described in Bartsch's account while providing a more principled explanation for why some verbs allow neg-raising and others do not.

With this theoretical background in place we can now return to example (6). I have proposed that the assertion of (6<sub>A</sub>) combined with the excluded-middle presupposition invoked by the verb *think* entails that the speaker in (6) has the belief that Trump will not comply. Formally, this is expressed as follows:

(6) [I don't think that Trump<sub>i</sub> will comply]<sub>A</sub>, but I don't know why [~~he<sub>i</sub> won't comply~~]<sub>E</sub>.

(6')  $\llbracket \text{I don't think that Trump will comply} \rrbracket_A^{w,s} = \neg \forall w [w \in W_{\text{dox},s} \rightarrow \text{comply}(t)(w)]$

Via the excluded middle presupposition conventionally associated with the verb *think*, A presupposes the following:

Excluded Middle Presupposition of (6<sub>A</sub>):

$[\forall w [w \in W_{\text{dox},s} \rightarrow \text{comply}(t)(w)] \vee \forall w [w \in W_{\text{dox},s} \rightarrow \neg \text{comply}(t)(w)]]$

<sup>9</sup>I ask my syntactically-inclined readers to please preview §3.2 to assuage objections to this choice.

The denotation of *think* assumed here can therefore be given as follows:

$$\llbracket \text{think} \rrbracket^{w,g} = \lambda p. \lambda x: [\forall w [w \in W_{\text{dox}, x} \rightarrow p(w)] \vee \forall w [w \in W_{\text{dox}, x} \rightarrow \neg p(w)]] \\ [\forall w [w \in W_{\text{dox}, x} \rightarrow p(w)]]$$

Because A expresses that the first disjunct of the excluded middle presupposition is false, the presupposition of A and the assertion of A together entail the second disjunct of the presupposition. This entailment produces the stronger reading that the speaker uttering (6) has a belief that Trump will not comply.

Local Givenness requires that the proposition elided in (6)—Trump will not comply—is entailed in its local context; however, as discussed, the strengthened neg-raising reading in (6)—that the speaker believes that Trump will not comply—does not semantically entail the elided proposition, as the speaker can have false beliefs. I argue here that the speaker's assertion of her belief of *p* can, in context and under certain conditions, be taken to assert *p* itself. This move relies on the proposal that, while doxastics such as *think* primarily report on the private mental state of an individual and therefore do not directly reference the common ground (or context), *think p* can be used in conversation to pragmatically assert *p*, as proposed in Anand and Hacquard (2014, 84).

The following steps apply Local Givenness to (6).

i. Starting Context:

$$c = W$$

ii. (6<sub>A</sub>) asserts that it is not true that the speaker believes that Trump will comply.

Semantic Denotation of (A):

$$\llbracket A \rrbracket^{w,g} = \neg \forall w [w \in W_{\text{dox}, s} \rightarrow \text{comply}(t)(w)]$$

iii. The pragmatic excluded middle presupposition of (6<sub>A</sub>)—conventionally associated with the verb *think*—requires that the speaker either believes that Trump will comply or believes that Trump will not comply.

Excluded Middle Presupposition of (A):

$$[\forall w [w \in W_{\text{dox}, s} \rightarrow \text{comply}(t)(w)] \vee \forall w [w \in W_{\text{dox}, s} \rightarrow \neg \text{comply}(t)(w)]]$$

iv. Steps (ii) + (iii) derive the strengthened neg-raised interpretation: Because (ii) asserts that it is not true that the speaker believes that Trump will comply, it follows from (iii) that the speaker believes that Trump will not comply. The utterance of (6<sub>A</sub>) thus asserts the strengthened meaning given below.

Strengthened Neg-Raised Interpretation of (A):

$$\forall w [w \in W_{\text{dox}, s} \rightarrow \neg \text{comply}(t)(w)]$$

- v. The assertion in step (iv) creates a local context  $c_L$  in which the worlds under consideration are only those compatible with the speaker's doxastic state, namely those worlds in which Trump does not comply.

$$c_L \text{ for E: } W \cap \{w: w \in W_{\text{dox}, s}\} = \{w: \neg \mathbf{comply}(t)(w)\} = c_{LE}$$

- vi. Semantic Denotation of (E):

$$\{w: \neg \mathbf{comply}(t)(w)\}$$

- vii. The local context includes only those worlds in which Trump will not comply, which entails the elided proposition that Trump will not comply (in fact there is mutual entailment between the world sets).

Local Givenness:

$$c_{LE} \subseteq \text{ExClo}(\llbracket E \rrbracket)^{w,g} = \{w: \neg \mathbf{comply}(t)(w)\} \subseteq \{w: \neg \mathbf{comply}(t)(w)\}$$

The entailment satisfies the Local Givenness requirement that the elided proposition be entailed by its local context, and we predict felicitous elision of the proposition expressed by (6E).

### 3.2. Polarity reversals over *remember*

The reader may, at this point, raise an objection that the previous example wrongly dismissed the possibility of a syntactic account of neg-raising as an explanation for the inference from  $\neg\phi p \rightarrow \neg p$ . Indeed, the classic analysis of neg-raising—originally advanced by, among others, Fillmore (1963) and Ross (1973) and revived recently by Collins and Postal (2014)—argues for a syntactic explanation. However, I show in this section that an appeal to a syntactic account of neg-raising will not save a semantic entailment account of sluicing. Instead, the inference  $\neg\phi p \rightarrow \neg p$  must, at least in some cases, be purely pragmatic in nature.

Example (8) is a corpus polarity reversal sluice containing *remember*.

- (8) [corpus example 91594, Santa Cruz Ellipsis Project]

**Context:** [O]n the day the Japanese invaded Pearl Harbor, Hummel was rounded up and locked in an internment camp along with about 2,000 other foreigners... So he and a British friend engineered an escape with the help of Nationalist guerrillas concealed nearby. He crawled over barbed-wire and walked most of the night and the next day. He was 20 and had no military training. But he was handed a small Belgian pistol, and he had little choice but to stay and help, harassing Japanese patrols by night and trying to defend a small patch of land against a communist takeover.

**Sluice:** “I don’t know why [~~I wasn’t scared~~], but I really can not remember being scared,” [Hummel] said. “It all seemed like great fun.”

Example (8) is illustrative in that it appears to behave like the neg-raising examples; specifically,  $\neg \text{remember } p$  is interpreted in context as entailing  $\neg p$ . However, *remember* is

not classified as a neg-raising verb in the literature and, indeed, the inference is more contextually dependent than that carried by neg-raising verbs. For example, A's utterance in (9) is perfectly acceptable, while A's utterance in (10) is grammatical but a bit unwieldy.

(9) I don't remember being scared, but apparently I was!

(10) ?I don't think that John went to the party last night, but that's because I don't know anything about his whereabouts last night.

Karttunen (1971) classifies *remember* as an *implicative* verb. As such, *remember* has the following properties when taking an infinitival complement:  $\text{remember } p \rightarrow p$ ,  $\neg \text{remember } p \rightarrow \neg p$ . For example, in (11) below there is a strong intuition that the assertion of the sentence commits the speaker to believing that she did not shut the door.

(11) I didn't remember to shut the door.

Higginbotham (2003) proposes that *remember* (along with *imagine*) in its usage with a gerund complement carries an obligatory *de se* reading when the embedded subject is PRO. For example, while (12) has both a possible *de re* and a possible *de se* reading, (13) carries only the *de se* reading, under which John remembers he himself going to the movies.

(12) John remembered his going to the movies.

(13) John remembered going to the movies. [Higginbotham 7&10]

Based on these discussions, I propose that the licensing of the inference  $\neg \text{remember } p \rightarrow \neg p$  in (8) is licensed by two defeasible contextual assumptions. The first assumption is that the speaker has a memory about the particular event represented by  $p$ .<sup>10</sup> I argue that this assumption is stronger in cases in which the subject of *remember* is remembering their own experience of the particular event, as in Higginbotham's *de se* examples. The second assumption is based on the idea that insofar as our memory of eventualities track with our beliefs about those eventualities, a speaker's memory represents the speaker's beliefs about the way the actual world was in the past. An assertion of memory can therefore in context be taken as doxastic evidence for or against a description of a particular eventuality and license inferences from memory to belief. These assumptions are defeasible in that a speaker can have the reliability of her memory challenged.

The following steps apply Local Givenness to (8).

(8) I don't know why [~~I wasn't scared~~]<sub>E</sub>, but [I can not remember being scared]<sub>A</sub>.

<sup>10</sup>I abstract away here from concerns about negative events, and assume that the event in question in (8) exists and that it was either an event of being scared or an event of being not scared. Another way to approach this is to say that the speaker either remembers the event  $e$  or remembers the maximal eventuality  $S$  of all eventualities  $e'$  in the relevant time period and  $e \sqsubseteq S$  (cf. Krifka (1989) and de Swart (1996), in which the following definition of event negation is used:  $\lambda P.\lambda s.[\text{MAX}(s) \wedge \neg \exists e[P(e) \wedge e \sqsubseteq s]]$ ).

i. Starting Context:

$$c = W$$

- ii. The presupposition associated with A is that the speaker has a memory of the particular event being discussed, namely an event of being scared or being not scared.

Presupposition of A:<sup>11</sup>

$$[\forall w[w \in W_{\text{MEM},s} \rightarrow \exists e[\neg \text{scared}(s)(e)(w)]] \vee \forall w[w \in W_{\text{MEM},s} \rightarrow \exists e[\text{scared}(s)(e)(w)]]]$$

- iii. The semantics of A expresses that the speaker does not remember an event of being scared: in all the worlds compatible with the memory of the speaker there was no event (in the relevant time period) in which the speaker was scared.  $W_{\text{MEM},s}$  here acts as an information state of the speaker containing all those worlds compatible with the memory of the speaker.

Semantic Denotation of A:

$$[[A]]^{w,g} = \forall w[w \in W_{\text{MEM},s} \rightarrow \neg \exists e[\text{scared}(s)(e)(w)]]$$

- iv. Steps (ii) and (iii) together entail the proposition that the speaker remembers an event of his being not scared. Therefore, an assertion of A expresses the following:

Presuppositionally-enriched Denotation of A:

$$\forall w[w \in W_{\text{MEM},s} \rightarrow \exists e[\neg \text{scared}(s)(e)(w)]]$$

- v. Under the inference that the speaker's memories of the past represent the speaker's beliefs about the history of the actual world, we can infer the following from Step (iv).

Inference of Speaker's Belief:

$$\forall w[w \in W_{\text{DOX},s} \rightarrow \exists e[\neg \text{scared}(s)(e)(w)]]$$

- vi. Step (v) pragmatically asserts that the speaker was not scared.<sup>12</sup> The context is then updated with this proposition.

Context Update:

$$W \cap \{w: \exists e[\neg \text{scared}(s)(e)(w)]\} = \{w: \exists e[\neg \text{scared}(s)(e)(w)]\} = c_{\text{LE}}$$

vii. Existential Closure of E:

$$\text{ExClo}([E])^{w,g} = \{w: \exists e[\neg \text{scared}(s)(e)(w)]\}$$

viii. Local Givenness:

$$c_{\text{LE}} \subseteq E = \{w: \exists e[\neg \text{scared}(s)(e)(w)]\} \subseteq \{w: \exists e[\neg \text{scared}(s)(e)(w)]\}$$

<sup>11</sup>Contextual domain restriction assumed throughout.

<sup>12</sup>One could also argue that the assertion creates a subordinating context for the embedded *why* question. I see no crucial difference between the two implementations here.

The existential closure of E is entailed by its local context, and we correctly predict felicitous elision of E.

As a closing note, the fact that example (8) is a cataphoric sluice was ignored for our purposes here. Something must, of course, be said about these sluices, which are common in the Santa Cruz sluicing corpus. I leave this aside for further investigation, besides noting that these sluices seem to involve some sort of processing hold in which the sluice is not interpreted until a relevant antecedent is encountered, analogous to instances of pronominal cataphora.

### 3.3. Polarity reversals with exclusive disjunction

The resourceful reader might at this point object that, instead of jettisoning our familiar bidirectional entailment account, a simpler path is to simply enrich the bidirectional entailment condition to include pragmatic and not merely semantic content. I show here that a pragmatically enriched bidirectional entailment account still fails to generate the full range of polarity reversal data. The polarity reversal examples discussed in this section involve exclusive disjunction. A corpus example is given in (14) and a constructed example in (15).

- (14) [corpus example 22987, Santa Cruz Ellipsis Project]

**Context:** On Dec. 10, [Senator] McCain sent a letter to the FCC urging the five-member board to end two years of deliberations and decide whether Paxson Communications should be given a license for a Pittsburgh station. Angela J. Campbell, an attorney for opponents to the deal, told the Globe that McCain's letter likely 'tipped' the scales in favor of the decision.

**Sluice:** "Senator McCain said, 'Do it by December 15 or explain why [~~you didn't do it by December 15~~],' and the commission jumped to it and did it that very day," Campbell told the Globe.

- (15) [constructed example]

**Context:** Students in a semantics class were given the option to do an extra credit problem, and were required to mark the number of the problem that they did on a spreadsheet accessible by the course's professor and TA. Both the professor and TA thought that John, a student in the class, would have chosen to do a problem. They look at the spreadsheet and see that nothing is marked down under John's name. The TA says to the professor:

**Sluice:** Either [John<sub>j</sub> didn't do an extra credit problem]<sub>A</sub>, or he<sub>j</sub> didn't mark which one<sub>i</sub> [~~he<sub>j</sub> did <sub>i</sub>~~]<sub>E</sub>.

Note that these examples illustrate that negation can be either "added" into the ellipsis site, as in (14), or "deleted" from the ellipsis site, as in (15).<sup>13</sup>

<sup>13</sup>Thank you to Jason Merchant (p.c.) for pointing out that these data run counter to the claim made in Merchant (2013: 15) that negation present in the antecedent of a sluicing construction requires a corresponding negation present in the ellipsis site.

I focus here on example (15), the utterance of which asserts that either (A) *John didn't do an e.c. problem* or (E) *John did an e.c. problem*. The disjunction is exclusive because the two disjuncts are opposites: they cannot both be true (or false) at the same time. The analysis of (15) given here relies on Karttunen's (1974) proposal of the local contexts for exclusive disjunction constructions. Specifically, Karttunen gives the following asymmetric proposal for disjunctive constructions:

Karttunen's Local Context for Exclusive Disjunction:

For propositions  $p, q$  such that  $p \vee q$  is uttered in a context  $c$ :

- $c_L$  for  $p = c$ ,  
 $c_L$  for  $q = c + \neg p$ .

The proposal says that the local context for the first disjunct of an exclusive disjunction construction—that is, the context in which the disjunct can be felicitously uttered—is the global conversational context. The local context for the second disjunct is the global conversational context intersected with the negation of the first disjunct. The intuition for this proposal is that for an exclusive disjunction to be true one of the disjuncts must be true, but not both. Therefore, the context in which the first disjunct is admitted is just the global conversational context, but the context in which the second disjunct is admitted takes into account its opposition to the first disjunct, and so all the worlds in which the first disjunct holds are excluded.

The following steps apply Local Givenness to the disjunction in (15).

i. Starting Context:

$$c = W$$

ii. Denotation of A:

$$\llbracket A \rrbracket^{w,g} = \{w: \neg \exists x[\text{extra credit problem}(x)(w) \wedge \text{do}(x)(j)(w)]\}$$

iii. Denotation and Existential Closure of E:<sup>14</sup>

$$\text{ExClo}(\llbracket E \rrbracket^{w,g}) = \{w: \exists x[\text{extra credit problem}(x)(w) \wedge \text{do}(x)(j)(w)]\}$$

iv. Karttunen's Local Context for A and E:

$$c_{LA} = c = W$$

v. Local Givenness:

$$\begin{aligned} c_{LE} &\subseteq \text{ExClo}(\llbracket E \rrbracket^{w,g}) = \{w: \neg \neg \exists x[\text{extra credit problem}(x)(w) \wedge \text{do}(x)(j)(w)]\} \\ &\subseteq \{w: \exists x[\text{extra credit problem}(x)(w) \wedge \text{do}(x)(j)(w)]\} \end{aligned}$$

<sup>14</sup>Note that the wh-phrase *which one* is d-linked in the sense of Pesetsky (1987), meaning that it ranges over a salient set in the discourse. One could assume here, following Cinque (1989), that d-linked wh-phrases are referential and therefore leave behind a referentially indexed trace. Existentially closing over this trace would then restrict the possible identity of the thing to which the existentially bound variable can refer to a member of a particular set present in the discourse. However, as the d-linking is orthogonal to the example here, I suppress this issue for the sake of expositional clarity.

Local Givenness is satisfied in step (iv) because the local context for E entails the proposition expressed by E, assuming a classical logic in which a doubly negated proposition equals its unnegated equivalent. We therefore correctly predict felicitous elision of E.

The possibility of polarity reversal sluices in disjunction constructions illustrates the necessity of local contextual entailment in the current account. The global context of (15) does not entail the proposition that John did any extra credit problems, as both possibilities—of John having done extra credit problems and of him not having done any—are being entertained as possibilities. It is only in the local context of the second disjunct that the proposition that John did extra credit problems is entailed, as the local context excludes those worlds in which John didn't do any extra credit problems. Furthermore, examples such as (15) show that a pragmatically-enriched bidirectional entailment account is insufficient to explain the polarity reversal data, as no pragmatic enrichment of the semantic content of A and E in (15) will yield bidirectional entailment of the propositions. Instead, the crucial licensing factor in this example is the disjunctive operator—which contributes its heritage properties<sup>15</sup> to A and E—and not the propositional content of A and E themselves.

#### 4. Concerns of overgeneration

The analysis proposed here is necessarily more permissive than syntactic or semantic entailment accounts of sluicing; this additional permissiveness is required in order to capture the structural and semantic differences between the antecedent and elided phrases in polarity reversal sluices. However, there are concerns that a pragmatics-based sluicing account will overgenerate or be overly permissive. I sketch here several constraints to alleviate these concerns.<sup>16</sup>

First, I adopt the constraint that focus-marked constituents cannot be elided (Rooth 1992; Heim 1997; Merchant 2001). Second, I adopt what I call the Well-Formedness Condition on Sluicing (see Dayal and Schwarzschild 2010):

*The Well-Formedness Condition on Sluicing:*

If a pre-sluice is infelicitous, then the corresponding sluice will not be well-formed.<sup>17</sup>

Dayal and Schwarzschild propose the restriction in order to rule out cases such as (16), comparable to (3) above, which motivate the bidirectionality condition of e-GIVENness:

(16) Abby<sub>i</sub> called Brian an idiot, but I don't know who [~~#she<sub>i</sub> insulted t~~]<sub>E</sub>.

The Condition is both empirically supported and intuitively satisfying. It seems desirable that a question that is infelicitous when uttered overtly will remain infelicitous when partially elided. By adopting the Well-Formedness Condition we are able to rule out examples like

<sup>15</sup>See Karttunen and Peters (1979), Heim (1983), and Kadmon (2001).

<sup>16</sup>See a more extensive discussion of overgeneration concerns in Kroll (in prep). Additional concerns with a pragmatic approach are case matching facts (Merchant 2001) and the Chung's Generalization facts (Chung 2006, 2013). Case matching facts are captured in this account's adoption of Merchant's PF deletion account (2001); see Kroll (in prep) for an account of the Chung's Generalization facts.

<sup>17</sup>The term *infelicitous* was chosen here in order to allow for the proposed amelioration of islands under sluicing (Merchant 2001).

(16) independently, obviating the need for a stronger bidirectional entailment condition in these cases.

A question naturally raised at this point is why the pre-sluices of examples like (16) are infelicitous. I propose that this is because it is infelicitous to ask a question that already has a partial answer available in the discourse (Romero 1997; Fitzpatrick 2005; Barros 2014; a.o.).<sup>18 19</sup> For example, B's question in (17) is infelicitous without the inclusion of *other*:

- (17) A: I saw some tigers today at the zoo.  
 B: {What/which} #(OTHER) animals did you see today at the zoo?<sup>20</sup>

B's response is infelicitous without *other* because A has already asserted that she has seen some tigers that day at the zoo, which is a partial answer to the question 'What animals did you see today at the zoo?'. *Other* contributes a presupposition that A has seen *some* particular animal at the zoo that day. Unlike previous discussions of this discourse requirement on questions, I propose that the behavior be accounted for using Heim's (1991) *Maximize Presupposition*:

*Maximize Presupposition*:

Given two contextually equivalent alternatives, speakers must use the alternative whose presuppositions are stronger and happen to be met in the context of use.

Maximize Presupposition captures exactly the generalization that we want, which is that a question must ask for only new information in a discourse and must presuppose the existence of any partial answers that are already available. The additional benefit of using Maximize Presupposition is that it relates this characteristic of questions to a more general constraint on felicitous utterances in a discourse, making it unnecessary to posit a separate constraint purely for questions.

Last, I integrate into the current account an intuitively satisfying pragmatic constraint that for a proposition to be elided it must be *uniquely salient* at the time the sluice is uttered. The idea is motivated by the common sense principle that in order for a speaker to felicitously not pronounce some part of an utterance, the meaning of the unpronounced piece of the utterance must be recoverable by the speaker's interlocutor in the discourse. The integration of this constraint correctly rules out the infelicitous sluice in (18), which is not ruled out by Local Givenness as given in §3 nor by the Well-Formedness Condition.

- (18) [Abby called [Joe]<sub>F</sub> an idiot]<sub>A</sub>, but I don't know who [else]<sub>F</sub> [~~Abby insulted~~]<sub>E</sub>.

The saliency constraint is integrated into the final version of Local Givenness, provided below.

<sup>18</sup>See also Barker's (2013) Answer Ban and Ginzburg's (2012) Question Introduction Appropriateness Condition. While the Answer Ban is intended to apply to sluices, this is clearly a more general constraint on questions in a discourse. The QIAC deals with the resolution (complete answers) of questions in the discourse.

<sup>19</sup>I assume here a definition of partial answers based on partition semantics (Groenendijk and Stokhof 1981, 1984; Lahiri 2002, a.o.).

<sup>20</sup>Where *animals* is given a kind reading, so the relevant alternatives are tigers, lions, llamas, etc.

**Local Givenness (Final):** A TP  $\alpha$  can be deleted iff  $ExClo(\llbracket \alpha \rrbracket^g)$  expresses a proposition  $p$ , such that  $c_L \subseteq p$  and  $p$  is uniquely salient.

Additionally, the following test of saliency is proposed:

**Test for saliency:**  $p$  is salient at time  $t$  if  $p$  can be picked out by a propositional discourse anaphor, such as *that*, at time  $t$ .

That positive polarity sentences license the propositional discourse anaphor *that* is pointed out in Webber (1988), among others. That negative sentences also license discourse anaphora is observed in Asher (1993), Hwang (1992), and de Swart (1996):

- (19) John didn't know<sub>i</sub> the answer to the problem. This<sub>i</sub> lasted until the teacher did the solution on the board. [Asher, pg. 53]

The propositional discourse anaphor *that* is anaphoric to "activated" entities in the sense of Gundel et al. (1990); that is, it is anaphoric to entities that the speech participants are currently aware of, i.e. have access to due to the entities' presence in the immediate discourse context. Note that this type of anaphoric reference to the sluiced content is possible in the polarity reversal cases:

- (20) A: I don't know why [~~I wasn't scared~~]<sub>i</sub>, but I really can not remember being scared.  
B: That<sub>i</sub>'s impossible! You were just a child.

In (20), the deictic demonstrative *that* is anaphoric to the sluiced proposition *I wasn't scared*. That is, the meaning of the first sentence in B's utterance is "It's impossible that you weren't scared."

The strong claim that anaphoric reference with *that* is a necessary and sufficient condition to test the salience of a proposition in all cases is not being advocated here. Saliency is a more complicated notion than can be captured in a single test, as the extensive literature on pronominal saliency and reference attests. The anaphora test is merely intended to be one way to probe this issue. The larger question of how to determine the saliency of a proposition in a given discourse requires more thought and investigation than space allows here.<sup>21</sup>

## 5. Conclusion

Polarity reversal sluicing data present a new challenge to the enterprise of determining the conditions under which linguistic content can be felicitously elided. This paper shows that, counter to its dominant treatment in the syntactic literature, ellipsis is an inherently pragmatics-sensitive phenomenon subject to contextual licensing. I argue that the ability to elide linguistic content fits naturally into general theories of constraints regulating coherent discourses, and have detailed one way to account for the pragmatic sensitivity of data that

<sup>21</sup>Note that the claim here is that the sluiced proposition licenses the anaphora; the antecedent material may contribute a discourse referent equivalent to the pragmatically enriched proposition, but the theory here does not predict that it necessarily does.

present serious challenges for non-pragmatic theories. Many challenges to developing a complete theory of sluicing and ellipsis, of course, remain.

# Common nouns as variables: Evidence from conservativity and the temperature paradox<sup>1</sup>

Peter LASERSOHN — *University of Illinois at Urbana-Champaign*

**Abstract.** Common nouns and noun phrases have usually been analyzed semantically as predicates. In quantified sentences, these predicates take variables as arguments. This paper develops and defends an analysis in which common nouns and noun phrases themselves are treated as variables, rather than as predicates taking variables as arguments. Several apparent challenges for this view will be addressed, including the modal non-rigidity of common nouns. Two major advantages to treating common nouns as variables will be presented: Such an analysis predicts that all nominal quantification is conservative, rather than requiring conservativity to be stipulated as a constraint on determiner denotations; and it makes possible some improvements to the analysis of the temperature paradox, allowing for quantificational examples without adding a spurious layer of modal variability.

**Keywords:** common nouns, variables, rigidity, conservativity, temperature paradox

## 1. Introduction

Common nouns are frequently analyzed semantically as predicates. Beginning logic students are trained to represent sentences like (1)a. using formulas like (1)b., in which the 1-place predicate *M* seems to correspond directly to the common noun *man*, just as the 1-place predicate *S* corresponds to the verb *smiles*:

- (1) a. Every man smiles.  
b.  $\forall x[M(x) \rightarrow S(x)]$

*M* and *S* here are syntactically and semantically similar in every way: Both combine with an argument to form a formula; both are the sort of thing which can be truthfully or falsely predicated of an individual; and therefore both are naturally analyzed as denoting the set of individuals of which they can be truthfully predicated (or almost equivalently, the characteristic function of this set).

Montague (1973) treated common nouns as belonging to logical type  $\langle\langle s, e \rangle, t\rangle$  — that is, as 1-place predicates of “individual concepts.” Following Bennett (1975), most subsequent literature in the Montague-derived tradition (including major textbooks such as Dowty, et al. (1981), Gamut (1991), Heim and Kratzer (1998) and many others) has analyzed them as belonging to type  $\langle e, t \rangle$  — as 1-place predicates of individuals. In both approaches, common nouns are treated identically to intransitive verbs. Exceptions are sometimes made for relational nouns such as *mother*, *brother*, *top*, *bottom*, etc., which are then treated as being of type  $\langle e, \langle e, t \rangle \rangle$ ; but this still gives such nouns the status of predicates — just 2-place predicates rather than 1-place.

---

<sup>1</sup> This paper was presented to the Harvard Linguistics Circle and at the University of Chicago in addition to Sinn und Bedeutung. Thanks to the audiences at both talks, and especially to Nicholas Asher, Gennaro Chierchia and Uli Sauerland for comments and suggestions.

Proper names, in contrast, are most often treated as being of type *e*. That is, each proper name is analyzed in such a way that it denotes some particular individual, rather than “holding true” of all the individuals in some class. This results in a sharp division of semantic function with proper names on one side but verbs and common nouns together on the other. This division is preserved even in most analyses which do not treat proper names as individual-denoting — for example by assimilating proper names to quantifiers, as in Russell’s (1910) theory of proper names as “disguised definite descriptions” or in more modern treatments of names and quantifiers as second order predicates (whether of type  $\langle\langle e, t \rangle, t\rangle$  or Montague’s more baroque  $\langle\langle s, \langle\langle s, e \rangle, t \rangle \rangle, t \rangle$ ).

Occasionally, proper names have been analyzed as predicates (Quine (1960), Fara (2015)), but then, of course, common nouns are treated as predicates too: verbs, common nouns and proper names are all treated similarly, with no clear semantic correlate to the morphosyntactic distinction between verbs and nouns (whether proper or common).

What I will argue in this paper is that common nouns are similar in semantic type to proper names, and differ in type from verbs. The morphosyntactic distinction between nouns and verbs thus corresponds directly to a difference in semantic type. More particularly, I will argue that common nouns are *variables*, in roughly the same sense as the variables of predicate logic. *Man* is more like the *x* in (1)b. than the *M*.

This is not an entirely new idea. Lepore and Ludwig (2007), for example, say “In ‘All men’, ‘men’ functions as if it were a variable restricted to taking on as values only men...” But this suggestion appears only in their informal discussion. In their formalization, common nouns are not treated this way — or analyzed at all, really: Lepore and Ludwig give formalized rules only for interpreting a simplified artificial version of English which does not contain sentences like (1)a. but only predicate-logic-like formulas such as (2):

(2) [Every *x* : *x* is a man](*x* smiles)

No interpretation rule is given for the single word *man* (or any other common noun), but only for the whole open formula ‘*x* is a man’. If any semantic analysis of the single word *man* is intended, it is not made explicit; and the notation here, with separate elements ‘*x*’ and ‘man’, does not suggest that the noun itself is a variable, despite Lepore and Ludwig’s informal discussion.

To my knowledge, the idea that common nouns are variables has never been developed or defended in detail.<sup>2</sup> The idea faces a number of technical and theoretical challenges: How can we deal with relational nouns? With mass nouns? With quantification? With intensionality? Can such an analysis be made compositional? Even if all these challenges are met, is there any *advantage* to treating common nouns as variables, or does this idea turn out to be equivalent (or inferior) to a treatment of common nouns as predicates?

<sup>2</sup> Aside from Ludwig and Lepore, an interesting comparison may be made to Luo (2012). The idea that common nouns are variables is also, I suspect, the motivating intuition behind Breul (2013), but I must confess an inability to make sense of Breul’s formalism.

I think that each of these challenges can be answered, and that there are in fact several advantages to treating common nouns as variables, over treating them as predicates. Showing this in detail is a larger project than can be presented in this short paper, so I will focus here on meeting just one of the “challenges” and two of the “advantages.” Specifically, I will show how we can reconcile an analysis of common nouns as variables with the fact that typical common nouns are modally non-rigid; and I will argue that such an analysis predicts that all nominal quantification is conservative, so that conservativity does not need to be stipulated as a condition on determiner denotations; and that it makes possible some improvements to the analysis of the temperature paradox, allowing for quantificational examples without adding a spurious layer of modal variability.

## 2. First pass: Common nouns as variables

What does it mean to say that common nouns are variables? This will depend on exactly what a “variable” is, of course. Unfortunately, there is no universally agreed-on, standard definition of variables, so our main thesis is somewhat obscure at the outset. We shall therefore have to begin with a technique for the semantic analysis of variables which I think most readers will at least find familiar, and show how common nouns can be treated as variables using this technique. In the end, I will adopt a somewhat different approach to the semantics of variables; but starting with a more familiar technique should at least clarify the intuition underlying the claim that common nouns are variables.

In this familiar technique, expressions are assigned denotations relative to a series of parameter values, including an *assignment of values to variables*. Semantic rules are given in such a way that one can derive equations of the form in (3), where  $\alpha$  is a linguistic expression,  $g$  is an assignment of values to variables, and the three dots abbreviate whatever other parameters denotations are relativized to:

$$(3) \quad \llbracket \alpha \rrbracket^{\dots g} = a$$

*Variables* are expressions whose denotations are fixed directly by the assignment of values to variables. That is,  $\alpha$  is a variable iff for all  $g$  (and all ways of filling in the three dots):

$$(4) \quad \llbracket \alpha \rrbracket^{\dots g} = g(\alpha)$$

Variable *binding* is analyzed as the assignment of denotations relative to a given assignment  $g$  based on denotations relative to assignments which agree with  $g$  in what they assign to all variables other than the one being bound.<sup>3</sup> For example, we can define standard variable binding operators like  $\forall$  and  $\exists$  as in (5):

- (5) a.  $\llbracket \forall \alpha \varphi \rrbracket^{\dots g} = 1$  iff  $\llbracket \varphi \rrbracket^{\dots h} = 1$  for all  $h$  agreeing with  $g$  on all variables other than  $\alpha$ .
- b.  $\llbracket \exists \alpha \varphi \rrbracket^{\dots g} = 1$  iff  $\llbracket \varphi \rrbracket^{\dots h} = 1$  for at least one  $h$  agreeing with  $g$  on all variables other than  $\alpha$ .

---

<sup>3</sup> This phrasing does not imply that the relevant assignments differ from  $g$  in what they assign to the variable being bound. Any assignment  $g$  agrees with itself on all variables other than  $\alpha$  (for any variable  $\alpha$ ).

With this understanding of what variables and binding are as background, how can we treat common nouns as variables?

Instead of giving lexical stipulations like those in (6), we may specify the meanings of common nouns as part of the definition of an assignment of values to variables, as in (7):

- (6) a.  $\llbracket student \rrbracket = \lambda x . x$  is a student  
 a.  $\llbracket professor \rrbracket = \lambda x . x$  is a professor
- (7)  $g$  is an *assignment of values to variables* iff
- $g$  is a function with domain  $\{x \mid x \text{ is a common noun token}^4 \text{ or } \dots\}$ ;
  - If  $\alpha$  is a token of *student*, then  $g(\alpha)$  is a student;
  - If  $\alpha$  is a token of *professor*, then  $g(\alpha)$  is a professor;
  - etc.

It should be noted that under (7), *student* and *professor* are of type  $e$ , not  $\langle e, t \rangle$ .

We shall have to revise the definition in (7) several times before the end of this paper; but let us adopt it for the moment, and explore how it may function in a larger theory of quantification and binding for English.

I assume that LF representations are derived via an operation of Quantifier Raising, which adjoins a quantifier phrase to its scope, leaving a trace in its original position. I will also assume here that Quantifier Raising is clause-bounded. This means we normally cannot use it to obtain transparent readings for quantifier phrases in opaque contexts; but alternative techniques are available, and perhaps better motivated anyway.<sup>5</sup>

By the *antecedent* of a trace, let us mean the NP of the DP whose trace it is. That is:

- (8) Where  $\delta$  is a determiner token and  $\kappa$  is a common noun phrase token:  $\text{antecedent}(\text{trace}(\delta \kappa)) = \kappa$ .

Note that this is a slightly non-standard use of the term *antecedent*. In [*every professor* [*e smiles*]], *professor*, not *every professor*, is the antecedent of *e*. We do not assume that traces are co-indexed with their antecedents (or with the DPs containing their antecedents). The analysis is compatible with such co-indexation, but does not require it, provided there is some way of identifying the antecedent of each trace.

Traces will be interpreted as variables, with a requirement that (relative to any assignment of values to variables  $g$ ) a trace co-denotes with its antecedent:

- (9)  $g$  is an *assignment of values to variables* iff
- $g$  is a function with domain  $\{x \mid x \text{ is a common noun token, trace token or } \dots\}$ ;
  - If  $\alpha$  is a token of *student*, then  $g(\alpha)$  is a student;
  - If  $\alpha$  is a token of *professor*, then  $g(\alpha)$  is a professor;

<sup>4</sup> Instead of assigning values to expression tokens, we could assign values to pairs of an expression type and a context of use. In the long run, this may be the preferable option; but a consideration of the issue here would force a long digression from our central concerns in this paper, so I assign values to tokens here in the interest of simplicity.

<sup>5</sup> See, e.g., Cresswell (1990).

- d. etc.;
- e. If  $\varepsilon$  is a trace token, then  $g(\varepsilon) = g(\text{antecedent}(\varepsilon))$ .

We write “ $g \sim_{\kappa} h$ ” to mean that assignment  $h$  agrees with assignment  $g$  on all common noun phrases other than  $\kappa$ . Now we can define *every* syncategorematically:

$$(10) \quad \llbracket \text{every } \kappa \varphi \rrbracket^g = 1 \text{ if } \forall h [g \sim_{\kappa} h \rightarrow \llbracket \varphi \rrbracket^h = 1]; \\ 0 \text{ if } \exists h [g \sim_{\kappa} h \ \& \ \llbracket \varphi \rrbracket^h = 0].$$

It is easy to confirm that this gives the correct result that *Every professor  $e$  smiles* is true iff for every  $x$  such that  $x$  is a professor,  $x$  smiles. Other quantifiers can be defined analogously (but revisions will be necessary to deal with more complex cases).

It is perhaps worth noting at this point that if we analyze quantification in the way just sketched, there is no semantic motivation any more to have QR move whole DPs, rather than just determiners, or to have QR leave traces. We could get the same effect simply by moving the determiner, and leaving the NP in situ. But let us leave that issue aside, in order to concentrate on semantic matters rather than syntax.

### 3. First advantage: Conservativity is predicted

Even though our analysis is not in its final form, we can already see one advantage to treating common nouns in this way, rather than treating them as predicates: The analysis predicts that all nominal quantification is conservative.<sup>6</sup>

This claim must be clarified, because the relevant notion of conservativity here is not exactly the traditional textbook sense. The standard definition is in (11):

$$(11) \quad D \text{ is conservative iff for all } A, B: D(A, B) \text{ iff } D(A, A \cap B)$$

But if we take  $D$  to be a determiner denotation,  $A$  to be a common noun phrase denotation, and  $B$  to be a predicate denotation, this definition presupposes that common nouns denote sets. Analyses which treat common nouns in some other way will *never* claim that determiners are conservative in exactly this sense. In order to compare theories, we need a more general notion of conservativity, which is not tied so tightly to a particular approach to the analysis of common nouns and determiners.

A more useful way to conceptualize conservativity for our current purposes is to recognize that the intuitive content of the standard definition is that  $A$  functions as a *domain of quantification*. That is, in ascertaining whether  $D(A, B)$ , one need not consider those members of  $B$  which are not in  $A$ . Put differently (and more sloppily and English-specifically): in determining the truth value of a sentence of the form  $D N VP$ , you only need to consider the  $N$ 's: Which  $N$ 's does  $VP$  apply to and which  $N$ 's doesn't  $VP$  apply to? You never need to consider the truth value that results from applying  $VP$  to something which isn't an  $N$ .

<sup>6</sup> The suggestions made in this section may be interestingly compared to proposals like those in Fox (2002), Sauerland (2004), Sauerland (2007), Romoli (2015); but such a comparison will have to wait for another occasion.

In any analysis, some distinction must be drawn between the things which a given noun accurately describes and those which it doesn't. If common nouns are analyzed as denoting sets, these are the members of the set denoted by the noun; if common nouns are analyzed as denoting functions of type  $\langle e, t \rangle$ , these are the things mapped onto 1 by the function denoted by the noun; if common nouns are analyzed as variables, these are the things assigned to the noun by the various assignments of values to variables. No matter which approach is taken, a theory claims that determiner quantification is conservative iff whenever a determiner-noun combination combines with a predicate  $P$  to form a sentence, the truth value of that sentence can be ascertained by considering only how  $P$  applies to the things accurately described by the noun, so that the truth values which result from applying  $P$  to things not accurately described by the noun are irrelevant.

Now we can see how conservativity falls out from the general approach to determiner quantification just outlined. Assignments of values to variables, in this approach, are functions from common noun phrases (and traces) to individuals. For any such function, the individual assigned to a given noun  $N$  is something which “is an  $N$ ” — something which would be a member of the extension of  $N$  in a more conventional analysis. As one considers a class of assignments which differ from one another at most in what they assign to  $N$ , therefore, one is effectively considering the things which are accurately described by the noun. As long as object-language quantification over individuals is analyzed in terms of metalanguage quantification over assignments of values to variables, and as long as determiner-noun combinations are interpreted by quantifying over those assignments which agree on all variables other than the noun with which the determiner combines, conservativity is automatic.

To give just a little more detail: Assume that interpretation rules for quantifiers conform to the following general template, based on the rule for *every*:

- (12)  $\llbracket \delta \kappa \varphi \rrbracket^g = 1$  if for  $\delta$ -many assignments of values to variables  $h$  such that  $g \sim_\kappa h$ ,  
 $\llbracket \varphi \rrbracket^h = 1$ ;  
 $= 0$  if it is not the case that for  $\delta$ -many assignments of values to variables  $h$   
 such that  $g \sim_\kappa h$ ,  $\llbracket \varphi \rrbracket^h = 1$ .

Rules conforming to this template derive a value for  $\llbracket \delta \kappa \varphi \rrbracket^g$  based on  $\llbracket \varphi \rrbracket^h$ , for various assignments  $h$  which differ from  $g$  at most in what they assign to  $\kappa$  (and any trace with  $\kappa$  as its antecedent). But  $h(\kappa)$  will always be something which is accurately described by  $\kappa$ , and so will  $h(\varepsilon)$ , where  $\text{antecedent}(\varepsilon) = \kappa$ . There simply *are* no assignments of values to variables relative to which  $\varepsilon$  receives a value which is not accurately describable by  $\kappa$ , so it makes no sense to ask whether the truth value of  $\varphi$  is relative to such assignments is relevant to the truth value of the whole sentence  $[\delta \kappa \varphi]$ .

That is, quantification is just over those individuals which are accurately described by the noun, which is to say, the quantification is conservative — and this follows from the general architecture of the theory. In contrast, if we assume simply that determiners denote 2-place

relations between sets (or functions of type  $\langle\langle e, t \rangle, \langle\langle e, t \rangle, t \rangle\rangle$ ), nothing guarantees conservativity; it must be independently stipulated.<sup>7</sup>

#### 4. Adding intensionality: Non-rigid variables

Analyzing common nouns as variables will not work properly in an intensional semantics, if we treat variables in the traditional way. Standard versions of intensional logic and quantified modal logic incorporate a principle like that in (13):

(13) If  $\alpha$  is a variable, then  $\llbracket \alpha \rrbracket^{M,w,g} = g(\alpha)$ .

This gives the effect that for all  $w, w'$ ,  $\llbracket \alpha \rrbracket^{M,w,g} = \llbracket \alpha \rrbracket^{M,w',g}$ . That is, variables are modally rigid. But now recall (9)b.: “If  $\alpha$  is a token of *student*, then  $g(\alpha)$  is a student.” In which world must  $g(\alpha)$  be a student? Since no world is mentioned, we standardly assume the condition is meant to apply in the *actual* world  $w@$ . Since variables are rigid, this gives the effect that for any  $w$ ,  $\llbracket student \rrbracket^{M,w,g}$  is a student in  $w@$  — but nothing requires  $\llbracket student \rrbracket^{M,w,g}$  to be a student in  $w$ . This is obviously wrong — it results in incorrect truth conditions for sentences like (14):

(14) *John believes that every student  $e$  smiles*

Assuming our current semantics including (9), (10) and (13), combined with a standard possible-worlds analysis of *believe* along the lines of Hintikka (1969), (14) is assigned a reading which is true (in the actual world  $w@$ ) iff in every world  $w$  compatible with John’s belief state (in  $w@$ ), everyone who is a student in  $w@$  smiles in  $w$ . It is not assigned a reading which is true (in  $w@$ ) iff in every world  $w$  compatible with John’s belief state (in  $w@$ ), everyone who is a student in  $w$  smiles in  $w$ . In other words, the analysis wrongly predicts that all common nouns should be interpreted transparently.

To allow opaque readings, we need to allow *modally non-rigid variables*.<sup>8</sup> This requires us to revise our definition of an assignment of values to variables:

- (15)  $g$  is an assignment of values to variables iff
- $g$  is a partial<sup>9</sup> function with domain  $\{x \mid x \text{ is a common noun token, trace token or } \dots\} \times W$ ;
  - If  $\alpha$  is a token of *student*: for all  $w$ , if there exists an  $x$  such that  $x = g(\alpha, w)$ , then  $g(\alpha, w)$  is a student in  $w$ ;
  - If  $\alpha$  is a token of *professor*: for all  $w$ , if there exists an  $x$  such that  $x = g(\alpha, w)$ , then  $g(\alpha, w)$  is a professor in  $w$ ;
  - etc.;
  - If  $\varepsilon$  is a trace token, then for all  $w$ ,  $g(\varepsilon, w) = g(\textit{antecedent}(\varepsilon), w)$ .

<sup>7</sup> Our discussion in this section raises the question of how to deal with *only* and other quantifiers which appear not to be conservative. I assume in such cases, the quantifier binds a variable which is constructed in part based on intonational focus or other factors, rather than simply binding the NP (if any) which serves as its syntactic complement. That is, the quantification in such cases is not strictly “nominal.” A detailed consideration of such cases will have to await another occasion.

<sup>8</sup> These have rarely been suggested before, but see e.g. Hughes and Cresswell (1968: 195–201).

<sup>9</sup> We allow  $g$  to be a partial function because in some worlds, there aren’t any students or professors.

Making this change necessitates corresponding revisions to our definition for the double brackets, and to our definition of what it means for one assignment to agree with another on all values other than a particular one:

- (16) If  $\alpha$  is a variable, then for all worlds  $w$  and assignments  $g$ :  $\llbracket \alpha \rrbracket^{w,g} = g(\alpha, w)$ .
- (17)  $g \sim_{\kappa,w} h$  iff
- there exists some  $x$  such that  $h(\kappa, w) = x$ ; and
  - for all common noun phrases  $v$  and worlds  $w'$ : if  $v \neq \kappa$  then  $g(v, w') = h(v, w')$ .

We also need to revise our rule for *every* to reflect the change made in (17):

- (18)  $\llbracket \text{every } \kappa \ \phi \rrbracket^{w,g} = 1$  if  $\forall h [g \sim_{\kappa,w} h \rightarrow \llbracket \phi \rrbracket^{w,h} = 1]$ ;  
 0 if  $\exists h [g \sim_{\kappa,w} h \ \& \ \llbracket \phi \rrbracket^{w,h} = 0]$ .

It is easy to confirm that our rules now give the desired modal profile for sentences like *Every student e smiles*.

However, our revisions have introduced another problem. Some variables *should* be rigid — specifically *pronouns*, assuming these can be bound across the borders of intensional contexts.

For example, consider (19), assuming that *professor* is the antecedent of *she*.

- (19)  $\llbracket \text{Every professor } e \text{ believes } [\text{that she smiles}] \rrbracket$

If we treat the pronoun here the way we have treated traces — as codenoting, in each world  $w$ , with its antecedent — we assign the wrong truth conditions. Intuitively, (19) is true in  $w@$  only if for every  $x$  such that  $x$  is a professor in  $w@$ , in every world  $w$  compatible with  $x$ 's belief state in  $w@$ ,  $x$  smiles in  $w$ . But if we require, for every assignment  $g$ , world  $w$  and pronoun  $\pi$ , that  $g(\pi, w) = g(\text{antecedent}(\pi), w)$  — like we did with traces — we do not get that reading, because nothing requires that  $g(\text{she}, w) = g(\text{professor}, w@)$ . Quantifying on assignments that agree with  $g$  on all values other than  $g(\text{professor}, w@)$  will not quantify over values for *she* in the “belief worlds”.

To solve this problem, we must again revise our definition of assignment functions, so that each one is keyed to a particular world:

- (20)  $g$  is an assignment of values to variables for  $w$  (or “ $w$ -assignment”) iff
- $g$  is a partial function with domain  $\{x \mid x \text{ is a common noun token, trace token, pronoun token, or } \dots\} \times W$ ;
  - If  $\alpha$  is a token of *student*: for all  $w'$ : if there exists an  $x$  such that  $x = g(\alpha, w')$ , then  $g(\alpha, w')$  is a student in  $w'$ ;
  - If  $\alpha$  is a token of *professor*: for all  $w'$ : if there exists an  $x$  such that  $x = g(\alpha, w')$ , then  $g(\alpha, w')$  is a professor in  $w'$ ;
  - etc.;

- e. If  $\epsilon$  is a trace token, then  $g(\epsilon, w') = g(\text{antecedent}(\epsilon), w')$ ;
- f. If  $\pi$  is a pronoun token, then  $g(\pi, w') = g(\text{antecedent}(\pi), w)$ .

Note the difference between clauses e. and f. Relative to each world  $w'$ , a trace is required to denote the same thing as the denotation of its antecedent in  $w'$ , but a pronoun is required to denote the same thing as the denotation of its antecedent in  $w$ , the world to which the assignment is keyed. This guarantees that relative to any given assignment, the denotation of a pronoun is modally rigid.

Now we revise the tilde notation so that agreeing assignments must be keyed to the same world:

- (21)  $g \sim_{\kappa, w} h$  iff
- a.  $g$  and  $h$  are both  $w$ -assignments;
  - b. there exists some  $x$  such that  $h(\kappa, w) = x$ ; and
  - c. for all common noun phrases  $v$  and worlds  $w'$ : if  $v \neq \kappa$  then  $g(v, w') = h(v, w')$ .

Our rule for *every* in (18) can remain notationally the same, but operates differently due to the replacement of (17) with (21). In (18),  $g$  and  $h$  are now both required to be  $w$ -assignments — so relative to  $h$ , any pronouns in  $\phi$  will rigidly denote what  $\kappa$  denotes relative to  $h$  in  $w$ . This ensures that (19) will be true relative to a world  $w$  only if for every  $x$  such that  $x$  is a professor in  $w$ , for every  $w'$  compatible with  $x$ 's belief state in  $w$ ,  $x$  smiles in  $w'$ . The person who smiles in each professor's belief worlds is correctly required to be that same person who is a professor in  $w$ , and holds the belief. There is no requirement that every professor must be a professor in all her belief worlds.

## 5. Second advantage: The temperature paradox

We can now turn to a second major advantage to treating common nouns as variables: It allows some improvements in how we analyze the temperature paradox. The paradox and its proposed solution in Montague (1973) are familiar to most readers and will only be briefly sketched here: The argument in (22) is of a form which seems naturally representable as in (23), but (23) is a valid argument and (22) is not.

- (22) The temperature is rising.  
The temperature is 90.  
Therefore, 90 is rising.
- (23)  $\exists x[\text{temperature}(x) \ \& \ \forall y[\text{temperature}(y) \rightarrow x = y] \ \& \ \text{rise}(x)]$   
 $\exists x[\text{temperature}(x) \ \& \ \forall y[\text{temperature}(y) \rightarrow x = y] \ \& \ x = n]$   
 $\therefore \text{rise}(n)$

Montague's solution is to treat *rise* as a predicate of functions from indices (including times) to individuals, but treat *is* as holding (at a given index) between two such functions iff they

return the same value for that index.<sup>10</sup> Under this analysis, (22) can be paraphrased as (24), which is easily seen as invalid:

- (24) The unique temperature function is a rising function.  
 The unique temperature function and the 90 function currently yield the same value.  
 Therefore the 90 function is a rising function.

The analysis is made more formal through the use of  $\wedge$ - and  $\vee$ -operators, defined as in (25) and (26):

$$(25) \quad \llbracket \wedge \alpha \rrbracket^{M,w,t,g} = \text{that function } f \text{ with domain } W \times T \text{ such that for all } w' \in W, t' \in T: f(w', t') = \llbracket \alpha \rrbracket^{M,w',t',g}$$

$$(26) \quad \llbracket \vee \alpha \rrbracket^{M,w,t,g} = \llbracket \alpha \rrbracket^{M,w,t,g}(w, t)$$

Now the argument may be represented as (27) rather than (23):

- (27)  $\exists x[\text{temperature}(x) \ \& \ \forall y[\text{temperature}(y) \rightarrow x = y] \ \& \ \text{rise}(x)]$   
 $\exists x[\text{temperature}(x) \ \& \ \forall y[\text{temperature}(y) \rightarrow x = y] \ \& \ \vee x = \vee n]$   
 $\therefore \text{rise}(n)$

In (27), the variables  $x$  and  $y$  are of type  $\langle s, e \rangle$ , not of type  $e$ . Hence **rise** and **temperature** must both be of type  $\langle \langle s, e \rangle, t \rangle$ . In the case of **rise**, this is intuitive and appropriate. What counts as rising at a time  $t$  depends on how things are at times other than  $t$ . It is impossible to ascertain whether the temperature is rising at a moment by examining a photograph of a thermometer taken at that moment; one needs multiple photographs, taken at different times. It therefore makes sense to treat *rise* as taking functions from times to numbers as its arguments, so that *rise* can “see” what is going on at other times; there is a clear intuitive basis for treating *rise* as temporally intensional.

But the situation with **temperature** is quite different: To tell whether a particular value is the temperature at a given moment, a single photograph taken at that moment suffices, and photographs taken at other times are irrelevant. There isn’t the same intuitive basis for letting *temperature* take functions from times to numbers as its arguments as there is for *rise*; *temperature* is not temporally intensional in its conditions of application like *rise* is.

This feature of Montague’s analysis leads to a problem pointed out by Anil Gupta.<sup>11</sup> Intuitively, the argument in (28) is valid. But it is translated into Intensional Logic as in (29), and (29) is *not* a valid argument:

- (28) Necessarily, the temperature is the price.  
 The temperature is rising.  
 Therefore, the price is rising.

<sup>10</sup> I have simplified Montague’s analysis here by setting aside some irrelevant complications with type assignment.

<sup>11</sup> Gupta’s problem is outlined in Dowty, et al. (1981: Appendix III)

- (29)  $\Box \exists x[\text{temperature}(x) \ \& \ \forall y[\text{temperature}(y) \rightarrow x = y] \ \& \ \exists z[\text{price}(z) \ \& \ \forall y[\text{price}(y) \rightarrow z = y] \ \& \ \forall x = \forall z]$   
 $\exists x[\text{temperature}(x) \ \& \ \forall y[\text{temperature}(y) \rightarrow x = y] \ \& \ \text{rise}(x)]$   
 $\therefore \exists x[\text{price}(x) \ \& \ \forall y[\text{price}(y) \rightarrow x = y] \ \& \ \text{rise}(x)]$

To see that (29) is invalid, let  $T_1, T_2, T_3, P_1, P_2, P_3$  be the functions given in (30). Now consider a model where **temperature** holds at  $\langle w_1, t_1 \rangle$  uniquely of  $T_1$ , at  $\langle w_1, t_2 \rangle$  of  $T_2$ , and at  $\langle w_1, t_3 \rangle$  of  $T_3$ , and where **price** holds at  $\langle w_1, t_1 \rangle$  uniquely of  $P_1$ , at  $\langle w_1, t_2 \rangle$  of  $P_2$ , and at  $\langle w_1, t_3 \rangle$  of  $P_3$ :

- |      |                       |                      |                      |
|------|-----------------------|----------------------|----------------------|
| (30) | $T_1(w_1, t_1) = 99$  | $T_2(w_1, t_1) = 89$ | $T_3(w_1, t_1) = 79$ |
|      | $T_1(w_1, t_2) = 100$ | $T_2(w_1, t_2) = 90$ | $T_3(w_1, t_2) = 80$ |
|      | $T_1(w_1, t_3) = 101$ | $T_2(w_1, t_3) = 91$ | $T_3(w_1, t_3) = 81$ |
|      | $P_1(w_1, t_1) = 99$  | $P_2(w_1, t_1) = 91$ | $P_3(w_1, t_1) = 83$ |
|      | $P_1(w_1, t_2) = 98$  | $P_2(w_1, t_2) = 90$ | $P_3(w_1, t_2) = 82$ |
|      | $P_1(w_1, t_3) = 97$  | $P_2(w_1, t_3) = 89$ | $P_3(w_1, t_3) = 81$ |

It is easy to see that the first premise of (29) is true: at each world-time pair there is a unique temperature function, and a unique price function, and the two functions return the same current value — 99 at  $\langle w_1, t_1 \rangle$ , 90 at  $\langle w_1, t_2 \rangle$ , and 81 at  $\langle w_1, t_3 \rangle$ . The second premise of (29) is also true at all indices, under an intuitive definition of **rise** and an assumption that  $t_1$  precedes  $t_2$  and  $t_2$  precedes  $t_3$ : At each index, the unique temperature function is a rising function, returning a higher value at each successive time. For example, at  $\langle w_1, t_2 \rangle$  the unique temperature function is  $T_2$ , which returns 89 at  $\langle w_1, t_1 \rangle$ , 90 at  $\langle w_1, t_2 \rangle$ , and 91 at  $\langle w_1, t_3 \rangle$ . However, the conclusion of (29) is false at every index, since at every index the unique price function is a falling function, not a rising one.

In Lasersohn (2005) I suggested a solution to this problem, which unfortunately did not work. I argued that the source of the problem was in treating *the* as a variable-binding quantifier. In the sentence *The temperature is rising*, this quantificational analysis of *the* requires *temperature* to take the same variable as its argument as *is rising* does, which in turn forces *temperature* into the intuitively unjustified type  $\langle \langle s, e \rangle, t \rangle$ , which allows different temperature functions (and not just different temperature values) at different times, which leads to Gupta's problem. But if we switched to a non-quantificational analysis of *the*, I argued, we could avoid using a single variable both as argument to *temperature* and as argument to *is rising*. Specifically, if we represent *the temperature* as  $\iota x \text{ temperature}(x)$ , where **temperature** is of type  $\langle e, t \rangle$  and the iota-operator is interpreted as in (31), then *The temperature is rising* can be represented as in (32):

- (31)  $\llbracket \iota x P(x) \rrbracket^{M,w,t,g} = \text{the unique element } u \text{ such that } \llbracket P \rrbracket^{M,w,t,g}(u) = 1 \text{ if there is such a unique element, undefined otherwise.}$
- (32) **rise**( $\iota x \text{ temperature}(x)$ )

At each index,  $\iota x \text{ temperature}(x)$  denotes the unique temperature (value) at that index. By the semantics of the  $\iota$ -operator in (25),  $\iota x \text{ temperature}(x)$  will rigidly denote the function

mapping each index onto the unique temperature at that index. In this way, we derive just one temperature function — the same one at every index — and just one price function. Hence, if at every index the temperature function yields the same value as the price function (so they are really the very same function), and the temperature function is a rising function, then the price function must be a rising function too. Gupta’s problem is eliminated.

However, this solution cannot be correct, as Romero (2008) was quick to point out. By tying the solution to a non-quantificational analysis of *the*, I made it impossible to deal with more clearly quantificational examples in the same way. But such examples exist; in fact, Montague himself gave such an example, perhaps because he anticipated the kind of analysis I was proposing:

- (33) A price rises.  
       Every price is a number.  
       Therefore, a number rises.

In light of such examples, I concede the point that the temperature paradox does not really provide us with evidence for a non-quantificational theory of the definite article. Considerations of space preclude a review of Romero’s very interesting analysis here, but it should be acknowledged that it accounts successfully for the validity of Gupta’s argument.

However, it also retains an odd feature of Montague’s original analysis, which seems to me to be very unintuitive: It allows nouns like *temperature* to denote different sets of functions relative to different times. That is, we can have temporal variation not just in what values get returned by the temperature function (or functions), but in which functions count as temperature functions in the first place.

Intuitively, that can’t happen. Suppose we are talking about the temperature of one particular object, in one particular world. If at time  $t_1$ , the temperature function for that object in that world maps  $t_1$  to 90,  $t_2$  to 91, and  $t_3$  to 92, then it cannot happen that at  $t_2$ , the temperature function for that object in that world maps  $t_1$  to 85,  $t_2$  to 84, and  $t_3$  to 83. This kind of temporal variation is easy enough to rule out by meaning postulate (or some similar lexical stipulation), but it would be preferable, if possible, to find a more “architectural” solution, which prevented a case like this from coming up in the first place.

If we analyze common nouns as variables, and allow variables to be temporally non-rigid in the same way as we allowed them to be modally non-rigid, such a solution is available. First, to allow for temporal intensionality, we revise the definition of assignment functions in (20) so that assignments give values to variable-world-time *triples*, and add a clause for the noun *temperature*:

- (34)  $g$  is an assignment of values to variables for  $w, t$  (or “ $w, t$ -assignment”) iff
- $g$  is a partial function with domain  $\{x \mid x \text{ is a common noun token or trace token or pronoun token or } \dots\} \times W \times T$
  - If  $\alpha$  is a token of *student*: for all  $w', t'$ : if there exists an  $x$  such that  $x = g(\alpha, w', t')$ , then  $g(\alpha, w', t')$  is a student in  $w'$  at  $t'$ ;

- c. If  $\alpha$  is a token of *professor*: for all  $w', t'$ : if there exists an  $x$  such that  $x = g(\alpha, w', t')$ , then  $g(\alpha, w', t')$  is a professor in  $w'$  at  $t'$ ;
- d. If  $\alpha$  is a token of *temperature*: there is some pragmatically relevant object or location  $x$ , such that for all  $w', t'$ :  $x$  exists at  $w', t'$  iff  $g(\alpha, w', t')$  is the temperature of  $x$  in  $w'$  at  $t'$  (in the relevant scale — °F, °C, etc.)
- e. etc.;
- f. If  $\varepsilon$  is a trace token: for all  $w', t'$ :  $g(\varepsilon, w', t') = g(\text{antecedent}(\varepsilon), w', t')$ ;
- g. If  $\pi$  is a pronoun token: for all  $w', t'$ :  $g(\pi, w', t') = g(\text{antecedent}(\pi), w, t)$ .

Notice that according to (34)d., for each assignment function  $g$  and token of the noun *temperature* there is one particular object or location whose temperature at various times and worlds is tracked by the values which  $g$  assigns to that token (relative to those times and worlds). The value which  $g$  assigns to a token of *temperature* relative to a world  $w$  and time  $t$  is just a number — an entity of type  $e$  — not a function or set of functions. So for any given world and any given object, there will be just one function which picks out the temperature of that object in that world at each time — not different such functions at different times. This eliminates the source of Gupta's problem.

In a semantic theory using (34), the intension of a token of *temperature* relative to a given assignment  $g$  will naturally be a function mapping each world-time pair onto the temperature of one particular object or location in that world at that time.

Verbs like *rise* must remain at type  $\langle\langle s, e \rangle, t\rangle$ . But now we have a problem: If traces are required to co-denote with their antecedents, and nouns like *temperature* are type  $e$ , then the trace left by phrases like *the temperature* or *every price* will also be of type  $e$ , so it will not be of the right type to serve as argument to *rise*. Therefore, we now allow traces (and pronouns) of type  $\langle s, e \rangle$ . If a trace or pronoun is in position to fill an  $\langle s, e \rangle$  argument place, the trace/pronoun must be of type  $\langle s, e \rangle$ . If it is in position to fill a type  $e$  argument place, it must be of type  $e$ . If a trace or pronoun is of type  $\langle s, e \rangle$ , its denotation must be the same as the intension of its antecedent, rather than its extension. More formally, we replace (34)f., g. with (35)a., (35)b.:

- (35) a. If  $\varepsilon$  is a trace token: for all  $w', t'$ :  $g(\varepsilon, w', t') = g(\text{antecedent}(\varepsilon), w', t')$  or  $g(\varepsilon, w', t') =$  that function  $f: W \times T \rightarrow \mathbf{D}_e$  such that for all  $w'', t''$ ,  $f(w'', t'') = g(\text{antecedent}(\varepsilon), w'', t'')$ , according as  $\varepsilon$  is of type  $e$  or of type  $\langle s, e \rangle$ ;
- b. If  $\pi$  is a pronoun token: for all  $w', t'$ :  $g(\pi, w', t') = g(\text{antecedent}(\pi), w, t)$  or  $g(\pi, w', t') =$  that function  $f: W \times T \rightarrow \mathbf{D}_e$  such that for all  $w'', t''$ ,  $f(w'', t'') = g(\text{antecedent}(\pi), w'', t'')$ , according as  $\pi$  is of type  $e$  or of type  $\langle s, e \rangle$ .

Finally, we need to make the obvious updates to the notation used in our rules and definitions, to reflect the fact that assignments are now to a time parameter in addition to a world. We replace (21) with (36):

- (36)  $g \sim_{\kappa, w, t} h$  iff
  - a.  $g$  and  $h$  are both  $w, t$ -assignments;
  - b. there exists some  $x$  such that  $h(\kappa, w, t) = x$ , and

- c. for all common noun phrases  $v$ , worlds  $w'$  and times  $t'$ :  
if  $v \neq \kappa$ , then  $g(v, w', t') = h(v, w', t')$ .

And (18) with (37):

$$(37) \quad \llbracket \text{every } \kappa \phi \rrbracket^{w,t,g} = \begin{aligned} &1 \text{ if } \forall h [g \sim_{\kappa,w,t} h \rightarrow \llbracket \phi \rrbracket^{w,t,h} = 1]; \\ &0 \text{ if } \exists h [g \sim_{\kappa,w,t} h \ \& \ \llbracket \phi \rrbracket^{w,t,h} = 0]. \end{aligned}$$

Now our semantics (unlike that of Lasersohn (2005)) will assign a coherent interpretation to sentences like  $\llbracket \text{Every temperature } [e \text{ rises}] \rrbracket$ . In order to serve as argument to *rises*, the trace  $e$  must be of type  $\langle s, e \rangle$ . Therefore, relative to any assignment  $g$ , it must denote the intension of its antecedent, *temperature*, relative to  $g$ . Relative to  $g$ , the intension of *temperature* is a function tracking the temperature of one particular object or location — but relative to another assignment, the intension of the *temperature* might be a function tracking the temperature of some other relevant object or location. The sentence is true relative to an assignment  $g$  iff  $\llbracket e \text{ rises} \rrbracket$  is true relative to every assignment  $h$  agreeing with  $g$  on all nouns other than *temperature*. That is, it is true if the temperature function of each relevant object or location is a rising function.

The original temperature paradox argument correctly comes out invalid, even if we adopt a quantificational analysis of definites. We may define *the* as in (38):

$$(38) \quad \llbracket \text{the } \kappa \phi \rrbracket^{w,t,g} = \begin{aligned} &1 \text{ if } \exists h [g \sim_{\kappa,w,t} h \ \& \ \forall i [g \sim_{\kappa,w,t} i \rightarrow h = i] \ \& \ \llbracket \phi \rrbracket^{w,t,h} = 1]; \\ &0 \text{ if } \neg \exists h [g \sim_{\kappa,w,t} h \ \& \ \forall i [g \sim_{\kappa,w,t} i \rightarrow h = i] \ \& \ \llbracket \phi \rrbracket^{w,t,h} = 1]. \end{aligned}$$

Consider the truth condition assigned to (39) under this rule:

$$(39) \quad \llbracket \text{The temperature } [e \text{ rises}] \rrbracket$$

In order for (39) to be true relative to an assignment  $g$  (in  $w$ , at  $t$ ), there must be exactly one assignment  $h$  which agrees with  $g$  on all common noun tokens other than the token of *temperature* in this example. If  $h$  agrees with  $g$  in this way, there must be some pragmatically relevant object or location, whose temperature  $h$  assigns to this token at each world and time. Since  $h$  is unique, there can be only one function which maps a pragmatically relevant object or location onto its temperature at each world and time. That is to say, despite the fact that *temperature* is of type  $e$ , according to our rules (39) requires a unique temperature *function*, not just a unique temperature *value*. Of course this unique temperature function must also be a rising function in order for (39) to be true.

In contrast, (40) is true (relative to  $w, t, g$ ) iff the value of the unique temperature function at  $w, t$  is 90; the trace here is of type  $e$ , and therefore denotes the extension, not the intension of its antecedent.

$$(40) \quad \llbracket \text{The temperature } [e \text{ is ninety}] \rrbracket$$

Assuming that the intension of *ninety* is the constant function mapping each world-time pair onto 90, (41) will always be false, even if (39) and (40) are true:

(41) [*Ninety rises*]

It is also easy to see that Gupta's argument comes out valid. Sentence (42)a. equates, at all world-time pairs, the value of the unique temperature function with the value of the unique price function. If the unique temperature function yields the same value at every pair as the unique price function, then they are the same function; so if the temperature function is rising, the price function is rising.

- (42) a. Necessarily, the temperature is the price.  
       b. The temperature is rising.  
       c. Therefore, the price is rising.

## 6. Conclusions

Common nouns which are usually analyzed predicates of type  $\langle e, t \rangle$  may instead be analyzed as being of type  $e$  by treating them as restricted variables. Treating them this way, in combination with a standard understanding of what variable-binding is, predicts that all nominal quantification is conservative, and does so without any independent restriction on determiner meanings.

In order to assign correct truth conditions to sentences in which common nouns appear in intensional contexts, an analysis which treats them as variables must allow variables to be modally non-rigid. Certain other variables, notably pronouns, should continue to be analyzed as rigid.

Allowing modally non-rigid variables makes possible an analysis of the temperature paradox which can deal with quantificational examples, without requiring extra stipulations to rule out modal variation in which functions count as temperature functions, thus solving "Gupta's problem."

These arguments are not by themselves sufficient to establish that common nouns should be analyzed as variables. That would be a far larger project, requiring much more thorough and intensive investigation than can be accomplished in a single paper. Several important challenges to this view have not been addressed here: How can we deal with relational nouns? With complex noun phrases containing modifiers? With mass and plural nouns? Can the treatment of quantification be formulated in such a way that determiners are assigned denotations, instead of being interpreted syncategorematically, as they were in this paper? I believe all these challenges can be met; but demonstrating this will have to wait for another occasion.

Additional advantages to analyzing common nouns and noun phrases as variables also suggest themselves: Such an analysis may allow for a closer, more systematic correlation between syntactic categories and semantic types. If complex phrases like *farmers who own a donkey* can be treated as type  $e$  variables, a new pathway opens for the analysis of the

“proportion problem” in sentences like *Most farmers who own a donkey beat it*. Treating common nouns as type *e* variables promises a more natural analysis of “collectivizing” conjunction of common nouns, as in the reading of *this man and woman* where it denotes a group whose members are a man and a woman. These and other topics must here be left to later investigation.

# Bayes nets and the dynamics of probabilistic language

Daniel LASSITER — *Stanford University*

**Abstract.** This paper is about a shared concern of linguistic semantics and pragmatics, epistemology, and many other areas of cognitive science: the formal representation of information and uncertainty. It is common in many of these areas, and increasingly in linguistics, to represent agents' information using probability—an enrichment of classical semantics. However, each application of probability must answer difficult questions about whether a probabilistic representation is rich enough to capture the nuances of our information states. Two such problems—the epistemological distinction between uncertainty and ignorance, and the dynamic effects of probabilistic language in formal pragmatics—seem to suggest a negative answer, and to support a more complicated model that represents uncertainty in terms of *sets of* probability measures. Following insights due to Judea Pearl (1988), I argue that the simplest probabilistic approach may be sufficient to handle these problems if we pay close attention to the *hierarchical* structure of information states, as encoded explicitly in the graphical representation of relationships among questions known as “Bayesian networks” or “Bayes nets”.

**Keywords:** epistemic modality, probability, dynamics, epistemology

## 1. Three scenarios and two puzzles

- (1) Two teams, A and B, are about to compete in a soccer game. You've seen them compete many times, and you are certain that they are evenly matched. What probability should you assign to the sentence “A will win”?
- (2) Two teams, A and B, are about to compete at soccer. You know nothing at all about these two teams. What probability should you assign to the sentence “A will win”?

If pushed, most people will give the same answers to these questions: “50%”. But our reason for giving these answers is obviously different in (1) and (2). In (1), we have a lot of relevant information to justify making this choice with confidence. In (2), our choice is made in ignorance: we just don't have any reason at all to favor one team over the other. Obviously, there is an epistemologically relevant difference, and it would be a mistake to represent our information identically in (1) and (2). But probabilistic representation seems not to make a distinction here.

- (3) As in example (2), there are two teams, A and B, who are about to compete, and you know nothing at all about them. However, a knowledgeable friend assures you that “Team A is likely to win.” What probability should you assign to “A will win”?

Here we move from a mainly epistemological question to one that lies at the border of epistemology, formal pragmatics, and computational cognitive science. Epistemologists and psychologists worry about the way that people do (or should) modify their states of information in light of *new information, however acquired*. Formal pragmaticists and dynamic semanticists worry about the way that people do (or should) modify their states of information in light of *new information acquired by linguistic means*. The latter kind of question being a special case

of the former, both groups of theorists should care about what information is conveyed by the sincere assertion of a statement with probabilistic import, like “Team A is likely to win”. This is a particularly important problem for theorists of a Bayesian bent, since for them probability—or “credence”—is the basic currency of belief. Unfortunately, there is no general theory of the informational effects of probabilistic language to date. An attempt to frame one must balance three considerations, each difficult in its own right: getting the empirical facts right, integrating with existing accounts of linguistic dynamics, and remaining plausible in light of a broader accounts of epistemology and the cognitive science of learning and reasoning.

This paper treats the dynamics of probabilistic language and the confidence/ignorance distinction as two sides of an epistemological coin. The first approach takes ordinary probability to be inadequate as a representation of agents’ credence states, and opts for a richer model using imprecise credences—i.e., sets of probability measures. Probabilistic language, in turn, is modeled in terms of filtering on this set. The second approach tries to explain both the confidence/ignorance distinction and the dynamic effects of probabilistic language in terms of a single probability model that incorporates a hierarchical structure—such as that of a Bayes net. The need to include hierarchical structure in probabilistic models enjoys vast psychological, philosophical, and computational motivation (e.g., Pearl 1988, 2000; Glymour 2001; Sloman 2005; Woodward 2003; Tenenbaum et al. 2011; Danks 2014). Hierarchical models can also be used to model the interplay between statistical and causal reasoning, which is crucial in many linguistic, cognitive, and philosophical applications. There is an obvious gain in theoretical simplicity, then, if we can apply this independently motivated modeling approach to resolve the problems discussed here as well. However, I will argue that the primary motivation for the hierarchical approach is that it yields a better account of the basic empirical facts.

None of this calls directly into doubt whether further phenomena might motivate the use of imprecise probabilities in epistemology, psychology, or linguistics. Nor does it bear on the rather different question of whether imprecise-probability models are useful in modeling epistemic phenomena that extend beyond the minds of individuals, such as group belief or conversational common ground. (See brief comments on the latter in §5 below.) The main claim of the current work is rather that certain phenomena which appear to problematize Bayesian models of individual agents’ informational states and their (linguistic and non-linguistic) dynamics in fact already have an illuminating explanation within these models.

## 2. Precise and imprecise credences

Say that an agent  $a$  has *precise credences* just in case  $a$ ’s state of information is well-represented by a probability measure  $P_a$ . Since this function is being used here to model  $a$ ’s state of belief, or “credence”, we’ll also call it a “credence function”.  $P_a$  assigns a number between 0 and 1 to each proposition  $A \in \wp(W)$ , subject to the usual laws of probability (Kolmogorov, 1933):  $P_a(W) = 1$ , and  $P_a(A \cup B) = P_a(A) + P_a(B) - P_a(A \cap B)$ . (These definitions assume that  $W$  is finite, inessentially, in order to simplify the math.) Just what it means for  $a$ ’s information to be “well-represented” by  $P_a$  is a difficult theoretical question that I will leave at an intuitive level here. Explicit judgments about probability, other linguistic behaviors, overt choices, and dispositions to choose in particular ways are some of the many ways that we might want to

evaluate whether a candidate  $P_a$  is a good representation of  $a$ 's information. Notice that this model does not compete with classical semantics, but rather *presupposes* and *extends* it: a set of worlds  $W$  generates a Boolean algebra  $\wp(W)$  whose elements are propositions that receive probabilities. Probability assignments are constrained by classical logic. For example, if  $A$  and  $B$  are contradictory— $A \cap B = \emptyset$ —then  $P(A \cap B) = 0$ . If  $A$  entails  $B$ — $A \subseteq B$ —then  $P_a(A) \leq P_a(B)$ . (Indeed, the probabilistic model inherits some important limitations of the classical semantics, such as problems around logical omniscience and hyperintensionality.)

Precise credence models have many epistemological and cognitive advantages, and are also subject to many kinds of objections. One well-known objection involves experimental evidence that ordinary people make systematic errors in probabilistic reasoning (e.g., Tversky and Kahneman 1974; Kahneman et al. 1982). While this kind of critique is surely relevant, I want to set it aside here with a few quick comments. First, there are many additional experiments in which people seem to reason appropriately with probabilities. Second, experiments in which people are asked to reason explicitly about probabilities may be less theoretically revealing than those in which probabilistic inference is implicit in the way that uncertainty informs judgment and decision (e.g., Griffiths and Tenenbaum 2006; Trommershäuser et al. 2008). The logic is essentially the same as that which motivates linguists to pay closer attention to unreflective linguistic productions and judgments than to explicit metalinguistic judgments. Third, recent work has suggested a reconciliation, where at least some errors and biases in probabilistic reasoning may be explicable in terms of performance factors, interactions among cognitive systems, or strategies for efficient approximation (Griffiths et al., 2012; Vul et al., 2014).

The objections that motivate imprecise credence models are primarily of a different kind. Kahneman and Tversky argued that ordinary people's credence states, to the extent that they are not consistent with a precise credence model, fail to meet a normatively correct epistemological standard. Proponents of imprecise credences, in contrast, argue that it would in many cases be normatively inappropriate for an agent to have a credence state that is consistent with a precise credence model. A typical example is scenario (2): two teams compete in a game, and you know nothing at all about their relative skills. Joyce (2005, 2010) argues that, in such a scenario, you are making a mistake if you have *any* precise credence in team A winning. What possible grounds could you have for such "extremely definite beliefs ... and very specific inductive policies", when "the evidence comes nowhere close to warranting such beliefs and policies" (Joyce 2010, p.285)? Depending on the teams' relative skills, the right credence to have might be any value in the range  $[0, 1]$ ! You don't know enough to exclude *any* of these.

This objection is closely related to the problem of insufficient expressiveness that we began with. When asked for a probability estimate in scenarios (1) and (2), I might produce "50%" in both cases—but confidently in (1), and with hesitation and confusion in (2). Similarly, I would immediately reject an uneven bet on either team in (1), but might have a harder time making up my mind in (2). Either way, the precise model seems to miss at least two important differences between these judgments: differences in their evidential basis, and in their phenomenology. Any two events to which I give credence 0.5 just have credence 0.5, end of story. As a result, precise credences are not fine-grained enough to provide a good model of my credence state. As Halpern (2003, p.24) puts it, "Probability is not good at representing ignorance".

### 3. Confidence and ignorance: An imprecise model

The proposed alternative is to represent an agent  $a$ 's information not by a single measure  $P_a$ , but by a *set* of measures  $\mathbb{P}_a$  (e.g., Levi 1974; Jeffrey 1983). This is sometimes called  $a$ 's "Representor" (van Fraassen, 1990). Each  $P \in \mathbb{P}_a$  conforms to the probability axioms. This model has no expressive difficulty in the sporting examples. In the first scenario, where I am confident that the teams are evenly matched, my  $\mathbb{P}$  has the property that, for every  $P \in \mathbb{P}$ ,  $P(A \text{ wins}) = 0.5$ . In the second scenario, where I have no relevant information, my  $\mathbb{P}$  has the property that, for every  $r \in [0, 1]$ , there is a measure  $P \in \mathbb{P}$  such that  $P(A \text{ wins}) = r$ . In the first case I have an "extremely definite belief" (Joyce, 2010) that  $P(A \text{ wins}) = 0.5$ , and I am right to. In the second I have no definite belief about the value of  $P(A \text{ wins})$ , and I am right not to.

Despite this apparent success, some important objections have been made to the use of imprecise probabilities. One is that it is difficult to frame a plausible decision theory for agents with imprecise credences. Elga (2010), in particular, canvasses a number of options and shows that each makes pathological predictions in certain cases; see also White 2010. A second kind of objection involve examples where imprecise models seem to predict, rather oddly, that learning a new fact should lead to a net loss of information ("probabilistic dilation": Seidenfeld and Wasserman 1993), or where learning something that is intuitively irrelevant to an event  $A$  leads to a gain of information about  $A$ 's probability (White, 2010). (However, see Pedersen and Wheeler 2014 for important subtleties that may help to improve the plausibility of dilation.) These particular objections are two of many, and they are still a matter of active controversy in the epistemological literature. I don't want to take a stand on whether they are decisive, but I do think they give us sufficient reason to look for a model that combines naturally with well-understood, well-behaved Bayesian models of learning and decision. First I will discuss a third objection which introduces some of the motivation for the hierarchical alternative.

Perhaps the most troubling objection to imprecise probability models, from our current perspective, is the observation that they "preclude[] inductive learning in situations of extreme ignorance" (Joyce 2010, p.290; see also White 2010; Rinard 2013). For example, consider a biased coin example analogous to scenario 2 above. Suppose I am uncertain about the probability of getting heads when a certain coin is tossed. This probability could in principle be anywhere in  $[0, 1]$ . On any given toss, the probability of getting heads— $P(\text{heads})$ —is equal to the coin's bias  $\pi$ , which is a fixed fact about the world, determined by the coin's objective properties. My uncertainty about  $P(\text{heads})$  reduces to uncertainty about the value of  $\pi$ .

Suppose I had precise credences, with a prior distribution on  $\pi$ —say, a Beta distribution. If I wanted to be maximally noncommittal, I might use a Beta(1, 1) distribution, which puts equal prior probability on every bias  $\pi \in [0, 1]$  (see Fig. 1, left). Given this model, after conditioning on the observation of  $n$  heads and  $m$  tails my posterior probability is given by Beta(1 +  $n$ , 1 +  $m$ ). (In general, conditioning a Beta( $a$ ,  $b$ ) prior on  $n$  heads/successes/wins and  $m$  tails/failures/losses yields a Beta( $a + n$ ,  $b + m$ ) posterior. See Griffiths et al. 2008; Hoff 2009 for introductions to the Beta-Binomial model.) So, for example, if I had a maximally noncommittal Beta(1, 1) prior, after observing 150 heads in 300 tosses my beliefs about the bias  $\pi$  would be updated to a Beta(151, 151) distribution. This prior-to-posterior mapping is pictured in Fig. 1. The quite

Figure 1: Prior-to-posterior mapping for an agent with precise credences and a Beta(1,1) prior, after observing 150 heads/successes out of 300 trials. The red line indicates the expected value of the parameter  $\pi$ , which does not change with this evidence even though our uncertainty about the estimate (i.e., the variance of  $\pi$ ) decreases dramatically.

reasonable prediction is that, after observing 150/300 heads, you can be quite confident that the coin's bias  $\pi$  is close to 0.5—even if you were maximally noncommittal about  $\pi$  to begin with.

Not so in the imprecise credence model with the standard update rule of pointwise conditioning. I have no idea about the probability of heads initially, so my initial representor  $\mathbb{P}_0$  contains, for every  $r \in [0, 1]$ , a credence function  $P$  such that  $P(\text{heads}) = r$ . For example,  $\mathbb{P}_0$  might contain, for every possible Beta prior, a measure that encodes a binomial model with that prior.

$$\mathbb{P}_0 = \{P \mid P(\pi) \sim \text{Beta}(a, b), \forall a, b \in [0, \infty)\}$$

(Using only Beta priors is a significant restriction relative to Joyce's philosophical desiderata, but using the full range of possible distributions would only make the problem worse.) Now, suppose I observe 150/300 heads and update  $\mathbb{P}_0$  to  $\mathbb{P}_1$  by pointwise conditionalization, discarding measures that assign probability 0 to the observations and so cannot generate the sequence. In this case, the latter condition requires us to discard any Beta prior with a 0 in either position, which could only generate “all heads” or “all tails” sequences. All other measures in  $\mathbb{P}_0$  assign positive probability to the observed sequence of 150 heads and 150 tails, and survive in conditionalized form as Beta( $a + 150, b + 150$ ) measures:

$$\begin{aligned} \mathbb{P}_1 &= \{P \mid P(\pi) \sim \text{Beta}(a + 150, b + 150), \forall a, b \in (0, \infty)\} \\ &= \{P \mid P(\pi) \sim \text{Beta}(a', b'), \forall a', b' \in (150, \infty)\} \end{aligned}$$

When we look at a few of these distributions, it is clear that something has gone wrong. Alongside reasonable-ish posteriors like Beta(160, 200) [so  $P(\text{heads}) \approx .44$ ] and Beta(200, 160) [so  $P(\text{heads}) \approx .56$ ], the posterior belief state contains a Beta( $150.1, 10^{14}$ ) posterior [where  $P(\text{heads}) < 10^{-10}$ ] and a Beta( $10^{14}, 150.1$ ) posterior, where  $P(\text{heads})$  is indistinguishable from 1. This is truly remarkable, since the probability that we would have seen 150 or more heads in 300 if  $P(\text{heads}) = 10^{-10}$  is around  $10^{-87}$ —but this failure of prediction is not taken into account in update by pointwise conditioning. In fact, for every  $r$  in the open interval  $(0, 1)$ , there is a measure in  $\mathbb{P}_1$  such that  $P(\text{heads}) = r$ . As far as the spread of probabilities for heads is concerned,

all that we have gained from our observations is to contract the interval  $[0, 1]$  to  $(0, 1)$ , ensuring that both heads and tails are *possible* outcomes. We have learned *nothing else* about the coin's bias. But in reality, a sequence of 150 heads and 150 tails can and should teach us a lot, even if we know nothing at all about the coin to begin: it is almost certainly fair, or very close to it. Inductive learning *is* possible from a starting point of ignorance.

Several responses are possible here. First, we could search for an alternative to pointwise conditioning as an update rule. I won't speculate about how this would go. A second option would be to rule out representors where  $P(\text{heads})$  may fall anywhere in  $[0, 1]$  or  $(0, 1)$ . This would avoid the narrow problem addressed here, but it seems poorly motivated. If imprecise credences are motivated in the first place by considering belief under ignorance, how can we justify dealing with theoretical problems by *pretending* to know something that we don't? (Never mind that many such restricted models will still exhibit no learning, or will learn at an unbelievably slow rate.) A third option, floated by Joyce (2010), is to conclude that it is in fact *not* possible to learn in a rational way from a starting point of total ignorance. However, Joyce continues, real people employ non-rational heuristics to help them get by psychologically, such as restricting attention to measures that give high enough probability to the observed evidence. This response seems desperate, and if taken seriously it may imply that all of our beliefs are irrationally held: after all, for each of my beliefs there was some point at which I was totally ignorant on the subject.<sup>1</sup> A fourth option is to take this problem to demonstrate the impossibility of providing a precise formal model of belief states (Rinard, 2013). This could be correct, but I hope it isn't.

My preferred response is to reject imprecise credences as a model of individuals' belief states. To plump for this option, let me point out the key technical difference between precise- and imprecise-credence models that is creating this problem: whether we place a probability distribution on top of the set of credence functions in  $\mathbb{P}_0$ . Imprecise models decline to assign probabilities to the elements of  $\mathbb{P}_0$ , leaving it as an unstructured set. If we did put a distribution on  $\mathbb{P}_0$ , we would end up with a precise-credence model with a hierarchical structure, as I will describe in the next section. In this case, many kinds of (hyper-)priors on  $\mathbb{P}_0$  would yield plausible results with ordinary conditioning. We can see why this small change makes a difference if we break down conditioning using Bayes' rule. With a distribution on the measures in  $\mathbb{P}_0$ , the posterior probability of each  $P \in \mathbb{P}_0$  would be proportional to the product of the prior and the likelihood, where the latter is the probability that we would have observed the data if  $P$  were the true distribution. Conditioning re-ranks credence functions to take into account such facts—e.g., that 150/300 heads is moderately likely under a  $\text{Beta}(160, 200)$  distribution, and astronomically unlikely under a  $\text{Beta}(150.1, 10^{14})$  distribution. In contrast, imprecise models do not represent information about the relative plausibility of the measures in the representor, and pointwise conditioning does not take into account how well the measures in  $\mathbb{P}_0$  fare in the goal of predicting the data (a likelihood term). This seems to be the basic reason why imprecise models fare so poorly when confronted with simple examples of inductive learning.

In order to extract a plausible treatment of learning from imprecise credence models we need

<sup>1</sup>We all began, in the womb, in a state of total ignorance, though we must presumably have been endowed with inductive biases. As psychologists and machine learning researchers are fond of reminding us, learning without initial biases (i.e., a hypothesis space and priors) is impossible: see, for example, Perfors 2012.

to put a distribution on  $\mathbb{P}_0$  so that we can apply ordinary conditioning. In other words, we need a prior on our priors, which is the basic idea of hierarchical models.

#### 4. Confidence and ignorance: A hierarchical model

This is, to be sure, a roundabout way of getting to a simple objection. We just don't *need* imprecise credences to represent the difference between confidence and ignorance in the sporting scenarios we started with. Arguments against precise models based on a supposed failure to represent this distinction are simply misdirected. Confidence and ignorance can be given a satisfying treatment within hierarchically structured models, which are well-developed formally and strongly motivated psychologically and computationally.

Recall Joyce's (2010, p.285) objection to precise models quoted above: in a situation of ignorance, it is not justifiable for you to have "extremely definite beliefs ... and very specific inductive policies", because "the evidence comes nowhere close to warranting such beliefs and policies". Already in the coin-bias example, though, this objection is at least partly misplaced.<sup>2</sup> If your prior on the bias parameter  $\pi$  is a Beta(1, 1) distribution (Fig. 1, left), your belief is anything but definite. It is true that  $\pi$  has a precise expected value 0.5, and also that your marginal belief about  $P(\mathbf{heads})$  is 0.5. However, you are extremely uncertain about both of these beliefs: depending on what evidence you receive, you could come to a very definite conclusion that  $\pi$  and  $P(\mathbf{heads})$  are both 0, both 1, or anywhere in between. For example, after observing 0/300 heads, your posterior distribution on  $\pi$  would be Beta(1, 301), with  $P(\mathbf{heads})$  indistinguishable from 0. This would be an "extremely definite" opinion, and one that is justified by the evidence. Similarly, after seeing 150/300 heads, you have a fairly definite opinion that  $\pi$  and  $P(\mathbf{heads})$  are close to 0.5 (Fig. 1, right). Even though the summary estimate  $P(\mathbf{heads}) = 0.5$  (red dashed line) does not change, the transition from the information state described by the left of Fig. 1 to the one on the right clearly represents a significant change in your beliefs about  $P(\mathbf{heads})$ .

More generally, I suggest—building on observations made in another context by de Finetti 1977 and Pearl 1988 (p.357ff.)—that many of the intuitive arguments for imprecise probabilities discussed above can be accounted for in a better-motivated way once we take into account the hierarchical structure of belief. Our beliefs are interconnected, and probability estimates involving one variable usually depend on uncertain beliefs about others. Uncertainty about one variable—e.g., the bias  $\pi$  of a coin—may influence our uncertainty about a probability estimate of interest—e.g., the probability that the coin will come up heads on a given flip. Given the richness of our belief systems, there will usually be many layers of uncertainty. Even though such a model will always yield a precise numerical probability for any event of interest, this

<sup>2</sup>The part that may well hit home nonetheless is the accusation that precise credence models give rise to "very specific inductive policies" which are not warranted by the evidence. This is essentially the same point as the correct observation that precise credence models require priors that are not chosen on the basis of experience. Some authors have argued that priors should be chosen so as to maximize entropy (Jaynes, 2003; Williamson, 2009), though there are well-known objections to this move (van Fraassen, 1989). Does this mean that no choice of priors can be uniquely justified? Perhaps, but it is not clear why this should be so troubling. Since learning without priors is impossible, Bayesian cognitive models imply that evolution has supplied us with priors that are good enough to enable successful learning, starting in the womb. These may well vary between individuals, and there is no reason to expect that nature's choice of priors should be uniquely justified or rational. All we can expect is that they should get the job done with respect to the ultimate goals of survival and reproduction.

numerical value does not have any special place in the model: it is just what you get when you marginalize over the uncertainty of other relevant variables. In a hierarchical model, probability estimates can vary enormously in how “definite” they are—more precisely, in their variance.

Hierarchical models are used in many modern applications in psychology, philosophy, artificial intelligence, and statistics. In these models, probabilities are derived from graphs representing causal relations among variables, together with the conditional distribution on each variable given its parents. Uncertainty about one variable may influence the kind and degree of uncertainty in the value of another. For simplicity I will focus on Bayesian networks (“Bayes nets”), a simple propositional language for describing hierarchical models. (For discussion of richer languages for describing hierarchical Bayesian models that can treat uncertainty about individuals, properties, relations, etc., see for example Goodman et al. 2008; Goodman and Tenenbaum electronic; Tenenbaum et al. 2011 and, for a linguistically-oriented presentation, Goodman and Lassiter 2015.) I will impose a causal interpretation on the Bayes nets described in this paper. While this is not obligatory, it helps to gain intuitions about their meaning, and it is crucial to their psychological motivation (e.g., Glymour 2001; Sloman 2005).

The sporting example that we began with allows us to illustrate Bayes nets and their ability to represent confidence and ignorance alike. Formally, a Bayes net  $B$  is an enrichment of familiar intensional semantics models, consisting of a set of possible worlds  $W$  together with:

1. A set of “variables”  $V \in \mathbb{V}$ , where each  $V$  is a partition of  $W$ . (A cell is a “value” of  $V$ .)
2. A set of “arrows”, i.e., an acyclic binary relation on  $\mathbb{V}$ . (The inclusion of an arrow from  $V_i$  to  $V_j$  indicates that  $V_i$  is immediately causally relevant to  $V_j$ .)
3. A set of conditional probability tables which assign a distribution  $P(V \mid \text{Parents}(V))$  to each  $V \in \mathbb{V}$ , where  $\text{Parents}(V) = \{V' \mid \langle V', V \rangle \in \mathbb{V}\}$ .

A probability measure  $P$  is *compatible* with Bayes net  $B$  if and only if  $P$  satisfies the *Markov condition*: each  $V \in \mathbb{V}$  is probabilistically independent of its nondescendents, given its parents.

To situate the hierarchical modeling concept within our sporting examples, consider: In case (2), when asked to reason about the competition between unknown teams **A** and **B**, did you really know *nothing at all* about these teams? I doubt it. Most likely, you brought to bear on the problem a rich network of relevant background knowledge. You knew that the outcomes of matches are determined largely by the performance of the teams; that teams are composed of players who have different roles; that they have latent characteristics like skill and consistency; that not all teams are equally skilled or consistent; and so forth. In addition, your experience may have provided you with relevant population statistics which can help you to make an informed guess about the distribution of these characteristics among teams, even without any specific knowledge of the team. All of this background knowledge enabled you to make a reasonable guess about how a randomly chosen team would perform, and what factors you should attend to if you want to use observations to improve your forecast of a team’s performance.

As a start in modeling the richer background knowledge that we implicitly bring to bear on

such problems, consider the simplified representation in Fig. 2.<sup>3</sup> This model represents two key features of teams that are relevant to their performance: their **skill** and their **consistency**. Performance of team  $i$  is modeled as a Gaussian (normal) distribution with parameters  $\mu_i$  (**skill**) and  $\sigma_i$  (**consistency**). As a result, the team's performance in any given competition is a noisy reflection of the team's true skill. Skill and consistency are, in turn, objects of uncertainty that we are trying to estimate when observing the outcomes of competitions. This means that we must place a prior on them as well. In a realistic model, these variables might be connected to many further factors—e.g., the team's composition, quality of coaching, motivation, etc. To simplify the example, I will summarize all of these sources of uncertainty with simple priors on the parameters:  $\mu_A$  and  $\mu_B$  are both distributed as  $\mathcal{N}(0, 1)$ , and  $\sigma_A = \sigma_B = .1$ .

Figure 2: Hierarchical model of a match between teams **A** and **B**.

In this model  $P(\mathbf{A} \text{ wins})$  is equal to  $P(perf_A > perf_B)$ —the probability that **A**'s noisy performance exceeds **B**'s. Note that this model does *not* generate a single, determinate prediction about **A**'s performance in any given match. Instead it generates for each team a distribution over an infinite set of performance values  $(-\infty, \infty)$ . A few of these distributions are shown in the top left of Fig. 3. As a result, the model encodes a distribution over an infinite set of values for  $P(\mathbf{A} \text{ wins})$ , which could be anywhere in  $(0, 1)$  depending on subsequent observations.

While the model does yield a precise best guess about the performance difference—and so about  $P(\mathbf{A} \text{ wins})$ —this guess has no special status in the model: it is merely the result of marginalizing over our uncertainty about the parent variables (skill and consistency). Indeed, two models that generate the same probability estimate for this event—say,  $P(\mathbf{A} \text{ wins}) = .5$ —may vary considerably in how confident (“definite”, “determinate”) the probability estimate is.<sup>4</sup> A key factor is, of course, how much evidence the estimate is based on.

<sup>3</sup>The model is directly inspired by the Microsoft Trueskill system that is used to rank Xbox Live players in order to ensure engaging match-ups in online games: see Bishop 2013. It is also closely related to the tug-of-war model explored by Gerstenberg and Goodman (2012); Goodman and Lassiter (2015).

<sup>4</sup>As Pearl (1988, p.361-2) writes: “The point is to notice that by specifying a causal model for predicting the outcome ... we automatically specified the variance of that prediction. In other words, when humans encode probabilistic knowledge as a causal model of interacting variables, they automatically specify not only the marginal and joint distributions of the variables in the system, but also a particular procedure by which each marginal is to be computed, which in turn determines how these marginals may vary in the future. It is this implicit dynamic that makes probabilistic statements random events, admitting distributions, intervals, and other confidence measures.” As a consequence, Joyce (2010, p. 283) is simply wrong in his assertion that “Proponents of precise models ... all agree that a rational believer must take a definite stand by having a sharp degree of belief” in situations of ignorance. While Joyce is right that taking a “definite stand” in case of ignorance is unreasonable, his conclusion

Figure 3: Some distributions implicit in the Fig. 2 model. Top left: some of the  $\infty$  performance distributions that could turn out to be the true distribution for either team. Top right: Marginal on  $\text{perf}_{A/B}$  with no specific evidence. Bottom row: Distribution of  $\text{perf}_A - \text{perf}_B$  with no observations (left) and after observing that each team won 15 of 30 matches (right).

Consider our two leading examples again. In case (1), we “know nothing”—i.e., only general domain knowledge is available. As a result, the variance of the estimated performance difference is high, and confidence in the estimate  $P(\mathbf{A} \text{ wins}) = .5$  is low (Fig. 3, bottom left). In case (2), there is ample evidence to indicate equal skill—many previous matches, with each team winning an equal number. In this case, the variance of the estimated performance difference is low, and confidence in the estimate  $P(\mathbf{A} \text{ wins}) = .5$  is high. The bottom right panel of Fig. 3 shows the model’s predictions about  $P(\text{perf}_A > \text{perf}_B)$  once we have observed each team winning 15 of 30 matches. Here we can infer that the teams have roughly equal skill, and that we should forecast roughly equal performance in the next game:  $P(\mathbf{A} \text{ wins}) = .5$ .

Bayes nets offer a precise credence model that represents the distinction between confidence and ignorance in a straightforward way. The need to represent this distinction does not, therefore, give us a reason to abandon precise credence models in favor of a more complex representation that also introduces new problems involving learning and decision. The apparent problem with precise models—that radically different credal states could generate the same probability estimate  $P(\mathbf{A} \text{ wins}) = .5$ —was not due to any expressive limitation. Instead, the problem is generated by our habit as theorists of treating such numerical estimates as representations of belief states, forgetting that they give only a narrow window into the rich structure of a probability distribution and its potential to change in response to experience.

## 5. Dynamics of probabilistic language: An imprecise model

The third puzzle that we started with was how to understand the informational effect of explicitly probabilistic language. Example (3) is repeated here:

that precise credence models are inappropriate is a non sequitur: precise probability estimates can be extracted from hierarchical models, but these models do not generally imply a “definite stand” on these estimates.

- (4) Two teams A and B who are about to compete, and you know nothing at all about them. However, a knowledgeable friend assures you that “Team A is likely to win.” What probability should you assign to “A will win”?

This puzzle is a special case of the more general question of how we should update our beliefs on the basis of new information. However, in (3) the new information is provided in linguistic form, and so we have the dual problem of supplying an interpretation and an update procedure that will generate the right mapping from information states to modified information states.

In familiar models of linguistic dynamics, information states  $I$  are usually modeled as sets of worlds—or sometimes as sets of structured objects that segment out different kinds of information and handle them separately. Sentences  $S$  pick out, relative to a context  $c$ , properties of the kind of objects contained in  $I$ . So, if  $I$  is a set of worlds,  $\llbracket S \rrbracket^c$  is a set of worlds as well. The algorithm for incorporating the information conveyed by  $S$  in  $c$  into state  $I$  is simple: we transition from state  $I$  to state  $I \cap \llbracket S \rrbracket^c$ , eliminating from  $I$  any worlds that are not in  $\llbracket S \rrbracket^c$ . On this approach to conversational dynamics, information states and sentence-meanings-in-context must be objects of the same type. This means that, if our language contains sentences whose meaning is not well treated as a set of worlds, an eliminative theory of update requires us to enrich the representation of information states accordingly.<sup>5</sup>

Now, recent work has given considerable semantic motivation to the claim that the interpretation of *A is likely to win* in (4) makes direct reference to a probability—roughly, “ $P(\mathbf{A} \text{ wins}) > .5$ ” (Swanson, 2006; Yalcin, 2007, 2010; Lassiter, 2010, 2011, 2017a; Moss, 2015). This leaves us with a theoretical dilemma. If we want to hold to the eliminative conception of update, we can either try to give this probability statement a world-relative interpretation, or we can assign it some other interpretation and enrich our model of information states to compensate.

Yalcin 2012 proposes a simple eliminative model of update for both factual and probabilistic statements, building on Yalcin 2007. On this account epistemic statements—including probabilistic statements—do not have a world-relative interpretation. Instead, they depend on the value of a *sui generis* information state parameter which varies independently of the choice of evaluation world, and which determines a probability measure  $P$ . Briefly, the idea is that a conversational common ground  $C$  is a set of pairs  $i = \langle s_i, P_i \rangle$ , where  $s_i$  is a set of worlds and  $P_i$  is a probability measure with  $P_i(s_i) = 1$ . For factual statements such as *It’s raining*, update eliminates from  $C$  those  $i$  for which it is not raining everywhere in  $s_i$ , without constraining  $P_i$ .

$$I \xRightarrow{\text{update}} I \cap \{ \langle s, P \rangle \mid \forall w \in s : \text{It's raining at } w \}.$$

For probabilistic statements such as *It’s likely to rain*, update eliminates points  $i \in C$  that do not assign sufficiently high probability to rain, but places no direct constraints on  $s_i$ .

$$I \xRightarrow{\text{update}} I \cap \{ \langle s, P \rangle \mid P(\mathbf{rain}) > .5 \}.$$

<sup>5</sup>An alternative is to modify the definition of update, giving pointwise definitions for individual expressions, as Veltman (1996) does for *might* and several other epistemic operators. However, this approach is not promising for *likely*, and I will not consider it further.

This formal model of conversational dynamics bears a striking resemblance to the sets-of-measures model of credence that we considered above. However, there are two very different ways to interpret it. Yalcin's proposal is to use it to model the dynamics of conversational common ground, in the mold of Stalnaker 1978. The idea is that, as a conversation proceeds, the acceptance of utterances leads to an accumulation of constraints on interlocutors' information. Once "It's likely to rain" is accepted, the common ground contains the information that  $P(\mathbf{rain}) > .5$ , meaning that interlocutors are publicly committed to this constraint. This interpretation is conceptually close to the "group belief" interpretation of imprecise probability models discussed above. As mentioned above, I have no quarrel with the group belief interpretation of imprecise credences, where measures in the set represent assignments of probability that are consistent with existing group commitments; the objections canvassed were specifically leveled at an application to individual psychology. For similar reasons, Yalcin's interpretation seems unproblematic as a way of treating the way that conversational commitments constrain the way that common ground constrains (but does not determine) probability assignments.

Solving the puzzle in (3)/(4) requires a more ambitious theory, though. It is not enough to require that someone who accepts *A is likely to win* must assign  $P(\mathbf{A\ wins}) > .5$ . This constraint does not tell us enough about what that person *should* come to believe about  $P(\mathbf{A\ wins})$ , other than the bare fact that  $P(\mathbf{A\ wins})$  cannot fail to exceed .5. What we are interested in is a mapping from an *individual's* prior state of information to a posterior state, which would determine what she should believe if she begins in state *I* and then gains some explicit information about the likelihood of events. While it was not proposed for this purpose, Yalcin's formal apparatus could equally be put to use in this way (cf. also Rothschild 2012). On this interpretation, an individual's state of information *I* is a set of pairs  $i = \langle s_i, P_i \rangle$ , and we have a simple algorithm for updating with the information conveyed by *A is likely to win*: as in Yalcin's proposal, map *I* to the subset of *I* containing all  $\langle s_i, P_i \rangle$  for which  $P_i(\mathbf{A\ wins}) \not> .5$ .

While this proposal is *prima facie* plausible, it encounters some serious difficulties. First, as a representation of individual psychological states its plausibility is threatened by general objections to the use of imprecise credence models for this purpose: problems with framing a decision theory, with updating beliefs from a starting point of ignorance, and so forth. Second, even if we were to accept imprecise credence models along the lines of Joyce (2005, 2010), the update procedure just described would not be sufficiently general. The problem is that imprecise probabilities are intended to represent situations where probabilities are not known—but probabilistic statements can be informative about known and unknown probabilities alike.

Consider a scenario in which a ball is drawn from one of two urns. Urn A contains 10 red and 5 blue balls, so  $P(\mathbf{red} \mid \mathbf{A}) = 2/3$ . Urn B contains 5 red and 10 blue balls, so  $P(\mathbf{red} \mid \mathbf{B}) = 1/3$ . A fair coin was flipped to determine which urn the ball would come from—A if heads, B if tails. So,  $P(\mathbf{A}) = P(\mathbf{B}) = 1/2$ . If someone who knows what urn was selected tells us *The ball is probably red*, how should we respond? Clearly, we can conclude that the coin toss came up heads and A was selected. So the posterior probability of **red**, after update with *The ball is probably red*, should be equal to  $P(\mathbf{red} \mid \mathbf{A}) = 2/3$ .

However, it is not possible to model this kind of update by filtering in a standard imprecise

probability model: paradoxically, we know too much. That is, we could attempt to represent this situation in terms of an imprecise model where some measures have  $P(\text{red}) = 2/3$  and some have  $P(\text{red}) = 1/3$ . Then, upon learning that the ball is probably red, we could model the update effect of this information by eliminating the measures where  $P(\text{red}) = 1/3$ . But as Joyce (2005, 2010) emphasizes, this model is inappropriate: it leaves out known probabilities, i.e., the information that the choice of urn was determined by the flip of a fair coin. Since  $P(\mathbf{A}) = P(\mathbf{B}) = 1/2$ , all measures  $P$  in our information state have

$$\begin{aligned} P(\text{red}) &= P(\text{red} \mid \mathbf{A}) \times P(\mathbf{A}) + P(\text{red} \mid \mathbf{B}) \times P(\mathbf{B}) \\ &= 2/3 \times 1/2 + 1/3 \times 1/2 \\ &= .5 \end{aligned}$$

But if  $P(\text{red}) = .5$  according to all measures in our information state, the model of probabilistic update under consideration—“throw out all measures on which  $P(\text{red}) \neq .5$ ”—will yield the empty information state. If only we didn’t know that the choice of urn was determined by a fair coin toss, we could update with the information that the ball is probably red! The filtering approach to update with probabilistic language does not, it appears, play nicely with the kinds of imprecise credence models that have been given independent motivation in the philosophical and statistical literature.

## 6. Dynamics of probabilistic language: A hierarchical model

Our problem is to explain why, in the urn model just given, update with *The ball is probably red* leads to a coherent result—and to one which somehow yields the judgment that  $P(\text{red})$  is precisely  $2/3$ . As in the general discussion of precise vs. imprecise credence models, I suggest that the solution to our problem is to pay closer attention to the hierarchical structure of information states. Consider a causal Bayes net representing this process (Fig. 4). The key thing to observe about this model is that the intuitive update effect of *The ball is probably red* is exactly the same as the intuitive update of *The coin came up heads*. Our goal is to find a way to use the structure of the Bayes net to guarantee that this will be the result, against this informational background. Once this is done, we may be able to define a general update procedure that applies to probabilistic and non-probabilistic language alike.

Figure 4: Causal Bayes net modeling the urn scenario.

A Bayes net defines a way of partitioning the space of possible worlds into increasingly fine-grained cells as a causal process unfolds. The first step in the process is the flip of a coin, which has two possible outcomes with specified probabilities. If we happen to be at a world  $w$  in which the coin came up heads, then an urn is selected. In this model, the urn is  $\mathbf{A}$  with probability 1 in this case. So,  $w$ —and any other heads-world—is also an  $\mathbf{A}$ -world. The red/blue mix of the urn selected in  $w$  is  $10/5$ , and so the probability that the ball selected will be red is  $2/3$ . The

next step is the choice of a ball: at any  $w$ , either the ball chosen is actually red, or it is actually blue. Nevertheless, it is a fact about  $w$  that the probability of a red ball being selected is  $2/3$ , even if the random selection process actually unfolds so that a blue ball is chosen. The Bayes net thus suggests a world-relative probability concept, where probabilities are dissociated from the actual occurrence of events. As long as our observations do not include the ball's color or any downstream effects of this variable, it is true at any such  $w$  that the ball is probably red, because this is a world at which the coin came up heads and the urn selected was A.

My suggestion, then, is to interpret probability statements as involving a kind of world-bound probability, but relativized to a Bayes net  $B$ . (At least probability statements with an “objective” flavor—see caveats below.) Suppose that the statement is *The ball is probably red*. Rather than looking for a global, world-independent parameter  $P$  and checking the value of  $P(\mathbf{red})$  (as in Yalcin 2007, 2012), we look to  $P_w(\mathbf{red})$ , the probability that  $B$  assigns to  $\mathbf{red}$  at world  $w$ . With a world-bound probability concept available, we could then model update with *The ball is probably red* as simple conditionalization, a procedure that works equally for factual statements. Here, update means conditioning on the set of worlds  $w'$  such that  $P_{w'}(\mathbf{red}) > .5$ .

- (5) a.  $\llbracket \text{The ball is probably red} \rrbracket^{B,w} = 1$  iff  $P_w(\mathbf{red}) > .5$ .  
 b.  $P \xrightarrow[\text{update with (5a)}]{} P(\cdot \mid \{w' \mid P_{w'}(\mathbf{red}) > .5\})$ .

If this is to work, the key question is how  $B$  and  $w$  conspire to determine  $P_w$ . Recall from above that the intuitive update resulting from *The ball is probably red* is the same as the update from *Urn A was selected*: both tell us, in effect, that  $P(\mathbf{red}) = 2/3$ . Relative to the Bayes net in Fig. 4, then, the set of worlds in which *The ball is probably red* is true should be the same as the set of worlds in which *Urn A is selected* is true. As a first approximation, we could define  $P_w(\mathbf{red})$ , relative to  $B$ , to be equal to the conditional probability of  $\mathbf{red}$  in  $B$  given the actual value(s) at  $w$  of the immediate parent(s) of the variable of which  $\mathbf{red}$  is a value. Since the only parent of  $\mathbf{color}$  is  $\mathbf{urn}$ , this means that  $P_w(\mathbf{red}) = P(\mathbf{red} \mid \mathbf{urn}_w)$ , where  $\mathbf{urn}_w$  is the actual value of  $\mathbf{urn}$  at  $w$ . If the urn is A in  $w$ , then  $P_w(\mathbf{red}) = 2/3$ . If the urn is B at  $w$ , then  $P_w(\mathbf{red}) = 1/3$ .

If we define  $P_w$  in terms of the structure of a Bayes net in this way, the contextual equivalence of *The ball is probably red* and *Urn A was selected* follows immediately. Relative to the Bayes net in Fig. 4, the set of worlds  $w$  where  $P_w(\mathbf{red}) > .5$  is the same as the set of worlds where  $P(\mathbf{red} \mid \mathbf{urn}) > .5$ , relative to the actual value of  $\mathbf{urn}$  at  $w$ . Relative to this model, the intension of *The ball is probably red*— $\{w \mid P_w(\mathbf{red}) > .5\}$ —is the same as the intension of *The Urn selected is A*. So, of course, conditioning on either has the same update effect.

We can now return to the puzzle around how to update with (3)/(4), *Team A is likely to win*. If we know nothing about these teams beyond general domain knowledge, our information might be represented by the Bayes net in Fig. 2 above. On the present proposal the intension of *Team A is likely to win*, relative to this Bayes net, is  $\{w \mid P_w(\mathbf{winner} = A) > .5\}$ . The parents of  $\mathbf{winner}$  in this model are  $\mathbf{perf}_A$  and  $\mathbf{perf}_B$ . So, by the definition of  $P_w$  offered above, this is the set of worlds  $w$  where the probability of A winning is greater than .5, given the actual values of  $\mathbf{perf}_A$  and  $\mathbf{perf}_B$  at  $w$ . This result is problematic, since it implies that  $P_w(\mathbf{winner})$  should be 1 or 0 at every world. This is because the value of  $\mathbf{winner}$  is a deterministic function of its

parents—**winner** =  $A$  if  $perf_A > perf_B$ , otherwise =  $B$ . My suggestion is that we should look not necessarily to a variable's immediate parents, but to its closest non-deterministic parents.

Final proposal:  $P_w(V = v)$  is equal to the conditional probability of  $A$  given the actual values at  $w$  of  $V$ 's closest non-deterministic ancestors in  $B$ .

On this proposal, the truth-value of *Team A is likely to win* at any  $w$ , relative to this model, is determined by the values of  $\mu_A, \sigma_A, \mu_B$ , and  $\sigma_B$  at  $w$ . These variables represent the facts at  $w$  about the teams' skill and consistency, respectively. Given the assumptions that we made in setting up the Fig. 2 model, *Team A is likely to win* ends up having a sensible update effect: it is equivalent to  $\mu_A > \mu_B$ , i.e., the proposition that Team A is more skilled than Team B. Fig. 5 shows graphically the effect of updating an uninformed prior distribution with this information.

Figure 5: Left: 2-dimensional Gaussian representing an uninformed prior on the teams' skills. Right: posterior after learning that Team A is likely to win.

This proposal is tentative and subject to important caveats: I will mention only two for reasons of space. First, the final proposal might need to be circumscribed so that it applies only when neither  $V$  nor any of its descendants has been observed. After all, if we have observed that  $A$  won, then  $P(\mathbf{winner} = A)$  should be 1. However, note that this observation could not have been made in the scenario under consideration, since the key example was a prediction about a future event which could not in principle have been observed. In general, a complete theory along these lines will need to be more explicit about the role of time—about the way that causal processes unfold in time, about the way that probability estimates change over time in response to new observations, and any interactions between the two. While I do not feel that I have a complete grasp of the complex issues at stake here, it does seem worth noting that it is often unproblematic to assert an explicitly tensed statement of the form  $\phi$  *was likely* and  $\neg\phi$ —e.g., *Team A was likely to win, but they didn't win*. This is striking, since present-tense statements of the form  $\phi$  *is likely*, but  $\neg\phi$  are generally infelicitous (Yalcin, 2007). The difference in the past-tense case seems to be that there are two different times involved: an earlier time at which the “worldly” probability of  $A$  winning was greater than .5, e.g., because  $A$  is a more skilled team; and a later time at which the speaker learned that  $A$  didn't win, despite their advantageous position. So, we should not redefine  $P_w$  such that  $P_w(V = v)$  is always 0 or 1 whenever the value of variable  $V$  has been observed. Instead, we need to explicitly incorporate an element of time:  $P_{(w,t)}(V = v)$  is 0 or 1 if  $V$  has been observed at or before  $t$ . However, I will not attempt it in this

space to working out the temporal aspect in detail or its connections to Yalcin’s observations about “epistemic contradictions”.

A second caveat is that my proposal may apply only to certain kinds of probability statements. Theoretical and corpus studies have found evidence that what we have called “probabilistic” language is ambiguous between multiple kinds of probability that are ontologically and psychologically distinct (Kahneman and Tversky, 1982). The probability statements that I have analyzed in the second part of this paper seem to relate to a kind of “objective”, “worldly”, or “stochastic” probability, relating to the unfolding of an indeterministic causal process. In contrast, most theorists in the semantic literature on probability expressions have explicitly or implicitly assumed that the subject matter of probabilistic language is *subjective* uncertainty. These positions are not in competition: Ülkümen et al. (2016), in particular, have shown that English has the semantic resources to talk about both kinds of uncertainty. They show that the two kinds of uncertainty are even distinguished lexically to some extent, with items such as *likely* and *chance* favoring stochastic interpretations while *confident*, *certain*, etc. favor subjective interpretations. Lassiter (2017b) gives further corpus evidence for this conclusion, and argues for several more semantically distinct interpretations of probability expressions.

The proposal floated here is most clearly suited to language describing stochastic causal processes, including (but not limited to) many future-oriented uses of probability expressions. I am exploring ways to extend it to clearly subjective uses like that in the corpus example in (6) (Lassiter, 2017b), where there is a clear fact of the matter and information is simply lacking.

- (6) [T]he residential-scale reservoirs ... were likely used around 900 B.C. It’s likely that the systems were lined with a thick, clay “plaster” ...

I am unsure whether this effort will be successful. I believe that it would be also be consistent with the proposal given here to model the update effect of such examples from a different perspective, such as Madsen’s (2015) framework of “multi-agent statistics”.

## 7. Conclusion

Imprecise credence models, which represent uncertainty using sets of probability measures, have a good deal of philosophical and linguistic motivation. However, their scope is more limited than has generally been recognized. Where the formal representation of uncertainty is concerned, imprecise credences may well be useful as a treatment of group belief. However, they encounter severe problems as a representation of individual-level uncertainty, particularly involving learning from a starting point of ignorance. I argued that these problems can be resolved by adopting an explicitly hierarchical perspective on belief states, and that hierarchical models already account for the confidence/ignorance distinction that has been used to motivate imprecise models as a representation of individual-level uncertainty. While I formalized this perspective using causal Bayes nets, there are also other, richer hierarchical models based on probabilistic programming techniques, which will probably be needed in a fuller treatment.

A second puzzle involving the update effects of expressions like  $\phi$  is *likely* and *probably*  $\phi$

seemed initially to point to a formally parallel model, where information states are sets of measures (or something strictly richer). This model may well be sufficient as a common-ground model. However, it fails as a solution to the psychological problem of how agents can/should incorporate such statements into their information states, because it predicts that they should have trivial update effects when probabilities are known. I argued that we may be able to resolve this issue as well by attending to the hierarchical structure of belief states, interpreting at least some probabilistic statements as factual claims about stochastic causal processes rather than expressions of subjective uncertainty. While there is much more to be done to shore up this suggestion, I hope at least to have demonstrated that direct engagement between semantics and pragmatics, formal epistemology, computational cognitive science, and Bayesian statistics has significant potential to generate new concepts and useful theoretical models.

# Quantified indicative conditionals and the relative reading of *most*<sup>1</sup>

Sven LAUER — *University of Konstanz*

Prerna NADATHUR — *Stanford University*

**Abstract.** Kratzer (in press) notes a curious ‘reverse’ reading for certain quantified conditionals with *most*. The existence of this reading is problematic for accounts that aim at compositionally deriving the perceived interpretation of quantified conditionals, especially for those that take *if*-clauses to semantically restrict the domain of nominal quantifiers. We show how the reverse reading can be derived on such a restrictor account, as an instance of the relative reading of *most*. The derivation closely parallels a recent account of the ‘reverse proportional’ reading of *many* (Romero, 2015). Our account is entirely compositional and draws on independently motivated assumptions about the interpretation of *most*.

**Keywords:** conditionals, quantifiers, *most*, superlatives

## 1. Introduction: an old ‘embarrassment’

Conditionals that appear to be embedded under other operators present a difficult testing ground for semantic theories of the natural language conditional. In this paper, we are concerned with quantified indicative conditionals (QICs), which combine an *if*-clause and a nominal quantifier:

- (1) a. Every student passed if she studied hard.
- b. No student failed if she studied hard.

Although (1a) and (1b) are intuitively paraphrases (assuming that failing is not passing), analyses of QICs which simply embed an *if*-conditional under the quantifier have struggled to produce equivalent interpretations for these statements: “The embarrassment had been known for a long time, but nobody dared talk about it. Then Higginbotham (1986) dragged it into the open” (Kratzer, in press), by demonstrating the insufficiency of the classical material conditional analysis of *if* for interpreting the sentences in (1). While  $\supset$  arguably produces acceptable truth conditions for (1a), the interpretation that results for (1b) is not equivalent — and, moreover, is patently inappropriate: (1b) does not entail that all students studied hard.

- (2) a.  $(1a) \equiv \forall[\text{STUDENT}][\text{STUDY-HARD} \supset \text{PASS}]$   
*All students are such that studying hard ensured passing.*
- b.  $(1b) \equiv \neg\exists[\text{STUDENT}][\text{STUDY-HARD} \supset \neg\text{PASS}]$   
 $\equiv \forall[\text{STUDENT}][\text{STUDY-HARD} \& \text{PASS}]$   
*All students are such that they both studied hard and passed.*

This unfortunate result arises from the (now unpopular) identification of the material conditional  $\supset$  with *if*. However, simply embedding the influential ‘restrictor’ conditional of Kratzer

This support is gratefully acknowledged.

(1986) does not fare much better. Kratzer treats *if*-clauses as restricting the domain of a (covert) universal modal quantifier; (3) shows the results of embedding this under nominal quantifiers.

- (3) a.  $(1a) \equiv \forall[\text{STUDENT}][\Box[\text{STUDY-HARD}][\text{PASS}(x)]]$   
*All students are such that studying hard must have resulted in success.*  
 b.  $(1b) \equiv \neg\exists[\text{STUDENT}][\Box[\text{STUDY-HARD}][\neg\text{PASS}]]$   
 $\equiv \forall[\text{STUDENT}][\Diamond[\text{STUDY-HARD}][\text{PASS}]]$   
*All students are such that it is possible that studying hard resulted in success.*

### 1.1. The ‘folkloric’ solution: *if*-clauses restrict nominal quantifiers

One route around this problem questions whether QICs truly comprise embedded structures à la (2)-(3). A suggestion in the spirit of the Lewis-Kratzer conditional comes from von Fintel (1998). He suggests interpreting the *if*-clauses as restricting the nominal quantifiers directly. This yields the truth conditions in (4), which are both intuitively sensible and equivalent.

- (4) a.  $(1a) \equiv \forall[\text{STUDENT} \ \& \ \text{STUDY-HARD}][\text{PASS}]$   
*All students who studied hard passed*  
 b.  $(1b) \equiv \neg\exists[\text{STUDENT} \ \& \ \text{STUDY-HARD}][\neg\text{PASS}]$   
*No student who studied hard did not pass.*

This ‘folkloric’ solution (named by von Fintel and Iatridou, 2002) is challenged by von Fintel and Iatridou (2002), Higginbotham (2003), and Huitink (2009). The main thrust of their objections involves comparisons between QICs and corresponding sentences where the *if*-clause is replaced by a relative clause attached directly to the overt restriction of the quantifier:

- (5) a. Every coin is silver if it is in my pocket.  
 b. Every coin that is in my pocket is silver.

On the account in (4), these two sentences have identical truth conditions: treating the *if*-clause as restricting the quantifier domain should reduce it, functionally, to a restrictive relative clause. However, the sentences are not intuitively equivalent: (5a) suggests a non-accidental or rule-based connection between the location of a coin and its composition, which (5b) does not.

Leslie (2009) defends the restrictor analysis against this objection. She points out that the problematic QICs seem rule-oriented precisely because they appear to involve a generalization over multiple instances. That is, in the same way that (6a), on the standard restrictor account, has truth-conditions which require the specified coin to come up heads across all situations in which it is flipped, (6b) requires the same to hold of all the coins in the relevant domain.

- (6) a. This coin comes up heads if it is flipped.  
*In all accessible worlds in which this coin is flipped, it comes up heads.*  
 b. Every coin comes up heads if it is flipped.  
*In all accessible worlds, all of these coins that are flipped come up heads.*

Leslie points out that a fair coin intuitively falsifies (6b), even if it happens to come up heads in a particular trial or set of trials. Thus, the truth conditions of (6) require quantification over situations, and suggest *modalizing* the restrictor account. On Leslie's proposal, *if*-clauses restrict nominal quantifiers, but, in cases like (6), this occurs below a wide-scope modal. This gives the truth conditions in (7) for our original QIC examples:

- (7) a. (1a)  $\equiv \Box \forall [\text{STUDENT} \ \& \ \text{STUDY-HARD}] [\text{PASS}]$   
*All accessible worlds are such that all students who studied hard passed.*  
 b. (1b)  $\equiv \Box \neg \exists [\text{STUDENT} \ \& \ \text{STUDY-HARD}] [\neg \text{PASS}]$   
*All accessible worlds are such that no students who studied hard did not pass.*

As with von Fintel's (1998) solution, Leslie's *modalized restrictor conditional* provides sensible and equivalent truth conditions for these QICs. Her proposal arguably solves the problem of the contrast between QICs and restrictive relative clauses in cases like (5): the first case necessarily involves a modal quantifier, whereas the second does not.

- (8) a. (5a)  $\equiv \Box \forall [\text{COIN} \ \& \ \text{IN-MY-POCKET}] [\text{SILVER}]$   
*In all accessible worlds, all coins in my pocket are silver.*  
 b. (5b)  $\equiv \forall [\text{COIN} \ \& \ \text{IN-MY-POCKET}] [\text{SILVER}]$   
*In the actual world, all coins in my pocket are silver.*

The 'non-accidental' connection in (5a) on this account emerges from quantification over accessible worlds. On the other hand, (5b) simply describes an actual-world situation.

## 1.2. The road ahead

Against this backdrop, Kratzer (in press) observes a new and surprising reading for certain QICs. In her examples, the conditional consequent appears to enter into the restriction of a nominal quantifier, and the conditional antecedent provides its scope (see Section 2). This seems to provide direct evidence against any kind of restrictor analysis.

This paper defends the restrictor conditional against this challenge. We argue that the key to 'reversed' readings of QICs comes from reverse proportional readings of quantified statements with *many* and *few* (Westerståhl, 1985). Building on Romero (2015), we propose that 'reverse' readings of *most*-QICs are instances of the relative reading of *most*, analyzed as the composition (Hackl, 2009; Romero, 2016) of parametrized MANY and the superlative, focus-sensitive morpheme *-est* (Heim, 1999). When composed with a restrictor analysis of conditionals, this predicts reverse readings for *most*-QICs in precisely the circumstances that Kratzer describes. We argue that our account improves on Kratzer's (in press) in terms of predictive power: reverse readings are predicted only for determiners (e.g., *most*, *many*, *few*) which contain the right focus-sensitive components, but not for other determiners (*every*, *all*, or *no*).

## 2. The reverse reading of *most*-QICs

Kratzer's empirical challenge centers on a previously unobserved reading for certain QICs:

- (9) Most kids asked for calculators if they had to do long divisions. [Kratzer: pp.20-21]
- a. *Vanilla reading*: (standard)  
The majority of kids who had to do long divisions asked for calculators.  
 $| \text{long-division kids} \cap \text{calculator kids} | > | \text{long-division kids} - \text{calculator kids} |$
  - b. *Reverse reading*: (novel)  
The majority of kids who asked for calculators had to do long divisions.  
 $| \text{calculator kids} \cap \text{long-division kids} | > | \text{calculator kids} - \text{long-division kids} |$

Given the standard interpretation (10) for *most*, the vanilla reading of (9) is easily generated. The contents of the *if*-clause appear to enter into the restriction ( $A = \text{KID} \cap \text{DO-LONG-DIV}$ ) of *most*, while the matrix clause provides its nuclear scope ( $B = \text{USE-CALCULATOR}$ ). This produces an interpretation equivalent to (9a).

$$(10) \quad \text{Most}[A][B] := |A \cap B| > |A - B|$$

The reverse reading, on the other hand, is not so neat. Given (10), the matrix clause appears to enter the quantifier's restriction, while the *if*-clause provides its nuclear scope. This is a startling result, and it presents a serious problem for any restrictor analysis of *if*-clauses.

We concur with Kratzer that this new reading exists, and that it only emerges under very particular contextual conditions. (11) gives an appropriate context for reversal. Crucially, the matrix clause is backgrounded, while the *if*-clause provides new, or *focused* information.

- (11) **You:** Did you see kids using calculators when you volunteered in your son's school yesterday? What did they use the calculators for?  
**Me:** *Most kids asked for calculators if they had to do long divisions.* But I am pleased to report that most kids in my son's school do long divisions by hand.

The felicity of the sentence which follows (9) in the dialogue in (11) clearly demonstrates the reality of the reverse reading in this scenario. On the vanilla reading (9a), the final sentence directly contradicts the content of the QIC. On the other hand, if (9) is taken to mean (9b), it is perfectly coherent to continue with the information that the number of children doing long division by hand is greater than the number doing long division by other means.

Reverse readings do not seem to exist without the topic-focus structure illustrated in (11). In support of this point, consider (12), which backgrounds long division instead of calculator use.

- (12) **You:** Did you see kids doing long division when you volunteered in your son's school yesterday? Were they able to do it by hand?  
**Me:** *Most kids asked for calculators if they had to do long divisions.* #But I am pleased to report that most kids in my son's school do long divisions by hand.

Ultimately, the existence of reverse QIC readings in any context presents a serious challenge to restrictor analyses, whether folkloric, modalized, or otherwise. If the contents of an *if*-clause are entered into the restriction of a quantifier, it is not at all clear how they are available to provide its nuclear scope as well. Given the tools to hand, including the quantifier meaning (10) for *most*, it seems that we must give up on the concept of *if* as an operator on quantifier domains if we wish to be able to account for the empirical QIC terrain.

### 3. Kratzer's analysis

#### 3.1. A bomb defused

Based on the arguments mentioned in the introduction, Kratzer's approach to the QIC problem begins from the premise that *if*-clauses do not restrict nominal quantifiers. Instead, she postulates a embedded structure in which a binary conditional operator ( $\triangleright$ ) and its sentential arguments are fully contained in the nuclear scope of the quantifier, as shown in (13).

- (13) a.  $(1a) \equiv \forall[\text{STUDENT}][\text{STUDY-HARD} \triangleright \text{PASS}]$   
 b.  $(1b) \equiv \neg \exists[\text{STUDENT}][\text{STUDY-HARD} \triangleright \neg \text{PASS}]$

Given this structure, Kratzer argues that  $\triangleright$  must support the following set of logical inferences:

- (14) a. **Modus ponens.**  $\phi \triangleright \psi$  and  $\phi$  jointly entail  $\psi$   
 b. **Contraposition.**  $\phi \triangleright \psi$  entails  $\neg \psi \triangleright \neg \phi$   
 c. **Conditional excluded middle.** For all  $\phi, \psi$ : either  $\phi \triangleright \psi$  or  $\phi \triangleright \neg \psi$   
 d. **Weak Boethius' thesis.**  $\phi \triangleright \neg \psi$  entails  $\neg(\phi \triangleright \psi)$

The first two patterns are relatively standard assumptions in the literature on conditionals, although they are not without challenge (see McGee, 1985). (14c) follows from the structural assumption in (13), and the desired equivalence between (1a) and (1b):

- (15)  $\forall x[\phi \triangleright \psi] \equiv \neg \exists x[\phi \triangleright \neg \psi]$  (desired equivalence, cf (1))  
 $\implies \forall x[\phi \triangleright \psi] \equiv \forall x \neg [\phi \triangleright \neg \psi]$  (DeMorgan's law)  
 $\implies \phi \triangleright \psi \equiv \neg [\phi \triangleright \neg \psi]$   
 $\implies \neg [\phi \triangleright \psi] \equiv \phi \triangleright \neg \psi$

(14d) follows from (14c), on the assumption that at most one of  $\phi \triangleright \psi$  or its negation ( $\phi \triangleright \neg \psi$ ) can be true. Given a bivalent logic, these inferences lead to a 'bombshell' for the semantics of conditionals (Pizzi and Williamson, 2005). Any connective  $\triangleright$  which satisfies all of the properties in (14) must be equivalent to the material biconditional:  $\phi \triangleright \psi \equiv \phi \supset \psi \wedge \psi \supset \phi$ !

This result leaves Kratzer in a difficult position, since it is not plausible that natural language *if* ... *then* semantically expresses the material biconditional outside of QICs. The only apparent workaround is to suggest, as Kratzer does, that "some element in the syntactic environment of the embedded conditionals ... obscures their compositional meaning contribution." The particular element she appeals to is pragmatic domain restriction (von Fintel, 1994; Stanley and

Szabó, 2000), associated with the determiner. The argument proceeds as follows.

Kratzer proposes that (past-tense) QICs embed a material conditional. This leaves us with Higginbotham's original problem: (1a) and (1b) are no longer equivalent, and the truth conditions for (1b) (reproduced below) do not reflect its intuitive meaning.

- (16) No student failed if she studied hard.  
 $\neg\exists[\text{STUDENT}][\text{STUDY-HARD} \supset \neg\text{PASS}]$   
*All students both studied hard and passed.*

Now, however, the quantificational determiner comes along with a domain variable. This variable is valued pragmatically, and its value ends up in the quantifier restriction.

- (17)  $\text{No}_D$  student failed if she studied hard.  
 $\neg\exists[\text{STUDENT} \& D][\text{STUDY-HARD} \supset \neg\text{PASS}]$

Kratzer suggests that a natural default for the value of  $D$  is the *if*-clause. Since this is also part of the material conditional, this means that *if*-clauses in 'neutral' QICs perform double duty: as pragmatic restrictors of nominal quantifiers and as antecedents of embedded conditionals.

- (18)  $\text{No}_D$  student failed if she studied hard.  
 $\neg\exists[\text{STUDENT} \& \text{STUDY-HARD}(=D)][\text{STUDY-HARD} \supset \neg\text{PASS}]$

If the conditional antecedent is pragmatically assigned to the domain variable, as in (18), its role in the conditional becomes redundant, and we wind up with the interpretation in (19c). von Fintel (1998)'s folkloric solution, (4), in which the *if*-clause was taken to semantically restrict the quantifier domain. As a result of this, the combination of an embedded conditional with pragmatic domain restriction does indeed produce interpretive equivalence between (1a) and (1b).

- (19) Every $_D$  student passed if she studied hard.  
 a. **Semantic meaning:**  $\forall[\text{STUDENT}][\text{STUDY-HARD} \supset \text{PASS}]$   
 b. **After pragmatic restriction:**  
 $\forall[\text{STUDENT} \& \text{STUDY-HARD}][\text{STUDY-HARD} \supset \text{PASS}]$   
 c. **Equivalent to:**  $\forall[\text{STUDENT} \& \text{STUDY-HARD}][\text{PASS}]$
- (20)  $\text{No}_D$  student failed if she studied hard.  
 a. **Semantic meaning:**  $\neg\exists[\text{STUDENT}][\text{STUDY-HARD} \supset \neg\text{PASS}]$   
 b. **After pragmatic restriction:**  
 $\neg\exists[\text{STUDENT} \& \text{STUDY-HARD}][\text{STUDY-HARD} \supset \neg\text{PASS}]$   
 c. **Equivalent to:**  $\neg\exists[\text{STUDENT} \& \text{STUDY-HARD}][\neg\text{PASS}]$

The semantic meanings in (19a) and (20a) do not reflect the perceived equivalence of (1a) and (1b). This means that the conditional operator  $\supset$  need not satisfy *conditional excluded middle* (14c) and *weak Boethius' thesis* (14d), and Pizzi and Williamson's bombshell does not apply.

### 3.2. Reversal

Reverse readings enter the picture at this point, as evidence of the process of pragmatic domain restriction. In the unmarked case, domain restriction proceeds as above: the antecedent enters into the restriction of the quantifier, and we obtain the vanilla reading for a conditional like (9).

- (21) Most<sub>D</sub> kids asked for calculators if they had to do long divisions.
- Semantic meaning:**  $Most[KID][LONG-DIV \supset CALC]$
  - After pragmatic restriction:**  $Most[KID \& LONG-DIV][LONG-DIV \supset CALC]$
  - Equivalent to:**  $Most[KID \& LONG-DIV][CALC]$
  - Paraphrase:** *Most kids who had to do long divisions used calculators.*

However, since domain restriction occurs pragmatically, it should be possible for something other than the conditional antecedent to value the domain variable *D*. Kratzer suggests that this happens in marked (non-neutral) cases, like the context in (11). Specifically, a reverse reading is predicted if the domain variable picks up the conditional consequent as its value: this situation plausibly occurs when the consequent is backgrounded and the antecedent is focused.

- (22) Most<sub>D</sub> kids asked for calculators if they had to do [long divisions]<sub>F</sub>.
- Semantic meaning:**  $Most[KID][LONG-DIV \supset CALC]$
  - After pragmatic restriction:**  $Most[KID \& CALC][LONG-DIV \supset CALC]$
  - Paraphrase:** *Most kids who used calculators either did not have to do long divisions or used calculators (to do them).*

If *D* is the conditional consequent, the embedded material conditional is not reducible, and we get the interpretation in (22). This is not quite the meaning we are after: note that (22) is satisfied if most of the students who used calculators simply did not have to do long-divisions. To get us to the correct interpretation, on which most of the calculator users did in fact have to do long divisions, Kratzer posits that the conditional operator in this case must be interpreted biconditionally, via an embedded application of *conditional perfection* (Geis and Zwicky, 1971).

- (23) Most<sub>D</sub> kids asked for calculators if they had to do long divisions]<sub>F</sub>.
- Semantic meaning:**  $Most[KID][LONG-DIV \supset CALC]$
  - After pragmatic restriction:**  $Most[KID \& CALC][LONG-DIV \supset CALC]$
  - After embedded perfection:**  $Most[KID \& CALC][LONG-DIV \equiv CALC]$
  - Equivalent to:**  $Most[KID \& CALC][LONG-DIV]$
  - Paraphrase:** *Most kids who used calculators had to do long divisions.*

If perfection turns the embedded conditional into a biconditional, we wind up in a similar position as in (19) and (20). In this case, since it is the consequent that enters the restriction of the quantifier, it is the consequent that is redundant. This results in the interpretation indicated in (23d) and (23e), which effectively reverses the roles of conditional antecedent and consequent as compared to the neutral case in (21).

### 3.3. The consequences

Kratzer's approach represents a rather radical move. The account she presents is ultimately non-compositional: even the accessible vanilla interpretation of QICs like (1a)-(1b) does not result from the simple composition of a conditional with a wide-scope nominal quantifier, but also requires the input of a pragmatic operation which – crucially – can have a different outcome. In addition, the appeal to conditional perfection for the reverse reading is not wholly innocent. For one, it must be applied in an embedded position, which throws into question its widely-accepted status as a pragmatic inference. Moreover, conditional perfection in many cases strengthens a conditional to something weaker than a full biconditional: for instance, *if p, then q* may suggest that *q* is not unconditional, rather than the full converse, *if not p, then not q* (von Fintel, 2001; Franke, 2009). If conditional perfection is to unerringly produce the result required for the derivation in (23), it seems that we will require a new, more direct, mechanism.

Finally, there is a rather more immediate problem with Kratzer's account: it makes incorrect predictions. Concretely, the crucial feature in producing a reverse interpretation for a conditional is the presence of focus within the antecedent; properties of the wide-scope quantifier do not play a role. As a result, reverse readings should exist, given the right context, for QICs with any quantifier, not just with *most*. This is not the case: these readings are unattested with the universal quantifier (24), and do not arise even when the appropriate context is provided (25).<sup>2</sup>

- (24) Every kid asked for a calculator if she had to do long divisions.
- a. **Predicted vanilla reading (attested):**  
All kids who had to do long divisions asked for calculators.
  - b. **Predicted reverse reading (unattested):**  
All kids who asked for calculators were ones who had to do long divisions.
- (25) **You:** Did you see kids using calculators when you volunteered in your son's school yesterday? What did they use the calculators for?  
**Me:** *Every kid asked for a calculator if she had to do long divisions.* #But I am pleased to report that some kids in my son's school do long divisions by hand.

As in (11), a reverse reading of the conditional in (25) would be compatible with the given continuation, but the vanilla reading produces a contradiction. We find only the latter case, against the prediction made by Kratzer's account.

We suggest that it is not an accident that the first attestation of a reverse reading uses the quantifier *most*. Rather, it is because the choice of quantifier plays a role in the availability (and derivation) of these interpretations. Together with the theoretical issues noted above, Kratzer's problematic predictions make holding out for a different analysis of QICs an attractive option. A suitable analysis, we propose, should (i) derive the equivalence of (1a) and (1b) as the outcome of semantic composition. It should also (ii) account for the existence of reverse readings in the contexts described by Kratzer – but it should, crucially, only do this for the quantifiers which actually exhibit these readings.

<sup>2</sup>The two readings are equivalent under *no*, due to the symmetric property of this determiner.

We have already seen that a restrictor analysis can deliver on (i). In the remainder of this paper, we show that it can also deliver on (ii): when the properties that differentiate quantifiers like *most* from those like *every* (and *no*) are taken into account, a restrictor analysis is not only able to produce reverse readings but also improves on Kratzer's predictions in this regard. Crucial inspiration for our account comes from recent work on reverse proportional readings of *many*.

#### 4. The reverse-proportional reading of *many*

Descriptively, we can distinguish at least three meanings for sentences of the form *Many Ps are Qs*. The first two are the *cardinal* reading in (27) and the *proportional* reading in (28).

(26) Many Scandinavians have won the Nobel Prize in literature.

(27) **Cardinal:**  $\text{Many}_{\text{card}}[P][Q] \equiv |P \cap Q| > n$ , where  $n$  is 'large' number.  
The number of Scandinavians NP-lit winners is large.

(28) **Proportional:**  $\text{Many}_{\text{prop}}[P][Q] \equiv \frac{|P \cap Q|}{|P|} > k$ , where  $k$  is a 'large' proportion.  
The ratio of Scandinavian NP-lit winners to all Scandinavians is high.

Westerståhl (1985) points out that, with 14 Scandinavian Nobel winners (as of 1984) and millions of Scandinavians, both these readings likely come out false. And yet, (26) appears to have a reading on which it is true, and this is intuitively so because 14 Scandinavians out of 81 Nobel Prize winners "seems rather (too?) many" (p. 403). But neither (27) nor (28) compares the number of Scandinavian winners ( $|P \cap Q| = 14$ ) to the number of all winners ( $|Q| = 81$ ). We can characterize this 'reverse proportional' reading as in (29).

(29) **Reverse proportional:**  $\text{Many}_{\text{r-prop}}[P][Q] \equiv \frac{|P \cap Q|}{|Q|} > k$ , where  $k$  is a 'large' proportion.  
The ratio of Scandinavian NP-lit winners to all NP-lit winners is high.

Note that the reverse proportional reading is just the proportional reading with the arguments reversed, *i.e.*,  $\text{Many}_{\text{r-prop}}[P][Q] \equiv \text{Many}_{\text{prop}}[Q][P]$ . Just as antecedent and consequent seem to 'switch places' in the reverse readings of *most*-QICs, the nominal complement and the VP seem to 'switch places' in the reverse proportional reading of *many*.

Stipulating (29) as a separate lexical meaning of *many* is undesirable not only on general grounds (Grice's 'modified Occam's razor'), but also because, if (29) were the meaning of a lexicalized determiner, it would violate the *conservativity universal* (Barwise and Cooper, 1981; Keenan and Stavi, 1986). Consequently, several authors have sought to reduce (29) to one of the other recognized readings. Here, we draw on Romero (2015)'s analysis of the reverse proportional reading, as it is the one most readily adapted to our purposes. Romero extends Hackl's (2000, 2009) account of *more* and *most* as the combination of an underlying operator MANY with the comparative *-er* and the superlative *-est*, respectively. Likewise, Romero takes English *many* to decompose into MANY plus the (silent) positive morpheme POS that is also present in the positive form of adjectives (von Stechow, 1984).

Romero also draws on arguments by Schwarz (2010) showing that POS displays a relative/absolute ambiguity, and combines this with Herburger's (1997) observation that the reverse proportional reading is facilitated by stress on the first argument of the determiner. Consequently, she provides a lexical entry for POS that is dependent on a set of alternatives generated by an alternative semantics (Rooth, 1992), much as in Heim (1999)'s analysis of the superlative.

Romero takes the underlying operator MANY to be ambiguous between a cardinal and a proportional reading. Both are 'parameterized determiners' in the sense of Hackl (2000), i.e., they have generalized determiner meanings with an extra (degree) argument.  $MANY_{card}$  simply counts the individuals that jointly satisfy both its non-degree arguments, while  $MANY_{prop}$  computes their proportion. Both of these meanings are conservative for any fixed degree  $d$ .

- (30) a.  $MANY_{card} := \lambda d_n \lambda P_{et} \lambda Q_{et}. |P \cap Q| \geq d$ , where  $n$  is the degree-type.  
 b.  $MANY_{prop} := \lambda d_n \lambda P_{et} \lambda Q_{et}. (|P \cap Q| : |P|) \geq d$

In order to yield a truth-evaluable statement, both these operators must combine with a degree operator like POS (for surface *many*), comparative *-er* (*more*) or superlative *-est* (*most*). POS combines with a property  $P$  of degrees and claims that there is a degree  $d$  of which  $P$  is true and which exceeds the standard of comparison  $\theta$ . Crucially, this standard of comparison is calculated on the basis of a comparison class  $C$  (a set of degree properties):<sup>3</sup>

- (31)  $POS = \lambda C_{nt,t} \lambda P_{nt}. \exists d [P(d) \wedge d > \theta(C)]$   
 where  $\theta$  is a function that maps comparison classes to degrees.<sup>4</sup>

As in Heim (1999)'s analysis of the superlative, the degree morpheme scopes independently and uses focus structure to constrain  $C$ : the comparison class must be a subset of the focus-alternative value of the sister of POS.

With these ingredients, Romero derives the two proportional readings (standard and reverse) from the single lexical entry for  $MANY_{prop}$ , as follows: on both readings, POS moves out of the DP to the sentence level. As is standard for QR in LF-based theories, POS leaves behind a trace (of type  $n$  in this case) that is bound by a lambda abstract created by the movement operation. That is, on both proportional readings, the sentence in (32a) has a logical form like the one sketched in (32b).

- (32) a. Many Scandinavians vacation in the countryside.  
 b.  $[[POS\ C] [1 [t_1 -MANY_{prop} [Scandinavians] [vacation\ in\ countryside]]] \sim C]$

What differs between the two readings is the focus structure of the sentence, which results in

<sup>3</sup>Romero's entry is more complicated because she also aims to decompose *few* into MANY, POS and an antonymizing morpheme LITTLE, à la Heim (2006). To achieve this, Romero uses the analysis from von Stechow (2009), according to which POS claims that its degree property argument is true of all degrees contained in the 'neutral segment' of the scale. This complication is not relevant for our purposes here.

<sup>4</sup>Romero takes the value delivered by  $\theta$  to be dependent on the distribution of values over its comparison class argument, cf. Fernando and Kamp 1996; Schöller and Franke 2015.

different comparison classes. If the focus (or contrastive topic)<sup>5</sup> is outside of the restriction of the quantifier, a regular proportional reading results:

- (33) Many Scandinavians vacation [in the countryside]<sub>F</sub>.
- Logical form:**  

$$[[[\text{POS C}][1[t_1\text{-MANY}_{\text{prop}}[\text{Scandinavians}]][\text{vacation in countryside}_F]]] \sim \text{C}]$$
  - Alternatives:**  

$$[\text{C}] \subseteq \left\{ \begin{array}{l} \lambda d'.d'\text{-MANY}_{\text{prop}}[\text{Scandinavians}][\text{vacation in countryside}], \\ \lambda d'.d'\text{-MANY}_{\text{prop}}[\text{Scandinavians}][\text{vacation at the beach}], \\ \lambda d'.d'\text{-MANY}_{\text{prop}}[\text{Scandinavians}][\text{vacation in the mountains}], \\ \lambda d'.d'\text{-MANY}_{\text{prop}}[\text{Scandinavians}][\text{vacation in urban centers}], \\ \dots \end{array} \right\}$$
  - Truth-conditions:**  

$$\exists d : d\text{-MANY}_{\text{prop}}[\text{Scandinavians}][\text{vacation in countryside}] \& d > \theta([\text{C}])$$
  - Paraphrase:**  
 The proportion of Scandinavians who vacation in the countryside is high compared to the proportion of Scandinavians vacationing in other places.

The reverse proportional reading emerges if the focus/contrastive topic instead occurs within the restrictor of *many*:

- (34) Many [Scandinavians]<sub>F</sub> vacation in the countryside.
- Logical form:**  

$$[[[\text{POS C}][1[t_1\text{-MANY}_{\text{prop}}[\text{Scandinavians}_F]][\text{vacation in countryside}]]] \sim \text{C}]$$
  - Alternatives:**  

$$[\text{C}] \subseteq \left\{ \begin{array}{l} \lambda d'.d'\text{-MANY}_{\text{prop}}[\text{Scandinavians}][\text{vacation in countryside}], \\ \lambda d'.d'\text{-MANY}_{\text{prop}}[\text{Mainland Europeans}][\text{vacation in countryside}], \\ \lambda d'.d'\text{-MANY}_{\text{prop}}[\text{Americans}][\text{vacation in countryside}], \\ \lambda d'.d'\text{-MANY}_{\text{prop}}[\text{East Asians}][\text{vacation in countryside}], \\ \dots \end{array} \right\}$$
  - Truth-conditions:**  

$$\exists d : d\text{-MANY}_{\text{prop}}[\text{Scandinavians}][\text{vacation in countryside}] \& d > \theta([\text{C}])$$
  - Paraphrase:**  
 The proportion of Scandinavians who vacation in the countryside is high compared to the proportion of people from other world regions who vacation in the countryside.

Romero's truth-conditions are not exactly those characterized in (28)–(29). For example, applying the semantics of (29) to (32a) would require that the ratio comparing Scandinavian countryside-vacationers to all countryside-vacationers worldwide is 'high'. (34) instead compares the ratio of Scandinavian countryside-vacationers to Scandinavians against the analogous ratio for other world regions. Romero argues that her truth-conditions are superior.<sup>6</sup>

<sup>5</sup>Romero leaves open whether stress marks focus (as assumed by Herburger 1997) or contrastive topic (as argued by Cohen 2001). We follow her in this regard, but to ease readability we will mark the stressed constituent with **F** rather than **F/CT**.

<sup>6</sup>Cohen (2001) argues that the number of all Scandinavians is relevant to the inverse proportional reading. To this, Romero adds examples showing that the individual alternative ratios must be taken into account. Whether or

## 5. The reverse reading as a relative reading of *most*

### 5.1. Our proposal

In a nutshell, our proposal is that the reverse reading of *most*-QICs arises as an instance of the relative reading of *most/-est*, which is analyzed in the manner of Heim (1999) and Hackl (2009). The only assumption that needs to be added is that the *if*-clause restricts the underlying ‘parameterized determiner.’ With this, the derivation of the reverse reading of *most*-QICs is entirely parallel to Romero’s derivation of the reverse proportional reading of *many*.

(35a) repeats the definition of  $\text{MANY}_{\text{card}}$ . In (35b), we give a Heim (1999)-style meaning for *-est*. Following Romero’s analysis, *-est* moves to the sentence level to gain scope. With focus in the *if*-clause, a restrictor analysis gives us the logical form sketched in (35c).<sup>7</sup>

- (35) a.  $\text{MANY}_{\text{card}} := \lambda d_n \lambda P_{et} \lambda Q_{et}. |P \cap Q| \geq d$   
 b.  $\llbracket -est \rrbracket = \lambda C_{dt,t} \lambda P_{dt}. \exists d [P(d) \ \& \ \forall C \in \mathbf{C} [C \neq P \rightarrow \neg C(d)]]$   
 c. Most students asked for calculators if they had to do [long divisions]<sub>F</sub>.  
**Logical form:**  
 $\llbracket -est \ C \rrbracket [1 [t_1 - \text{MANY}_{\text{card}} [\text{kid} \ \& \ \text{had to do [long division]}]_{\text{F}} [\text{asked for calculator}]]] \sim \mathbf{C}$

Again,  $\mathbf{C}$  is required to be a subset of the focus-semantic value of the LF-sister of *-est*. This leads to a set of alternatives like (36), where *long divisions* contrasts with other problem types.

(36) **Alternatives:**

$$\llbracket \mathbf{C} \rrbracket \subseteq \left\{ \begin{array}{l} \lambda d'. d' - \text{MANY}_{\text{card}} [\text{kid} \ \& \ \text{had-to-do-long-division}] [\text{asked-for-calc}], \\ \lambda d'. d' - \text{MANY}_{\text{card}} [\text{kid} \ \& \ \text{had-to-do-multiplication}] [\text{asked-for-calc}], \\ \lambda d'. d' - \text{MANY}_{\text{card}} [\text{kid} \ \& \ \text{had-to-do-decimals}] [\text{asked-for-calc}], \\ \dots \end{array} \right\}$$

The resulting truth-conditions are spelled out in (37a) and paraphrased in (37b):

- (37) a. **Truth-conditions:**  
 $\exists d : d - \text{MANY}_{\text{card}} [\text{kid} \ \& \ \text{had-to-do-long-division}] [\text{asked-for-calc}]$   
 $\wedge \forall C \in \mathbf{C} :$   
 $C \neq \lambda d'. d' - \text{MANY}_{\text{card}} [\text{kid} \ \& \ \text{had-to-do-long-division}] [\text{asked-for-calc}] \rightarrow \neg C(d)$   
 b. **Paraphrase:**  
 The number of calculator-using kids who had to do long divisions was larger than the number of calculator-using kids doing any other problem type.

not this dependence on ratios needs to be part of the denotation of *many* is subject to debate. For example, Penka (2018) proposes that, semantically, all three readings are derived from a version of  $\text{MANY}_{\text{card}}$ , and that the apparent dependence on ratios in certain examples instead results from the way the function  $\theta$  determines the standard on the basis of the comparison class. For our purposes, we can set this debate aside. We will be using  $\text{MANY}_{\text{card}}$  in our analysis of *most*-QICs, remaining agnostic whether there is, in addition, a  $\text{MANY}_{\text{prop}}$ .

<sup>7</sup>In our LF-sketches, we add the content of the *if*-clause as a conjunct of the restrictor of  $\text{MANY}_{\text{card}}$ . This is done for ease of exposition only, and we do not intend to claim that *if*-clause is actually part of the first argument of the determiner. In fact, there are good reasons to think that any workable restrictor analysis must reject this possibility, as we discuss in Section 5.2 below.

The truth-conditions in (37) importantly differ from the ones in Section 2, repeated in (38):

$$(38) \quad |\text{calculator kids} \cap \text{long-division kids}| > |\text{calculator kids} - \text{long-division kids}|$$

(37) characterizes a true relative reading, which only requires that the set of kids doing long divisions contained the largest group of calculator users. By contrast, (38) requires that more than half of the calculator users were long-divisioners. It is easy to see that the two readings can come apart in a situation where there are more than two problem types, namely if the largest group of calculator users for a given problem type is less than half of all calculator users. We think that the reading we derive is at least as appropriate as the alternative.<sup>8</sup>

This account correctly predicts that the reverse reading is only available when material in the *if*-clause is focused. More importantly, it also correctly predicts that this reading is only available for determiners that are focus-sensitive in the right way, and hence, unlike Kratzer's account, it does not predict the reverse reading for QICs with *every*.<sup>9</sup>

We do predict reverse readings for *many* and *few*, paraphrased in (39) and (40), respectively, on the assumption that these contain a Romero-style parameterized determiner. According to our intuitions, (39) and (40) are true in scenarios which satisfy their putative paraphrases. It is hard, however, to evaluate what this shows, given that with *many* (unlike with *most*), truth-value judgements are dependent on judgements of what counts as a 'high' number or proportion, relative to a comparison class.

(39) Many kids asked for calculators if they had to do [long divisions]<sub>F</sub>.

**Putative 'reverse' reading:**

The number/proportion of calculator users among the long-division kids was high compared to the number/proportion of calculator users doing other problem types.

(40) Few kids asked for calculators if they had to do [long divisions]<sub>F</sub>.

**Putative 'reverse' reading:**

The number/proportion of calculator users among the long-division kids was low compared to the number/proportion of calculator users doing other problem types.

## 5.2. *If*-clauses vs. relative clauses

Any restrictor account has to deal with the fact that QICs are not always equivalent to the analogous sentence where a relative clause replaces the *if*-clause. Our example sentences are a case in point: (41) has the vanilla reading, but does not have the reverse reading.

<sup>8</sup>Suppose the speaker has visited three classes of 20 children each. Each class did different kinds of problems: long division, logarithm and multiplication. 3 students in the logarithm class and 3 students in the multiplication class asked for calculators, and 8 students in the long division class did. To our ears, (35c) can be true in this situation, but we admit that the intuitions are somewhat subtle.

<sup>9</sup>Hallman (2016) proposes to analyze *all* as a superlative(-like) operator. Depending on the implementation, this analysis potentially predicts the reverse reading for a sentence like *All students asked for calculators if they had to do long divisions*.

- (41) Most kids who had to do long divisions asked for calculators.

The absence of the reverse reading for (41) arguably can be attributed to a constraint that is independently needed (and hence motivated, see Romero 2015, 2016):

- (42) **Constraint:** On a relative reading, the **F**-associate of *-est* cannot be internal to the DP where *-est* originates.

This constraint is active in examples with adjectival superlatives and *the most* (Pancheva and Tomaszewicz 2012):

- (43) John has the best albums by [U2]<sub>F</sub>.  
# ‘John has better albums by U2 than by any other band.’
- (44) John has the most albums by [U2]<sub>F</sub>.  
# ‘John has more albums by U2 than by any other band.’

Pancheva and Tomaszewicz (2012) provide an account of these facts. They also account for the fact that these readings actually are available in languages like Bulgarian and Polish as long as the DP where *-est* originates is not marked as definite. This explanation obviously does not directly translate to English DPs headed by *most* without a definite determiner, but the same constraint is needed for ‘bare’ *most* on any analysis that allows the determiner to have relative readings.<sup>10</sup> Otherwise, such accounts predict the analogue of the ‘reverse proportional’ reading of *many* for (45), contrary to fact:

- (45) Most [Scandinavians]<sub>F</sub> have won the nobel prize in literature.  
# ‘The number/proportion of Scandinavian NP-lit winners is larger than the number/proportion of NP-lit winners from any other world region.’

We want to suggest the following view. Even though in QICs, *if*-clauses restrict the quantifier in subject position, they are not ‘internal to the DP’ in the sense relevant to the constraint in (42), while relative clauses are. Thus, *if*-clauses allow speakers of English to circumvent the constraint and hence are the only environment where reverse readings of *most* can be produced.

Interestingly, as Romero (2016) notes, the putative ambiguity of the underlying parameterized determiner (MANY<sub>card</sub> vs MANY<sub>prop</sub>) is obscured with *most* unless the focus falls within the restriction of the determiner. This means that, in English, QICs are the only known environment where one could test whether there is a MOST<sub>prop</sub> (MANY<sub>prop</sub> + *-est*) in addition to MOST<sub>card</sub> (MANY<sub>card</sub> + *-est*). The crucial kind of scenario is given in (46).

<sup>10</sup>There is documented inter-speaker variation with respect to the acceptability of relative readings with bare *most*. Kotek et al. (2011, 2015) found evidence that only about a third of speakers could access a relative reading (which they dub the ‘superlative reading’). To our knowledge, no speakers perceive a reverse reading for (45).

- (46) In a class of 35 students, 10 had to practice long division, the rest had to practice multiplication problems. 5 of the long division kids asked for calculators, while 7 of the multiplication kids did.

According to our intuitions, Kratzer's example does not seem to have a true reading in this scenario, i.e., there is no evidence for  $\text{MOST}_{\text{prop}}$ . This is in line with what Romero reports for Bulgarian and Polish, where the difference between  $\text{MOST}_{\text{card}}$  and (putative)  $\text{MOST}_{\text{prop}}$  can be tested outside of conditionals as well.

### 5.3. Alternative accounts?

It might be thought that all that is needed to account for reverse readings is the basic idea underlying our analysis, viz., that reverse readings are relative readings. With this, one might think, any analysis of relative readings of *most* and any analysis of QICs can be combined to account for reverse readings. But this is not so: the space of options is actually quite constrained.

Our account is built on a Romero/Hackl-style analysis of *most* which has several salient alternatives that may be preferable on independent grounds. Penka (2018) develops a more parsimonious version of Romero's account, insofar as she dispenses with the need for  $\text{MANY}_{\text{prop}}$  in addition to  $\text{MANY}_{\text{card}}$ . Likewise, Beaver and Coppock (2014) provide an alternative analysis of *(the) most*, which Coppock and Josefson (2014) have argued is better equipped to handle the crosslinguistic variation in the distribution of the different readings of *(the) most*. What both these alternatives share in common is that they analyze *most* not as a 'parameterized determiner', but instead as a noun phrase modifier. As a consequence, it is not immediately obvious that these analyses can be combined with a restrictor analysis of QICs.

The problem is that the sentences in question must contain a quantifier for *if* to restrict. Penka's analysis, in theory, features such an operator, as she assumes that sentences with bare *most* receive their quantificational force from a silent existential determiner  $\emptyset$ . But it is not clear that it is plausible to assume that *if*-clauses restrict  $\emptyset$  in our examples, because quantifiers headed by overt existential determiners generally cannot be restricted by *if*-clauses: *Some students passed if they studied hard* does not have a reading on which it says that there are some students that both studied hard and succeeded. Things are even worse on Beaver and Coppock's account, where there is no quantificational operator in the structure of sentences with definites and indefinites (including *the most*)—instead, these DPs gain quantificational force (or reference) via a type-shifting operation when they are in argument position. As a consequence, it is not clear how a restrictor analysis would combine with their account. This is not to say that either of these accounts could not be made compatible with a restrictor analysis, suitably spelled out. Maybe Penka's  $\emptyset$  is different from overt existentials in a way that allows it to be restricted by *if*-clauses. Likewise, a suitable specification of the syntax-semantics interface could allow *if*-clauses to restrict the output of the type shifting operation in Beaver and Coppock's account.<sup>11</sup> All that we want to note here is that such a combination will not work 'out of the box.'

<sup>11</sup> Alternatively, Beaver and Coppock allow for the possibility that bare *most* is an operator that is not derivationally related to the *most* in *the most*-DPs. This *most* could be a *bona fide* determiner, which *if* could restrict.

Proponents of such alternative accounts may hence be especially interested in alternative accounts of QICs. Unfortunately, such alternatives do not seem workable to us. Let  $\text{MOST}_{\text{rel}}$  be an arbitrary account of relative *most*, and suppose that QICs have a full conditional structure embedded under the quantifier, as in (47):

- (47)  $\text{MOST}_{\text{rel}}$  [kids] [had to do long divisions  $\triangleright$  asked for calculators]

In order to derive the truth conditions we derive,  $\text{MOST}_{\text{rel}}$  has to compare the number of calculator users that had to do long division in relation to the number of calculator users that had to do other problem types. The question is how it can do that on an analysis like (47) without assuming that *if... then* can mean *and* when embedded under a quantifier.

## 6. Conclusion and outlook

We have shown that the reverse reading does not provide an insurmountable challenge for a restrictor analysis of QICs. On the contrary, on a restrictor analysis, the reverse reading emerges rather straightforwardly as an instance of the relative reading of *most*, given a number of independently motivated ingredients. Some open issues remain.

Empirically, it is worth noting that not all speakers can access the reverse reading in *most*-QICs. Even those that can perceive the reading, do so only under favorable circumstances. This is not entirely unexpected on our account, as it has been shown (e.g., Kotek et al., 2015) that only a subset of speakers can access relative readings with bare *most*, and that even for those speakers, this reading is not dominant. Our account of the reverse reading makes a clear prediction that lends itself to experimental testing: The speakers who can access reverse readings of *most*-QICs should be the same ones that perceive relative readings with *most* more generally.

Theoretically, while Leslie's extended restrictor analysis is promising, it remains to be seen whether it can be spelled out in a way that deals with all challenges that have been identified in the literature. An additional question is why the presence of an *if*-clause restricting a nominal quantifier forces the presence of a wide-scope modal. At the same time, the interaction of *if*-clauses, the putative wide-scope modal, and tense deserves closer attention. Kratzer notes that some of the problematic differences between *if*-clauses and relative clauses disappear in the past tense. For example, consider the pair in (48). (48a) appears to quantify not only over actual goofers, but also students who *could* goof off, even though in actuality they do not (Leslie 2009). (48b), by contrast, only makes a claim about students who actually goofed off.

- (48) a. Every student will fail if she goofs off.  
b. Every student failed if she goofed off.

This contrast can arguably be accounted for if the wide-scope modal in Leslie's analysis quantifies over *historical alternatives* at the utterance time (Condoravdi, 2002). This quantification is trivialized in the past-tense, but not in the present and the future. More generally, we conjecture that many, if not all, apparent challenges for a restrictor analysis can be explained by a combination of (i) the presence of a wide-scope modal, (ii) temporal interpretation, and (iii)

the fact that domain restriction proceeds differently with *if*-clauses than with relative clauses. We intend to investigate the details of this idea in future work.

Open issues notwithstanding, we think that the existence of reverse readings (for some speakers) evens the score a bit: As noted in Section 5.3, it is not at all clear that non-restrictor accounts can analyze reverse readings as relative readings. Such accounts consequently face the challenge of how to predict these readings in a way that accounts for their distribution across determiners. As we have shown, restrictor accounts succeed on this front: hence, even skeptics should agree that they deserve another look.

# The number sensitivity of modal indefinites<sup>1</sup>

Jess H. K. LAW — *Rutgers, The State University of New Jersey*

**Abstract.** In this study, I take up the interaction between modal flavor and the number morphology of existential *wh*-indefinites in Mandarin, a phenomenon first discussed in Lin (1998). I argue that there are three essential theoretical pieces to this interaction: (i) types of nominal reference (quantized vs. cumulative), (ii) degrees of modal variation (total vs. partial), and (iii) achieving modal variation by exhaustification. I show that while exhaustifying alternatives contributed by quantized *wh*-indefinites may give rise to either total or partial modal variation, exhaustifying alternatives contributed by cumulative *wh*-indefinites may only give rise to partial modal variation.

**Keywords:** alternatives, exhaustification, modal indefinites, plurality

## 1. Introduction

Indefinites that give rise to modal inferences are called modal indefinites. Well-known examples of modal indefinites include those introduced by determiners like English *any* (Kadmon and Landman 1993, Dayal 1998, Chierchia 2013, a.o.) German *irgendein* (Kratzer and Shimoyama 2002, a.o.) Spanish *algún* (Alonso-Ovalle and Menéndez-Benito 2010) and Romanian *vreun* (Fălăus 2014). Take German *irgendein* indefinites as an example. They give rise to different modal inferences under the scope of epistemic modals and deontic modals (Aloni and Port 2010, Aloni and Franke 2013), as exemplified by (1) and (2) (taken from Aloni and Franke 2013). Specifically, in (1), the *irgendein* indefinite is in the scope of a deontic modal, and it gives rise to an inference that any man can be a marriage option for Mary; by contrast, in (2), the *irgendein* indefinite is in the scope of an epistemic modal, and it leads to an inference that signals speaker ignorance or indifference.

- (1) Mary musste irgendeinen Mann heiraten.  
Mary had-to irgendetw. man marry  
'Mary had to marry a man.'  
↪ Any man was a permitted marriage option for Mary.

- (2) Juan muss in irgendeinem Zimmer im Haus sein.  
Juan must in some room in-the house be  
'Juan must be in some room of the house'  
↪ The speaker does not know or does not care about which room Juan is in.

Aloni and Franke (2013) called the inference in (1) 'total variation inference,' and the inference in (2) 'partial variation inference.' These terms are based on the Modal Variability Hypothesis, which attributes distinct degrees of modal variation to epistemic and deontic modals (see also Aloni and Port 2010). According to Aloni and Franke (ibid), *deontic modals require total*

---

<sup>1</sup>I am indebted to Simon Charlow, Veneeta Dayal and Anthony Gillies for their generous comments on earlier versions of this work. I also thank Lucas Champollion, Yi-Hsun Chen, Mingming Liu and Haoze Li for helpful discussions.

*modal variation, but epistemic modals only require partial modal variation*, where total and partial modal variations are defined below (Aloni and Franke 2013:110): <sup>2</sup>

- (3) a. Total (modal) variation:  $\forall x \diamond \phi(x)$   
 All alternatives in the relevant domain qualify as a possible option.  
 b. Partial (modal) variation:  $\exists x \exists y (\diamond \phi(x) \wedge \diamond \phi(y) \wedge x \neq y)$   
 More than one (but not necessarily all) alternatives in the relevant domain qualify as a possible option.

The inference in (1) clearly follows the definition of total variation. The inference in (2) is identified as partial variation, because it is felicitous in the ‘hide and seek’ scenario described by Alonso-Ovalle and Menéndez-Benito (2010).

- (4) María, Juan, and Pedro are playing hide-and-seek in their country house. Juan is hiding. María and Pedro haven’t started looking for Juan yet. Pedro believes that Juan is not hiding in the garden or in the barn: he is sure that Juan is inside the house. Furthermore, Pedro is sure that Juan is not in the bathroom or in the kitchen. As far as he knows, Juan could be in any of the other rooms in the house.

In the above scenario, Pedro can felicitously utter (2), even though not all the rooms are epistemic possibilities for him—he knows that Juan is not in the bathroom or in the kitchen.

In this paper, I extend this line of research to include modal indefinites in Mandarin. I demonstrate that the distinction in total vs. partial modal variation has a reflex on the number morphology of modal indefinites. Adopting the Alternatives and Exhaustification approach outlined in Chierchia (2013), I show that total modal variation is not compatible with domain alternatives triggered by a modal indefinite that exhibit cumulative reference in the sense of Krifka (1989, 1998). This analysis is able to account for a long standing puzzle in Mandarin, i.e., a modal indefinite must occur with a numeral classifier under the scope of deontic modals (Lin 1998).

This paper is organized as follows. Section 2 introduces the core data and clarifies the correlation between modal flavor and degrees of modal variation. Section 3 provides an account for the interaction, which incorporates plurality into the framework of Alternatives and Exhaustification (Chierchia 2013, Fox 2007, a.o.). Section 4 concludes.

## 2. Modal indefinites in Mandarin

Mandarin makes use of *wh*-phrases, rather than a distinct determiner, to construct modal indefinites (Lin 1998, see also Li 1992). Consider the example in (5). This sentence makes an existential claim, but additionally conveys a modal inference that the speaker does not know

<sup>2</sup>As a terminological note, the term *total (modal) variation* is often taken to be synonymous with *free choice*, while the term *partial (modal) variation* is often simply referred to as *modal variation*, after Alonso-Ovalle and Menéndez-Benito (2010). I take modal variation to be a cover term for both total and partial modal variation in this paper.

which book(s) Zilu read.<sup>3</sup> Due to the modal inference, the speaker of (5) may not identify the book, whether by its name or its physical ostension, as suggested by the infelicity of the ‘namely’ continuation (see also Liao 2011: 8–9). The same infelicity is not shared by an ordinary indefinite, which lacks the modal inference, as shown in (6).

- (5) Zilu **keneng<sub>E</sub>** kan-le *shenme* shu. # Jiushi Halibote.  
 Zilu possibly read-ASP what book namely Harry.Potter  
 ‘Zilu possibly read some book(s), namely *Harry Potter*.’
- (6) Zilu **keneng<sub>E</sub>** kan-le yi-ben shu. Jiushi Halibote.  
 Zilu possibly read-ASP one-CL book namely Harry.Potter  
 ‘Zilu possibly read a book, namely *Harry Potter*’

In addition, Mandarin *wh*-indefinites can also occur within the scope of deontic modals (subscripted with *D*), as exemplified in (7). Intuitively, this sentence conveys that any book in a contextual relevant set can be an option for Zilu.

- (7) Zilu **keyi<sub>D</sub>** du yi-ben *shenme* shu.  
 Zilu can read one-CL what book  
 ‘Zilu can read any book.’

Based on this set of data, Liao (2011) argues that *wh*-indefinites in Mandarin should be taken to be modal indefinites. She proposes an analysis based on Alternatives and Exhaustification (Chierchia 2006, 2013, Fox 2007) to capture the modal variation effect and the fact that modals are required for these *wh*-indefinites to be well-formed.

Mandarin *wh*-indefinites are similar to German *irgendein* indefinites in their interactions with modals with different flavors. Specifically, a *wh*-indefinite under an epistemic modal expresses partial modal variation, but the same indefinite under a deontic modal expresses total modal variation. This contrast is verified by the following contexts.

### Context 1: Total variation

*John and Mary were planning a trip to Europe. John suggested:*

- (8) Women **keyi<sub>D</sub>** qu yi-ge Ouzhoude shenme chengshi.  
 we can go one-CL European what city  
 ‘We can go to an European city (whichever will work).’

*Mary knew that they could only visit an European city where they had a friend to stay with. Since they only had a friend in London and a friend in Berlin, she added:*<sup>4</sup>

<sup>3</sup>Mandarin lacks plural morphology, so depending on the context Zilu could have read one or more books. This property of bare noun phrases is central to the discussion of this paper.

<sup>4</sup>I chose not to narrow down the domain to a single city so that it can be clear that the objection is not to the lack of modal variation, but to how freely one can choose among the cities in Europe.

- (9) Bu dui. Women zhi **keyi<sub>D</sub>** qu Lundun huo Bolin.  
 no right we only can visit London or Berlin.  
 ‘No, we can only go to London or Berlin.’

Mary’s response is felt to be *felicitous* in this context. Under the deontic modal, which requires total modal variation, the sentence in (8) expresses that all the cities in Europe that are in the domain are open options for their visit. This total modal variation inference can be challenged by a denial, as shown in (9).

### Context 2: Partial variation

*John and Mary knew that Peter went on a trip last week, but they did not know where he went. They were talking about where Peter could have gone. John suggested:*

- (10) Ta **keneng<sub>E</sub>** qu-le yi-ge Ouzhoude shenme chengshi.  
 he possibly go-ASP one-CL European what city  
 ‘He could have gone to an European city.’

*Mary knew that Peter stayed with a friend during his trip, and Peter only had two overseas friends, one in London and one in Berlin. So, she added:*

- (11) #Bu dui. Ta zhi **keneng<sub>E</sub>** qu-le Lundun huo Bolin.  
 not right he only possible go-ASP London or Berlin  
 ‘No, he could only have gone to London or Berlin.’

This time, the response is felt to be *infelicitous*. Although modal variation is still perceived with (10), partial modal variation is enough for the epistemic environment. This means that not necessarily all European cities in the domain are taken into consideration. In this case, challenging total modal variation is not felicitous, because no total modal variation inference is generated. I argue that this is the reason why the response is odd.<sup>5</sup>

Although Mandarin *wh*-indefinites have modal variation inferences similar to German *irgendein* indefinites, they show a lesser known and intriguing interaction between the types of licensing modals and numeral classifiers in *wh*-phrases. In particular, as observed by Lin (1998), modal *wh*-indefinites under deontic modals must be accompanied by a numeral classifier (underlined), as evidenced by (12), whereas epistemic modals are compatible with *wh*-phrases

<sup>5</sup>A limitation of this diagnostic is that the contrast fails to hold between deontic and epistemic necessity modals. Using English as an example, we can see that (ib) is way more natural as an objection to (ia) than (iib) is to (iia):

- (i) a. A: John may read a book from the shelf.  
 b. B: No. He may not read *Harry Potter*.  
 (ii) a. A: John must read a book from the shelf.  
 b. B: # No. He may not read *Harry Potter*.

with or without numeral classifiers, as illustrated by the well-formedness of (13).<sup>6</sup> This generalization is true regardless of the modal force.

- (12) Zilu **yao<sub>D</sub>/keyi<sub>D</sub>** kan \*(yi-ben) *shenme* shu.  
 Zilu must/can read one-CL what book  
 ‘Zilu must/can read some book(s) (I don’t care which).’
- (13) Zilu **kending<sub>E</sub>/keneng<sub>E</sub>** kan-le (yi-ben) *shenme* shu.  
 Zilu certainly/possibly read-ASP one-CL what book  
 ‘Zilu possibly read some book(s) (I don’t know which).’

Represented configurationally, the classifier puzzle has the following form:

- (14) a. Epistemic modal ... (NUM-CL) *wh*-phrase  
 b. Deontic modal ... \*(NUM-CL) *wh*-phrase

Combining the terminology used in the literature of bare noun phrases and modal indefinites, I refer to existential *wh*-indefinites without numeral classifiers as ‘bare *wh*-indefinites’. In contrast, I refer to existential *wh*-indefinites with numeral classifiers as ‘non-bare *wh*-indefinites’.

In this paper, I develop an account for the classifier puzzle, couched primarily in the Alternatives and Exhaustification approach (Chierchia 2006, 2013, Liao 2011, a.o.), but incorporates insights from research on nominal reference (Link 1983, Krifka 1989, a.o.). Assuming that *wh*-indefinites are translated as existential quantifiers (Karttunen 1977), I argue that it is possible to tease apart bare and non-bare *wh*-indefinites in terms of their domain restrictions. The former are restricted by nominal predicates which denote sets containing atomic and plural individuals closed under sum formation. Following the classical terminology, we say that this type of predicates exhibit *cumulative reference*. The latter are restricted by nominal predicates whose denotations are not closed under sum formation. These predicates are known to exhibit *quantized reference*. The cumulativity-quantization distinction goes back at least to Link (1983) (who credits Quine 1960 for cumulativity) and is discussed in detail by Krifka (1989). In addition, I adopt an emerging view from the literature of modal variation that epistemic modals and deontic modals have different free choice potentials (see Aloni and Port to appear b, Fălăus 2014). Once this contrast is in place, we can see that *wh*-indefinites under epistemic modals express *partial modal variation*, while those under deontic modals express *total modal variation*.

After incorporating the distinctions between cumulativity vs. quantization and between total vs. partial modal variation, an analysis based on Alternatives and Exhaustification reveals the source of the classifier puzzle. Specifically, deriving total modal variation with a modal indefinite restricted by a cumulative predicate results in a contradictory inference. This contradiction can be avoided in two ways, either by replacing a cumulative predicate (i.e., a bare

<sup>6</sup>Some aspect markers on verbs that are available under epistemic modals are not so under deontic modals. *Le* is such an example. At this stage, it’s not clear to me whether this difference in aspect marking is related to the classifier puzzle.

*wh*-indefinite) with a quantized predicate (i.e., a non-bare *wh*-indefinite), or by lowering the degree of modal variation. The former explains why numeral classifiers can help deontic modals ‘license’ *wh*-indefinites. The latter accounts for the optionality of numeral classifiers with *wh*-indefinites in epistemic modal environments.

### 3. An Alternatives and Exhaustification approach to modal variation

#### 3.1. Key ingredients

My proposal is based on the Alternatives and Exhaustification approach initiated by Chierchia (2006, 2013) and Fox (2007), and especially follows the extension of these studies to Mandarin *wh*-indefinites by Liao (2011). Following these studies, a modal indefinite is taken to be an implicature trigger with a bi-dimensional denotation. An exhaustification operator makes use of this bi-dimensional denotation, giving rise to a modal inference and conditioning the distribution of the modal indefinite.

Concretely, a *wh*-indefinite in the form of *shenme shu* ‘what book’ is an generalized quantifier with a covert quantificational determiner  $\exists$  (cf. Karttunen 1977), as shown in (15a). Following Hamblin (1973) and recent works on Alternative Semantics (e.g., Kratzer and Shimoyama 2002), I take this *wh*-NP to denote a set of alternative individual books. For instance, in a model with two books *a* and *b*, this *wh*-NP denotes the set  $\{a, b\}$ , as illustrated in (15b).

- (15) a.  $[\text{DP } \exists [\text{NP what book}]]$   
 b.  $\llbracket \text{what book} \rrbracket = \{x \mid \text{book}_w(x)\} = \{a, b\}$

Combining the existential operator with the *wh*-NP gives rise to the ordinary denotation of the *wh*-indefinite, which is a generalized existential quantifier, as shown in (16a). In addition, it has a special, focus-like denotation, which is a set of alternatives to the ordinary denotation (16b).

- (16) a.  $\llbracket \text{DP} \rrbracket = \lambda Q. \lambda w. \exists x [x \in \llbracket \text{what book} \rrbracket \wedge Q_w(x)]$   
 b.  $\llbracket \text{DP} \rrbracket^A = \{\lambda Q. \lambda w. \exists x [x \in D' \wedge Q_w(x)] : D' \subset \llbracket \text{what book} \rrbracket \wedge D' \neq \emptyset\} \cup \{\lambda Q. \lambda w. \forall x [x \in \llbracket \text{what book} \rrbracket \rightarrow Q_w(x)]\}$

The alternative set consists of two different kinds of alternatives. The first one is *domain alternatives*. They are alternatives constructed from *non-empty proper subsets* of a quantificational domain, as shown in (17a). If the domain contributed by  $\llbracket \text{what book} \rrbracket$  has two atomic books, as suggested by (15b), then the set of domain alternatives has two members, each a proper subset of this domain, as exemplified in (17b).

- (17) a.  $\llbracket \text{DP} \rrbracket^{\text{DA}} = \{\lambda Q. \lambda w. \exists x [x \in D' \wedge Q_w(x)] : D' \subset \llbracket \text{what book} \rrbracket \wedge D' \neq \emptyset\}$   
 b.  $\{D' : D' \subset \{a, b\}\} = \{\{a\}, \{b\}\}$

The second variety is the *scalar alternative*. Following Chierchia (2013), it is determined by replacing existential quantification in the ordinary denotation with universal quantification.<sup>7</sup>

<sup>7</sup>Alonso-Ovalle (2008) has offered a different mechanism for deriving scalar alternatives, which crucially relies

These two types of alternatives have to be operated on by an alternatives-sensitive operator, often abbreviated as  $\mathbb{O}$  (after *only*, or **Exh** (after *exhaustification*)). Based on Chierchia (2013), I offer the following lexical entry for  $\mathbb{O}$ :

- (18) a.  $\llbracket \mathbb{O} S \rrbracket = \lambda w [\llbracket S \rrbracket(w) \wedge \forall q \in \llbracket S \rrbracket^{\text{Exh-Alt}} [q \rightarrow \lambda w' [\llbracket S \rrbracket(w') \subseteq q]]$   
 b.  $\llbracket S \rrbracket^{\text{Exh-Alt}} = \{\mathbb{O}_{\text{IE}}(p) : p \in \llbracket S \rrbracket^{\text{A}}\}$

This is often known as a ‘recursive’ exhaustification operator. When applying to a sentence  $S$ , it first applies pointwise to the set of alternatives of  $S$ , generating a set of pre-exhaustified alternatives, as done in (18b). Note that pre-exhaustification is subject to a condition called ‘Innocent Exclusion’ (Fox 2007, see also Sauerland 2004), which is defined below:

- (19) a.  $\text{IE-ALT}_p = \cap \{X \subseteq \text{ALT} : \text{CONS}(p \wedge \neg \cap X) \wedge \forall q \in \text{ALT} [\text{CONS}(p \wedge \neg \cap X \wedge \neg q) \rightarrow q \in X]\}$ , where  $\text{CONS}(p) = p$  is consistent  
 b.  $\mathbb{O}_{\text{IE}}(p) = p \wedge \forall q \in \text{ALT} [(q \in \text{IE-ALT}_p \wedge p \not\subseteq q) \rightarrow \neg q]$

The role of Innocent Exclusion in pre-exhaustification is to avoid excluding alternatives that may lead to contradictory inferences. Each pre-exhaustified alternative that is not entailed by the assertion is negated, helping to generate a strengthened assertion.<sup>8</sup>

With the mechanism to derive alternatives and the operator that operates on alternatives, this approach derives the ill-formedness of *wh*-indefinites when they are not in the scope of a modal as a logical contradiction. Since explaining the modal requirement is not the primary concern of this paper, I refer the reader to Liao (2011) and Chierchia (2013) for detailed discussions on this point. How modal variation is achieved can be found in Section 3.3.

### 3.2. Pluralities

Since the seminal work of Link (1983), it has been well accepted into the semantic literature that (i) the domain of individuals ( $D_e$ ) consists of both atomic and plural individuals, (ii) plural individuals are sums of atomic individuals or sums of other plural individuals, and (iii)  $D_e$  is closed under sum formation. For example, a domain with three atomic individuals  $a$ ,  $b$ , and  $c$  have the following mereological structure ( $\oplus$  is the sum formation operator; each line represents a partial order):

---

on Alternative Semantics.

<sup>8</sup>Two notes on the exhaustification operator. First, it is based on Chierchia (2013) but differs from it in having the exhaustification of scalar alternatives and the exhaustification of domain alternatives merged, for the purpose of simplification. Second, it differs from Fox’s (2007) exhaustification operator in being able to lead to contradictions. It is worth noting that whether an exhaustification operator with an innocent exclusion component should be contradiction-free is subject to debate. For instance, while Fox (2007) argues for the desirability of a contradiction-free exhaustification operator, Gajewski (2012) and Chierchia (2013) point out a few merits for allowing an exhaustification operator to derive contradictions. For Chierchia (2013), one of these merits is that it explains why modal indefinites have a restricted distribution in many languages: they are illegitimate precisely when contradictory inferences are induced.

Following Link (1983), Schwarzschild (1996) and many others, I assume that noun phrases with distinct number morphologies have different denotations. Take noun phrases in English as an example. A singular count noun like *book* denotes a subset of  $D_e$ , which contains only atomic books. For instance, if  $a$  and  $b$  in  $D_e$  are books, then the denotation of *book* is as shown in (20a). By contrast, a bare plural noun like *books* denotes as its extension a set involving the atomic books **as well as their sums**, as in (20b).

- (20) a.  $\llbracket \text{book} \rrbracket = \{a, b\}$   
 b.  $\llbracket \text{books} \rrbracket = \{a, b, a \oplus b\}$

According to Krifka (1989) (see also Quine 1960, Link 1983), these two types of predicates differ in terms of nominal reference. A predicate has *cumulative reference* iff, when it holds of two distinct individuals, it also holds of their sums (Krifka 1989:78, D12). Obviously, the bare plural *books* has cumulative reference, since the sum of any two books still belongs to the denotation of *books*. On the contrary, a predicate has *quantized reference* iff, when it holds of an individual, it doesn't hold of any proper subparts thereof (Krifka 1989:78, D14). The singular count noun *book* has quantized reference, since the sum of  $a$  and  $b$  is not in the denotation of *book*. Likewise, in English predicates with numerals like *two books* are also quantized (despite being plural), because a collection of two units of *two books* results in *four books*, rather than *two books*.

Chierchia (1998) argues that Mandarin bare nouns, which lack plural morphology, share the same type of denotation with English bare plurals. In other words, the denotation of *shu* 'book' is comparable to that of *books* (see also Yang 2001; Jiang 2012), ignoring the implicature associated with the plural morphology (Krifka 1989, Sauerland 2003). This view, which is rather standard in the current literature, meets the empirical requirement that *shu* may refer to one or more books in Mandarin. Hence, we can conclude that Mandarin bare nouns exhibit cumulative reference. To create quantized predicates, the use of a numeral classifier is needed. In this regard, the function of numeral classifiers is very similar to the function of numerals in English—they both create quantized predicates.<sup>9</sup> It is easy to demonstrate that nouns with numeral classifiers are quantized: the sum of two units of *yi-ben shu* 'one book' is not *yi-ben shu*, but *liang-ben shu* 'two books'.

<sup>9</sup>In the neo-Carlsonian approach, bare nouns are kind terms and numeral classifiers are lexical predicativizers that help bring a kind term to its predicate use (Krifka 1995, Chierchia 1998, Yang 2001). This view is entirely compatible with the cumulativity-quantization distinction defended here, as long as we bring in the type-shifters that are part and parcel in the neo-Carlsonian approach. However, to avoid complicating the semantic composition, I omit the derivation of bare nouns from kind terms to predicates and assume that bare nouns start out as predicates.

I argue that the cumulativity-quantization distinction can be extended to *wh*-indefinites. In particular, bare *wh*-indefinites are cumulative predicates while non-bare *wh*-indefinites are quantized predicates. Recall that a *wh*-phrase provides the quantificational domain for a covert existential quantifier (see Section 3.1). As shown in (21), the existential determiner quantifies over individuals restricted by *books*, which is cumulative. Assume that there are two atomic books, *a* and *b*. The denotation of *shenme shu* ‘what books’ is a set of alternative books closed under sum formation, as illustrated in (21a). The bi-dimensional denotation of the *wh*-indefinite is derived as (21b) and (21c).

- (21) a.  $\llbracket \text{what books} \rrbracket = \{x \mid \text{books}_w(x)\} = \{a, b, a \oplus b\}$   
 b.  $\llbracket \exists \text{ what books} \rrbracket = \lambda Q. \lambda w. \exists x [x \in \llbracket \text{what books} \rrbracket \wedge Q_w(x)]$   
 c.  $\llbracket \exists \text{ what books} \rrbracket^A = \{\lambda Q. \lambda w. \exists x [x \in D' \wedge Q_w(x)] : D' \subset \llbracket \text{what books} \rrbracket\} \cup \{\lambda Q. \lambda w. \forall x [x \in \llbracket \text{what books} \rrbracket \rightarrow Q_w(x)]\}$

After putting the bare *wh*-indefinite in a sentential context, the bi-dimensional meaning in (22) is obtained (the propositional correlates of the individuals are set in boldface). The underlined parts represent the extra contribution of the cumulative nominal predicate after plurality is brought into the picture.

- (22) a.  $\llbracket \text{Zilu read what books} \rrbracket = a \vee \mathbf{b} \vee \mathbf{a \oplus b}$   
 b.  $\llbracket \text{Zilu read what books} \rrbracket^A = \{\mathbf{a \vee b}, \mathbf{a}, \mathbf{b}, \mathbf{a \oplus b}, \mathbf{a \wedge b}\}$

Note that the assertion in (22a) has an additional disjunct, contributed by the plural individual in the domain (21a). Since the domain alternatives are derived from the proper subsets of the domain, the addition of the plural individual to the domain has non-trivial effects on the set of domain alternatives. Specifically, there is a *weakest alternative*, i.e.,  $\mathbf{a \vee b}$ , which is truth-conditionally equivalent to the assertion  $\mathbf{a \vee b \vee a \oplus b}$ . In addition, there is a *strongest alternative*, in this case  $\mathbf{a \oplus b}$ , which is truth-conditionally equivalent to the scalar alternative  $\mathbf{a \wedge b}$ , when lexical distributivity is assumed. Throughout this paper, I assume lexical distributivity and hence the equivalence of the maximal alternative and the scalar alternative. Whenever the maximal alternative is present, I suppress the scalar alternative.

Now, I turn to non-bare *wh*-indefinites, i.e., those with numeral classifiers. Like bare existential *wh*-phrases, a covert determiner  $\exists$  is still posited for this type of expression. The structure of *yi-ben shenme shu* ‘one-CL what books’ is (23).

- (23)  $[_{DP} \exists [_{NP} \text{one-CL what books}]]$

Just like (21a), *shenme shu* ‘what books’ denotes a set of alternative individual books including both atomic and plural individuals. This is repeated in (24a). A numeral classifier serves as a function that can select a subset from a set. The denotation of the numeral classifier under consideration is formulated as in (24b). It takes the set denoted by *what books* as an argument and returns a set whose only members are those in  $\llbracket \text{what books} \rrbracket$  and have one atomic part.<sup>10</sup> As shown in (24c), the denotation of NP essentially *excludes the maximal individual* from

<sup>10</sup>Following the notation in Landman (2004), the function ATOM maps an individual to its atomic parts.

$\llbracket \text{what books} \rrbracket$ , giving rise to a quantized predicate. Finally, the denotation of DP is represented in (24d) and the set of its alternatives is shown in (24e).<sup>11</sup>

- (24) a.  $\llbracket \text{what books} \rrbracket = \{x \mid \text{books}_w(x)\} = \{a, b, a \oplus b\}$   
 b.  $\llbracket \text{one-CL} \rrbracket = \lambda D \{x \mid x \in D \wedge |\text{ATOM}(x)| = 1\}$   
 c.  $\llbracket \text{NP} \rrbracket = \{x \mid x \in \llbracket \text{what books} \rrbracket \wedge |\text{ATOM}(x)| = 1\}$   
 d.  $\llbracket \text{DP} \rrbracket = \lambda Q. \lambda w. \exists x [x \in \llbracket \text{what books} \rrbracket \wedge |\text{ATOM}(x)| = 1 \wedge Q(x)]$   
 e.  $\llbracket \text{DP} \rrbracket^A = \{\lambda Q. \lambda w \exists x [x \in D' \wedge |\text{ATOM}(x)| = 1 \wedge Q_w(x)] : D' \subset \llbracket \text{what books} \rrbracket\} \cup \{\lambda Q. \lambda w \forall x [x \in \llbracket \text{what books} \rrbracket \wedge |\text{ATOM}(x)| = 1 \rightarrow Q_w(x)]\}$

The difference between this example and the case with a bare *wh*-indefinite is most clearly seen in a sentential context. Consider a sentence with a non-bare *wh*-indefinite:

- (25) a.  $\llbracket \text{Zilu read one-CL what books} \rrbracket = a \vee b$   
 b.  $\llbracket \text{Zilu read one-CL what books} \rrbracket^A = \{a, b, a \wedge b\}$

A noticeable difference is that the maximal individual  $a \oplus b$  is no longer part of the ordinary denotation. Relatedly, it is also absent in the set of alternatives.

### 3.3. Deontic modals: contradiction and repairing

This section answers the first part of the classifier puzzle, namely, why deontic modals militate against bare *wh*-indefinites. Consider the following ill-formed sentence:

- (26) \*Zilu **keyi**<sub>D</sub> kan *shenme* shu.  
 Zilu may read what book  
 ‘Zilu may read some book(s) (I don’t care which).’

In the Alternatives and Exhaustification approach, the interaction of epistemic modals and modal indefinites is captured by recursively applying the exhaustification operator  $\odot$  (Fox 2007, Liao 2011, Chierchia 2013). Therefore, the LF structure of (27) can be represented as follows:

- (27) \* $[\text{IP}_4 \odot [\text{IP}_3 \text{ may}_D [\text{IP}_2 [\text{DP} \exists [\text{what books}]]]_1 [\text{IP}_1 \text{ Zilu } [\text{VP read } t_1]]]]]$

The bi-dimensional denotation of IP2 is equivalent to example (22), i.e., (28). Then, the denotation of IP3 incorporates the contribution of the modal ( $[\diamond]$  is a shorthand for a deontic possibility modal), as illustrated in (29).

- (28) a.  $\llbracket \text{IP}_2 \rrbracket = a \vee b \vee a \oplus b$   
 b.  $\llbracket \text{IP}_2 \rrbracket^A = \{a \vee b, a, b, a \oplus b, a \wedge b \wedge a \oplus b\} = \{a, b, a \vee b, a \oplus b\}$

<sup>11</sup>I have ignored the potential scalar alternatives associated with the numeral.

- (29) a.  $\llbracket \text{IP3} \rrbracket = [\diamond](\mathbf{a} \vee \mathbf{b} \vee \mathbf{a} \oplus \mathbf{b})$   
 b.  $\llbracket \text{IP3} \rrbracket^A = \{[\diamond](\mathbf{a} \vee \mathbf{b}), [\diamond]\mathbf{a}, [\diamond]\mathbf{b}, [\diamond](\mathbf{a} \oplus \mathbf{b})\}$

Recall that combining  $\odot$  and IP3 requires the affirmation of the assertion of IP3 and the negation of all the pre-exhaustified alternatives of IP3. The assertion of IP3 is given in (30a) and the set of pre-exhaustified alternatives is given in (30b) and elaborated in (30bi)–(30biv). Note in (30biv) that pre-exhaustifying the maximal alternative returns itself, as this alternative is the strongest member in the set.

- (30) a.  $\llbracket \text{IP3} \rrbracket = [\diamond](\mathbf{a} \vee \mathbf{b} \vee \mathbf{a} \oplus \mathbf{b})$   
 b.  $\llbracket \text{IP3} \rrbracket^{\text{Exh-Alt}} = \{\odot[\diamond](\mathbf{a} \vee \mathbf{b}), \odot[\diamond]\mathbf{a}, \odot[\diamond]\mathbf{b}, \odot[\diamond](\mathbf{a} \oplus \mathbf{b})\}$   
 (i)  $\odot[\diamond](\mathbf{a} \vee \mathbf{b}) = [\diamond](\mathbf{a} \vee \mathbf{b}) \wedge \neg[\diamond]\mathbf{a} \oplus \mathbf{b}$   
 (ii)  $\odot[\diamond]\mathbf{a} = [\diamond]\mathbf{a} \wedge \neg[\diamond]\mathbf{b} \wedge \neg[\diamond]\mathbf{a} \oplus \mathbf{b}$   
 (iii)  $\odot[\diamond]\mathbf{b} = [\diamond]\mathbf{b} \wedge \neg[\diamond]\mathbf{a} \wedge \neg[\diamond]\mathbf{a} \oplus \mathbf{b}$   
 (iv)  $\odot[\diamond]\mathbf{a} \oplus \mathbf{b} = [\diamond]\mathbf{a} \oplus \mathbf{b}$

When  $\odot$  combines with IP3 to give rise to the meaning of IP4, an undesirable inference is generated:

$$(31) \quad \llbracket \text{IP4} \rrbracket = [\diamond](\mathbf{a} \vee \mathbf{b} \vee \mathbf{a} \oplus \mathbf{b}) \wedge \underbrace{[\diamond]\mathbf{a} \rightarrow ([\diamond]\mathbf{b} \vee \mathbf{a} \oplus \mathbf{b})}_{\neg\odot[\diamond]\mathbf{a}} \wedge \underbrace{[\diamond]\mathbf{b} \rightarrow ([\diamond]\mathbf{a} \vee [\diamond]\mathbf{a} \oplus \mathbf{b})}_{\neg\odot[\diamond]\mathbf{b}} \\
\wedge \underbrace{[\diamond](\mathbf{a} \vee \mathbf{b}) \rightarrow [\diamond]\mathbf{a} \oplus \mathbf{b}}_{\neg\odot[\diamond](\mathbf{a} \vee \mathbf{b})} \wedge \underbrace{\neg[\diamond]\mathbf{a} \oplus \mathbf{b}}_{\neg\odot[\diamond]\mathbf{a} \oplus \mathbf{b}}$$

It is undesirable as the combination of the underlined conjuncts, derived from the weakest and the strongest alternative, leads to the following inference, which *contradicts* the assertion:

$$(32) \quad \neg[\diamond]\mathbf{a} \oplus \mathbf{b} \wedge ([\diamond](\mathbf{a} \vee \mathbf{b}) \rightarrow [\diamond]\mathbf{a} \oplus \mathbf{b}) = \neg[\diamond]\mathbf{a} \oplus \mathbf{b} \wedge \neg[\diamond](\mathbf{a} \vee \mathbf{b})$$

The contradiction can be repaired by adding a numeral classifier to the *wh*-phrase. In other words, replacing the bare *wh*-indefinite in (26) with a non-bare one, as shown in (33), can avoid the undesirable result in (32).

- (33) Zilu **keyi**<sub>D</sub> kan yi-ben *shenme* shu.  
 Zilu may read one-CL what book  
 ‘Zilu may read some book (I don’t care which).’

As exemplified in (24), repeated in (34), the denotation of the *wh*-phrase remains unchanged, denoting a set of books closed under sum formation, and the numeral classifier is a subset selection function, applying to the *wh*-denotation and collecting those members with only one atomic part. The resulting denotation (34c) is the set  $\{a, b\}$ , which is not cumulative. After applying the existential closure operator, the bi-dimensional denotation of the DP containing *one-CL what books* is given in (34d) and (34e).

- Now, let us consider the derivation of (33), whose LF is represented in (35).

- After combining DP pointwise with IP1, we can get a bi-dimensional propositional denotation, as in (36a) and (36b). Adding the deontic possibility modal results in (36c) and (36d).

- Recursive exhaustification applies to the IP3, generating and then in turn negating the pre-exhaustified alternatives in (37a), finally deriving the inference in (37b).

- (37) does not result in any contradiction. In addition, it encodes total modal variation, namely, that both **a** and **b** are permitted, as long as they are permitted in different worlds.

This section is devoted to the account of why epistemic modals are compatible with bare *wh*-indefinites as well as non-bare ones. Let us begin with bare *wh*-indefinites. Consider the following sentence, whose LF is given in (39).

- (39)  $[_{IP4} \textcircled{ } [_{IP3} \textbf{possibly} [_{IP2} [_{DP} \exists [\text{what books}]]_1 [_{IP1} \text{Zilu} [_{VP} \text{read } t_1] ] ] ] ]$

(40) Partial (modal) variation:  $\exists x \exists y (\Diamond \phi(x) \wedge \Diamond \phi(y) \wedge x \neq y)$   
 More than one (but not necessarily all) alternatives in the relevant domain qualify as a possible option.

(41) a.  $\llbracket \exists [\text{what books}] \rrbracket^{\text{DA}^{\text{Sing.}}}$   
 $= \{ \lambda Q. \lambda w. \exists x [x \in D' \wedge Q_w(x)] : D' \subset \llbracket \text{what books} \rrbracket \wedge D' \text{ is a singleton set} \}$   
b.  $\llbracket \text{what books} \rrbracket = \{a, b, a \oplus b\}$   
c.  $\{D'\} = \{\{a\}, \{b\}, \{a \oplus b\}\}$

$$(42) \quad \begin{array}{ll} \text{a.} & \llbracket \text{IP2} \rrbracket = \mathbf{a} \vee \mathbf{b} \vee \mathbf{a} \oplus \mathbf{b} \\ \text{b.} & \llbracket \text{IP2} \rrbracket^A = \{\mathbf{a}, \mathbf{b}, \mathbf{a} \oplus \mathbf{b}\} \\ \text{c.} & \llbracket \text{IP3} \rrbracket = \diamond(\mathbf{a} \vee \mathbf{b} \vee \mathbf{a} \oplus \mathbf{b}) \\ \text{d.} & \llbracket \text{IP3} \rrbracket^A = \{\diamond \mathbf{a}, \diamond \mathbf{b}, \diamond \mathbf{a} \oplus \mathbf{b}\} \end{array}$$
$$\begin{aligned}
(43) \quad & \text{a. } \llbracket \text{IP3} \rrbracket^{\text{Ex-Alt}} = \{\odot \diamond \mathbf{a}, \odot \diamond \mathbf{b}\} \\
& \quad \text{Assertion} \quad \text{Scalar implicature} \\
& \text{b. } \llbracket \text{IP4} \rrbracket = \overbrace{(\diamond(\mathbf{a} \vee \mathbf{b} \vee \mathbf{a} \oplus \mathbf{b})) \wedge \neg \diamond(\mathbf{a} \oplus \mathbf{b})}^{\text{Assertion} \quad \text{Scalar implicature}} \wedge \overbrace{\diamond \mathbf{a} \rightarrow (\diamond \mathbf{b} \vee \diamond \mathbf{a} \oplus \mathbf{b}) \wedge \diamond \mathbf{b} \rightarrow (\diamond \mathbf{a} \vee \diamond \mathbf{a} \oplus \mathbf{b})}^{\text{MV implicature}} \\
& \quad \quad \quad \neg \odot_1 \diamond \mathbf{a} \quad \quad \quad \neg \odot_1 \diamond \mathbf{b} \\
& \quad \quad \quad \text{Assertion} \quad \text{Scalar implicature} \quad \text{MV implicature} \\
& \quad \quad \quad = \overbrace{\diamond(\mathbf{a} \vee \mathbf{b} \vee \mathbf{a} \oplus \mathbf{b})}^{\text{Assertion}} \wedge \overbrace{\neg \diamond(\mathbf{a} \oplus \mathbf{b})}^{\text{Scalar implicature}} \wedge \overbrace{\diamond \mathbf{a} \leftrightarrow \diamond \mathbf{b}}^{\text{MV implicature}}
\end{aligned}$$

Proceedings of *Sinn und Bedeutung* 21  
 Edited by Robert Truswell, Chris Cummins, Caroline Heycock, Brian Rabern, and Hannah Rohde

Under the scope of epistemic modals, non-bare *wh*-indefinites do not lead to a contradiction, either. Take as an example the following sentence, whose LF structure is represented as (45).

- (44) Zilu **keneng<sub>E</sub>** kan-le yi-ben *shenme* shu.  
 Zilu possibly read-ASP one-CL what book  
 ‘Zilu possibly read some book. (I don’t know which)’

- (45)  $[IP_4 \odot [IP_3 \text{ possibly } [IP_2 [\text{one-CL what book}]_1 [IP_1 \text{ Zilu}_{VP} \text{ read } t_1]]]]]$

Similar to what we have discussed in the last section, the numeral classifier excludes the maximal individual from the domain given by the *wh*-phrase, as shown by (24) and repeated in (46a). Hence, the denotations of IP2 are derived as (46b) and (46c) (see also (25)).

- (46) a.  $\llbracket \text{one-CL what books} \rrbracket = \{a, b\}$   
 b.  $\llbracket IP_2 \rrbracket = a \vee b$   
 c.  $\llbracket IP_2 \rrbracket^A = \{a, b, a \wedge b\}$

Adding the epistemic modal results in (47), which is the denotation of IP3. Exhaustification makes use of the denotation of IP3 and the set of pre-exhaustified alternatives in (47b).

- (47) a.  $\llbracket IP_3 \rrbracket = \diamond(a \vee b)$   
 b.  $\llbracket IP_3 \rrbracket^{\text{Exh-Alt}} = \{\odot \diamond a, \odot \diamond b, \odot \diamond(a \wedge b)\}$

Finally, exhaustification affirms the assertion of IP3 and negates all the pre-exhaustified alternatives not entailed by the assertion, generating the following inference, which is free of contradiction:

$$(48) \quad \llbracket IP_4 \rrbracket = \overbrace{\diamond(a \vee b)}^{\text{Assertion}} \wedge \underbrace{\overbrace{\neg \diamond(a \wedge b)}^{\text{Scalar implicature}}}_{\neg \odot \diamond(a \wedge b)} \wedge \overbrace{\diamond a \rightarrow \diamond b \wedge \diamond b \rightarrow \diamond a}^{\text{MV implicature}}_{\neg \odot \diamond a \quad \neg \odot \diamond b}$$

#### 4. Conclusion

In this study, I have argued that the interaction between modal flavors and the number morphology of existential *wh*-indefinites in Mandarin should be understood along the lines of Alternatives and Exhaustification, as long as nominal references are allowed to play a role in structuring the domain of alternatives. In particular, total modal variation, facilitated by deontic modals, is shown to be only compatible with existential *wh*-indefinites with quantized reference. This is why numeral classifiers are required in existential *wh*-indefinites in a deontic environment. On the other hand, partial modal variation, allowed by epistemic modals, is shown to be compatible with both existential *wh*-indefinites with quantized reference and cumulative reference, hence explaining why numeral classifiers are optional with existential *wh*-indefinites in an epistemic environment.

# Event-related relative measurement<sup>1</sup>

Haoze LI — *New York University*

**Abstract.** This paper is concerned with relative measurement, which is expressed by percentage nouns and fractions. It has been observed that in some languages a sentence with relative measurement is ambiguous between two readings. I argue that these two readings involve two types of measurement—individual-related measurement and event-related measurement. I also provide a compositional analysis for the ambiguity of relative measurement. My analysis is able to capture many intriguing contrasts between the two readings of relative measurement, including those related to counting recycled individuals, compatibility with verbal affixes, structural distribution and scope.

**Keywords:** Relative measurement, measure function, event-individual pairs, event semantics

## 1. Introduction

One of the important properties of natural language is its capacity to express measurement. There are two kinds of measurement: absolute measurement, which is expressed by words such as *liter* and *inch*, and relative measurement, which is expressed by a class of measure items such as proportional nouns like *percent* and fractions like *thirds*. The former type of measurement has received a lot of attention in the semantic literature, while the latter has not until a series of works by Sauerland and Ahn (Sauerland 2014; Ahn and Sauerland 2015a, b, 2017). Unlike absolute measurement, relative measurement concerns the relation between two amounts. For example, in (1), relative measurement is expressed by the relative measure phrase, which consists of the relative measure item *30%* and the nominal phrase *the locals*. This sentence expresses that the local employees at Lenovo made up 30% of all the locals given in the context.

(1) Lenovo hired [30% of the locals].

Beyond the basic pattern, Ahn and Sauerland notice that English has another relative measurement construction, as exemplified in (2). Structurally, this sentence differs from (1) in not having the partitive *of* and the definite determiner, while semantically, it targets a different quantity relation. What this sentence means is that the local employees at Lenovo made up 30% of all the employees at Lenovo. It can be paraphrased as ‘30% of the people hired by Lenovo were locals.’

(2) Lenovo hired 30% locals.

In some languages, like Mandarin, these two interpretations arise from a single surface structure, as shown in (3).

---

<sup>1</sup>I would like to thank Adina Williams, Anna Szabolcsi, Chris Barker, Dorothy Ahn, Dylan Bumford, Lucas Champollion, Jeff Lin, Jess Law, Qiongpeng Luo, Simon Charlow, Uli Sauerland and Yu’an Yang for their generous comments on various versions of this work. I also thank the audiences at SuB 21. As usual, all inadequacies are mine.

- (3) Lianxiang gu-le 30% de bendiren  
 Lenovo hire-ASP 30% DE locals
- a. ‘Lenovo hired 30% of the locals.’ (NP-internal)  
 $\Rightarrow |\{x : \mathbf{locals}(x) \wedge \mathbf{Lenovo-hired}(x)\}| = 30\% \times |\{y : \mathbf{locals}(y)\}|$
- b. ‘Lenovo hired 30% locals’ (NP-external)  
 $\Rightarrow |\{x : \mathbf{locals}(x) \wedge \mathbf{Lenovo-hired}(x)\}| = 30\% \times |\{y : \mathbf{Lenovo hired}(y)\}|$

Here, *30% de bendiren* ‘30% locals’ is a noun phrase. In reading (3a), the amount of local employees at Lenovo is measured relative to the set of all locals, which is provided by the NP complement. I call it the ‘NP-internal’ reading. In reading (3b), the amount of local employees at Lenovo is measured relative to the set of all the people hired by Lenovo, which is provided by the NP-external material, i.e., *Lianxiang gu-le* ‘Lenovo hired.’ I call it the ‘NP-external’ reading.

Intuitively, the NP-internal reading in (3a) expresses a quantity relation between two sets of locals—the set of locals hired by Lenovo and the set of all locals; whereas the NP-external reading in (3b) expresses a quantity relation between two sets of event participants—the set of theme participants of some hiring events who are locals and the set of all theme participants of some hiring events. Following this intuition, I argue that the NP-internal reading differs from the NP-external reading essentially in their domains of measurement: the former involves measurement of individuals, while the latter involves measurement of event-individual pairs, whose ontological status is considered to be stages of individuals (Barker 1999, 2010). (For example, if John dances twice, he participates in two non-overlapping dancing events  $e_1$  and  $e_2$ . The event-individual pairs  $\langle e_1, \mathbf{John} \rangle$  and  $\langle e_2, \mathbf{John} \rangle$  stand for two stages of John).

This claim is based on the observation that although the two readings seem to measure individuals, only the NP-external reading shows event-related properties (Section 2). I propose that there are two kinds of relative measure heads: one implements measurement on a domain of individuals, while another encodes measurement on a domain of event-individual pairs. These two relative measure heads essentially give rise to the NP-internal reading and the NP-external reading (Section 3). I also show that these two readings can be compositionally derived (Section 3.2). My analysis is able to account for a series of contrasts between the NP-internal reading and the NP-external reading, which involve a structural constraint on the NP-external reading (Section 4), the monotonicity condition of measure functions (Section 5) and scope patterns of relative measure phrases (Section 6). Finally, I compare my analysis with the focus mapping approach to relative measurement proposed by Ahn and Sauerland (Sauerland 2014; Ahn and Sauerland 2015a, b) (Section 7).

## 2. Counting recycled individuals

Let’s consider the following scenario. Town A has a population of 10,000, among which 2,000 are children. In the past quarter, a clinic in the town had 5,000 visits by 2,000 different patients. Among the 5,000 visits there were 1,500 visits by 500 different children. In the quarterly business meeting, if the administrator of the clinic states (4), the statement is inaccurate. Instead, if she states (5), the statement is accurate.

- (4) Women zhe yi jidu shouzhi-le quanzheng 30% de ertong.  
 we this one quarter treat-ASP whole.town 30% DE children  
 ‘We treated 30% of the children in the town this quarter.’ (NP-internal)
- (5) Women zhe yi jidu shouzhi-le 30% de ertong.  
 we this one quarter treat-ASP 30% DE children  
 a. ‘We treated 30% of the children (in the town) this quarter.’ (NP-internal)  
 b. ‘We treated 30% children this quarter.’ (NP-external)

Due to the explicit mentioning of the town, which helps to fix the domain of the children, (4) only has an NP-internal reading. It is clear why (4) is false: the number of children treated in the clinic is 500 but the total child population in the town is 2,000, so 30% is not an accurate proportion to report.

(5) is ambiguous between an NP-internal reading and an NP-external reading. As we know that the NP-internal reading is false, the truth judgment must come from the NP-external reading. However, only under a specific circumstance may the NP-external reading give rise to a true statement—a single individual can be counted more than once if she makes more than one visit. To see this, note that if we merely count the number of child patients (i.e., 500) relative to the number of total patients (i.e., 2,000), we get 25% instead of 30%. However, if we count the number of child visits (i.e., 1,500) relative to the number of total visits (i.e., 5,000), we get 30%. In short, the truth of (5) tells us that the NP-external reading allows counting recycled individuals.

The possibility of counting recycled individuals should remind us of Krifka’s (1990) famous example in (6). This sentence is argued to have two interpretations. The first one is an object-related interpretation and the second one is an event-related interpretation, as paraphrased in (6a) and (6b), respectively. If a certain ship passed through the lock twice, it is counted once in the first reading and twice in the second reading.

- (6) Four thousand ships passed through the lock last night.  
 a. There were 4000 ships such that they passed through the lock. (Object-related)  
 b. There were 4000 events such that in each of them a ship passed through the lock. (Event-related)

Since Krifka (1990), various proposals have been defended to account for the ambiguity of (6), such as Moore (1994), Doetjes and Honcoop (1997) and Barker (1999). These proposals share the core idea that recycled individuals are counted by relation to events. The fact that the NP-external reading allows the counting of recycled individuals suggests that this reading should, too, be event-related.

To see that counting recycled individuals is indeed readily compatible with the NP-external reading of relative measurement and hence is not an artifact of Scenario 1, it is worthwhile to consider more examples:

- (7) Women jiudian qunian jiedai-le 30% de gaoguan.  
 we hotel last.year serve-ASP 30% DE high-ranking.officials  
 a. 'Last year, our hotel served 30% of the high-ranking officials. (NP-internal)  
 b. 'Last year, our hotel served 30% high-ranking officials.' (NP-external)
- (8) Women tushuguan qunian jiechu-le 70% de xiaoshuo.  
 we library last.year lend.out-ASP 70% DE novel  
 a. 'Last year, our library lent out 70% of the novels.' (NP-internal)  
 b. 'Last year, our library lent out 70% novels.' (NP-external)

In these sentences, the identities of the individuals being talked about are irrelevant and easy to ignore in the NP-external reading. In (7), if some high-ranking officials stayed in our hotel twice, each of them could only be counted once in the NP-internal reading, but each of them was counted twice in the NP-external reading. In (8), the same contrast can be observed between the NP-internal reading and the NP-external reading, if some novels were lent out more than once.

### 3. Proposal

In this paper, I propose that relative measurement generally measures the size of one set relative to another, but the members of the sets can be **individual objects** or **event-related stages** of individuals. Measuring individuals yields the NP-internal reading, while measuring event-related stages results in the NP-external reading. Ontologically, an event-related stage can be understood as an instance of an individual object that participates in a specific event (see also Barker 1999, 2010). Following Barker (1999), I model event-related stages as event-individual pairs  $\langle e, x \rangle$  associating an individual  $x$  with an event  $e$ . As a first approximation, the two readings of (9) can be represented as (9a) and (9b).

- (9) Lianxiang gu-le 30% de bendiren.  
 Lenovo hire-ASP 30% DE local
- a. NP-internal:  $|\{x : \text{locals}(x) \wedge \text{Lenovo-hired}(x)\}| = 30\% \times |\{y : \text{locals}(y)\}|$   
 (The individuals  $x$  such that  $x$  are locals and hired by Lenovo made up 30% of the locals)
- b. NP-external:  $|\{\langle e, x \rangle : \text{locals}(x) \wedge \text{Lenovo-hired}(e, x)\}|$   
 $= 30\% \times |\{\langle e', x' \rangle : \text{Lenovo-hired}(e', x')\}|$   
 (The event-related stages  $\langle e, x \rangle$  such that  $x$  are locals and were hired by Lenovo in  $e$  made up 30% of the event-related stages  $\langle e', x' \rangle$  such that  $x'$  were hired by Lenovo in  $e'$ )

In the following subsections, I lay out the formal details of my proposal, showing how the two readings are compositionally derived.

### 3.1. Two relative measure heads

I propose that a relative measure item is decomposed into two parts—a percentage number and a relative measure head (RM). The former simply denotes a number of type *d* and the latter encodes measurement, which can be individual-related or event-related. I define the individual-related RM ( $RM_I$ ) and the event-related RM ( $RM_E$ ) as follows:

$$(10) \quad \llbracket RM_I \rrbracket = \lambda n_d \lambda P_{et} \lambda Q_{et} \cdot \exists x. P(x) \wedge Q(x) \wedge \mathbf{card}(x) = n \times \mathbf{max} \left( \lambda n' \exists x' \left[ \begin{array}{l} P(x') \wedge \\ \mathbf{card}(x') = n' \end{array} \right] \right)$$

$$(11) \quad \llbracket RM_E \rrbracket = \lambda n''_d \lambda P_{et} \lambda T_{\langle e, \langle e, vt \rangle \rangle} \lambda y_e \lambda e''_v. \mathbf{MXT}(e'') \wedge \\ \exists \langle e, x \rangle. e \sqsubseteq e'' \wedge T(e, y, x) \wedge P(x) \wedge \mathbf{card}'_{\lambda z \lambda e''' \cdot T(e''', y, z)}(e, x) = \\ n \times \mathbf{max} \left( \lambda n' \exists \langle e', x' \rangle \left[ \begin{array}{l} e' \sqsubseteq e'' \wedge R(e', y, x') \wedge \\ \mathbf{card}'_{\lambda z \lambda e''' \cdot T(e''', y, z)}(e', x') = n' \end{array} \right] \right)$$

A note on notation: **max** and **MXT** stand for a maximal operator on degrees and a maximal operator on events, respectively. The former takes a set of degrees and returns the biggest element in this set, while the latter applies to maximal events consisting of the sum of all smaller events within a given time interval. They are defined as follows:

$$(12) \quad \begin{array}{ll} \text{a. } \mathbf{max}(D) := \iota n [D(n) \wedge \forall n' [D(n') \rightarrow n' \leq n]] \\ \text{b. } \mathbf{MXT}(e) := \exists t. e = \bigoplus (\lambda e' [\tau(e') \sqsubseteq t]) \end{array} \quad (\text{Krifka 1989})$$

In (10),  $RM_I$  introduces a measure function **card** (cardinality) on the domain of individuals. In this paper, I use the term *measure function* to denote a mapping from a class of entities to a degree scale that preserves an ordering relation, such as “be taller than” or “be heavier than.” Examples of typical measure functions are height, weight, and temperature. Following Krifka (1998), we define **card** as a function mapping individual entities to natural numbers.

In (11),  $RM_E$  introduces a measure function **card'** on the domain of event-individual pairs. In this study, I follow Doetjes and Honcoop's (1997) definition of measure functions on event-individual pairs. Adopting the algebraic semantic approach (Krifka 1989, 1990), Doetjes and Honcoop identify the domain of event-individual pairs as a join semi-lattice on the basis of the join semi-lattice structure of the domain of events. Then, the partial ordering on ordered event-individual pairs can be defined as (13) in terms of the partial ordering of events and the partial ordering of individuals.

$$(13) \quad \begin{array}{ll} \text{a. } \langle e, x \rangle \sqsubseteq \langle e', x' \rangle \leftrightarrow \langle e, x \rangle \oplus \langle e', x' \rangle = \langle e', x' \rangle \\ \text{b. } \langle e, x \rangle \oplus \langle e', x' \rangle = \langle e'', x'' \rangle \leftrightarrow e \oplus e' = e'' \wedge x \oplus x' = x'' \end{array}$$

Based on this algebraic structure, they implement Krifka's (1990) proposal on the measurement of events. The main idea that their implementation relies on is that the measure function **card'** on event-individual pairs can be standardized with respect to its corresponding measure function **card** on individuals. Take children-treating events as an example. If every child is treated once, measuring the  $\langle e, x \rangle$  pairs such that  $x$  is a child and  $x$  is treated in  $e$  yields the same value

as measuring children that are treated. In this case, different children are involved in different events. As a consequence, if there are  $n$  different children, there are the same number of pairs of treating events and children.

However, there is a problem: if some children were treated more than once, the equivalence of the pair measurement and the object measurement does not hold. In this case, the relation on treating children has the aspectual property of iterativity as defined below (Krifka 1989; Doetjes and Honcoop 1997):

- (14) **Definition (Iterativity (ITER))** For any event  $e$ , object  $x$  and relation  $R$ ,  
 $\text{ITER}(e, x, R) \leftrightarrow R(e, x) \wedge \exists e' \exists e'' \exists x' [e' \sqsubseteq e \wedge e'' \sqsubseteq e \wedge e' \neq e'' \wedge x' \sqsubseteq x \wedge R(e', x') \wedge R(e'', x')]$   
 (a relation  $R$  is iterative with respect to an event  $e$  and an object  $x$  just in case there is a part of  $x$  which is involved in different parts of  $e$ , as specified by  $R$ )

It does not mean that standardizing one measure function with respect to another cannot work in this case. On the basis of the fact that every iterative event can be partitioned into non-iterative subevents, Krifka (1990) proposes that an iterative event  $e$  can be correctly counted by dividing  $e$  into non-iterative subevents, applying a measure function on events to each non-iterative subevent, and adding all the values of the non-iterative subevents together. Following the spirit of this proposal, Doetjes and Honcoop define a measure function on  $\langle e, x \rangle$  in terms of its corresponding measure function on objects. Based on their study, I define the measure function on event-individual pairs as (15).

- (15) Let  $\mu$  be a measure function and  $R$  be an event-individual relation. Then the object induced event-individual pair measure function  $\mu'_R$  can be defined as follows:  
 $\mu'_R$  = the event-individual pair measure function  $\mu'$  with the smallest domain such that
- Standardization** For any event  $e$ , individual  $x$  and relation  $R$ ,  
 $[\neg \text{ITER}(e, x, R) \wedge R(e, x)] \rightarrow [\mu'(e, x) = n \leftrightarrow \mu(x) = n]$
  - Generalization** For any events  $e$  and  $e'$ , and any individuals  $x$  and  $x'$ ,  
 $[\neg \langle e, x \rangle \circ \langle e', x' \rangle \wedge \mu'(e, x) = n \wedge \mu'(e', x') = n'] \rightarrow [\mu'(\langle e, x \rangle \oplus \langle e', x' \rangle) = n + n']$   
 Here,  $\circ$  stands for 'overlapping' and  $\langle e, x \rangle \circ \langle e', x' \rangle \leftrightarrow e \circ e' \wedge x \circ x'$

Consider a toy scenario. Three children  $C_1$ ,  $C_2$  and  $C_3$  are involved in three treating events  $e_1$ ,  $e_2$  and  $e_3$ , respectively. Additionally,  $C_1$  is treated a second time, so it is also involved in a fourth treating event  $e_4$ . Therefore, the pair  $\langle e_1 \oplus e_2 \oplus e_3 \oplus e_4, C_1 \oplus C_2 \oplus C_3 \rangle$  is in the relation of children-treating. Standardization can partition the pair into two parts  $\langle e_1 \oplus e_2 \oplus e_3, C_1 \oplus C_2 \oplus C_3 \rangle$  and  $\langle e_4, C_1 \rangle$ . Then, the measure function  $\mu'$  yields the value 3 for  $\langle e_1 \oplus e_2 \oplus e_3, C_1 \oplus C_2 \oplus C_3 \rangle$ , and the value 1 for  $\langle e_4, C_1 \rangle$ . Generalization adds up the two values to 4. The result is as if  $C_1$  is counted twice. Thus,  $\mu'$  provides an explicit way to count recycled individuals described in Section 2.

### 3.2. Composition

Recall example (3) in the first section, repeated here as (16). According to the proposal discussed in the previous section, the relative measure item *30%* consists of a percentage number and a null relative measure head, which can be  $RM_I$  or  $RM_E$ .

- (16) Lianxiang gu-le 30% de bendiren

| <i>gu</i> 'hire'          | $\lambda x \lambda y \lambda e.*\mathbf{hire}(e) \wedge *\mathbf{th}(e) = x \wedge *\mathbf{ag}(e) = y$ | $\langle e, \langle e, \mathbf{vt} \rangle \rangle$                                                                                                 |
| $RM_I$                    | see (10)                                                                                                | $\langle d, \langle \mathbf{et}, \langle \mathbf{et}, t \rangle \rangle \rangle$                                                                    |
| $RM_E$                    | see (11)                                                                                                | $\langle d, \langle \mathbf{et}, \langle \langle e, \langle e, \mathbf{vt} \rangle \rangle, \langle e, \mathbf{vt} \rangle \rangle \rangle \rangle$ |

In event semantics, a transitive verb is assumed to have three arguments—two individual arguments and one event argument (Krifka 1998; Landman 2000). The individual arguments serve as the agent (**ag**) and the theme (**th**) of the event. The event argument is bound by an existential closure operator (EC) at the sentential level. Additionally, I assume that not only plural nouns but also event predicates and thematic roles are closed under sum, which is indicated by the \*-operator (Landman 2000; Kratzer 2007; Champollion 2010).

In Mandarin, the particle *de* is often used as a modification marker, but it can also be used in measurement constructions, as in (17). Its status is not clear in these measurement constructions (Cheng and Sybesma 2009; Li and Rothstein 2012; a.o.). In this paper, I simply assume that the particle *de* is a type-neutral identity function, which passes up the meaning of a constituent that combines with it.

- (17) san-bang de rou                      suoyou de xuesheng  
 three-pound DE meat                      all DE student  
 'three pounds of meat'                      'all of the students'

Let's consider the NP-external reading first. The object relative measure phrase is composed via Functional Application (FA), as illustrated in (18).

$$\begin{aligned}
(18) \quad & \llbracket de \rrbracket(\llbracket RM_E \rrbracket(\llbracket 30\% \rrbracket))(\llbracket locals \rrbracket) \xRightarrow{FA} \\
& \lambda T \lambda y \lambda e'' . \mathbf{MXT}(e'') \wedge \\
& \quad \exists \langle e, x \rangle . e \sqsubseteq e'' \wedge T(e, y, x) \wedge *local(x) \wedge \mathbf{card}'_{\lambda z \lambda e''' . T(e''', y, z)}(e, x) = \\
& \quad 30\% \times \mathbf{max} \left( \lambda n' \exists \langle e', x' \rangle \left[ \begin{array}{l} e' \sqsubseteq e'' \wedge R(e', y, x') \wedge \\ \mathbf{card}'_{\lambda z \lambda e''' . T(e''', y, z)}(e', x') = n' \end{array} \right] \right)
\end{aligned}$$

As a result, the relative measure phrase denotes a function of type  $\langle \langle e, \langle e, vt \rangle \rangle, \langle e, vt \rangle \rangle$ . It maps the set characterized by a transitive verb, i.e., a set of  $\langle e, y, x \rangle$  sequences, to the set characterized by a verb phrase, i.e., a set of  $\langle e, y \rangle$  sequences.

$$\begin{aligned}
(19) \quad a. \quad & \llbracket 30\% RM_E de locals \rrbracket(\llbracket hire \rrbracket) \xRightarrow{FA} \\
& \lambda y \lambda e'' . \mathbf{MXT}(e'') \wedge \exists \langle e, x \rangle . e \sqsubseteq e'' \wedge \\
& \quad \llbracket hire \rrbracket(e, y, x) \wedge *local(x) \wedge \mathbf{card}'_{\lambda z \lambda e''' . \llbracket hire \rrbracket(e''', y, z)}(e, x) = \\
& \quad 30\% \times \mathbf{max} \left( \lambda n' \exists \langle e', x' \rangle \left[ \begin{array}{l} e' \sqsubseteq e'' \wedge \llbracket hire \rrbracket(e', y, x') \wedge \\ \mathbf{card}'_{\lambda z \lambda e''' . \llbracket hire \rrbracket(e''', y, z)}(e', x') = n' \end{array} \right] \right) \\
b. \quad & \llbracket EC \rrbracket(\llbracket hire 30\% RM_E de locals \rrbracket(\llbracket Lenovo \rrbracket)) \xRightarrow{FA} \\
& \exists e'' . \mathbf{MXT}(e'') \wedge \exists \langle e, x \rangle . e \sqsubseteq e'' \wedge \\
& \quad \llbracket hire \rrbracket(e, \mathbf{l}, x) \wedge *local(x) \wedge \mathbf{card}'_{\lambda z \lambda e''' . \llbracket hire \rrbracket(e''', \mathbf{l}, z)}(e, x) = \\
& \quad 30\% \times \mathbf{max} \left( \lambda n' \exists \langle e', x' \rangle \left[ \begin{array}{l} e' \sqsubseteq e'' \wedge \llbracket hire \rrbracket(e', \mathbf{l}, x') \wedge \\ \mathbf{card}'_{\lambda z \lambda e''' . \llbracket hire \rrbracket(e''', \mathbf{l}, z)}(e', x') = n' \end{array} \right] \right)
\end{aligned}$$

(19b) says: there is a maximal event within a specific time interval; the maximal event contains hiring subevents whose agents are Lenovo and whose themes are locals; the measure function  $\mathbf{card}'_{\lambda z \lambda e''' . \llbracket hire \rrbracket(e''', \mathbf{l}, z)}$  applies to the theme participants of these events, which are stages of individuals participating in these hiring events. The result is equal to 30% times the maximal number of the theme participants of the events of Lenovo's hiring.

Turning to the NP-internal reading, the object relative measure phrase in (16) denotes a generalized quantifier of type  $\langle et, t \rangle$ , as illustrated by the following compositional process.

$$\begin{aligned}
(20) \quad & \llbracket de \rrbracket(\llbracket RM_I \rrbracket(\llbracket 30\% \rrbracket))(\llbracket locals \rrbracket) \xRightarrow{FA} \\
& \lambda Q \exists x . *local(x) \wedge Q(x) \wedge \mathbf{card}(x) = 30\% \times \mathbf{max} \left( \lambda n' \exists x' \left[ \begin{array}{l} *local(x') \wedge \\ \mathbf{card}(x') = n' \end{array} \right] \right)
\end{aligned}$$

Hence, we can compose the relative measure phrase with the rest of the sentence by Quantifier Raising, as shown in (21).

$$(21) \quad \llbracket 30\% \text{ RM}_I \text{ de locals} \rrbracket (\lambda x. \llbracket [\text{EC} [\text{Lenovo hire } t_1]] \rrbracket^{g[1/x]}) \stackrel{\text{FA}}{\Rightarrow} \\ \exists x \exists e. * \text{local}(x) \wedge \llbracket \text{hire} \rrbracket(e, \mathbf{l}, x) \wedge \text{card}(x) = 30\% \times \max \left( \lambda n' \exists x' \left[ \begin{array}{l} * \text{local}(x') \wedge \\ \text{card}(x') = n' \end{array} \right] \right)$$

(21) says: there are locals hired by Lenovo; the measure function **card**(*x*) applies to them and the result is equal to 30% times the maximal number of locals.

According to my proposal, the NP-external reading involves the measure function on event-individual pairs. As we have presented in Section 3.1, the measure function counts recycled individuals more than once. By contrast, the NP-internal reading involves the measure function on individuals. Therefore, when an individual participates in an event twice, it can only be counted once. This is the reason for the contrast between the NP-internal reading and the NP-external reading on counting recycled individuals.

In addition to counting recycled individuals, the current analysis can account for more contrasts between the NP-internal reading and the NP-external reading, which are listed below:

- The NP-external reading is only available when a relative measure phrase occupies the object position, but the NP-internal reading is not subject to this constraint;
- When a relative measure phrase has a NP-external reading, the Monotonicity Condition constrains measure functions on event-related domains, whereas when a relative measure phrase has a NP-internal reading, the Monotonicity Condition constrains the individual domain.
- A relative measure phrase with a NP-external reading shows weak island sensitivity. For example, it cannot scope over negation or universal quantifiers. However, a relative measure phrase with a NP-internal reading does not have this property.

The following sections discuss these contrasts and demonstrate how the current analysis captures them.

#### 4. A structural constraint

The first intriguing contrast between the NP-external reading and the NP-internal reading is a structural constraint. Specifically, the NP-external reading may only be observed when a relative measure phrase is used as the object of a transitive verb, but the NP-internal reading is not subject to the same constraint. As shown in (22), a relative measure phrase in the subject position does not give rise to the NP-external reading.

- (22) 30% de kuaguo gongsi gu-le bendiren.  
 30% DE international company hire-ASP locals
- a. ‘30% of the international companies hired locals.’ (NP-internal)
- b. #‘30% of the units that hired locals were international companies.’ (NP-external)

According to my analysis, a relative measure phrase with a NP-external reading has the type  $\langle\langle e, \langle e, vt \rangle \rangle, \langle e, vt \rangle\rangle$ . Following Krifka (1989) and Landman (2000), I assume that the agent and the theme are syntactic arguments of a transitive verb, i.e., a transitive verb has the type  $\langle e, \langle e, vt \rangle \rangle$ . Consequently, a relative measure phrase with a NP-external reading must combine with a transitive verb, instead of an element of type  $\langle e, vt \rangle$ , such as an intransitive verb or a verb phrase. Structurally speaking, therefore, the NP-external reading should only be observed when a relative measure phrase is used as the object of a transitive verb.

The same contrast is observed between objects and PP complements, as exemplified by the following examples.

- (23) Zhengfu [PP *gei bendiren*] *fenpei-le* 50% *de* *gongwu*.  
 government to locals assign-ASP 50% DE public.housing  
 a. ‘The government assigned 50% of the public housing to locals.’ (NP-internal)  
 b. ‘50% of the housing that government assigned to locals is public housing.’  
 (NP-external)
- (24) Zhengfu [PP *gei 50% de bendiren*] *fenpei-le* *gongwu*.  
 government to 50% DE locals assign-ASP public.housing  
 a. ‘The government assigned public housing to 50% of the locals.’ (NP-internal)  
 b. #‘50% of the people that the government assigned public housing to are locals.’  
 (NP-external)

Generally, a preposition is a function taking an individual element of type  $e$  and returning a verb phrase modifier of type  $\langle\langle e, vt \rangle, \langle e, vt \rangle\rangle$ . We may reason that its type is  $\langle e, \langle\langle e, vt \rangle, \langle e, vt \rangle\rangle\rangle$ . Given this type, a relative measure phrase with the NP-external reading cannot combine with a preposition.

It should be noted that the type  $\langle\langle e, \langle e, vt \rangle \rangle, \langle e, vt \rangle\rangle$  is not specific to relative measure phrases. In Mandarin, many event-related modifiers share the same type. For example, it has been a long-standing puzzle that temporal and spatial measure phrases are often used as NP-internal modifiers (Huang 1992), as shown below:

- (25) Libai *chi-le* *yi-ge* *xiaoshi* *de* *pingguo*.  
 Libai eat-ASP one-CL hour DE apple  
 ‘Libai ate apples for an hour.’
- (26) Libai *kai-le* *yibai* *gongli* *de* *che*.  
 Libai drive-ASP one.hundred km DE car  
 ‘Libai drove for 100 km.’

There is no doubt that *yi-ge xiaoshi* ‘one hour’ and *yibai gongli* ‘100 km’ in these examples measure the temporal duration of the apple-eating event and the distance of the driving event, respectively. Their English counterparts are in the form of *for*-adverbials, but they syntactically look like nominal modifiers.

The current proposal on relative measure items with the NP-external reading can be extended to these event-related NP-internal elements. Specifically, they all involve event-related measurement and have a uniform semantic type— $\langle \text{et}, \langle \langle \text{e}, \langle \text{e}, \text{vt} \rangle \rangle, \langle \text{e}, \text{vt} \rangle \rangle \rangle$ . It means that all the NP-internal elements take as arguments an individual predicate and an event-individual relation. The latter enables them to exhibit event-related interpretations. Based on previous studies on temporal and space measure phrases (Moltmann 1991; Krifka 1998; Zwarts 2005; Champollion 2010; a.o.), I suggest the following lexical entries for *yi-ge xiaoshi* ‘one hour’ and *yibai gongli* ‘100 km.’

$$(27) \quad \llbracket \text{one hour} \rrbracket = \lambda P_{\text{et}} \lambda R_{\langle \text{e}, \langle \text{e}, \text{vt} \rangle \rangle} \lambda y \lambda e \exists x. P(x) \wedge R(e, y, x) \wedge \mathbf{hour}'(e) = 1$$

$$(28) \quad \llbracket 100 \text{ km} \rrbracket = \lambda P_{\text{et}} \lambda R_{\langle \text{e}, \langle \text{e}, \text{vt} \rangle \rangle} \lambda y \lambda e \exists x. P(x) \wedge R(e, y, x) \wedge \mathbf{km}'(e) = 100$$

Similar to relative measure items with an external reading, both *one hour* and *100 km* introduce an event-related measure function, i.e.,  $\mathbf{hour}'$  and  $\mathbf{km}'$ . The former is standardized for events by requiring that  $\mathbf{hour}'(e) = \mathbf{hour}(\tau(e))$ , in which the trace function  $\tau$  maps an event to its running time. The latter must apply to motion events denoted by movement predicates like *walk* and *drive*. The measure function  $\mathbf{km}'$  is standardized for movement events by defining that  $\mathbf{km}'(e) = \mathbf{km}(\sigma(e))$ , in which the trace function  $\sigma$  maps a motion event to the path that the event is linked to.

After combining these NP-internal modifiers with the NP complement, the object phrases in (25) and (26) have the same type as the relative measure phrases with the NP-external reading, i.e.,  $\langle \langle \text{e}, \langle \text{e}, \text{vt} \rangle \rangle, \langle \text{e}, \text{vt} \rangle \rangle$ . It is predicted that these object phrases cannot be dislocated as topics. This is borne out, as in (29). In these examples, IP should have the type  $\langle \text{e}, \text{vt} \rangle$ , and hence cannot combine with the topic phrases.

- (29) a. \**Yi-ge xiaoshi de pingguo*, [<sub>IP</sub> *Libai chi-le*].  
           one-CL hour   DE apple       Libai eat-ASP  
           ‘Libai ate apples for a hour.’  
       b. \**Yibai gongli de che*, [<sub>IP</sub> *Libai kai-le*].  
           one.hundred km   DE car       Libai drive-ASP  
           ‘Libai drove for 100 km.’

In addition, these event-related lexical items are not the only ones that can claim the type  $\langle \langle \text{e}, \langle \text{e}, \text{vt} \rangle \rangle, \langle \text{e}, \text{vt} \rangle \rangle$ . Working in an event-free semantics, Szabolcsi (1989, 1992, 2014) essentially suggests that reflexives and bound pronouns also have the same type (minus the event argument). In Keenan’s (2016) theory, quantifiers can be regarded as arity-reducers. They apply to an  $n$ -place function and return an  $(n - 1)$ -place function, and they do so in all their grammatical occurrences. On this view, a relative measure phrase of type  $\langle \langle \text{e}, \langle \text{e}, \text{vt} \rangle \rangle, \langle \text{e}, \text{vt} \rangle \rangle$  is considered a quantifier that applies to a three-place function of type  $\langle \text{e}, \langle \text{e}, \text{vt} \rangle \rangle$  and returns a two-place function of type  $\langle \text{e}, \text{vt} \rangle$ .

## 5. Event maximalization suffixes

Mandarin has some verbal suffixes serving to assert that the events denoted by a verb are realized to the maximal degree. Examples of these suffixes include *wan* and *guang*, which are understood as ‘completely,’ ‘entirely’ or ‘fully’ in English. Consider the following sentences with such a suffix:

- (30) Libai chi-wan/guang-le ershi-ke shuijiao.  
 Libai eat-WAN/GUANG-ASP twenty-CL dumpling  
 ‘Libai completely ate twenty dumplings.’
- (31) Libai chi-wan/guang-le shuijiao.  
 Libai eat-WAN/GUANG-ASP dumpling  
 ‘Libai completely ate the dumplings.’

The uses of *wan/guang* in (31) and (30) are to assert that Libai’s eating of dumplings is realized to the maximal degree (see also Filip 2008). (30) says that twenty dumplings were eaten and none of them was left. In (31), the bare noun *shuijiao* ‘dumplings’ must be understood as a definite noun and refer to the unique and maximal set of dumplings in a given context. The sentence is true if and only if Libai ate all of the dumplings in some time interval. In this paper, I call these suffixes ‘event maximalization suffixes’ (EMS).

Interestingly, the occurrence of an EMS blocks the NP-external reading of a relative measure phrase. Consider (32), in which only the NP-internal reading is available. As a minimal pair to this sentence, (33) shows that the NP-external reading returns when the EMS is removed.

- (32) Libai chi-wan/guang-le yi-duo-ban de shuijiao.  
 Libai eat-WAN/GUANG-ASP one-more-half DE dumplings  
 a. NP-internal: ‘Libai completely ate more than half of the dumplings.’  
 b. #NP-external: ‘More than half of the food that Libai completely ate were dumplings.’
- (33) Libai chi-le yi-duo-ban de shuijiao.  
 Libai eat-ASP one-more-half DE dumplings  
 a. NP-internal: ‘Libai ate more than half of the dumplings.’  
 b. NP-external: ‘More than half of the food that Libai ate were dumplings.’

This contrast would be mysterious if the NP-external reading and the NP-internal reading both involved measurement of individuals. However, if the NP-external reading involves measurement in an event-related domain, its disappearance in (32) is expected. The unavailability of the NP-external reading is due to the requirement of EMSs that event predicates they combine with must be telic.

To my knowledge, there have not been formal studies on this kind of verbal suffixes in Mandarin. Both Moltmann (1997) and Piñón (2005) propose formal analyses for English adverbial *completely*, which can be seen as the semantic counterpart of EMSs. While it is not impossible to formalize EMSs using ingredients from these approaches to fit in the current picture, doing

so adds substantial complexity to the compositional semantics developed so far and would take us too far afield. In this section, I just illustrate the function of EMSs with the help of the picture in (34).

(34) The events of eating dumplings

This picture demonstrates a set of partially ordered events, i.e., the events of eating dumplings. This set is ordered relative to the cardinality of the dumplings being consumed in the context (see Krifka 1989, 1998, Kennedy 2012). All the five events are in the set denoted by the verb phrase *chi shuijiao* ‘eat dumplings,’ but only  $e_5$ , in which all the dumplings were eaten, is in the set denoted by the verb phrase *chi-wan shuijiao* ‘completely eat the dumplings.’ In short, the verb phrase with an EMS denotes an event in which its theme participant must be the sum of all the things affected by the event in some time interval.

Consequently, the domain denoted by the verb phrase with an EMS has a trivial part-whole structure. As illustrated in the figure, only  $e_5$  is in the domain of *chi-wan shuijiao* ‘completely eat the dumplings.’ None of its proper subparts belongs to the same domain. In slightly more formal terms, this means that a verb phrase with an EMS is quantized, and hence, according to Krifka (1989, 1998), telic. (35) shows that such a verb phrase is incompatible with an NP-internal temporal measure phrase, which is the counterpart of English *for*-adverbials (see Section 4). By contrast, a verb phrase with an EMS is compatible with (and in fact required by) an *in*-adverbial, as shown in (36) (see also Xuan 2010).

- (35) Libai chi-(\*wan/guang)-le yi-ge xiaoshi de shuijiao.  
 Libai eat-WAN/GUANG-ASP one-CL hour DE dumpling  
 ‘Libai (\*completely) ate (\*the) dumplings for one hour.’

- (36) Libai yi ge xiaoshi zhilei jiu chi-\*(wan/guang)-le shuijiao.  
 Libai one CL hour within just eat-WAN/GUANG-ASP dumpling  
 ‘Libai \*(completely) ate \*(the) dumplings in one hour.’

According to the literature (Dowty 1979; Krifka 1998; Rothstein 2004; a.o.), a telic predicate can be modified by *in*-adverbials but resists *for*-adverbials. The (in)compatibility of a verb phrase with an EMS is hence a telltale sign about the event structure of the VP denotation.

Returning to relative measurement, the NP-external reading of (32) is blocked by the EMS because event-related measurement is not compatible with telic predicates. In this example, the event domain is characterized by the incremental verb with an EMS, i.e., *chi-wan*. As described before, a verb suffixed by an EMS denotes an event whose theme is maximal with respect to a time interval, and hence it and its sub-parts do not belong to the same domain. In other words, the domain characterized by *chi-wan* has a trivial part-whole structure. Applying a measure function on this domain leads to violation of a general constraint, namely, that the domain must have a non-trivial part-whole structure. This constraint has been repeatedly verified in various measurement constructions, such as pseudopartitives (Schwarzschild 2002, 2006; Champollion 2017), comparatives (Wellwood 2015) and Japanese split measure phrase constructions (Nakanishi 2007).

## 6. Scope and weak islands

Doetjes and Honcoop (1997) argue that quantification over event-individual pairs is sensitive to weak islands in the sense of Szabolcsi and Zwarts (1992). Specifically, event-related interpretations are not available if quantification over event-individual pairs scopes over negation or universal quantifiers. The same pattern is also observed for the NP-external reading of relative measurement.

The NP-external reading and the NP-internal reading of relative measurement show a contrast with respect to scope-taking. When a relative measure phrase has a NP-internal reading, it can take wide or narrow scope relative to negation, as illustrated in (37).

- (37) Lianxiang **meiyou** gu 70% de bendiren.  
 Lenovo not hire 70% DE locals  
 a. 'It is not the case that Lenovo hired 70% of the locals.' (*not* > 70%<sub>internal</sub>)  
 b. '70% of the locals were such that Lenovo didn't hire them.' (70%<sub>internal</sub> > *not*)

By contrast, if a relative measure phrase has a NP-external reading, it cannot take wide scope over negation, as shown in (38).

- (38) Lianxiang **meiyou** gu 70% de bendiren.  
 Lenovo not hire 70% DE locals  
 a. 'It is not the case that 70% of the people hired by Lenovo were locals.' (*not* > 70%<sub>external</sub>)  
 b. #'70% of the people that Lenovo didn't hire were locals.' (70%<sub>external</sub> > *not*)

Similar to negation, universal quantification has to take scope over relative measure phrases in order to preserve the NP-external reading, as exemplified by the following example.

- (39) Mei nian cha shui de shihou, zhengfu dou hui shencha 20% de  
 every year review tax DE time government DOU will audit 20% DE  
 kuaguo gongsi.  
 international company
- a. ‘Every tax year, 20% of the organizations that the government audits are international companies.’  
 (*every* > 20%<sub>external</sub>)
  - b. #‘20% of the units that the government audits every tax year are international companies.’  
 (20%<sub>external</sub> > *every*)
  - c. ‘Every tax year, the government audits 20% of the international companies.’  
 (*every* > 20%<sub>internal</sub>)
  - d. ‘There are 20% of international companies *x* such that the government audits *x* every tax year.’  
 (20%<sub>internal</sub> > *every*)

(39c) and (39d) show that the universal quantifier can take wide scope or narrow scope with respect to the relative measure phrase with the NP-internal reading. However, it cannot take narrow scope when the relative measure phrase has a NP-external reading, as in (39b).

In the literature, there are several formal analyses offered to capture weak island effects. Szabolcsi and Zwarts (1992) propose that weak islands can be understood if we pay attention to the Boolean operations that particular quantificational elements are associated with. For example, universal quantification corresponds to ‘meet,’ existential quantification ‘join’ and negation ‘complementation.’ A sentence is not acceptable if a quantificational element in this sentence needs to perform its corresponding Boolean operation on an algebraic structure for which the operation is not defined. Doetjes and Honcoop (1997) follow this analysis and argue that complementation and meet cannot be performed on the domain of event-individual pairs. They assume that the domain of event-individual pairs constitutes a join semi-lattice (see Section 3.1). This essentially follows from the fact that the domain of events has no bottom element. Consequently, the domain of event-individual pairs does not have a bottom element either. In (38b) and (39b), the negation and the universal quantifier performs complementation and meet on the domain of event-individual pairs. Since there is no bottom element in this domain, complementation and meet are undefined.

Besides the algebraic semantic approach, Honcoop (1998) and Abrusán (2014) propose two other alternative approaches to weak island effects. The former relies on dynamic semantics, while the latter is based on the semantic and pragmatic properties of questions. The current study remains open to these alternative approaches. The crucial point is that the weak island sensitivity of the NP-external reading provides another piece of evidence for my analysis that this reading is event-related.

## 7. A previous approach: Focus mapping

In this section, I compare my analysis with Ahn and Sauerland’s studies on relative measurement (Sauerland 2014; Ahn and Sauerland 2015a, b). Following the Focus Mapping Hypothesis (Herburger 2000; Beaver and Clark 2008; a.o.), they propose that the NP-external reading of

relative measurement is derived by focusing on the NP complement of a relative measure item. For example, in (40), the NP complement is focused.

- (40) Lianxiang gu-le 30% de [bendiren]<sub>F</sub>.  
 Lenovo hire-ASP 30% DE local  
 ‘Lenovo hired 30% [locals]<sub>F</sub>.’ (NP-external)

According to the Focus Mapping Hypothesis, focus determines the structure of a quantificational element: focused materials are mapped onto the scope, while non-focused materials are mapped onto the restriction. Therefore, in (40), the quantificational structure induced by the relative measure item *30%* can simply be represented as follows:

- (41) [30% *x* : **Lenovo-hired**(*x*)] **locals**(*x*)

Although the focus approach is elegant and based on a widely assumed hypothesis, it faces some empirical problems. First, it cannot account for the event-related properties discussed in this paper. Under the focus approach, both the NP-internal reading and the NP-external reading are individual-related. As a result, the contrasts involving counting recycled individuals, the monotonicity constraint and weak island sensitivity cannot be easily captured in this approach.

Second, at least in Mandarin, focus is not required to derive the NP-external reading. Consider the question-answer pair in (42).

- (42) a. Lianxiang qunian gu-le duoshao bendiren?  
 Lenovo last.year hire how.many locals  
 ‘How many locals did Lenovo hire last year?’  
 b. Lianxiang qunian gu-le [30%]<sub>F</sub> de bendiren  
 Lenovo last.year hire-ASP 30% DE locals  
 (i) ‘Last year, Lenovo hired 30% of the locals.’ (NP-internal)  
 (ii) ‘Last year, Lenovo hired 30% locals.’ (NP-external)

In a question-answer pair, the constituent in the answer corresponding to the *wh*-word is the focus (Jackendoff 1972; a.o.). Accordingly, in (42a), *30%* should be the focus since it directly corresponds to the *wh*-word of the preceding question. Its NP complement as a piece of repeated information is not focused. However, (42b) is still ambiguous, i.e., the NP-external reading is available even though the NP complement of a relative measure item does not bear focus.

## 8. Conclusion

This paper takes up relative measurement in Mandarin. It is argued that relative measurement may involve event-related measurement or individual-related measurement. Furthermore, an explicit compositional analysis is offered to derive these two readings. The analysis is shown to account for various contrasts between individual-related relative measurement and event-related relative measurement. My analysis also highlights the similarities in NP-internal elements with an external event-related interpretation.

# Mandarin *dou*: The common core of distributivity, maximality, and EVEN<sup>1</sup>

Mingming LIU — Hunan University

**Abstract.** The paper presents a unified analysis of Mandarin *dou* as an alternative-sensitive (sentential) operator whose semantics equals to Karttunen and Peters (1979)’s EVEN. Different ‘uses’ of *dou* are analyzed by associating *dou* with different types of alternative sets: *even-dou* involves non-entailment-based alternative sets, while distributive-*dou* entailment-based ones.

**Keywords:** distributivity, maximality, *even*, Mandarin *dou*.

## 1. Introduction

Mandarin *dou* is well discussed in the literature (Lee 1986; Cheng 1995; Shyu 1995; Huang 1996; Lin 1998; Hole 2004; Chen 2008; Xiang 2008; Cheng 2009; Dong 2009; Liao 2011; Xiang 2016, a.o.). This very short paper will not examine every claim previously made concerning *dou*. Instead, it starts from a simple *dou* sentence as in (1) and checks it against two influential accounts of *dou*. It then shows that neither treating *dou* as a distributivity operator (Lin 1998; Chen 2008) nor taking it to be a maximality operator (Giannakidou and Cheng 2006; Xiang 2008) captures all aspects of (1). It then proposes that *dou* is an alternative-sensitive operator (cf. Liao 2011; Xiang 2016); specifically, it is EVEN. Different interpretations of a *dou* sentence are explained by associating *dou* with alternative sets of different properties: EVEN-*dou* corresponds to a (propositional) alternative set whose members stand in a likelihood relation, while DISTRIBUTIVE-*dou* corresponds to an alternative set based on entailment.

- (1) San.ge xuesheng dou mai.le shi.ben shu.  
three-CL student DOU buy.ASP ten.CL book  
a. EVEN-*dou*: ‘A group of three students together bought 10 books, which is unlikely.’  
b. DISTRIBUTIVE-*dou*: ‘The three students each bought 10 books.’

Let me introduce the basic facts of *dou* exhibited in (1). (1) is ambiguous between (1a) and (1b) (with stress disambiguating the two).<sup>2</sup> Under (1a), *dou* adds an *even*-flavor and the sentence is interpreted collectively (the collective-cumulative distinction is irrelevant to our discussion), while in (1b) *dou* is *even*-less but triggers a distributive effect (Lin 1998) and a maximality effect (see especially Cheng, 2009: 67), indicated by the *each* and *the* in the gloss respectively.

## 2. Two previous accounts

### 2.1. *Dou* as a distributivity operator

Lin (1998) takes *dou* to be Link (1987)’s distributivity operator, as in (2). Being a predicate

<sup>1</sup>This paper reports some of the results of Liu (2017). I thank the persons acknowledged there, as well as reviewers and participants (Brian Buccola, Martina Faller, Yael Greenberg, Bernard Schwarz, Eytan Zweig) at SuB 21 for helpful discussion and comments. All errors are my own.

<sup>2</sup>Specifically, putting stress on *san* ‘three’ facilitates (1a) while stressing *dou* renders (1b). The paper will leave to another occasion an explanation of this fact at the semantics-prosody interface.

modifier, *dou* turns a mixed predicate such as *bought ten books* into a strictly distributive one, *each bought ten books* in this case.

$$(2) \quad \llbracket dou_{Lin} \rrbracket = \lambda P \lambda X \forall y [y \leq X \wedge Atom(y) \rightarrow P(y)]$$

While (2) straightforwardly explains the *each* in (1b), it fails to capture *dou*'s maximality/definiteness effect in the same environment — the *the* in (1b). Importantly, bare numerals such as *san.ge xuesheng* 'three students' in other contexts are not interpreted as definites in Mandarin. This is already evidenced by (1a) which can be felicitously (and truthfully) uttered in a context where there were more than three students in the context but only three bought books, and the three book-buyers together bought ten books.

## 2.2. *Dou* as a maximality operator

The maximality aspect of *dou* has been emphasized in Xiang (2008) and Cheng (2009), who follow Giannakidou and Cheng (2006) analyzing *dou* as a maximality operator as in (3).

$$(3) \quad \llbracket dou_{G\&C} \rrbracket = \lambda P. \sigma x P(x)^3$$

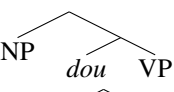

(3) is essentially what Sharvy (1980) and Link (1983) posit for the meaning of the definite article in English. It thus directly captures the maximality/definiteness effect of *dou* in (1b) (with *three* treated as having an adjectival semantics  $\lambda P \lambda X. |X| = 3 \wedge P(X)$ ).<sup>4</sup>

However, remember that (1b) also shows the distributive effect. It only has the distributive reading that the three students each bought ten books; it lacks the collective reading that the three students together bought ten books. This is not captured by treating *dou* as a definite determiner/maximality operator.

In sum, neither the distributivity operator analysis nor the maximality operator analysis captures the behavior of *dou* in (1b). Additionally, neither of the two offers a ready explanation of *dou*'s *even*-flavor in (1a).

<sup>3</sup>Giannakidou and Cheng (2006) and Cheng (2009) use  $\iota$ , while following Link (1983) I use  $\sigma$ . I also ignore intensionality. Finally, Giannakidou and Cheng do not specify the semantics of  $\sigma$  explicitly. I adopt the standard treatment:  $\sigma x. P(x)$  is defined if  $\bigoplus P \in P$ , and if defined  $\sigma x. P(x) = \bigoplus P$ , following Sharvy (1980).

<sup>4</sup>We also need to tamper with the syntax. Instead of having the structure in (ia), which is required by a distributivity operator analysis of *dou* and agrees with *dou*'s adverbial status, we need (ib) to make (3) work (see especially Giannakidou and Cheng 2006: (78)).

- (i) a.   
 b. 

### 3. *Dou* as EVEN

We present a unified analysis of Mandarin *dou* that captures not only its distributive and maximality effects in (1b), but also its *even*-flavor in (1a). The central idea is that *dou* is just EVEN, with the semantics of English *even* proposed in Karttunen and Peters (1979) (cf. Liao 2011: 217). In (4),  $\pi$  stands for the prejacent of *dou*, and  $\llbracket \pi \rrbracket^{Alt}$  its alternative semantic value (Rooth, 1985, 1992), a set of propositions in this case. Notice that I assume for simplicity that *dou* takes sentential scope, which could be achieved either by movement of *dou*, similar to movement of *even* (Wilkinson 1996, Karttunen and Peters 1979, Lahiri 1998, Crnič 2014), or by making *dou* an indicator of a covert *even* that has sentential scope (Liao, 2011: 215). In the latter view, *dou* does not have its own meaning. The paper adopts the movement view as in (5), but nothing crucial hinges on this. Finally, I take it that in (1), *three* is the alternative trigger (evidenced by the prosodic profile of (1a), see footnote 2), and I use  $_F$  to mark it.

- (4)  $\llbracket dou(\pi) \rrbracket$  is defined  
 iff  $\forall q \in \llbracket \pi \rrbracket^{Alt} [\neg(\llbracket \pi \rrbracket = q) \rightarrow \llbracket \pi \rrbracket \prec_{likely} q]$   
 if defined,  $\llbracket dou(\pi) \rrbracket = \llbracket \pi \rrbracket$  (Karttunen and Peters, 1979)  
 In words: *dou* is truth conditionally vacuous but presupposes that its prejacent is the most unlikely proposition among its alternatives (we set aside the additive presupposition of *even*).

Treating *dou* as EVEN naturally accounts for its *even*-flavor in (1a). (6) below is the alternative set I propose for (1a) (with *san.ge xuesheng* ‘three students’ interpreted as standard existentials, hinted by the *there were* ... in (6)). The prejacent indeed seems to be the most unlikely one among its alternatives.

- (6)  $\llbracket \pi_{(1a)} \rrbracket^{Alt} = \left\{ \begin{array}{l} \dots \\ \text{three were 5 students such that they together bought 10 books,} \\ \text{there were 4 students such that they together bought 10 books,} \\ \text{there were 3 students such that they together bought 10 books (= } \pi \text{)} \end{array} \right\}$

Two questions arise at this point. First, why is the proposition *that there were 2 students such that they together bought 10 books*, which presumably is more unlikely than the prejacent, not in (6)? I think the answer has to do with contextual pruning. The same process would explain the felicity of *she even made it to the semi-finals<sub>F</sub>*, even though *that she made it to the finals* is more unlikely (Kay, 1990).

A second question involves the obligatory collective reading of (1a). Why is the distributive reading not allowed with *dou*'s *even*-flavor? The next subsection is devoted to answering this question.

### 3.1. *Even*-less *dou*'s distributive effect

Let me first clarify my assumption about distributive readings. I analyze distributive readings by a covert distributivity operator (7) optionally on VP (Link, 1987).

$$(7) \quad \llbracket Dist \rrbracket = \lambda P \lambda x \forall y [(y \leq x \wedge Atom(y)) \rightarrow P(y)]$$

The existence of a covert distributivity operator in Mandarin Chinese is independently justified by (8a), where *dou* is absent but a distributive reading is possible and strongly preferred for every speaker consulted. In this respect, our judgment agrees with Xiang (2008: 229), but differs from Lin (1998: 201), who claims that (definite) plurals in Mandarin do not have distributive readings, unless *dou*, according to Lin a distributivity operator, is added. However, it seems that Lin did not take context into consideration. For (8a), even Lin himself (personal communication) agrees that a distributive reading is the preferred one. Below, (8b) and (8c) spell out the LF and semantics of (8a).

- (8) a. (Context: I asked who among the kids drew two pictures; you replied:)  
 Zhangsan he Lisi hua le liang fu.  
 Zhangsan and Lisi draw ASP two CL  
 'Zhangsan and Lisi each drew two pictures.'
- b.  $[_{TP} \text{Zhangsan and Lisi } [_{VP} Dist [_{VP} \text{drew two pictures} ]]]$
- c.  $\forall y [(y \leq z \oplus 1 \wedge Atom(y)) \rightarrow \exists X [|X| = 2 \wedge pics(X) \wedge draw(y, X)]]$

With *Dist*, the prejacent of *dou* in (1)/(5) can be interpreted distributively. Specifically, I propose that (9) is the alternative set associated with *dou* in (1b), with *each* representing the distributivity operator *Dist*.

$$(9) \quad \llbracket \pi_{(1b)} \rrbracket^{Alt} = \left\{ \begin{array}{l} \text{there were 3 students such that each bought 10 books } (= \pi), \\ \text{there were 2 students such that each bought 10 books,} \\ \text{there were 1 students such that each bought 10 books,} \end{array} \right\}$$

Note that the propositions in  $\llbracket \pi_{(1b)} \rrbracket^{Alt}$  stand in a very interesting relation: *dou*'s prejacent  $\pi$  logically (asymmetrically) entails all the other alternatives.

We have proposed that *dou* is EVEN, whose semantics requires that the prejacent  $\pi$  be less likely than all  $\pi$ 's alternatives. But entailment is stronger than likelihood: if  $p$  entails  $q$ ,  $p$  is at least as unlikely as  $q$  (Lahiri, 1998; Crnič, 2014). Thus, the EVEN-presupposition of *dou*, which essentially is a requirement on the shape of its alternative set, is weaker than what we

already know about the  $\llbracket \pi_{(1b)} \rrbracket^{Alt}$  and is automatically satisfied.<sup>5</sup> In this case, the *even*-flavor is trivial (cf. Liao 2011).

In other words, when the alternatives all stand in an entailment relation with the prejacent of *dou*, *dou*'s *even* presupposition can be trivialized.<sup>6</sup> Crucially, since the entailment is made possible by the distributive operator (the *each* in (9)), the correlation between *even*-less *dou* and distributive readings is observed. This, I claim, is how *dou*'s *even* meaning could disappear in a distributive context in (1b), and the distributive effect of *even*-less *dou* is explained.

This also explains why (1a) is obligatorily collective. Only by being collective can the alternatives avoid standing in an entailment relation with the prejacent (*that 3 students together bought 10 books* has nothing to do with *that 4 students together bought 10 books*), and consequently likelihood and the *even*-flavor could surface.

### 3.2. *Even*-less *dou*'s maximality effect

The maximality/definiteness effect of *dou* also follows from our proposal. To illustrate, consider contexts where there are exactly three students. In such contexts, any alternative of the form *there were n students such that each bought 10 books* with  $n > 3$  won't be included in the actual alternative set. This is because it does not make sense to consider a proposition like *that there were 4 students such that each bought 10 books* if we already know there could only be three students. Thus, the alternative set has to be the one in (9) and we have already seen how *dou* is licensed there without triggering an *even*-flavor.

Things change when there were more than three students in the context. Suppose there were four as in (10). In this case, there is a proposition *q* in the alternative set entailing the prejacent; *dou*'s presupposition then cannot be satisfied (again, if *p* entails *q*, *q* cannot be more unlikely than *p*) and the sentence is thus infelicitous in the context.

<sup>5</sup>We also need to assume that non-equivalent propositions within  $\llbracket \pi_{(1b)} \rrbracket^{Alt}$  have different likelihood, which I take to be satisfied by normal contexts.

<sup>6</sup>A few more words on *dou*'s *even*-flavor and its disappearance in distributive contexts. When I said *dou*'s *even*-flavor is trivialized, I meant its (un)likelihood-flavor is indiscernible — that is, we do not feel any relation based on (un)likelihood between *dou*'s prejacent and its alternatives, and this is, I argued, due to the existence of a stronger entailment relation among the alternatives, because of distributivity. Some readers may find this intuitively hard to digest, but I believe the reason has to do with our choice of using comparative likelihood as the scale the semantics of *even* (and thus of *dou*) is based on (Karttunen and Peters, 1979). Several authors however argue that the scale of *even* should really be based on “pragmatic entailment”, “better informativeness” (Kay, 1990), “noteworthiness” (Herburger, 2000), or simply a contextually determined scale (Greenberg, 2016). With these theories, the disappearance of likelihood of *dou* in entailment contexts is more transparent: when entailment is available, *dou*'s prejacent can be the most noteworthy/informative by logically entailing all the other alternatives; only when entailment is unavailable is likelihood needed to make sense of noteworthiness/better informativeness. I take the above reasoning to be a variant of the idea presented in the main text, but I will stick to the proposal made above, trading popularity (of Karttunen and Peters (1979)'s semantics) for transparency.

$$(10) \quad \llbracket \pi_{n>3} \rrbracket^{Alt} = \left\{ \begin{array}{l} \text{there were 4 students such that each bought 10 books } (= q), \\ \text{there were 3 students such that each bought 10 books } (= \pi), \\ \text{there were 2 students such that each bought 10 books,} \\ \text{there were 1 students such that each bought 10 books,} \end{array} \right\}$$

In other words, to get the *even*-less *dou* in (1b), the context has to contain exactly 3 students.<sup>7</sup> In this way, we have derived the maximality/definiteness effect of *dou* in (1b) from its *even* presupposition.

#### 4. Concluding remarks

By examining a single *dou* sentence, the paper has sketched an analysis of Mandarin *dou* that captures its *even*-flavor, its distributive effect, its maximality effect, and the interaction among the three. For a detailed exposition of the analysis, its theoretical implications to the theory of pluralities and the theory of alternatives, and a comparison of the analysis with its close relative Liao (2011), the interested reader is referred to Liu (2017).

# A solution to Karttunen's Problem<sup>1</sup>

Matthew MANDELKERN — *Massachusetts Institute of Technology*

**Abstract.** There is a difference between the conditions in which one can felicitously assert a 'must'-claim versus those in which one can use the corresponding non-modal claim. But it is difficult to pin down just what this difference amounts to. And it is even harder to account for this difference, since assertions of  $\Box \varphi$  and assertions of  $\varphi$  alone seem to have the same basic goal: namely, coming to agreement that  $\llbracket \varphi \rrbracket$  is true. In this paper I take on this puzzle, known as *Karttunen's Problem*. I begin by arguing that a 'must'-claim is felicitous only if there is a shared argument for its prejacent. I then argue that this generalization, which I call *Support*, can explain the more familiar generalization that 'must'-claims are felicitous only if the speaker's evidence for them is in some sense indirect. Finally, I sketch a pragmatic derivation of *Support*.

**Keywords:** epistemic modals, indirectness of 'must', Karttunen's Problem, strength of 'must'.

## 1. Introduction

Compare (1) and (2):

(1) It must be raining out.

(2) It is raining out.

Intuitively, an assertion of (1) and an assertion of (2) have the same basic aim: they are both proposals to accept that it is raining out. Once an assertion of (1) has been accepted, interlocutors are disposed to accept the content of (2): that it is raining out. Thus (1) seems to be *as strong as* (2). But it does not seem to be *stronger* than (2): it is very strange to assert (1) after (2) is already accepted, as witnessed by the oddness of (3):

(3) ??It's raining; and moreover, it must be raining.

This suggests that assertions of (1) and (2) carry the same basic information. Yet the conditions under which they can be felicitously asserted differ in subtle ways. Suppose that Jane is in a windowless room, and sees her colleagues come in with wet umbrellas. Then she can assert either (1) or (2). But now suppose that Jane is looking out a window at the rain. She can still assert (2), but an assertion of (1)—'It must be raining out'—would be decidedly odd.

---

<sup>1</sup>I am grateful to audiences at MIT, the 2015 University of Chicago Workshop on Modality and Subjectivity, the New York Philosophy of Language Workshop, Arché, and Hampshire College; to reviewers for *Sinn und Bedeutung* 21; and to Justin Bledin, David Boylan, Agnes Callard, Nilanjan Das, Brendan de Kenessey, Janice Dowell, Daniel Drucker, Vera Flocke, Irene Heim, Matthias Jenny, Angelika Kratzer, Daniel Lassiter, Rose Lenehan, Sarah Murray, Dilip Ninan, Jacopo Romoli, Bernhard Salow, Ginger Schultheis, Brett Sherman, Alex Silk, Daniel Skibra, Eric Swanson, and Roger White for very helpful comments and discussion. Special thanks to Kai von Fintel, Justin Khoo, Robert Stalnaker, and Stephen Yablo.

Generally there exists a systematic difference between the conditions in which one can felicitously assert a 'must'-claim with complement  $\varphi$ , versus the conditions in which one can felicitously assert  $\varphi$  alone.<sup>2</sup> This puzzle, known as *Karttunen's Problem*,<sup>3</sup> gets to the heart of a number of broad foundational questions concerning the meaning of epistemic modals and the structure of conversation, and will be the topic of this paper.

The argument of the paper comes in three parts. In §2, I get clear on the data: what exactly the difference in felicity conditions between sentences like (1) and (2) amounts to. The main claim in the literature, which I call *Indirectness*, is that a 'must'-claim is felicitous only if the speaker's evidence for its prejacent is *indirect*, whereas its bare prejacent can be asserted whether the speaker's evidence is direct or indirect. I argue that, while *Indirectness* is correct, there is another, equally important, generalization which plays a key role in solving Karttunen's Problem: namely, that a 'must'-claim is felicitous only if the speaker ensures there is a salient argument in support of the claim's prejacent. I call this constraint *Support*. In §3, I show that once we have *Support* clearly in sight, we can derive *Indirectness* through general pragmatic reasoning. In §4, I give a Gricean account of why *Support* arises in the first place. This solution to Karttunen's Problem predicts that assertions of 'Must  $\varphi$ ' and  $\varphi$  have the same basic update effect, while explaining why the former, but not the latter, requires that the speaker share an argument for  $\llbracket \varphi \rrbracket$ , and that her evidence for  $\llbracket \varphi \rrbracket$  be indirect.

## 2. The data

The main extant claim regarding the difference between an assertion of 'Must  $\varphi$ ' versus an assertion of  $\varphi$  alone is that it amounts to an *Indirectness* constraint:<sup>4</sup>

*Indirectness*: A claim of 'Must  $\varphi$ ' is felicitous only if the speaker's evidence for  $\llbracket \varphi \rrbracket$  is indirect; a claim of non-modal  $\varphi$  can be felicitous whether the speaker's evidence for  $\llbracket \varphi \rrbracket$  is direct or indirect.

*Indirectness* is motivated by considering pairs of sentences like (4a) and (4b):

- (4)    a.    It must be raining.  
          b.    It's raining.

First suppose that the speaker of (4a) is looking out at the rain. Then her assertion is distinctly odd; whereas if she said (4b), it would be unmarked. By contrast, if she has a piece of indirect evidence for rain—say, wet umbrellas—then either is felicitous. *Indirectness* is the most natural generalization to draw from data like these.

*Indirectness* partly characterizes the difference in felicity between 'Must  $\varphi$ ' and  $\varphi$ , but does it exhaust that difference? Most of the literature on Karttunen's Problem has indeed focused exclusively on *Indirectness*. But a different, mostly neglected, thread has pointed to a further

<sup>2</sup>A 'must'-claim is a claim containing an unembedded strong epistemic necessity modal.

<sup>3</sup>Following von Fintel and Gillies (2010), who credit Karttunen (1972) with bringing the issue to attention.

<sup>4</sup>Karttunen (1972), Veltman (1985), Kratzer (1991), von Fintel and Gillies (2010), Kratzer (2012), Matthewson (2015), Lassiter (2016), Giannakidou and Mari (2016), Sherman (2016).

contrast in felicity conditions between 'Must  $\varphi$ ' and  $\varphi$ : in making a 'must'-claim, the speaker must ensure that an *argument* for its prejacent is salient to all the interlocutors.<sup>5</sup>

*Support*: A claim of 'Must  $\varphi$ ' is felicitous only if there is an argument for  $\llbracket \varphi \rrbracket$  salient to all the interlocutors; a claim of non-modal  $\varphi$  can be felicitous whether or not there is a salient argument for  $\llbracket \varphi \rrbracket$ .

The data that motivate *Support* are less clearcut than those that motivate *Indirectness*. This is unsurprising: evaluating *Support* requires evaluating discourses as a whole, rather than single utterances, and it can be difficult to determine, in a given context, whether an argument has been made salient. In the remainder of this section, I will provide new data to argue that *Support* is indeed required to account for the difference in felicity conditions between 'Must  $\varphi$ ' and  $\varphi$ .

Consider the following case:

- (5) Patch the rabbit sometimes gets into the box where her hay is stored. On his way out, Mark hears a snuffling from the box. At work, Bernhard asks him how Patch is.
- a. [Mark:] She's great. She must have gotten into the hay box this morning.
  - b. [Bernhard:] Cute!

Suppose the conversation ends here, and assume that Bernhard doesn't know anything about Patch's set-up at Mark's house, or anything else which might help him figure out why Mark thinks that Patch was in the box of hay. There is something distinctly odd about this exchange. Intuitively, what Mark has said needs elaboration; either Mark should have proffered reasons to think that Patch was in the hay box, or Bernhard should have asked him for reasons, perhaps with, 'Why do you say that?' Here is a more felicitous version of (5); assume the same setup:

- (6) a. [Mark:] She's great. I heard a snuffling from the box of hay on my way out—she must have gotten into the box.
- b. [Bernhard:] Cute!

Now suppose the conversation ends here. This exchange has none of the peculiarity of (5). Likewise, a non-modal variant of (5) is perfectly fine:

- (7) a. [Mark:] She's great. She got into the box of hay this morning.
- b. [Bernhard:] Cute!

The infelicity of (5) thus seems to be due to the fact that a 'must'-claim is made while no argument for its prejacent is given.

Cases like this provide our first piece of evidence for *Support*. To get another case of this kind on the table, consider (8), adapted from Murray (2014):

---

<sup>5</sup>See especially Stone 1994.

- (8) On her way to a meeting in a windowless building, Sarah sees Jim enter with a wet umbrella. Sarah enters the meeting. Thomas, who didn't see the umbrella, asks 'What's the weather like?' Sarah responds:
- a. It must be raining out.
  - b. It's raining out.
  - c. It must be raining out; I just saw Jim come in with a soaking wet umbrella.
  - d. It's raining out; I just saw Jim come in with a soaking wet umbrella.

Thomas replies: 'Oh, too bad. Ok, let's talk about the agenda for this meeting.'

If the conversation ends here, then (8a)—the variant with a 'must' and no argument—is odd, while the other variants are fine—again, just as *Support* predicts.

Comparing 'must' with other words that might at first glance seem to work in a similar way can help bring out the plausibility of *Support*. Consider (9), adapted from a television spy drama:

- (9) a. The suspect is fleeing south. We've sent agents ahead to Mattapan.  
 b. Why Mattapan?  
     (i) Apparently the Russians have a safe-house there.  
     (ii) The Russians must have a safe-house there.

If the conversation ends here, then (9bii) is peculiar in a way that (9bi) isn't. 'Apparently', like 'must', is constrained by a form of *Indirectness*; but 'apparently', unlike 'must', is acceptable here without an argument. *Support* predicts precisely this contrast (assuming that no corollary governs 'apparently').

Finally, I note that the patterns reported here are robust across strong epistemic necessity modals, in English and in all the other languages I have checked.<sup>6</sup>

I thus conclude that we should adopt *Support* as part of our characterization of the difference in felicity conditions between a 'must'-claim and its bare prejacent. Before moving on, let me say more about what *Support* amounts to. First, what does an *argument* amount to? I will think of an argument for  $\llbracket \varphi \rrbracket$  in a particular context as a set of propositions which the speaker is commonly recognized to believe provides reason to believe  $\llbracket \varphi \rrbracket$ —either by deductively entailing its conclusion; by inductively supporting the conclusion; or by showing how the conclusion follows from what is already accepted.

Second, what does 'salience' amount to? I won't say much about this, but a few features are worth noting. First, an argument need not itself be commonly accepted (i.e. *common ground* (Stalnaker, 1970)). One can felicitously assert an argument conjoined with a 'must'-claim, even if the argument has not yet been (and never is) accepted by all the speakers (if Bernhard doesn't believe me that I heard a snuffling from the box of hay, this does not render (6) infelicitous). The sense in which an argument  $\Gamma$  must be salient is rather that it must be common ground that the speaker takes  $\Gamma$  to provide reason to believe the prejacent of her 'must'-claim, and that she

<sup>6</sup>Bengali, French, German, Hindi, Japanese, Russian, Spanish, Swiss German, and Turkish.

is proposing to add  $\Gamma$  to the common ground. I will refer to an argument with this status as 'salient' or 'shared' or 'publicly available'.

An important point about salience is that an argument can be salient without being made explicit. If Bernhard and Mark can both hear snuffling from the box of hay, then Mark can say 'Patch must be in the hay box', without any further argument. Here, the premise that merits Mark's conclusion—that Mark can hear snuffling from the box—is sufficiently salient, rendering the 'must'-claim acceptable. Similarly, arguments can sometimes be *accommodated*, provided it is clear enough from the context what the speaker has in mind.

Another noteworthy feature of salience is that the argument in question need not be salient *at the time of the assertion*; it can be provided shortly after the assertion, as in (10):<sup>7</sup>

- (10)    a. [Mark:] Patch must have gotten into the box of hay.  
           b. [Bernhard:] Why do you say that?  
           c. [Mark:] I heard her snuffling around when I was leaving.

### 3. Explaining *Indirectness* via *Support*

*Support*, in addition to *Indirectness*, is thus necessary to characterize the difference in felicity conditions between a 'must'-claim and its bare prejacent.<sup>8</sup> How should we explain these differences? There are three possible strategies: account for *Indirectness* and *Support* separately; account for *Support* in terms of *Indirectness*, and give an independent account of *Indirectness*; or account for *Indirectness* in terms of *Support*, and give an independent account of *Support*. I will briefly arguing against the first two strategies and then pursue the third.

#### 3.1. Against the first two strategies

Considerations of theoretical parsimony tell against the first strategy. What about the second? This strategy is *prima facie* attractive, since there are a number of extant attempts to give an independent account of *Indirectness*; it is natural to try to recruit them to explain *Support*. But there are two significant problems with this approach. The first is that I do not believe that extant accounts of *Indirectness* are satisfying. I will not make this case here, however, because a second, simpler point suffices to show that the second strategy is wrong-headed: there does not seem to be any way to reduce *Support* to *Indirectness*.

A natural first thought is that this reduction would go by way of a general pragmatic constraint that requires a speaker to share her evidence for a claim if that evidence is indirect. But there is no such pragmatic constraint, as we saw in cases above where non-modal claims were felicitous without shared evidence. A closely related thought is that there is a general pragmatic constraint which requires a speaker to share her evidence if she explicitly indicates the source of her

<sup>7</sup>As for other constructions that require something to be made salient, like anaphora resolution.

<sup>8</sup>I will not take a stand on the further question of whether they are jointly sufficient.

evidence.<sup>9</sup> But, again, as the example above with ‘apparently’ shows—and as cross-linguistic work on evidentials suggests (see Murray (2014))—there is no such constraint: one can use ‘apparently’ or evidential marking without sharing what your evidence is.

A natural second thought is that *Support* reduces to a requirement to assure your interlocutors that *Indirectness* is satisfied. But this approach is not plausible, for a few reasons. First, the cases given above that are felt to be infelicitous without an argument—Patch in her box, Sarah in her windowless office building, the Russian safe-house—there is simply no reason to worry that the speaker’s evidence might not be indirect. Second, it is not generally true that whenever a formulation is constrained by a form of *Indirectness*, the speaker must habitually share her evidence in order to reassure her interlocutors that it satisfies the constraint in question: again, we saw this in (9) with ‘apparently’, which is governed by an *Indirectness* constraint, but which doesn’t require a shared argument.<sup>10</sup> Finally, from a more theoretical standpoint, it is hard to see why an *Indirectness* constraint would ever directly yield an obligation to share one’s evidence: we are fairly charitable in assuming that speakers are complying with felicity conditions. For instance, if *Indirectness* were encoded as a presupposition, then, on a standard approach to presuppositions, it will be required that it be common ground that the speaker’s evidence for the prejacent is indirect. But in general interlocutors are perfectly happy to *accommodate* presuppositions,<sup>11</sup> leaving it puzzling why *Indirectness* would lead to a requirement for a speaker to share her evidence.

### 3.2. Deriving *Support* from *Indirectness*

I thus do not see a promising way for the second strategy to go. By contrast, I will argue now that the third strategy—deriving *Indirectness* from *Support*, and then giving an independent explanation of the latter—provides a satisfying solution to Karttunen’s Problem. In brief, the idea is as follows. I argue that an assertion of ‘Must  $\varphi$ ’ is a bid to update the common ground with  $\llbracket \varphi \rrbracket$ . *Support* then says that it is a proposal to do so *on the basis of an argument*  $\Gamma$ . General principles forbidding redundant assertions entail that  $\llbracket \varphi \rrbracket$  should not follow from  $\Gamma$  in a way that is mutually recognized to be obvious. Finally, speakers are generally obligated to give their best argument for  $\llbracket \varphi \rrbracket$  if they’re giving an argument for  $\llbracket \varphi \rrbracket$  at all. It follows that, in order for an assertion of ‘Must  $\varphi$ ’ to be felicitous,  $\llbracket \varphi \rrbracket$  should not follow in a mutually obvious way from the best argument a speaker of ‘Must  $\varphi$ ’ can have for  $\llbracket \varphi \rrbracket$ ; in other words, a form of *Indirectness*.

The first step in our derivation is the assumption that an assertion of ‘Must  $\varphi$ ’ is *pragmatically strong* in the sense that it is just as strong as an assertion of  $\varphi$ . Following Stalnaker (1978), I assume that an assertion of  $\varphi$  is a proposal to update the common ground with  $\llbracket \varphi \rrbracket$ . Then we can spell out *Pragmatic Strength* as saying that an assertion of ‘Must  $\varphi$ ’ is, *inter alia*, a proposal to update the common ground with  $\llbracket \varphi \rrbracket$ :

<sup>9</sup>Thanks to Justin Bledin for discussion.

<sup>10</sup>And, again, Murray (2014) likewise observes that grammatical evidential markers for indirectness do not give rise to any obligation to share one’s evidence.

<sup>11</sup>See e.g. Lewis (1979), Stalnaker (2002) and many others.

*Pragmatic Strength*: An assertion of  $\ulcorner \text{Must } \varphi \urcorner$  is as strong as an assertion of  $\varphi$ , in the sense that once the common ground is updated with  $\llbracket \text{Must } \varphi \rrbracket$ , it is updated with  $\llbracket \varphi \rrbracket$ .

*Pragmatic Strength* says that conversants do not typically leave open the possibility of  $\llbracket \neg \varphi \rrbracket$  after accepting  $\ulcorner \text{Must } \varphi \urcorner$ . To see its plausibility, note the weirdness of (11b) and (11c) as responses to (11a):

- (11) a. The gardener must be the murderer.  
 b. I concur. Moreover, the gardener is the murderer.  
 c. I concur. Let's bring him and the butler in to see if we can pin down which of them is the murderer.

*Pragmatic Strength* provides the most natural explanation of the infelicity of (11b) and (11c).

The second step is to note that in general, when a speaker tries to get her interlocutors to accept  $\llbracket \varphi \rrbracket$  on the basis of an argument, the argument must be *non-redundant* in a relevant sense. Compare the two variants in each of (12) and (13):

- (12) a. I put Patch in her box this morning, and no one has let her out. So she's in her box.  
 b. ??I see Patch in her box. So she's in her box.
- (13) a. Clinton has amassed a majority of pledged delegates and superdelegates. So a woman will clinch the Democratic nomination!  
 b. ??Clinton will clinch the Democratic nomination. So a woman will clinch the Democratic nomination!

Without further justification for their repetitiveness, there is something pedantic or redundant about (12b) and (13b). By contrast, (12a) and (13a) are fine. The difference seems to be that in (12a) and (13a), there is enough epistemic space left between the argument in the first sentence and its conclusion in the second that its conclusion is not felt to be redundant. This intuition can be regimented as a norm against redundant assertions, along the following lines:

*Non-Redundancy*: A proposal to update the common ground with  $\llbracket \varphi \rrbracket$  on the basis of an argument  $\Gamma$  is infelicitous if  $\llbracket \varphi \rrbracket$  follows from  $\Gamma$  in a way that is mutually recognized to be obvious.

*Non-Redundancy* nicely captures the contrast between (12a) and (12b). The first is acceptable, since having put Patch in her box in the morning, together with no one else having let her out, does not, in an intuitive sense, obviously entail that Patch is in the box. The second is not, since it does follow in a mutually obvious way from seeing Patch in her box that she is in her box. Likewise for (13).<sup>12</sup>

<sup>12</sup>Note that *Non-Redundancy* does not forbid post hoc *support* for an assertion with a redundant argument; it is perfectly fine to justify oneself, if challenged, with 'Because I saw it'. What *Non-Redundancy* forbids is making

The last step in our derivation says that a speaker must give the best argument for  $\llbracket \varphi \rrbracket$  that she has, if she's giving an argument for  $\llbracket \varphi \rrbracket$  at all. To see the plausibility of this constraint, consider (14):

- (14) John was at the Red Sox game and knows on this basis who won. He also read about the game in the *Boston Globe*.  
 a. [Max:] Who won the game?  
 b. [John:] ?? The Red Sox, according to the *Globe*.

If John intends (14b) to answer Max's question, then there is something strange about it; we expect John to give his strongest evidence for the claim that the Red Sox won. In general, speakers are required to share the best piece of evidence they have for a claim, if they are sharing evidence at all. This follows naturally from a broadly Gricean vantage point on conversational dynamics. In (14b), John is violating Grice's Maxim of Quantity by failing to 'make his contribution as informative as is required (for the current purposes of the exchange)' (Grice, 1989). More precisely, the general lesson of cases like this is a corollary of the Maxim of Quantity which I call *Strongest Evidence*:<sup>13</sup>

*Strongest Evidence*: When a speaker aims to update the common ground with  $\llbracket \varphi \rrbracket$  on the basis of an argument  $\Gamma$ , she is obligated to do so by providing the *strongest* argument—the best piece of evidence—which she has for that claim.

We can now put these pieces together to derive *Indirectness* from *Support*. *Support* says that an assertion of  $\ulcorner \text{Must } \varphi \urcorner$  is felicitous only if there is a shared argument for  $\llbracket \varphi \rrbracket$ . *Pragmatic Strength* says that an assertion of  $\ulcorner \text{Must } \varphi \urcorner$  is a proposal to update the common ground with  $\llbracket \varphi \rrbracket$ . I will make the plausible further assumption that an assertion of  $\ulcorner \text{Must } \varphi \urcorner$  is thus a proposal to update the common ground with  $\llbracket \varphi \rrbracket$  *on the basis of* a shared argument for  $\llbracket \varphi \rrbracket$  (this is an assumption that will fall out of the derivation of *Support* below). According to *Non-Redundancy*,  $\llbracket \varphi \rrbracket$  must not follow from that argument in a mutually obvious way. According to *Strongest Evidence*, that argument must constitute the best evidence the speaker has for  $\llbracket \varphi \rrbracket$ . It follows that in order for a speaker to be able to felicitously assert  $\ulcorner \text{Must } \varphi \urcorner$ ,  $\llbracket \varphi \rrbracket$  cannot follow in a mutually obvious way from the speaker's best piece of evidence for  $\llbracket \varphi \rrbracket$ . In other words, the speaker's best evidence for  $\llbracket \varphi \rrbracket$  must be indirect, in the sense of indirectness relevant to evaluating whether an argument is felt to be redundant.

Put differently: Suppose a speaker has direct evidence (in the sense relevant to judgments about redundancy) for  $\llbracket \varphi \rrbracket$ . If she were to assert  $\ulcorner \text{Must } \varphi \urcorner$ , then due to *Strongest Evidence* and *Support*, she would have to give that evidence as an argument on the basis of which she is proposing her interlocutors accept  $\llbracket \varphi \rrbracket$ ; but then she would be bound to violate *Non-Redundancy*. So if she has direct evidence for  $\llbracket \varphi \rrbracket$ , she cannot assert  $\ulcorner \text{Must } \varphi \urcorner$ .

an initial bid to update the common ground with something on the basis of an argument from which it follows in a mutually obvious way.

<sup>13</sup>See Faller (2012) for more careful discussion of how this kind of reasoning would go. To spell out *Strongest Evidence* in more detail, we need to be able to access a scale of evidential strength, according to which, say, direct perceptual evidence counts as stronger than any kind of testimonial evidence.

In sum, in asserting 'Must  $\varphi$ ', the speaker has to ensure there is a shared argument which represents her best evidence for  $\llbracket\varphi\rrbracket$ , and yet is not so strong that it makes the 'must'-claim sound redundant. Thus  $\llbracket\varphi\rrbracket$  can't follow in a mutually obvious way from her best evidence for  $\llbracket\varphi\rrbracket$ . No parallel constraint follows for non-modal claims—since *Support* requires only that 'must'-claims be supported by an argument—and thus *Support*, plus *Pragmatic Strength*, *Non-Redundancy*, and *Strongest Evidence*, entail a form of *Indirectness*.

### 3.3. Predictions

The present proposal derives *Indirectness* from general principles about redundant assertions, and thus makes a striking empirical prediction: namely, that S's evidence  $\Gamma$  for  $\llbracket\varphi\rrbracket$  counts as indirect in the sense relevant to *Indirectness* just in case an assertion of  $\varphi$  following sequential assertions of the elements of  $\Gamma$  does not strike us as redundant. In addition to providing a new explanation for *Indirectness*, this also provides a new characterization of the notion of indirectness involved, an answer which I will now argue provides a better characterization of the data than the natural alternative, according to which 'must' lexically encodes a requirement that the speaker's evidence be indirect in a sense that lines up with intuitions about whether evidence is direct or indirect, and with categories which are encoded by grammatical evidentials (I'll call this 'an evidential approach').

I will highlight a few points. First, the present approach predicts that 'must'-claims based on reliable testimony like (15) will not be acceptable:

(15) ??The website says the movie is at 7:30. So the movie must at 7:30.

Our approach predicts this, since reliable testimony for  $\llbracket\varphi\rrbracket$  is typically felt to be a redundant argument for  $\llbracket\varphi\rrbracket$ , as shown by examples like (16):<sup>14</sup>

- (16) a. What time is the movie?  
b. ??The cinema website says that it's at 7:30. So the movie's at 7:30.

By contrast, this is surprising on an evidential approach, since testimony is, intuitively, indirect evidence (it is natural to say that you know that the movie is at 7:30, but that you know *indirectly*, via the website). An evidential approach thus must simply stipulate that testimony 'counts as direct' for the purposes of evaluating 'must'.

The second prediction worth highlighting is that, on the present approach, what counts as redundant in a given context—and thus judgments about the felicity of 'must'—depends on what counts as mutually obvious in that context. Thus, e.g., while (15) is infelicitous out of the blue, it may be felicitous in a context in which the inference from website listings to fact is not generally accepted, as in (17):

<sup>14</sup> Why sequences like this are treated as redundant is, of course, an important question for theories of redundancy to address, but one I will not answer here.

- (17) Google says that the movie is at 7:30. Websites listing movie times are generally extremely unreliable. Google is extremely reliable, though, so the movie is indeed at 7:30.

Given the felicity of (17), we predict that a 'must'-claim will be felicitous here as well; and indeed, (18) is felicitous:

- (18) Google says that the movie is at 7:30. Websites listing movie times are generally extremely unreliable. Google is extremely reliable, though, so the movie must indeed be at 7:30.

More generally, we rightly predict that judgments about the felicity of 'must'-claims depend on what counts as mutually obvious in context. It is not as clear how an evidential approach would predict this, since it does not seem like what counts intuitively as direct versus indirect evidence varies from context to context: our evidence for the time of the movie is equally indirect, in an intuitive sense, in (18) as in (16).

Third, we can explain why 'must'-claims that conclude a complicated argument are generally acceptable, even if the premises of the argument entail its conclusion. Examples of this kind, in particular those involving mathematical or logical claims, are the most puzzling examples for an evidential approach to 'must'. 'Must' is often warranted in mathematical or logical contexts, like (19).<sup>15</sup>

- (19) If the set of validities were decidable, then the halting problem would be decidable. The halting problem is not decidable. So the set of validities must be undecidable.

It is not clear what the evidential approach would predict about (19). It is not clear that there is an intuitive sense on which our evidence that the set of validities is undecidable is indirect. Perhaps the evidential approach would claim that evidence for mathematical claims is *always* indirect in the relevant sense. But in addition to being somewhat stipulative, this response runs into trouble when it comes to examples like (20):

- (20) ??24 plus 24 must be 48.

If all evidence from mathematics is indirect, then the evidential approach will wrongly predict that 'must' is warranted in (20) and sentences like it. In any case, it is not clear how the evidential approach can distinguish between cases like (19) versus (20). By contrast, our approach can. The conclusion of (19) does not follow in a way that is mutually obvious from the premises, whereas the conclusion of (20) does.

<sup>15</sup>Is the 'must' here epistemic? Some have argued that this 'logical' 'must' is not genuinely epistemic (e.g. Giannakidou and Mari (2016), Goodhue (2016)). Two things militate against this option. First, it is inelegant to multiply modal flavors further than we need to. Second, even if we say that the logical 'must' is not epistemic, we still need a theory of its distribution, since it is not always warranted, even when its complement is a logical consequence of the common ground (as examples like (20) show); simply saying that this 'must' is logical, not epistemic, thus does not yet explain its behavior.

These points confirm the key claim of the present approach to *Indirectness*: what matters for determining whether a 'must' is warranted is not whether the speaker's evidence for it is indirect in a sense which lines up with our intuitions about sources of evidence, or with categories encoded by grammatical evidentials, but rather whether the speaker's evidence for it makes the prejacent *mutually obvious*.

I conclude by discussing a different prediction of the present account. I have proposed that *Indirectness* arises due to conversational norms. It is a hallmark of pragmatic phenomena like this that they can be cancelled, since the underlying conversational norms are generally defeasible. We thus predict that *Indirectness* will be cancelled when one of the underlying norms is not in play. This prediction, again, is borne out, in particular in contexts in which *Strongest Evidence* is not in play because it is overridden by considerations which prevent the speaker from sharing her strongest evidence for  $\llbracket \phi \rrbracket$ . For instance, suppose that Mary is at Tom's party. She goes out to the street to smoke, where she runs into Ben. She knows Ben wasn't invited to the party, and doesn't want him to know that she was invited. Ben can hear music coming from Tom's place, and asks Mary what's going on at Tom's. Mary wants to communicate that he's having a party, but she doesn't want to share her strongest evidence for this—and doesn't seem to be under any obligation to do so, since she is trying not to hurt Ben's feelings. In this context, she can felicitously assert (21):

(21) Given the music, it must be some kind of party.

(21) may be misleading, but it is perfectly felicitous, despite the fact that Mary's evidence is direct. The prediction of our pragmatic account is thus borne out: *Indirectness* can be violated when one of the underlying pragmatic norms can itself be appropriately ignored.<sup>16</sup>

## 4. Support

*Support* plus independently motivated pragmatic principles thus provide a satisfying explanation of *Indirectness*. I turn now to the question of how to account for *Support*. I briefly criticize extant proposals before giving my own account.

### 4.1. Extant proposals

*Support* says that 'must' requires that an argument for its prejacent be made salient. A natural first thought about how to account for *Support* is to treat 'must' as containing something like an implicit indexical which refers to an argument: 'must' means roughly 'it follows from *this argument* that...', where the implicit 'this' requires a salient referent. Stone (1994) suggests an account along just these lines: on his approach, 'must' has a lexical argument place which must be saturated by an argument made salient by context. In other words, 'must' denotes a two

<sup>16</sup>It is less clear to me whether similar cases can be constructed in which it is *Non-Redundancy* which is suspended, since *Non-Redundancy* already has an element of context-sensitivity built in (since what counts as 'mutually obvious'—in the objectionable sense relevant here—is itself context-dependent). But if we can find contexts in which it is suspended, then we predict that in those contexts as well, *Indirectness* will be suspended.

place operator, taking an argument and a proposition  $p$ , which says that the argument provides decisive reason to believe  $p$ .

But a solution along these lines, natural though it is, does not work. The issue stems from the fact that no parallel to *Support* shows up for unembedded epistemic possibility modals. Consider (22):

- (22) Julie's cat has been sneezing a lot lately. Ben asks her how the cat is doing. Julie says:
- a. Not so great. I need to take him to the vet, he might have an upper respiratory infection.
  - b. Not so great. I need to take him to the vet, he has an upper respiratory infection.
  - c. Not so great. I need to take him to the vet, he must have an upper respiratory infection.

Suppose the conversation ends here. As *Support* predicts, (22c) is infelicitous as it stands, without an argument. By contrast (22a)—like the non-modal variant in (22b)—is perfectly fine here. This suggests that 'might' is not subject to a *Support*-like constraint.

If we took Stone's approach, however, then, provided we assume that 'must' and 'might' are duals, we would predict that 'might' has an anaphoric requirement for an argument, just as 'must' does: if 'might' means 'not must not', then the argument requirement of 'must' will project through negation, and thus 'might' will require a salient argument, too.

We could avoid this by giving up the assumption that 'must' and 'might' are duals, and that 'might' does not have a lexical argument place for an argument. But, crucially, going this way leads to a serious new puzzle. Assuming we treat 'cannot' as equivalent to 'not might', then we will predict that unembedded 'cannot' does not have an anaphoric requirement for an argument any more than unembedded 'might' does. But this is wrong: the same examples we used to motivate *Support* for 'must' above can be used to motivate it for unembedded 'cannot' (*modulo* obvious changes). Thus, for instance, consider (23):

- (23) Emma notices that her neighbor Phil hasn't taken in his mail in some time, and concludes that he is out of town. Another neighbor asks if Phil is around. Emma responds:
- a. No, he can't be.
  - b. No, he's not.
  - c. No, he can't be: no one has taken his mail in for a week.
  - d. No, he's not: no one has taken his mail in for a week.

The exchange ends here.

(23a) is marked as compared with the other variants in (23). As with the examples involving 'must', then, 'can't' seems to require that an argument be made salient, in this case not for its prejacent but for its negation.

Thus a lexical derivation of *Support* along the lines Stone suggests faces a dilemma: either treat ‘must’ and ‘might/can’ as duals, and wrongly predict that the latter have a *Support*-like requirement; or do not treat them as duals, and wrongly predict that ‘cannot’ lacks a *Support*-like requirement. This approach thus strikes me as a non-starter.

Similar criticisms extend to the account suggested in Swanson (2015), who builds on Kratzer (1981) in adopting a premise semantics for epistemic modals, with the added requirement that those premises be publicly available. This approach faces the same dilemma. If we treat ‘might/can’ as the duals of ‘must’, then this explanation will overgenerate: it will wrongly predict that they are likewise subject to *Support*, since they will likewise require a set of premises to be made public. Alternately, we could abandon duality, but then we cannot explain *Support* for ‘cannot’. The present objection can also be extended to a treatment of *Support* as a presupposition.<sup>17</sup> Presuppositions project through negation; thus a presuppositional approach would either treat ‘might/can’ as duals of ‘must’, and thus wrongly predict that ‘might/can’ obey *Support*; or would abandon duality, and once again fail to predict *Support* for ‘cannot’.

#### 4.2. *Support* as a manner implicature

We can avoid these problems by deriving *Support* as a pragmatic implicature along the following lines. The derivation depends in part on adopting a semantics for ‘must’ defended in Stalnaker (2014) and Mandelkern (2016).<sup>18</sup> I will not try to motivate the semantics here in general terms, but here’s a sketch. The idea is that ‘must’ is a universal quantifier over the set of worlds compatible with what is common ground after the ‘must’-claim in question has been made and negotiated (either accepted or rejected; call this the *prospective common ground*). ‘Must  $\varphi$ ’ thus means, roughly, ‘We will commonly believe  $\llbracket\varphi\rrbracket$  after this claim is made and assessed’; ‘might’ is treated as the dual of ‘must’, and thus ‘Might  $\varphi$ ’ will mean ‘ $\llbracket\varphi\rrbracket$  is compatible with what we commonly believe, after this claim is made and assessed’.<sup>19</sup> The basic idea is the familiar one that ‘might’ and ‘must’ are used to coordinate on what structural properties the context set has. I adopt the present semantics for ‘must’ partly because I think it is plausible, and partly because it lends itself naturally to the present derivation. A similar derivation of *Support* may well be possible with a different underlying semantics for ‘must’; the crucial features of the semantics for present purposes are, first, that it is pragmatically strong; and, second, that it makes salient the question of the interlocutors’ collective doxastic relationship to its prejacent. Any semantics for ‘must’ with these two features will suffice for present purposes.

On the present approach, ‘Must  $\varphi$ ’ and  $\varphi$  alone have the same basic update effect: namely, adding  $\llbracket\varphi\rrbracket$  to the common ground. ‘Must  $\varphi$ ’ is thus in competition with a different assertion which has the same basic update effect but which is structurally simpler: namely, an assertion

<sup>17</sup>A suggestion due to Eric Swanson (p.c.).

<sup>18</sup>My approach and Stalnaker’s differ in some ways, but the differences do not matter for our purposes.

<sup>19</sup>This gloss is only rough, because these constructions embed differently. See Mandelkern (2016) for further discussion. The basic idea for embeddings is that the domain of quantification for embedded ‘must’ is determined by its *local context*. I will prescind from deciding whether to go in for a factive or a non-factive notion of common ground in spelling out this semantics.

of  $\varphi$  alone.<sup>20</sup> Because  $\varphi$  is structurally simpler,<sup>21</sup> choosing an assertion like  $\ulcorner \text{Must } \varphi \urcorner$  instead requires some explanation. Because the two options have the same update effect, the interlocutors cannot reason that the speaker chose one of them because she didn't know the other, or knew the other was false (as in scalar reasoning). There is, however, an important difference between  $\ulcorner \text{Must } \varphi \urcorner$  versus  $\varphi$  alone: namely, that the former makes salient the question of the interlocutors' collective doxastic relation to  $\llbracket \varphi \rrbracket$ , while the latter does not: it is only about  $\llbracket \varphi \rrbracket$ . There are a variety of ways to make this intuition precise; it doesn't matter for our purposes how we choose between them.<sup>22</sup> For our purposes, we can just treat the question raised by an assertion of any sentence  $\psi$  as the two cell partition  $\{\psi, \bar{\psi}\}$ . Then the question made salient by an assertion of  $\llbracket \varphi \rrbracket$  is just the question whether  $\llbracket \varphi \rrbracket$  is true; whereas the question made salient by an assertion of  $\ulcorner \text{Must } \varphi \urcorner$  is the question *whether we will come to commonly accept*  $\llbracket \varphi \rrbracket$ . Given that  $\ulcorner \text{Must } \varphi \urcorner$  has a simpler alternative with the same basic update effect (namely  $\varphi$ ), if a speaker chooses to use this more complex expressions, then we will seek an explanation of this fact. Given that the chief difference between  $\ulcorner \text{Must } \varphi \urcorner$  and  $\varphi$  is in the question made salient by each, we will therefore reason that, in choosing the more complex option, she wishes to raise to salience the question of the group's collective doxastic relation to  $\llbracket \varphi \rrbracket$ , and thus the group's reasons for accepting  $\llbracket \varphi \rrbracket$ .

What kind of reason for accepting  $\llbracket \varphi \rrbracket$  would be worth highlighting in this way? Whenever a speaker proposes to update the common ground with  $\llbracket \varphi \rrbracket$ , this provides *ceteris paribus* reason for her interlocutors to accept  $\llbracket \varphi \rrbracket$ : namely, the speaker's authority. A reason of this kind, therefore, is totally humdrum, and thus not worth highlighting. The use of an assertion like  $\ulcorner \text{Must } \varphi \urcorner$  rather than an assertion of  $\varphi$  alone thus can be justified only if the speaker wishes to highlight a substantial argument for  $\llbracket \varphi \rrbracket$ —i.e., an argument over and above the speaker's authority—on the basis of which the speaker wishes her interlocutors to accept  $\llbracket \varphi \rrbracket$ . In other words (the interlocutors will reason), the speaker wishes them to accept  $\llbracket \varphi \rrbracket$  on the basis of an argument that is commonly available to them. The speaker must, therefore, ensure that such an argument is salient—either by providing it, or being assured that her interlocutors can recover it from the common ground, possibly by accommodation.

In short: *Support* arises as a manner implicature, thanks to the fact that the speaker chose to propose to accept  $\llbracket \varphi \rrbracket$  by way of an assertion which makes reference to the interlocutors' doxastic relation to  $\llbracket \varphi \rrbracket$ .

This approach has a number of attractions. First, it derives *Support* from a simple, independently motivated modal semantics, rather than lexical stipulation, and thus explains why *Support* arises for anything that has the meaning of 'must'. Second, it avoids the problem raised

<sup>20</sup>See Degen et al. (2015) for a different manner-implicature based approach to explaining the behavior of 'must'. Like the present approach, that approach relies on the assumption that  $\ulcorner \text{Must } \varphi \urcorner$  is a costly alternative to  $\varphi$  whose use must be somehow explained. In contrast with the present approach, that approach attempts to derive *Indirectness* directly, rather than by way of *Support*, and without adverting to the different QUDs raised by modal vs. non-modal variants.

<sup>21</sup>I will not spell out assumptions about how we calculate which alternatives are relevant. It seems fairly plausible that however we do so,  $\varphi$  will count as a relevant alternative to  $\ulcorner \text{Must } \varphi \urcorner$  (and  $\ulcorner \neg \varphi \urcorner$  as a relevant alternative to  $\ulcorner \text{Can't } \varphi \urcorner$ ); this follows e.g. on the account given in Katzir (2007), according to which alternatives are calculated by the deletion or replacement of nodes at LF.

<sup>22</sup>See Lewis (1988), Roberts (2012) and citations therein.

above for extant approaches. If we treat 'might/can' as duals of 'must', we will predict that the corollary of *Support* will be blocked for 'might/can', but will still be derived for 'cannot'. First, the derivation of a *Support* constraint for 'might/can' will be blocked because a crucial step in our derivation of *Support* was that  $\lceil \text{Must } \varphi \rceil$  has a structurally simpler alternative with the same basic update effect; this obviously does not hold for  $\lceil \text{Might } \varphi \rceil$ , which has a very different update effect than  $\varphi$ . And, second, assuming that 'can' and 'might' mean the same thing, and that 'not' scopes over 'can' in 'cannot', the derivation given above will extend immediately to unembedded 'cannot', predicting in particular that *Support* and *Indirectness* arise for the negation of the prejacent of 'cannot', just as they do for the prejacent of 'must'.

Note that for the same reason that this derivation of *Support* is blocked for 'might', the corresponding derivation of *Support* will likewise be blocked for weak epistemic necessity modals like 'ought' and 'should', as well as probability modals, since assertions of  $\lceil \text{ought/should/probably } \varphi \rceil$  and  $\varphi$  do not have the same basic update effect. These predictions again seem correct:

- (24) a. When do you want to meet?  
       b. Let's say Thursday;  
           (i) I should be free then.  
           (ii) I ought to be free then.  
           (iii) I'll probably be free then.  
           (iv) I must be free then.

If the conversation ends here, responses (24bi), (24bii), and (24biii) are all acceptable; by contrast, (24biv) is a strange way to end the conversation, and seems to require that some argument be given ('...my secretary always leaves my Thursdays open'). The prediction of the present account, then—that modals which are not *Pragmatically Strong*, like 'might/ought/should/probably', do not carry a *Support* constraint—thus seems correct.<sup>23</sup>

The present proposal makes a prediction which is worth highlighting: any construction which has the features which played a role in the present derivation is predicted to give rise to a *Support*-like constraint. That is, any construction which has  $\varphi$  as a structurally simpler relevant alternative; which has the same basic update effect as an assertion of  $\varphi$ ; and which highlights the speakers' collective doxastic relation to  $\llbracket \varphi \rrbracket$ , is, *ceteris paribus*, predicted to give rise to *Support* (and thus also *Indirectness*). Further research should examine other expressions that share these three features to see if this prediction is borne out.<sup>24</sup>

<sup>23</sup>And the *Indirectness* inference for 'might/ought/should/probably' is easy to explain on pragmatic grounds without a detour through *Support*.

<sup>24</sup> $\lceil \text{It's agreed that } \varphi \rceil$ ,  $\lceil \text{Let's agree that } \varphi \rceil$ ,  $\lceil \text{We should believe } \varphi \rceil$ , and  $\lceil \text{It is clear that } \varphi \rceil$  all seem to have these properties, and do indeed appear to be governed by corollaries of *Support* and *Indirectness* (see Barker 2009 on the last of these). This suggests that, even if the pragmatic derivation I have given here is mistaken in some of its details, the explanation for both *Indirectness* and *Support* is pragmatic, and stems from the properties I have pointed to.

## 5. Conclusion

The argument of this paper has come in three parts. I began by arguing that, to fully characterize the differences in felicity conditions between an assertion of  $\ulcorner \text{Must } \varphi \urcorner$  and an assertion of  $\varphi$ , we need not only *Indirectness* but also *Support*. Next, I argued that we can derive *Indirectness* from *Support* together with general pragmatic principles about assertions, and I argued that this derivation of *Indirectness* makes attractive predictions about when a 'must'-claim is unacceptable. Finally, I made a proposal about how to derive *Support* as a manner implicature from a certain semantics for epistemic modals which treats them as quantifiers over the set of worlds compatible with the common ground.

The three parts of this argument are, to a degree, independent. If each of these moves is successful, however, then taken together, they constitute a solution to Karttunen's Problem: characterizing and explaining the differences in felicity conditions between an assertion of  $\ulcorner \text{Must } \varphi \urcorner$  and an assertion of  $\varphi$ . In short: because of its more complex form and the question it makes salient,  $\ulcorner \text{Must } \varphi \urcorner$ , unlike  $\varphi$  alone, requires that an argument be given for  $\llbracket \varphi \rrbracket$ ; and from the requirement, in turn, we can conclude that the speaker's evidence for  $\llbracket \varphi \rrbracket$  is relevantly indirect.

In conclusion, I highlight a few broad upshots of my approach to Karttunen's Problem. The first is about the relation between 'must' and evidentiality. I have argued that 'must' does not grammaticalize a certain constraint on the *type* of evidence, in any intuitive sense, which the speaker must have for its prejacent. Rather, the felt indirectness of 'must'-claims is accounted for pragmatically, and it is accounted for not directly in terms of judgments about type of evidence but rather in terms of judgments about *redundancy*.

The second is about the meaning of 'must'. My derivation of *Support* rests on a certain semantics for 'must'. If the derivation is successful, then it provides an argument for adopting that semantics, and presents a challenge for advocates of different semantics for 'must': to show how those approaches can explain *Support*.

The third regards the theory of redundancy. I have argued that the norms that governs redundancy in assertions play a crucial role in explaining our interpretation of modal language. My sketch of what those norms are like, however, leaves unanswered substantial questions, in particular about what counts as a 'mutually obvious' inference—questions which I hope to explore in future work. A theory of redundancy—in essence, a theory of how our minds structure and access information—will play a central role in understanding the way that information is structured in discourse, and judgments about 'must'-claims provide a rich source of data for this theory.

I close with an abstract point about the architecture of semantic and pragmatic theories. My proposal rests on the assumption that an assertion of  $\ulcorner \text{Must } \varphi \urcorner$  and an assertion of  $\varphi$  have the same basic update effect, but different semantic values. Indeed, on the semantics I have sketched,  $\ulcorner \text{Must } \varphi \urcorner$  and  $\varphi$  informationally entail one another—in the sense that a context updated with either one entails the other—but they do not semantically entail one another. The possibility of this divergence between update effect and meaning proved essential for simulta-

neously capturing the intuition that an update with  $\lceil \text{Must } \varphi \rceil$  is pragmatically strong, and the intuition that it cannot always be asserted where  $\varphi$  alone can be. Not everyone thinks that we should distinguish between semantic content and pragmatic update effect at all; in particular, at a high level, certain threads in dynamic semantics aims to identify these. If the present approach to Karttunen's Problem is the right one, however, then distinguishing semantic content from pragmatic update effect in our theorizing about natural language turns out to be crucial.

# Expletive negation and the decomposition of *only*<sup>1</sup>

Daniel MARGULIS — *Massachusetts Institute of Technology*

**Abstract.** This paper is focused on the seemingly superfluous sentential negation showing up in Hebrew *until*-clauses. I discuss a scalar implicature arising from *until*-clauses which surprisingly becomes uncancellable when this negation is present. I argue that this inference becomes obligatory due to the presence of an *only*-like exhaustivity operator, which gets (partially) spelled out as negation since it is composed of negation and an exceptive. Moreover, this negation is shown to share more properties with *only*.

**Keywords:** Expletive negation, exhaustification, scalar implicatures, *until*.

## 1. Introduction

A seemingly superfluous negation participates in a multitude of constructions, among which are certain temporal clauses. This paper is focused on the superfluous sentential negation showing up in Hebrew *until*-clauses.<sup>2,3</sup> I refer to sentential negation which does not make a straightforward contribution to meaning as EXPLETIVE NEGATION or EXN in short. The assumption that sentential negative morphemes are interpreted as negative operators is what makes EXN puzzling.<sup>4</sup>

In this paper I discuss a scalar implicature arising from *until*-clauses which surprisingly becomes uncancellable when EXN is present. I argue that this inference becomes obligatory due to the presence of an *only*-like exhaustivity operator, which gets (partially) spelled out as negation. According to the proposal put forward in the paper, negation is capable of realizing an *only*-like operator because such an operator is actually composed of negation and an exceptive, as has already been proposed for overt *only* in von Stechow and Iatridou (2007).

---

<sup>1</sup>For helpful comments and insightful discussion I thank Kai von Stechow, Danny Fox, Martin Hackl, Irene Heim, Sabine Iatridou, Ezer Rasin, and Roger Schwarzschild. I would also like to thank Moshe E. Bar-Lev, Itai Bassi, Gennaro Chierchia, Cleo Condoravdi, Luka Crnić, Veneeta Dayal, Michel DeGraff, Aron Hirsch, Roni Katzir, Giorgio Magri, David Pesetsky, Maribel Romero, and Milena Sisovics. Earlier versions of this paper were presented at the Hebrew University, Tel Aviv University, the Göttingen Negation workshop (September 2015), SNEWS 2015 at Harvard, and WCCFL 32 in Salt Lake City.

<sup>2</sup>The phenomenon is also attested at least in Bangla (Ishani Guha, p.c.), French (Sophie Moracchini, p.c.), German (Krifka, 2010), Italian (Tovena, 1996), and Russian (Abels, 2005).

<sup>3</sup>Other occurrences of puzzling negation which will not be discussed in this paper include negative concord (Zeijlstra, 2004, 2008: among many others), preposed negation in biased polar questions (Ladd, 1981; Büring and Gunlogson, 2000; Romero and Han, 2004; Han and Romero, 2004), rhetorical and tag questions, exclamatives (Portner and Zanuttini, 2000), complements of certain attitude predicates (Abels, 2005; Yoon, 2012; Makri, 2015), comparatives, and complements of *almost* (Kaufmann and Xu, 2013).

<sup>4</sup>The puzzle remains as long as one assumes a correspondence between the negative morpheme and an interpreted negative operator. In the simple case the negative morpheme itself carries the negative semantics. A sentential negative morpheme could also give rise to an interpreted negative operator when it is in a dependency with an abstract negation, as in Zeijlstra's (2004; 2008) work on negative concord. In both cases, a superfluous negative morpheme is perplexing.

Such an analysis predicts that EXN and *only* should share more properties. I show that this prediction is borne out: EXN is odd when there are no alternatives to exclude, it is incompatible with overt *only* and with downward entailing (DE) environments, it triggers optional stress and preposing of the *until*-clause, and cannot license negative concord.

The paper is structured as follows: §2 presents the data on EXN and its interpretive effect. §3 consists of the analysis in which *only* is decomposed into negation and an exceptive, and shows how it can capture the semantics and syntax of EXN. §4 discusses further predictions of the proposal and shows that they are borne out. §5 concludes and briefly mentions questions that are left open.

## 2. Data

### 2.1. EXN in *until*-clauses

A Hebrew *until*-clause can host the sentential negation *lo*, superficially without affecting interpretation, as demonstrated by the following examples.<sup>5</sup>

- (1) *adam hu xaf mi-peša ad Še (lo) huxexa ašmat-o*  
man he free from-crime until that NEG was proven guilt-his  
'A man is innocent until proven guilty.'
- (2) *ze lo nigmar ad Še ze (lo) nigmar*  
it NEG finished until that it NEG finished  
'It ain't over till it's over.'
- (3) *joni jašan ad Še ha-šxenim (lo) hidliku muzika*  
Y. slept until that the-neighbors NEG lit music  
'Yoni was asleep until the neighbors turned some music on.'
- (4) *ha-fvita timašex ad Še (lo) jeʔanu drifot ha-ovdim*  
the-strike will continue until that NEG will be answered demands the-workers  
'The strike will continue until the workers' demands are met.'
- (5) *miri lo nirdemet ad Še (lo) korʔim l-a sipur*  
M. NEG falls asleep until that NEG read.PL to-her story  
'Miri doesn't fall asleep until you read her a story.'

Note that (1)–(5) can in principle have an additional reading in which negation is interpreted as usual. For example, (1) can have the (odd) reading 'A man is innocent until *not* proven guilty'.<sup>6</sup>

<sup>5</sup>Examples (1) and (3) are modified versions of Eilam's (2007) examples (3) and (5).

<sup>6</sup>As Eilam (2007) observed, this reading is the only one available if the negative morpheme *lo* is stressed.

## 2.2. The Interruption Implication

### 2.2.1. Optional interruption without EXN

In this subsection I discuss English examples, but it should be noted that the facts are the same for Hebrew *until*-clauses when they do not contain EXN. The next subsection contains discussion of Hebrew EXN cases.

Sentences containing *until* generally give rise to an inference – which I call THE INTERRUPTION IMPLICATION – according to which the matrix eventuality came to an end upon the onset time of the *until*-phrase/clause. From (6) for example, one infers that Mary stopped playing the piano at five or at the time of John's opening the door.

- (6) Mary played the piano until five / until John opened the door.  
 $\rightsquigarrow \neg$ [Mary played the piano after five / after John opened the door].

The interruption implication has two properties of a scalar implicature: (i) it is cancellable, and (ii) it does not arise when the *until*-clause is embedded in a downward-entailing environment. None of (7a)–(7d) gives rise to the interruption implication.

- (7) **In all the following**  $\not\rightsquigarrow \neg$ [Mary played the piano after John opened the door]:
- Mary played the piano until John opened the door. *Moreover*, she was still playing the piano (when and) after he opened it.
  - Mary played the piano until John opened the door *and perhaps even afterwards*.
  - Mary played the piano *at least* until John opened the door.
  - Q: Is Mary still playing the piano?  
 A: *Well, I'm not sure but* (what I know is that) she definitely played the piano until John opened the door.

Scalar implicatures are known to disappear in downward-entailing environments. Compare (8a) to (8b), which embeds a minimally modified version of (8a) in the restrictor of a universal quantifier, a downward-entailing environment. If the *not all* inference in (8a) were part of the meaning of *some*, we should expect (8b) to quantify over students who did *only some* of the reading. However, it follows from (8b) that students who did all of the reading got an A just like those who did some but not all of it.

- (8) a. Mary did some of the reading.  
 $\rightsquigarrow$  Mary did **only** some of the reading. (= M. did some but not all of it.)
- b. Every student who did some of the reading got an A.  
 $\rightsquigarrow$  Every student who did **only** some of the reading got an A.

Similarly, the interruption implication in (9a) is not preserved in (9b). Those students who played the piano not only until John opened the door, but even until some later time, are entitled to a prize to no lesser degree than those who played the piano only until John opened the door. This is a reason not take the interruption implication to be part of the lexical semantics of *until*.

- The cancellability of the interruption implication and its disappearance in downward entailing environments puts it in the same group of inferences as scalar implicatures. Now let us see how ExN affects the availability of the interruption implication.

The facts are the same for Hebrew *until*-clauses, but only without EXN. EXN makes the interruption implication obligatory: it cannot be cancelled nor can an *until*-clause containing EXN be embedded in a downward-entailing environment.

- Example (13a), but not (13b), can be used in the exchange in (14), which requires at least partial ignorance regarding Yoni's awakening time (cf. (7d)).

- In the previous section we have seen scalar implicatures disappear in downward-entailing (DE) environments. Later I will propose that EXN is related to a grammatical mechanism generally responsible for scalar implicatures. If they disappear in DE environments because this mechanism cannot take place in such environments, we expect a clash between DE environments and EXN.

Consistent with the obligatoriness of the interruption implication with EXN, an *until*-clause containing EXN cannot be embedded in a DE environment such as the restrictor of a universal quantifier (15b) or the antecedent of a conditional (16b). Examples (15c) and (16c) show that EXN is allowed in related upward-entailing environments: the restrictor of *one* and the consequent of a conditional.

- (15) a. *kol mitmoded fe jaʔatsor et ha-nefima ad fe ha-paamon*  
 every contestant that 3.stop.FUT ACC the-breath until that the-bell  
*jetsaltse! jekabel pras*  
 3.ring.FUT 3.receive.FUT prize  
 ‘Every contestant who holds their breath until the bell rings will get a prize.’
- b. *ʔʔkol mitmoded fe jaʔatsor et ha-nefima ad fe ha-paamon lo*  
 every contestant that 3.stop.FUT ACC the-breath until that the-bell NEG  
*jetsaltse! jekabel pras (nixumim)*  
 3.ring.FUT 3.receive.FUT prize (consolations)  
 ‘Every contestant who holds their breath until the bell rings will get a (consolation) prize.’
- c. *mitmoded exad fe jaʔatsor et ha-nefima ad fe ha-paamon lo*  
 contestant one that 3.stop.FUT ACC the-breath until that the-bell NEG  
*jetsaltse! jekabel pras*  
 3.ring.FUT 3.receive.FUT prize  
 ‘One contestant who holds their breath until the bell rings will get a prize.’
- (16) a. *im miri taʔatsor et ha-nefima ad fe ha-paamon jetsaltse!, hi*  
 if M. 3.stop.FUT ACC the-breath until that the-bell 3.ring.FUT she  
*tekabel pras*  
 3.receive.FUT prize  
 ‘If Miri holds her breath until the bell rings, she will get a prize.’
- b. *ʔʔim miri taʔatsor et ha-nefima ad fe ha-paamon lo jetsaltse!, hi*  
 if M. 3.stop.FUT ACC the-breath until that the-bell NEG 3.ring.FUT she  
*tekabel pras*  
 3.receive.FUT prize  
 ‘If Miri holds her breath until the bell rings, she will get a prize.’
- c. *im miri rotsa le-kabel pras, hi taʔatsor et ha-nefima ad fe*  
 if M. wants to-receive prize, she 3.stop.FUT ACC the-breath until that  
*ha-paamon lo jetsaltse!*  
 the-bell NEG 3.ring.FUT  
 ‘If Miri wants to get a prize, she will hold her breath until the bell rings.’

To summarize the data in this section, the interruption implication, an otherwise optional scalar implicature, becomes obligatory with EXN. Moreover, EXN cannot be embedded in DE environments.

### 3. Analysis

#### 3.1. The core of the proposal: *only*

An intuition which can provide insight into the contribution of EXN is that adding EXN to an *until*-clause parallels the addition of *only*: *Mary played until John* **EXN** *opened the door*  $\approx$  *Mary played **only** until John opened the door*. Fleshing out this intuition will get us closer to an LF and allow us to predict the obligatoriness of the interruption implication with EXN.

(17) **Hypothesis:** *until*-clauses hosting EXN contain an *only*-like exclusive particle.

If an *only*-like exclusive particle is involved, we need to determine the set of alternatives it operates on. Suppose that  $\phi$  *until*  $t$  has the set of alternatives in (18), for any  $t_-, t, t_+$  such that  $t_- < t < t_+$ :

$$(18) \quad \text{Alt}(\phi \text{ until } t) = \{\dots, \phi \text{ until } t_-, \phi \text{ until } t, \phi \text{ until } t_+, \dots\}$$

That is, the alternatives of  $\phi$  *until*  $t$  differ from it only in the time until which  $\phi$  holds. This way we can generate a set of alternatives that exhausts the entire (contextually restricted) temporal domain.<sup>7</sup> Crucially, this set of alternatives is ordered by entailment, as shown in (19). For example,  $\phi$  *until* *five* asymmetrically (Strawson-)entails that  $\phi$  *until* *four*.

$$(19) \quad (\lambda w. \phi \text{ until } t_+ \text{ in } w) \subset (\lambda w. \phi \text{ until } t \text{ in } w) \subset (\lambda w. \phi \text{ until } t_- \text{ in } w)$$

To see that the hypothesis in (17) makes the correct predictions, let us assume for now that (20) holds. In the next section I modify (20) and explicate the affinity between EXN and *only*.

(20) **Assumption (to be modified):** EXN is semantically vacuous but triggers obligatory strengthening in the sense of Fox (2007); Chierchia et al. (2012); Chierchia (2013).

That is, EXN requires the alternatives of the clause in which it occurs to not be ignored but be taken into consideration by an exhaustivity operator. Such an operator is a covert counterpart of *only*, a simplified version of which is defined in (21). EXHAUST asserts the truth of its prejacent and the falsity of any alternative which is not entailed by the prejacent.<sup>8</sup> Assuming for simplicity that the only alternatives are the ones in (18), strengthening results as in (22).

$$(21) \quad \llbracket \text{EXHAUST} \rrbracket = \lambda A_{st,t}. \lambda p_{st}. \lambda w_s. p(w) = 1 \wedge \forall q \in A [(p \not\subseteq q) \rightarrow q(w) = 0] \approx \llbracket \text{Only} \rrbracket$$

$$(22) \quad \llbracket \text{EXHAUST}(\text{Alt})(\phi \text{ until } t) \rrbracket^w = 1 \text{ iff } \phi \text{ until } t \text{ in } w \wedge \text{for any } t_+ > t, \neg [\phi \text{ until } t_+ \text{ in } w]$$

<sup>7</sup>I am assuming that *until*'s complement has to denote a time, either inherently ('until five') or by definitizing a temporal property ('until John opened the door'). For more details see §3.3.1.

<sup>8</sup>The denotation in (21) omits Fox's (2007) qualification that the excluded alternatives be INNOCENTLY EXCLUDABLE. This is so since in the case of (18), the alternatives are already totally ordered, and in particular all non-weaker alternatives are innocently excludable.

This is so because both  $\varphi$  *until*  $t$  and  $\varphi$  *until*  $t_-$  are entailed by  $\varphi$  *until*  $t$ , but  $\varphi$  *until*  $t_+$  is not. Thus,  $\varphi$  *until*  $t$  ends up meaning  $\varphi$  *until*  $t$  **and no later than**  $t$ , giving us the interruption implication.<sup>9</sup>

Moreover, the incompatibility of EXN with DE-environments (§2.2.2) is predicted by the analysis when taken together with any grammatical theory of scalar implicatures which explains their disappearance in such environments by lack of exhaustification. In other words, since I propose to relate EXN with EXHAUST, all that is needed to predict EXN's incompatibility with DE-environments is a reason for EXHAUST to be incompatible with such environments. Since such incompatibility is in fact attested, I submit that once we have an explanation for this phenomenon the incompatibility of EXN with DE-environments would be predicted without further stipulations.<sup>10</sup>

### 3.2. Decomposing *only*

Why should the assumption in (20) hold? It would be peculiar for a negative morpheme to be ambiguous between actual negation and EXN, especially across so many languages (see fn. 2). So how should one think of the association between EXN and *only*?

If one entertains the possibility that EXHAUST is syntactically complex, containing a negative piece, one could better understand EXN as a plain compositional negation.

#### (23) **Revised hypothesis**

- a. *Until*-clauses hosting EXN contain an *only*-like operator. (= (17))
- b. The negative morpheme is a reflex of a negative component of that operator.

#### 3.2.1. Sufficiency Modal Constructions

One decomposition of *only* is proposed by von Stechow and Iatridou (2007), who discuss SUFFICIENCY MODAL CONSTRUCTIONS such as in (24):

- (24) To get good cheese, you *only* have to go to the North End.

They observe that crosslinguistically, one also finds a second pattern: *To get good cheese, you*

<sup>9</sup>For convenience I will continue referring to the interruption implication as a scalar implicature, even though under the grammatical view adopted here scalar implicatures are analysed as entailments.

<sup>10</sup>It should be noted that unlike EXHAUST and EXN, overt *only* is allowed in DE environments:

- (i) If the rhino eats *only* artichokes, it might be sick.
- (ii) Every rhino who ate *only* artichokes was examined by the vet.

Additionally, the preadjacent is treated differently by the two operators: EXHAUST asserts it, while *only* presupposes it. An idea suggested to me by Danny Fox (p.c.) would be that while *only* and EXHAUST are built of the same parts, EXHAUST involves local accommodation, thus turning the presupposed preadjacent into an asserted one.

*do not have but go to the North End*. The following are two examples adapted from von Fintel and Iatridou's (2)–(3):

- (25) ... *dhen echis para na pas sto North End*  
 NEG have.2SG EXCEPT NA go.2SG to.the North End  
 '... you only have to go to the North End' (Greek)
- (26) ... *tu n'as qu'à aller au North End*  
 you NE-have QUE-to go to.the North End  
 '... you only have to go to the North End' (French)

Another observation made by von Fintel and Iatridou is that for a (goal-oriented necessity) modal to be able to participate in a sufficiency modal construction, it has to be a non-PPI modal. That is, it has to be able to scope under negation.

Von Fintel and Iatridou propose to treat *only* crosslinguistically – even in languages where there are no overt negation-and-exceptive sufficiency constructions – as composed of a negation and an expletive. Together with the assumption that the expletive is (or hosts) an NPI, they allow the modal to take scope between the two components:

- (27) To get good cheese, you do *not* have to do *anything other than* going to the N. End.

### 3.3. Proposal: EXN is an exponent of *only*

To briefly sum up, the data involves a negative morpheme along with an obligatory interruption implication, which I submit results from an *only*-like exhaustivity operator (§3.1). The decomposition of *only* into a negative part and an expletive part as proposed by von Fintel and Iatridou (2007) paves the way to understanding EXN as a regular compositional negation: if EXN is the negative component of the exhaustivity operator, as I propose, we can predict the data while maintaining a single meaning for the negative morpheme. To achieve this I will assume that both pieces are syntactically present: negation is overt, while the expletive is covert.

A sentence of the form *A until EXN B* is thus paraphrasable as *A until not anything other than B*. As before, assuming that what *anything other than* ranges over is times (18), we would not be able to exclude any earlier time due to entailment, but *would* be able (and required) to exclude later times, thus predicting the interruption implication. In the following two sections I go through the details of the proposal.

#### 3.3.1. Assumptions

The following structure is what I take to be the LF for *Mary played the piano until John EXN opened the door*. I return to the decomposition of EXHAUSTP after discussing my assumptions below.

(28)

The movement step in (28) is a case of Focus-movement, a kind of sideways movement discussed in Wagner (2007) and Erlewine and Kotek (2017), among others. The associate of the focus-sensitive operator EXHAUST moves to it, as the associate of *only* would in Wagner's (2007) analysis.

I will assume that clauses denote temporal properties (i.e., characteristic functions of sets of time intervals).<sup>11</sup> I follow Condoravdi (2010) in: (i) taking *until* to uniformly compose with a time, even when its surface complement is a clause, and (ii) assuming that a maximality operator MAX (i.e., a definite determiner of type  $\langle it, i \rangle$ ) applies to *until*'s clausal complement to yield the desired time argument: the (smallest) maximal interval instantiating the complement.

*Until* will be analyzed as denoting a relation between times:  $\llbracket \text{until} \rrbracket \in D_{\langle i, it \rangle}$ . It composes with its first argument, be it a time-denoting DP or a clause, resulting in a temporal property (i.e., of type  $\langle i, t \rangle$ ). This temporal property then composes intersectively (i.e., by Predicate Modification) with the matrix clause.

To capture the entailment that the main clause was true at *all* times up to the time of the *until*-phrase, I take it that *until*'s quantificational force is universal. Just like other quantifiers, *until* has a contextually restricted domain (von Stechow, 1994). The domain of time intervals  $D_i$  is contextually restricted to its subset  $C_i$ . This would prevent *Mary played the piano until five* from entailing that she played the piano since the beginning of time.

<sup>11</sup>These functions of type  $\langle i, t \rangle$  could in principle be extended to other kinds of intensions in various ways (e.g., by assuming that type  $s$  is of world-time pairs and that clauses are of type  $\langle s, t \rangle$ , or that clauses are of type  $\langle i, st \rangle$  or  $\langle s, it \rangle$ ). Since this extension is immaterial to the analysis, I ignore worlds altogether.

Alternatives are derived by substituting *until*'s complement with other times in  $C_i$ . Thanks to keeping  $C_i$  constant, *until 5* ends up asymmetrically (Strawson-)entailing *until 4* (as far as Strawson-entailment is concerned, this is a variant of Condoravdi, 2010).

I implement von Stechow and Iatridou's (2007) view of the exceptive phrase as being an NPI and having existential force by taking the exceptive phrase to contain, in addition to the exceptive head, an existential quantifier restricted to a contextually salient domain. In the relevant cases the domain is the contextually restricted temporal domain  $C_i$ . Given these assumptions, the decomposition of EXHAUSTP in (28) is as follows:

(29) NEG [ $\exists$  [ $C_i$  [EXCEPT [MAX [John open the door]]]]]

Note that there is a tension between the semantics and the surface syntax regarding the position of negation. For interpretation, we need it scoping as high as possible to negate not only the *until*-clause but also the matrix clause. On the other hand, negation shows up inside the *until*-clause in the surface string (see more on this in §3.3.3). To allow a suitable configuration, I will assume the following structure, with a negation of type  $\langle itt, itt \rangle$ .<sup>12,13</sup>

(30)

<sup>12</sup>Other cases of high-type negation include determiner negation such as *no NP*, *not every NP*, as well as the ones in *impossible* and *unhappy*.

<sup>13</sup>The semantics is compatible with negation occupying a lower position, adjoined to the the existential quantifier in (29), or a higher position, c-commanding both the matrix clause and the *until*-clause. The former would be similar to determiner negation in fn. 12, while the latter would be plain propositional negation. The proposal ends up not taking either of these paths due to the surface position of negation, as discussed in §3.3.3.

## 3.3.2. Denotations and calculations

Below I specify the denotations of the components and their composition. The discussion considers nominal complements as well as clausal complements of *until*.

- (31)  $\llbracket P \rrbracket := \llbracket \text{Mary played the piano} \rrbracket = \lambda t_i. \text{Mary play the piano at } t$
- (32) a.  $\llbracket \text{until} \rrbracket = \lambda t'_i. \lambda t''_i. \forall t \in C_i [(t < t') \rightarrow (t \subseteq t'')]$ . In words, *until* relates two times, returning truth iff all times preceding the first are contained within the second.  
 b.  $\llbracket \text{until five} \rrbracket = \lambda t'_i. \forall t \in C_i [(t < 5pm) \rightarrow (t \subseteq t'')]$ . That is, the (characteristic function of the) set in  $C_i$  of all times which contain all times preceding *5pm*.
- (33) Entailment between alternatives (cf. (19)):  
 $\lambda t'_i. \forall t \in C_i [(t < 5pm) \rightarrow (t \subseteq t'')] \subset \lambda t'_i. \forall t \in C_i [(t < 4pm) \rightarrow (t \subseteq t'')]$   
 That is, the set of times containing everything in  $C_i$  which precedes *5pm* is a proper subset of the set containing everything in  $C_i$  preceding *4pm*. This is so because if all times up to five are in an interval, then all times up to four are also in that interval, so any interval in the former set will be in the latter set. The latter set additionally contains at least an interval whose right edge is four, which is not a member of the former set. Thus we have captured the downward entailment property of *until*.
- (34) Without interruption:  $\llbracket P \text{ until five} \rrbracket = \lambda t_i. \llbracket P \rrbracket (t) = 1 \wedge \forall t' \in C_i [(t' < 5pm) \rightarrow (t' \subseteq t)]$   
 That is, the (characteristic function of the) set in  $C_i$  of all times at which Mary played the piano and which also contain all times prior to five.<sup>14</sup>
- (35) a.  $\llbracket O \rrbracket := \llbracket \text{John opened the door} \rrbracket = \lambda t_i. \text{John open the door at } t$   
 b.  $\llbracket \text{Mary played the piano until John opened the door} \rrbracket = \llbracket P \text{ [until [MAX [O]]]} \rrbracket$   
 c.  $t_{O_j} := \llbracket \text{MAX}[O] \rrbracket = \text{the smallest } t \text{ s.t. } \forall t' [\llbracket O \rrbracket (t') = 1 \rightarrow t' \subseteq t]$ , if defined  
 d.  $\llbracket \text{until [MAX (O)]} \rrbracket = \lambda t'_i. \forall t \in C_i [(t < t_{O_j} \rightarrow (t \subseteq t''))]$   
 That is, the (characteristic function of the) set of all times which contain all times in  $C_i$  preceding John's door-opening.
- (36) **Without interruption:**  
 $\llbracket P \text{ until MAX } O \rrbracket = \lambda t'_i. \llbracket P \rrbracket (t'') = 1 \wedge \forall t \in C_i [t < t_{O_j} \rightarrow (t \subseteq t'')]$   
 That is, the (characteristic function of the) set in  $C_i$  of all times at which Mary played the piano and which also contain all times prior to John's door-opening.
- (37) **With interruption:**  
 $\llbracket (30) \rrbracket = 1 \text{ iff } \neg \exists t'' \in C_i [t'' \neq t_{O_j} \wedge \exists t' [\llbracket P \rrbracket (t') = 1 \wedge \forall t \in C_i [t < t'' \rightarrow t \subseteq t']]]$   
 That is, (30) is true iff there doesn't exist a time other than John's door-opening time until which Mary plays the piano.

<sup>14</sup>I am assuming that existential closure applies later and eliminates the final lambda-binder.

### 3.3.3. Linearization

In the Hebrew examples in §2, EXN appears on T(ense) of the embedded *until*-clause, whereas the analysis locates the negation responsible for it in the main clause. What can explain this?

It is important to note that even non-expletive occurrences of *lo* raise a linearization question, if we follow Zeijlstra (2004, 2008) in assuming that abstract negation is the semantic negation in strict negative concord languages such as Hebrew. I propose a PF rule for Hebrew negation which captures both EXN and other (‘ordinary’) occurrences of Hebrew negation:

(38) An (abstract) negation NEG is spelled out as *lo* on the closest T it c-commands.

This predicts both the distribution of ordinary negation and that of EXN, if we take NEG, as part of EXHAUST, to be locally above the *until*-clause. This will put it high enough for the embedded T to bear agreement, but too low for the matrix T. Exactly this kind of configuration is predicted by the LF in (30) because the complement of *until*, including its T head, moves to EXHAUST.<sup>15</sup>

## 4. Predictions

We have seen how the idea that EXN is an exponent of *only* predicts the obligatoriness of the interruption implication and the incompatibility of EXN with DE-environments. Furthermore, the current analysis predicts EXN to share more properties with *only*. This prediction is borne out in (i) EXN’s oddness when there are no alternatives to exclude, (ii) its incompatibility with overt *only*, (iii) its ability to trigger stressing and preposing of the *until*-clause, and (iv) the lack of negative concord licensing by EXN. I examine these predictions below.

### 4.1. #EXN when there are no alternatives to exclude

World knowledge makes (39b) odd, while felicitous without EXN. This is so because the pre-jacent is stronger than all other alternatives, rendering EXN – and *only* in the English translation – vacuous.<sup>16</sup>

- (39) a. *ani ohav ot-ax ad se jigamer ha-zman / jitpotsets ha-olam*  
           I love.FUT ACC-you until that end.FUT the-time / explode.FUT the-world  
           ‘I will love you until the end of time / until the world explodes.’  
       b. *#ani ohav ot-ax ad se lo jigamer ha-zman / jitpotsets ha-olam*  
           I love.FUT ACC-you until that NEG end.FUT the-time / explode.FUT the-world  
           ‘#I will love you **only** until the end of time / **only** until the world explodes.’

<sup>15</sup>Michel DeGraff (p.c.) suggests another way to capture the surface position of negation while allowing it to take wide scope: movement. Negation would have to start inside the *until*-clause, where it is pronounced, and move out of it at LF to take matrix scope. This seems to be in line with the observation that EXN tends to be accompanied by subjunctive mood in the *until*-clause in various languages.

<sup>16</sup>Just as in the English translation, (39b)’s oddness can be ameliorated by taking the speaker to have some alternatives (i.e., later times) in mind. This supports the claim that there must be some alternatives to exclude.

4.2. EXN is incompatible with overt *only*

Just like adding *only* to an existing *only* is ungrammatical, arguably because the second *only* would be vacuous, EXN cannot be accompanied by an overt *only* with the same associate:<sup>17,18</sup>

- (40) a. \**joni jaʃan rak ad fe ha-ʃxenim lo hidliku muzika*  
           Y. slept only until that the-neighbors NEG lit music  
       b. *joni jaʃan rak ad fe ha-ʃxenim hidliku muzika*  
           Y. slept only until that the-neighbors lit music  
           ‘Yoni was asleep only until the neighbors turned some music on.’

## 4.3. Preposing and stress

The relevant background on Hebrew is that contrastive focus can cause preposing of the focused phrase, as illustrated below. Both (42a) and (42b) are licit corrections to (41).<sup>19</sup>

- (41) *hu axal tapuax-adama*  
       he ate apple-earth  
       ‘He ate a potato.’
- (42) a. ARTIʃOK *hu axal*  
           artichoke he ate  
           ‘He ate an ARTICHOKE.’
- b. *hu axal* ARTIʃOK  
           he ate artichoke  
           ‘He ate an ARTICHOKE.’

Many of the speakers I have consulted prefer (some require) preposing the *until*-clause when it contains EXN and stressing *ad* ‘until’.<sup>20</sup> For example, take (4), repeated here as (43a). Its version (43b), with preposing of the *until*-clause and stress on *until* is judged by the informants I have consulted as preferable compared to (43a) if EXN is present.

- (43) a. *ha-ʃvita timaʃex ad fe (lo) jeanu drifot ha-ovdim*  
           the-strike will continue until that NEG will be answered demands the-workers  
           ‘The strike will continue until the workers’ demands are met.’
- b. A:D *fe (lo) jeanu drifot ha-ovdim ha-ʃvita timaʃex*  
           until that NEG will be answered demands the-workers the-strike will continue  
           ‘UNTIL the workers’ demands are met the strike will continue.’

<sup>17</sup>As long as EXN has sentential scope, an overt *only* with narrow focus is allowed, for example, associating with a DP.

<sup>18</sup>(40a) is grammatical – though odd – under a non-expletive interpretation of negation.

<sup>19</sup>Cf. English negative inversion, where association with focus causes optional overt movement:

- (i) Only in the living room did Kim agree to hang the photo.

<sup>20</sup>Rubinstein and Doron (2015) make a similar observation regarding EXN and stress in constituent conditionals, which is placed on a *wh*-item.

Stress and preposing, two hallmarks of association with focus, would be better understood if EXN were, as I propose here, a component of a focus-sensitive operator. Those speakers who require stress and preposing must have obligatory overt focus-movement.

#### 4.4. No negative concord with EXN

As noted in §2, negation in *until*-clauses can in principle also have an ‘ordinary’ negative interpretation. When a Negative Concord Item (NCI, a.k.a. *n-word*) is c-commanded by the negation *lo*, this becomes the only available interpretation. In other words, EXN cannot license negative concord.<sup>21</sup> In both (44) and (45) the first example contains the negation *lo* and has both interpretations available, whereas the second example contains a NCI replacing the embedded subject and causing *lo* to not be expletive.

- (44) a. *ha-saxkan himfix b-a-stsena ad fe joni (lo) baxa*  
 the-actor continued in-the-scene until that Y. NEG cried  
 –‘The actor continued with the scene until Yoni cried.’  
 –‘The actor continued with the scene until Yoni was no longer crying.’  
 b. *ha-saxkan himfix b-a-stsena ad Se af exad lo baxa (joter)*  
 the-actor continued in-the-scene until that no one NEG cried (more)  
 Only: ‘The actor continued with the scene until nobody was crying (anymore).’  
 (Not: ‘The actor continued with the scene until somebody cried.’)
- (45) a. *miri amda al ha-bama ad fe joni (lo) maxa kapaim*  
 M. stood on the-stage until that Y. NEG clapped palms  
 –‘Miri stood on the stage until Yoni applauded.’  
 –‘Miri stood on the stage until Yoni did not applaud (anymore).’  
 b. *miri amda al ha-bama ad fe af exad lo maxa kapaim (joter)*  
 M. stood on the-stage until that no one NEG clapped palms (more)  
 Only: ‘Miri stood on the stage until nobody was applauding (anymore).’  
 (Not: ‘Miri stood on the stage until somebody applauded.’)

Lack of negative concord under EXN follows from the independent generalization that exceptives are intervenors for negative concord, as (46) demonstrates. If EXN comes with a covert exceptive, as proposed here, negative concord is predicted not to be licensed. The only available reading in (44b) and (45b) arises from the need to parse these sentences without an exceptive, which would otherwise block negative concord.

<sup>21</sup>One might wonder whether NPIs are licensed by EXN. Modulo the archaic flavor of NPIs in Modern Hebrew, (i) in fact shows that the NPI *davar* ‘a thing’ cannot be licensed by EXN, similarly to NCIs in (44) and (45) above. I thank Luka Crnić for raising this question.

- (i) *servu le-faxrer-o mi-ma?atsar-minhali ad fe lo axal davar*  
 3.refused.PL to-release-him from-arrest-administrative until that NEG 3.ate.SG thing  
 Only: ‘They refused to release him from administrative detention until he did not eat anything (=until he went on a hunger strike).’  
 (Not: ‘They refused to release him from administrative detention until he ate something.’)

- (46) a. *miri lo ra'ata af exad*  
           M. NEG saw no one  
           'Miri didn't see anybody.'
- b. *\*miri lo ra'ata ela af exad*  
           M. NEG saw but no one
- c. *\*miri lo ra'ata milvad af exad*  
           M. NEG saw except no one

## 5. Conclusion

### 5.1. Summary

We have seen that expletive negation suspiciously mimics *only* and its covert counterpart EXHAUST: (i) It renders the interruption implication, which is an otherwise optional scalar implicature, uncancellable; (ii) EXN is incompatible with DE environments just like EXHAUST is; (iii) EXN is odd if there are no alternatives to exclude; (iv) It is incompatible with overt *only*; (v) It triggers optional stress on *until* and preposing of the *until*-clause, both of which are hallmarks of association with focus, and (vi) EXN cannot license negative concord.

I have proposed that EXN is in fact an ordinary compositional negation, being part of a negation-and-exceptive construction responsible for all the *only*-like phenomena, whereas the exceptive is covert. This follows von Stechow and Iatridou's (2007) proposal to decompose overt *only* into a negation and an exceptive.

The analysis predicts the obligatoriness of the interruption implication as an entailment of the decomposed *only*. EXN's incompatibility with DE environments results from an independent property of covert *only*, observable when scalar implicatures disappear in such environments. The vacuity of EXN when there are no alternatives to exclude or when there is a distinct, overt *only* explains why EXN is odd in such cases. Preposing and stress associated with EXN are compatible with EXN being part of a focus-sensitive operator, and EXN's incapability to license negative concord is expected since exceptives block negative concord.

The crosslinguistic picture arising from this proposal is one where a negation-and-exceptive construction can be pronounced as a single item (e.g., English *only*), as two items (e.g., French *ne...que*), as an overt negation with a covert exceptive (EXN), as an overt exceptive with a covert negation (e.g., archaic English *but as in the building had but a single window*), or not pronounced at all (EXHAUST).

### 5.2. Next steps

There are multiple questions pertaining to EXN and to the specific proposal advanced in this paper which are left unanswered:

1. **Covert exceptives** What governs the pronunciation of exceptive heads? That is, when can an exceptive be covert? This is needed to prevent all occurrences of *only* and of EXHAUST from being expressible as negation.
2. **Punctual *until*** Can the analysis be extended to punctual *until* in examples like (47), where an interruption-like inference is obligatory?<sup>22</sup>

(47) The dog didn't bark until Kim sneezed. ( $\rightsquigarrow$  The dog barked when Kim sneezed)

3. **Causality** EXN has an interpretive effect which is additional to the interruption implication and is not predicted by what I have proposed in this paper. *Until*-clauses containing EXN are felt to convey causality of sorts, as though the eventuality described by the *until*-clause *leads to* the interruption of the eventuality described by the main clause in a non-coincidental way.<sup>23</sup>
4. **Free Relatives** A question related to questions 1 and 3 above pertains to EXN in Free Relative clauses, as attested in Hebrew, Yiddish, Russian, Polish, Udmurt, Georgian (Eilam, 2007; Rubinstein and Doron, 2015; Rubinstein et al., 2015; Haspelmath and König, 1998), and Bangla (Ishani Guha, p.c.). As Eilam (2007) shows, the contribution of EXN in such cases is reminiscent of that of *-ever* in English Free Relatives, along with ignorance and indifference inferences. It is not clear that an exclusive inference parallel to the interruption implication is present in such cases. At the same time, a source of hope for a unified account comes from the observation that some Free Relatives can host an overt *only*, as illustrated in (48).<sup>24</sup>

(48) a. *ha-kelev ja?akov axarej-xa le-?an je-rak telex*  
 the-dog 3MSG.follow.FUT after-2MSG to-where that-only go.2MSG  
 'The dog will follow you wherever you go.'

<sup>22</sup>I thank Maribel Romero for raising this question.

<sup>23</sup>A related phenomenon, which to the best of my knowledge was not mentioned before, is the unavailability of *de re* readings with EXN. The EXN-less sentence in (i) can be true even if Miri is willing to be here until some time, say noon, and unbeknownst to her, Yoni is going to return at noon. When EXN is added in (ii) it can only be the case that Miri is willingly waiting for Yoni. In other words, in (i) she is willing to be here until some time that the *speaker* describes as Yoni's return time, but in (ii) she is willing to be here until some time that *she* describes as Yoni's return time.

- (i) *miri muxana li-hiyot po ad Se yoni yaxzor*  
 M. ready to-be here until that Y. return.FUT  
 'Miri is willing to be here until Yoni returns.' (✓*de re*; ✓*de dicto*)
- (ii) *miri muxana li-hiyot po ad Se yoni lo yaxzor*  
 M. ready to-be here until that Y. NEG return.FUT  
 'Miri is willing to be here until Yoni returns.' (\**de re*; ✓*de dicto*)

<sup>24</sup>Another telling observation is that similarly to the facts on *until* in fn. 23, Free Relatives hosting EXN are obligatorily read *de dicto*. That is, they are of the *wh-ever* kind, with ignorance and indifference inferences, and not plain extensional definite descriptions.

- b. *ha-kelev jaʔakov axarej-xa le-ʔan fe-lo telex*  
 the-dog 3MSG.follow.FUT after-2MSG to-where that-NEG go.2MSG  
 ‘The dog will follow you wherever you go.’

### 5. Negative concord Why are exceptives intervenors for negative concord?

I hope that future research will shed light on these issues.

# Predicting polar question embedding<sup>1</sup>

Clemens MAYR — *Leibniz-Zentrum Allgemeine Sprachwissenschaft*

**Abstract.** This paper shows that it is fully predictable whether a polar interrogative clause can appear under a declarative embedding predicate. The idea in a nutshell is as follows: whenever a predicate appears to not embed polar interrogatives, the interpretative component independently derives a trivial meaning for the sentence. Such trivial meanings manifest themselves in unacceptability. A crucial property of this proposal is that interrogative embedding is polarity-sensitive, which is shown to be empirically supported. As a consequence, one must not stipulate in the lexical entry of a given predicate whether or not it embeds polar interrogative clauses.

**Keywords:** question embedding, logic in grammar, polarity, embedding predicates.

## 1. Introduction

*Know* can embed both declarative and polar interrogative clauses, as shown in (1). From this one might expect that any proposition-taking predicate (PTP) shows this behavior.<sup>2</sup> As is well-known, this is, however, not the case. For instance, the closely related PTP *believe* does not embed polar interrogative clauses, as shown in (2). This is somewhat unexpected. The lexical meaning of *believe* is the one of *know* modulo additional meaning components.<sup>3</sup>

- (1) a. John knows that Mary smokes.  
b. John knows whether Mary smokes.
- (2) a. John believes that Mary smokes.  
b. \*John believes whether Mary smokes.

Following Lahiri (2002), I refer to PTPs embedding both declarative and interrogative clauses as responsive and those only embedding the former as non-responsive. The question posed by (1) and (2) can then be stated as in (3).

- (3) **The responsiveness puzzle:** Under what conditions is a PTP responsive?

The standard answer to this question, going back to Grimshaw (1979), is that predicates are lexically specified as to which type of complement clause they combine with. The assumption underlying such approaches is that whether a PTP embeds a given clause type is completely arbitrary and not predictable from independent principles. In other words, there simply are no special properties inherent to *know* that make it responsive, as implied by (3).

---

<sup>1</sup>I thank Gennaro Chierchia, Franzi Conradts, Andreas Haida, Irene Heim, Hazel Pearson, Nadirah Porter-Kasbati, Floris Roelofsen, Uli Sauerland, Viola Schmitt, Kerstin Schwabe, Benjamin Spector, and Hubert Truckenbrodt for comments and suggestions. I also thank audiences at ZAS, the universities of Belfast, Siena, Tübingen, and Vienna, and *Sinn und Bedeutung* 21. The work reported here has been supported by DFG grant STE 2555/2-1.

<sup>2</sup>Since the standard assumption is that declarative clauses denote propositions, I refer to predicates embedding them as proposition-taking ones.

<sup>3</sup>See for instance Gettier (1963).

This paper takes (3) seriously and argues against Grimshaw's 1979 conviction. Based on the observation that certain PTPs embed polar interrogative clauses only in particular contexts, I suggest that a lexical stipulation approach is untenable. PTPs are generally not specified with respect to whether they embed interrogative clauses or not. Rather, I argue that the distribution of embedded interrogative clauses is fully predictable on semantic grounds alone. The strong thesis followed in this paper is that whenever a PTP is seemingly unable to embed a polar interrogative, this is due to the interpretative component necessarily generating a trivial meaning for the sentence as a whole. Trivial meanings are tautologies and contradictions, which make themselves felt as unacceptability of the sentence (see Gajewski 2002; Chierchia 2006, 2013; Fox and Hackl 2006; Abrusán 2014 a.o.). Two factors play a role in determining whether a meaning is trivial or not: (i) the particular lexical semantics of the PTP, and (ii) the polarity of the sentence as a whole. The apparent impossibility of interrogative embedding under *believe* in (2b), for instance, is due the sentence denoting the tautology. (1b), on the other hand, does not have such a trivial denotation, and thus no degradedness is felt.

I show in the following that this simple approach can deal with numerous types of PTPs. As will be seen, the key insight here is that interrogative embedding necessitates an existential semantics (Spector and Egré 2015, see also Lahiri 2002; Theiler et al. 2016 a.o.). Confining myself to the embedding of polar interrogatives, which is done for reasons of space, moreover allows me to work with completely standard meanings for the PTPs discussed. For *wh*-interrogatives, however, the lexical semantics would have to be somewhat complicated. I refer the reader to Mayr (2017) for discussion of *wh*-interrogatives.<sup>4</sup>

The structure of the paper is as follows. In section 2, I discuss the issue that interrogative embedding poses for a theory of grammar in more detail. Section 3 introduces the proposed system. Section 4 shows its application to the *know-believe* distinction. Section 5 discusses further classes of PTPs. Section 6 concludes the paper.

## 2. Problems of interrogative embedding

### 2.1. Arguments for lexical stipulation

*Know* when embedding a declarative clause, as in (1a), licenses the inference that that clause is true. That is, *know* is veridical.<sup>5</sup> *Believe*, as in (2a), does not do so, i.e., it is non-veridical. An old intuition is therefore that a responsive PTP must be veridical (Hintikka, 1975; Berman, 1991; Ginzburg, 1995a, b; Egré, 2008). Indeed, many veridical PTPs, as in (4), embed interrogative clauses. And many non-veridical ones do not, as in (5). Here and below  $\rightsquigarrow X$  and  $\nrightarrow X$  indicate that the example has or does not have the proposition *that X* as an inference.

<sup>4</sup>Given what has just been said, I will not discuss the issue of emotive factive PTPs in this paper. These allow for embedding of *wh*-interrogatives but not of polar interrogatives (see Guerzoni 2007; Sæbø 2007; Nicolae 2013; Romero 2015; Roelofsen et al. 2017 a.o.).

(i) a. \*John is amazed / happy / surprised whether Mary smokes.  
b. John is amazed / happy / surprised which girls smoke.

<sup>5</sup>More precisely, *know* is, of course, not only veridical but also factive. A PTP is factive if the inference that the complement declarative clause is true remains under entailment-cancelling operators.

- (4) a. John *deduced / discovered / established / figured out / found out / forgot / learned / recalled / remembered* that Mary smokes.  $\rightsquigarrow$  Mary smokes  
 b. John *deduced / discovered / established / figured out / found out / forgot / learned / recalled / remembered* whether Mary smokes.
- (5) a. John *alleged / asserted / claimed / conjectured / desired / expected / feared / hoped / inferred / wanted / wished* that Mary smokes.  $\nrightarrow$  Mary smokes  
 b. \*John *alleged / asserted / claimed / conjectured / desired / expected / feared / hoped / inferred / wanted / wished* whether Mary smokes.

This conclusion is, however, called into question by the fact that there are PTPs which embed interrogative clauses yet are non-veridical, as (6) shows (see Grimshaw 1979; Lahiri 2002; Uegaki 2015).

- (6) a. John *announced / confirmed / declared / heard / predicted / reported / told us* that Mary smokes.  $\nrightarrow$  Mary smokes  
 b. John *announced / confirmed / declared / heard / predicted / reported / told us* whether Mary smokes.

Apart from veridicality, no other semantically discernible property has been found that would separate the responsive PTPs from the non-rogative ones. That is, neither the former nor the latter seem to form a coherent lexical class. It has thus been claimed that it is not predictable given formal semantic properties of a given PTP whether it is responsive or not (Grimshaw, 1979; Uegaki, 2015). In particular, Grimshaw has advanced the view that predicates are specified lexically for so-called s-selectional properties (see also Chomsky 1965; Baker 1968). That is, each PTP is at least specified for whether the embedded clause can be +declarative and +interrogative. The idea here is that such s-selectional specification does not follow from anything more basic.

## 2.2. Problems for lexical stipulation

According to the lexical specification hypothesis each PTP comes with a feature setting specifying whether an interrogative is a possible complement or not. The surrounding linguistic context should not be able to alter this setting. The data in (7) show that the PTP *be certain* contradicts this prediction. On its own *be certain* can embed declarative clauses as in (7a) but not polar interrogatives as in (7b). With negation as in (7c), however, embedding of a polar interrogative markedly improves (see for instance Eckardt 2007; Egré 2008).

- (7) a. John is certain that Mary smokes.  $\nrightarrow$  Mary smokes  
 b. \*John is certain whether Mary smokes.  
 c. John isn't certain whether Mary smokes.

Transitive *say*, in contrast to its ditransitive use, and *be convinced* exhibit a behavior parallel to *be certain*, as is shown by (8).

- (8) a. John *said / is convinced* that Mary smokes.  $\nrightarrow$  *Mary smokes*  
 b. \*John *said / is convinced* whether Mary smokes.  
 c. John *didn't say / isn't convinced* whether Mary smokes.

*Be certain* and the other PTPs just discussed are non-veridical. Interestingly, *be clear* is veridical, and yet it shows the same behavior as *be certain*. In other words, (non)-veridicality is once again not a good indicator as to whether interrogative embedding is possible at all.

- (9) a. It is clear that Mary smokes.  $\rightsquigarrow$  *Mary smokes*  
 b. \*It is clear whether Mary smokes.  
 c. It isn't clear whether Mary smokes.

The distribution of polar interrogative clauses as complements of the PTPs above is reminiscent of negative polarity items (NPIs) like *any* (Adger and Quer, 2001), as in (10).

- (10) a. \*John saw any girl.  
 b. John didn't see any girl.

Contexts other than negation which allow for NPIs improve the embedding of polar interrogatives under *be certain* as well. Typical such contexts are downward monotonic environments (see Fauconnier 1979; Ladusaw 1979; Linebarger 1987; Krifka 1995; Giannakidou 1999; Chierchia 2004, among many others): antecedents but not consequents of conditionals, negative quantifiers, and restrictors but not scopes of universal quantifiers. Indefinites thus never allow for NPIs. The following demonstrate that polar interrogatives under *be certain* show an NPI-like behavior:

- (11) a. If John is certain whether Mary smokes, he knows her well.  
 b. \*If John knows Mary well, he is certain whether she smokes.
- (12) a. No student who is certain whether Mary smokes does not know her.  
 b. No student who does not know Mary is certain whether she smokes.
- (13) a. Every student who is certain whether Mary smokes knows her well.  
 b. ?Every student who knows Mary well is certain whether she smokes.
- (14) a. \*Some student who is certain whether Mary smokes knows her well.  
 b. \*Some student who knows Mary well is certain whether she smokes.

### 2.3. Intermediate conclusion

Summarizing, I note two things: (i) the prediction of the lexical specification account that linguistic context cannot affect clausal embedding appears to be wrong. (ii) The way linguistic context affects clausal embedding is systematic and tracks the licensing of NPIs to a consider-

able extent. In light of this I conclude that the lexical specification hypothesis is untenable.<sup>6</sup>

Now, how could the embedding of polar interrogative clauses be similar to the distribution of NPIs? One of the main contending views regarding NPIs goes as follows: first, *any girl* in (10) denotes an existential quantifier over girls. Second, the sentence has alternatives about particular girls such as *John saw Mary* for (10a) and *John didn't see Mary* for (10b). Third, each sentence in (10) undergoes exhaustification with respect to its alternatives resulting in the conjunction of the sentence—its prejacent—with the negation of the alternatives. This leads to a contradiction without but not with negation, accounting for the pattern in (10) (see Heim 1984; Kadmon and Landman 1993; Krifka 1995; Chierchia 2006, 2013; Crnič 2014, among many others). In the following I show that something similar is happening in the case of the embedding of polar interrogatives.

### 3. A polarity system for polar interrogative embedding

In the case of polar interrogative clauses, it is the semantics for interrogative embedding necessitating existential quantification (Spector and Egré, 2015). The alternatives are contributed by the embedded interrogative (Klinedinst and Rothschild, 2011). The exhaustification process relative to these alternatives accounts for the patterns discussed in the preceding section.

Assume for *be certain* Hintikka's 1969 universal semantics for propositional attitudes:

$$(15) \quad \llbracket \text{be certain} \rrbracket = \lambda p_{st} . \lambda x_e . \lambda w_s . \forall w' [w' \in \text{Dox}_{x,w} \rightarrow p(w') = 1]$$

*Be certain* applied to a proposition  $p$  asserts that  $p$  is true in all of the subject's doxastic alternatives. This means  $p$  is true in all the worlds doxastically accessible to the subject from the world of evaluation  $w$ .

Consider now the sentences in (16) again. Assume that the denotation of the embedded interrogative is as in (17). This is an existential quantifier ranging over a set of propositions, i.e., over a question denotation in the sense of Hamblin (1973) and Karttunen (1977). The set contains the positive and the negative answer to the polar interrogative. In the following, I abbreviate this set as  $Q'$ —that is,  $\{\lambda w. \text{Mary smokes in } w, \lambda w. \text{Mary doesn't smoke in } w\} = Q'$ .

- (16) a. John isn't certain whether Mary smokes.  
b. \*John is certain whether Mary smokes.

$$(17) \quad \begin{aligned} \llbracket \text{whether Mary smokes} \rrbracket &= \lambda Q_{\langle st, t \rangle} . \lambda w_s . \exists p [p \in \{\lambda w' . \text{M smokes in } w', \\ &\quad \lambda w' . \text{M doesn't smoke in } w'\} \wedge Q(p) = 1] \\ &= \lambda Q_{\langle st, t \rangle} . \lambda w_s . \exists p [p \in Q' \wedge Q(p) = 1] \end{aligned}$$

Now, since the denotation of *be certain* requires a proposition as argument, it cannot apply to

<sup>6</sup>To this one might add the observation that the embedding patterns appear to be cross-linguistically stable. From the perspective of a lexical stipulation based account this is unexpected. Languages should be allowed to differ widely with respect to which PTP embeds which clause-type.

(17). Assume therefore, following Lahiri (2002), that the embedded interrogative must take scope over the entire clause, which gives the LFs in (18a) and (18b) for (16a) and (16b), respectively. The operator *Exh* is discussed below.

- (18) a.  $[S'_1 \text{ Exh}_{Alt} [S_1 \text{ not } [[\text{whether Mary smokes}] \lambda p[\text{John is certain } p]]]]$   
 b.  $[S'_2 \text{ Exh}_{Alt} [S_2 [\text{whether Mary smokes}] \lambda p[\text{John is certain } p]]]$

For (18a), on the one hand, the denotation of  $S_1$ —its literal meaning—corresponds thus to (19). This says that there is no proposition in  $Q'$  which is true in all of John's doxastic alternatives. (18b), on the other hand, has as its literal meaning (19b) saying that there is a proposition in  $Q'$  that is true in all of John's doxastic alternatives.

- (19) a.  $\llbracket S_1 \rrbracket^g = \lambda w. \neg \exists p[p \in Q' \wedge \forall w' [w' \in \text{Dox}_{J,w} \rightarrow p(w') = 1]]$   
 b.  $\llbracket S_2 \rrbracket^g = \lambda w. \exists p[p \in Q' \wedge \forall w' [w' \in \text{Dox}_{J,w} \rightarrow p(w') = 1]]$

Consider next the alternatives to the literal meanings in (19a) and (19b). I stipulate them to constitute sets of propositions satisfying the following requirement: each member corresponds to the denotation one would get by replacing the embedded interrogative in (17) with one of its answers in the set  $Q'$ . Since the answers are propositions *be certain* can be applied directly.<sup>7</sup>

- (20) a.  $\text{Alt}(\llbracket S_1 \rrbracket^g) = \{\lambda w. \neg \forall w' [w' \in \text{Dox}_{J,w} \rightarrow \text{Mary smokes in } w'],$   
 $\lambda w. \neg \forall w' [w' \in \text{Dox}_{J,w} \rightarrow \text{Mary doesn't smoke in } w']\}$   
 b.  $\text{Alt}(\llbracket S_2 \rrbracket^g) = \{\lambda w. \forall w' [w' \in \text{Dox}_{J,w} \rightarrow \text{Mary smokes in } w'],$   
 $\lambda w. \forall w' [w' \in \text{Dox}_{J,w} \rightarrow \text{Mary doesn't smoke in } w']\}$

Finally, each literal meaning derived in (19) is strengthened relative to its alternatives in (20). This is done with the help of the *Exh*-operator defined in (21) (see Groenendijk and Stokhof 1984; Krifka 1995; van Rooij and Schulz 2004; Chierchia 2006, 2013; Fox 2007; Spector 2007, among many others). *Exh* takes a proposition  $p$ —the prejacent  $S_1$  or  $S_2$ —asserts it and states that all propositions which are not Strawson-entailed by  $p$  are false. In the following  $\Rightarrow$  indicates regular entailment, and  $\Rightarrow_S$  Strawson-entailment. In the particular case at hand and more generally whenever a sentence is presuppositionless, Strawson-entailment reduces to regular entailment. For more discussion, see section 4.2.<sup>8</sup>

- (21)  $\llbracket \text{Exh}_{Alt} \rrbracket = \lambda w_s. p(w) = 1 \wedge \forall q \in \text{Alt}[p \not\Rightarrow_S q \rightarrow q(w) = 0]$

The denotation of the prejacent  $S_1$  of *Exh* in (18a), i.e., (19a), entails each of its alternatives in (20a). If John is ignorant with respect to whether Mary smokes, then it follows both that John is not certain that Mary smokes and that he is not certain that Mary does not smoke. As

<sup>7</sup>This can be derived more formally by having the existential quantifier ranging over  $Q'$  be restricted to exactly one of the answers in  $Q'$ . Such an implementation would use Chierchia's 2006 notion of domain alternatives.

<sup>8</sup>Entailment and Strawson-entailment (von Stechow, 1999) are defined as follows:

- (i) a. For any  $p, q \in D_{st}$ ,  $p$  entails  $q$ ,  $p \Rightarrow q$ , iff for all  $w \in D_s$  such that  $p(w) = 1$ ,  $q(w) = 1$ .  
 b. For any  $p, q \in D_{st}$ ,  $p$  Strawson-entails  $q$ ,  $p \Rightarrow_S q$ , iff for any presupposition  $r$  of  $q$  and all  $w \in D_s$  such that  $p(w) = r(w) = 1$ ,  $q(w) = 1$ .

a consequence Exh does not negate any of the alternatives, and the strengthened interpretation of (16a) is equivalent to its literal one without Exh:

$$(22) \quad \llbracket S'_1 \rrbracket^g = \lambda w. \neg \exists p[p \in Q' \wedge \forall w'[w' \in \text{Dox}_{J,w} \rightarrow p(w') = 1]]$$

(22) corresponds to the intuitive interpretation of the sentence. In particular, consider the sentence in the context in (23). Here it is unacceptable because the truth-conditions in (22) require John to not believe any of the propositions in  $Q'$ , which contradicts the context. Notice that (23) provides direct evidence for the assumption that there is existential quantification over answers involved (Spector and Egré, 2015). If the truth-conditions were about a particular answer, the sentence should be acceptable.

- (23)    **Context:** Mary smokes, but John believes she does not smoke.  
           #John isn't certain whether Mary smokes.

Consider next the denotation of the prejacent  $S_2$  of Exh in (18b) given in (19b). Each of its alternatives in (20b) entails it. For instance, if John believes that Mary smokes, then there is a proposition in  $Q'$  that John believes. Consequently, Exh negates each of the alternatives and conjoins them with the denotation of the prejacent yielding (24).

$$(24) \quad \begin{aligned} \llbracket S'_2 \rrbracket^g &= \lambda w. \exists p[p \in Q' \wedge \forall w'[w' \in \text{Dox}_{J,w} \rightarrow p(w') = 1]] \wedge \\ &\quad \neg \forall w'[w' \in \text{Dox}_{J,w} \rightarrow \text{Mary smokes in } w'] \wedge \\ &\quad \neg \forall w'[w' \in \text{Dox}_{J,w} \rightarrow \text{Mary doesn't smoke in } w'] \\ &= \top \end{aligned}$$

(24) is equivalent to saying that John either believes that Mary smokes or that he believes that she does not smoke but that he neither believes that she smokes nor that he believes that she does not smoke. This is a contradiction. Following Gajewski (2002), Fox and Hackl (2006), Chierchia (2006, 2013), Abrusán (2014) a.o., I assume that such trivial meanings lead to judgements of degradedness.

This assumption regarding triviality thus derives the pattern in (16). In particular, the system sketched here explains why *be certain* and other PTPs are only sometimes responsive. Moreover, the crucial reason why negation did not result in a contradiction and allowed for embedding of polar interrogatives was that it reverses the entailment patterns between the literal interpretation and the alternatives. As a consequence it follows that any entailment reversing environment, such as the downward monotonic contexts discussed in section 2.2 above, are predicted to not result in contradictions either.

#### 4. The *know-believe* distinction

Let me now return to the responsiveness puzzle and in particular the difference between *know* and *believe*. As already discussed, the former embeds polar interrogatives whereas the latter does not do so. Moreover, we need to add to this the observation that negation does not seem to affect either of these properties. The picture as it presents itself is thus as in (25) and (26).

- (25) a. John knows whether Mary smokes.  
 b. John doesn't know whether Mary smokes.
- (26) a. \*John believes whether Mary smokes.  
 b. \*John doesn't believe whether Mary smokes.

Now, both *know* and *believe* have lexical properties differentiating them from each other, but setting them also apart from *be certain*. *Know*, on the one hand, is factive, whereas the other two PTPs are not:

- (27) a. John (doesn't) know(s) that Mary smokes.  $\rightsquigarrow$  *Mary smokes*  
 b. John (doesn't) believe(s) that Mary smokes.  $\nrightarrow$  *Mary smokes*  
 c. John is(n't) certain that Mary smokes.  $\nrightarrow$  *Mary smokes*

*Believe*, on the other hand, is a neg-raising predicate (Horn, 1978). When negated it appears that the negation takes scope below *believe* giving rise to a stronger than expected inference, as shown in (28b). Neither *know* nor *be certain* is neg-raising, as (28a) and (28c) show.

- (28) a. John doesn't know that Mary smokes.  $\nrightarrow$  *John knows that Mary doesn't smoke*  
 b. John doesn't believe that Mary smokes.  $\rightsquigarrow$  *John believes that Mary doesn't smoke*  
 c. John isn't certain that Mary smokes.  $\nrightarrow$  *John is certain that Mary doesn't smoke*

In the following, I show how the lexical properties of neg-raising and factivity interact with the system sketched in the preceding section thereby deriving the patterns in (25) and (26).

#### 4.1. Neg-raising

Following Bartsch (1973), Löbner (2003) and Gajewski (2007) a.o., I assume that neg-raising PTPs presuppose that the subject is opinionated about the truth of the complement clause. That is, *believe* has a denotation parallel to *be certain* but presupposes that the subject either believe the propositional argument to be true or believe it to be false:<sup>9</sup>

$$(29) \quad \llbracket \text{believe} \rrbracket = \lambda p_{st} . \lambda x_e . \lambda w_s : \forall w' [w' \in \text{Dox}_{x,w} \rightarrow p(w') = 1] \vee \underline{\forall w' [w' \in \text{Dox}_{x,w} \rightarrow p(w') = 0]} . \forall w' [w' \in \text{Dox}_{x,w} \rightarrow p(w') = 1]$$

In the positive case of (27b) the presupposition in (29) is harmless as it is entailed by and in fact equivalent to the assertive component. In the negative case, however, the presupposition entails the assertion. The consequence of this is that even though the assertion has weak wide-scope negation, the presupposition strengthens the intuited inference to a meaning saying that John believes that Mary does not smoke.

<sup>9</sup>I adopt here and in the following Heim and Kratzer's 1998 notation for presuppositions, according to which  $\lambda \chi : \phi . \psi$  is a function that is only defined for objects  $\chi$  such that  $\phi$  holds. In addition presuppositions are underlined.

Consider now the degraded (30) repeated from above. Its truth-conditions before exhaustification are as in (31). What is the presupposition of (31)? Taking the first of the propositions in  $Q'$  and setting it for  $p$  in (31) gives the presupposition that John either believes that Mary smokes or that she does not smoke. Taking the second proposition in  $Q'$ , however, yields exactly the same. As a consequence, the presupposition of (31) is that John either believes that Mary smokes or that she does not smoke. Given the existential quantification in the assertive component of (31), the assertion is equivalent to the presupposition. This means that whenever (31) has a defined truth-value, it is true. It is a tautology. Therefore (30) has a trivial literal meaning and is degraded even without exhaustification.

(30) \*John believes whether Mary smokes.

$$(31) \quad \llbracket (30) \rrbracket^g = \lambda w. \exists p \in Q' : \frac{\forall w' [w' \in \text{Dox}_{J,w} \rightarrow p(w') = 1] \vee \forall w' [w' \in \text{Dox}_{J,w} \rightarrow p(w') = 0]}{\forall w' [w' \in \text{Dox}_{J,w} \rightarrow p(w') = 1]}$$

Given this it is easy to see why (32) is also degraded.

(32) \*John doesn't believe whether Mary smokes.

The truth-conditions are as in (33). The presupposition requires again that John either believes that Mary smokes or that she does not smoke. The assertive component now states that John does not believe any of the propositions in  $Q'$ . Thus whenever (33) is defined, it is false. (31) is therefore degraded because it also has a trivial literal meaning.

$$(33) \quad \llbracket (32) \rrbracket^g = \lambda w. \neg \exists p \in Q' : \frac{\forall w' [w' \in \text{Dox}_{J,w} \rightarrow p(w') = 1] \vee \forall w' [w' \in \text{Dox}_{J,w} \rightarrow p(w') = 0]}{\forall w' [w' \in \text{Dox}_{J,w} \rightarrow p(w') = 1]}$$

This treatment of *believe* predicts, of course, that other neg-raising PTPs are similarly non-rogative regardless of the polarity of the surrounding linguistic context. This is indeed the case as (34) and (35) show.

- (34) a. John doesn't *expect / reckon / think / assume / presume / reckon* that Mary drinks.  
 $\rightsquigarrow$  John *P-s* that Mary doesn't drink  
 b. \*John (doesn't) *expect(s) / reckon(s) / think(s) / assume(s) / presume(s) / reckon(s)* whether Mary drinks.

- (35) a. It isn't *advisable / desirable / likely / probable* that Mary drinks.  
 $\rightsquigarrow$  It is *P* that Mary doesn't drink  
 b. \*It is(n't) *advisable / desirable / likely / probable* whether Mary drinks.

The idea that neg-raising PTPs lead to trivial meanings when embedding an interrogative goes back to Zuber (1982), though it is implemented differently there (see also Theiler et al. 2016).

## 4.2. Factivity

Assume the standard lexical entry for *know* in (36). (36) applied to a proposition  $p$  and an individual  $x$  states that  $x$  believes  $p$  and presupposes that  $p$  is true.

$$(36) \quad \llbracket \text{know} \rrbracket = \lambda p_{st} . \lambda x_e . \lambda w_s : \underline{p(w) = 1} . \forall w' [w' \in \text{Dox}_{x,w} \rightarrow p(w') = 1]$$

As a consequence the literal meaning of (37) is as in (38).

$$(37) \quad \text{John knows whether Mary smokes.}$$

$$(38) \quad \llbracket (37) \rrbracket^g = \lambda w . \exists p \in Q' : \underline{p(w) = 1} . \forall w' [w' \in \text{Dox}_{J,w} \rightarrow p(w') = 1]$$

The literal meaning in (38) is non-trivial. It asserts that there is a proposition  $p$  in  $Q'$  that John believes. It presupposes that  $p$  is true in  $w$ . Thus in a world in which Mary smokes (38) says that John believes that Mary smokes, and in a world in which she does not smoke (38) says that she does not do so. That is, the factivity of *know* ensures that the subject stand in the know-relation to the true answer, whatever it is. Given the discussion in section 3, the alternatives to (38) used for strengthening by Exh are as in (39).

$$(39) \quad \text{Alt}(\llbracket S \rrbracket^g) = \{ \lambda w : \underline{\text{Mary smokes in } w} . \forall w' [w' \in \text{Dox}_{J,w} \rightarrow \text{Mary smokes in } w'], \\ \lambda w : \underline{\neg \text{Mary smokes in } w} . \forall w' [w' \in \text{Dox}_{J,w} \rightarrow \neg \text{Mary smokes in } w'] \}$$

Now recall that Exh negates only those alternatives that are not Strawson-weaker than its prejacent, i.e., those alternatives that are not Strawson-entailed by the prejacent. As defined in footnote 8 following von Stechow (1999), for a proposition  $p$  to Strawson-entail a proposition  $q$  the presuppositions of  $q$  must be assumed to be true. When we want to see whether (38) Strawson-entails the first alternative in (39), we must therefore assume that Mary smokes in some particular world  $w_o$  as in (40a), as this is the presupposition of the alternative. Now, (38) is true in  $w_o$  if (40b) holds. Since the two propositions in  $Q'$  contradict each other, the proposition in  $Q'$  that John knows in  $w_o$  must be that Mary smokes given (40a). Thus (40a) together with (40b) guarantees that Mary smokes is the true answer to  $Q'$  in  $w_o$  and that John believes that Mary smokes is true. Therefore, (38) Strawson-entails the first alternative in (39), as stated in (40c). By the same logic (38) also Strawson-entails the second alternative in (39). In fact, it is Strawson-equivalent to both its alternatives.

- (40)    a. Mary smokes in  $w_o$ .  
           b. For some  $p \in Q'$ , John knows  $p$  in  $w_o$ .  
           c. (40a) & (40b)  $\Rightarrow_s$  John knows in  $w_o$  that Mary smokes.

As a consequence, Exh does not negate any of the alternatives, and the strengthened meaning of (37) is equivalent to its literal meaning in (38). Since this meaning is non-trivial, we have explained why (37) is acceptable. We also immediately explain why its negation in (41) is equally acceptable. Since it is the factive presupposition of *know* that makes the alternatives Strawson-equivalent to the literal meaning, it follows that further embedding under negation

will not affect the result just obtained.

- (41) John doesn't know whether Mary smokes.

The first consequence of this treatment for *know* is that factive PTPs in general should be responsive. This is by and large borne out. All the veridical PTPs in (42), repeated from (4), are actually factive, thus explaining (42b).

- (42) a. John *deduced / discovered / established / figured out / found out / forgot / learned / recalled / remembered* that Mary smokes.  $\rightsquigarrow$  Mary smokes  
 b. John *deduced / discovered / established / figured out / found out / forgot / learned / recalled / remembered* whether Mary smokes.

Second, veridical PTPs that are not factive, such as *be clear*, are not predicted to license interrogative embedding across-the-board. Here a downward monotonic environment is necessary for embedding to be possible:

- (43) a. It is clear that Mary smokes.  $\rightsquigarrow$  Mary smokes  
 b. It isn't clear that Mary smokes.  $\nrightarrow$  Mary smokes  
 (44) a. \*It is clear whether Mary smokes.  
 b. It isn't clear whether Mary smokes.

Third, it should be stressed that the polarity system proposed in section 3 makes the fact that *be certain* embeds interrogatives only under negation the flip-side of the fact that *know* always does so.

Finally, note that the use of Strawson-entailment rather than of regular entailment is crucial for the account. One might therefore ask why this particular type of entailment should be used. I do not have an answer to this. However, NPI-licensing in general is subject to Strawson-entailment. As is well-known, it is the Strawson-downward-monotonic property of *only* that lets it license NPIs (von Stechow, 1999).

## 5. Other non-veridical predicates

### 5.1. Ambiguous predicates and being about the true answer

Recall now the PTPs in (45). In section 2.1 they were shown to be problematic for accounts relating interrogative embedding to veridicality directly. The reason for this is that the PTPs are non-veridical.

- (45) a. John *announced / confirmed / declared / heard / predicted / reported / told us* that Mary smokes.  $\nrightarrow$  Mary smokes  
 b. John *announced / confirmed / declared / heard / predicted / reported / told us* whether Mary smokes.  $\rightsquigarrow$  John P-ed the true answer to "Does Mary smoke?"

As seen in section 4.2, the present system does not rely on a connection between veridicality and responsiveness. Still, as it stands it does not predict the pattern in (45) either.

Now, notice that the PTPs are veridical with respect to the embedded interrogative: (45b) licenses the inference that the subject stand in the relation denoted by the PTP to the true answer to the embedded interrogative. Following Spector and Egré (2015), I assume that the PTPs in (45) come in both a factive and a non-factive version. Consider *tell* for concreteness. In (45a), on the one hand, its non-factive version in (46) is, or at least can be chosen. Thereby no veridicality inference is felt.

$$(46) \quad \llbracket \text{tell}_1 \rrbracket = \lambda p_{st} . \lambda y_e . \lambda x_e . \lambda w_s . \forall w' [w' \text{ is compatible with what } x \text{ tells } y \text{ in } w \rightarrow p(w') = 1]$$

The reason why, on the other hand, in (46b) the factive version in (47) must be chosen is now straightforwardly explained on the present account: using the non-factive version of *tell* in (46) would result in a trivial strengthened meaning and thereby degradedness. That is, it would lead to a contradiction after exhaustification completely parallel to what we have seen with *be certain* in section 3. On its factive interpretation, however, *tell* works just like *know*. Factivity blocks the contradiction otherwise derived by exhaustification, as seen in section 4.2.

$$(47) \quad \llbracket \text{tell}_2 \rrbracket = \lambda p_{st} . \lambda y_e . \lambda x_e . \lambda w_s : \underline{p(w) = 1} . \\ \forall w' [w' \text{ is compatible with what } x \text{ tells } y \text{ in } w \rightarrow p(w') = 1]$$

Recall moreover from section 4.2 that the factivity presupposition of *know* guarantees that the subject stand in the know-relation to the true answer to the embedded interrogative, whatever it is. The limited veridicality inference in (45b) with respect to the true answer thus follows on the present account: only (47) can be used here, and this necessitates a relation between the subject and the true answer. As far as I am aware, the present account is the first to be in a position to explain why seemingly non-veridical PTPs must be about the true answer when embedding an interrogative clause as in (45b).

This makes a testable prediction. Whenever one of the PTPs from (45) embeds an interrogative clause and moreover occurs in an environment where contradiction by exhaustification is avoided independently, the non-factive interpretation should be usable. That is, not even limited veridicality as in (45b) should ensue.

Consider (48). The sentence is odd in the context given. Now notice that on the factive interpretation of *tell* in (47) the sentence should be acceptable, as it would assert that John did not tell us the true answer to *Does Mary smoke?*. Since the context satisfies this, we conclude that the sentence does not have such truth-conditions. Without a factive presupposition, the sentence states that John did not tell us any possible answer to the question *Does Mary smoke?*. These truth-conditions are not fulfilled by the context accounting for the degradedness.

$$(48) \quad \text{Context: John told us that Mary smokes, which is in fact false.} \\ \# \text{John didn't tell us whether Mary smokes.}$$

The degradedness in (48) more precisely suggests that the factive version of *tell* and similarly ambiguous PTPs becomes usable only when the non-factive one would lead to a contradiction via exhaustification. This is unlike what Spector and Egré (2015) suggest. They argue that such PTPs can always have the non-factive interpretation when embedding interrogative clauses. They cite (49) as evidence for this, minimally modified to show a polar interrogative here. (49) seemingly does not require the subject to stay in a relation to the true answer.

- (49) Every day, the meteorologists *tell* the population / *predict* / *announce* whether it will rain the following day, but they are often wrong.

I suggest that the fact that (49) is not degraded is entirely expected on the present account. The surfacing of the non-factive interpretations of the PTPs involved is, in particular, due to the fact that they are embedded under the universal temporal quantifier *every day*. First, (49) becomes less acceptable when *every day* is absent:

- (50) #The meteorologists *tell* the population / *predict* / *announce* whether it will rain the following day, but they are often wrong.

Second, note that other universal quantifiers also license the use of the non-factive interpretation of the PTP:

- (51) The meteorologists are required to *tell* the population / *predict* / *announce* whether it will rain the following day, even if they don't know.

It is well-known that universal quantifiers obviate contradictions which would otherwise arise through exhaustification when occurring unembeddedly (e.g. Fox and Hackl 2006; Fox 2007; Chierchia 2013; Abrusán 2014). Let me show how this works for (51). Its LF with non-factive *tell* would be something like (52).

- (52)  $[_{S'} \text{Exh}_{Alt} [_{S} \text{required} [[ \text{whether it will rain} ] \lambda p [ \text{the meteorologists to tell}_1 \text{ the population } p ] ] ] ]$

The literal meaning of S states that in every deontically accessible world the meteorologists tell the population a possible answer to the question *Will it rain?*. This neither entails that in every such world the meteorologists tell the population that it will rain nor that in every world they tell them that it will not rain. That is, the literal meaning does not entail its alternatives. Therefore Exh negates them giving the strengthened meaning in (53).

- (53)  $[[S']]^g = 1 \text{ iff } \forall w'. \exists p [p \in Q' \wedge \text{the meteorologists tell the population } p \text{ in } w'] \wedge$   
 $\neg \forall w' [\text{the meteorologists tell the population in } w' \text{ it will rain}] \wedge$   
 $\neg \forall w' [\text{the meteorologists tell the population in } w' \text{ it will not rain}]$

Crucially, (53) is not trivial. (53) states that the meteorologists are required to tell the population some answer but that they are neither required to tell them that it will rain nor that they are required to tell them that it will not rain.

This raises the question why (54) with an existential modal is similarly acceptable, even though existential modals generally do not obviate contradictions via exhaustification.

- (54) The meteorologists are allowed to *tell* the population / *predict* / *announce* whether it will rain the following day, even if they don't know.

I suggest that in cases like (54) it is actually the factive version of the PTP that is used, as in the LF in (55), with Exh embedded under the modal.

- (55)  $[_{S'} \text{ allowed } [_S \text{ Exh}_{Alt} [ [ \text{ whether it will rain } ] \lambda p [ \text{ the meteorologists to tell}_2 \text{ the population } p ] ] ] ]$

This delivers the interpretation of  $S'$  in (56). First, notice that the alternatives to the prejacent of Exh are Strawson-equivalent to the prejacent. That is, Exh does not negate any of them, as in the case of *know* discussed in section 4.2. Second, the factive presupposition of *tell* is interpreted with respect to the world bound by the existential modal. As a consequence (56) says that in some deontically accessible world the meteorologists tell the population the true answer to the interrogative in that world. This does not entail anything about the true answer in the actual world. Now, if *know* in (54) moreover introduces a presupposition about the actual world, this does not lead to a contradiction with (56). In other words, with embedded exhaustification and the factive use of *tell*, (54) does not come out as degraded.

- (56)  $\llbracket S' \rrbracket^g = 1$  iff  $\exists w'. \exists p \in Q' : p(w') = 1$  . the meteorologists tell the population  $p$  in  $w'$

## 5.2. Predicates with an order-based semantics

Recall now the following desiderative PTPs from (5). (57a) has the inference that John prefers Mary smoking to her not smoking. This is generally accounted for by attributing an order-based semantics to the PTPs.

- (57) a. John *desired / wanted / wished* that Mary smokes.  $\nrightarrow$  Mary smokes  
                $\rightsquigarrow$  John prefers Mary to smoke  
        b. \*John *desired / wanted / wished* whether Mary smokes.

Since the PTPs in (57) are all non-veridical, we might expect interrogative embedding to improve under negation, similarly to *be certain*. But this is not the case as (58) shows. The PTPs in (58) are thus closer to *believe*.

- (58) \*John didn't *desire / want / wish* whether Mary smokes.

Indeed, such desiderative PTPs are neg-raising. Consider (59). If *want* were not neg-raising, (59) should be compatible with John not having a preference as to whether Mary smokes or not given the inference observed for (57a). However, (59) rather implies that John prefers Mary to not smoke.

- (59) John doesn't want that Mary smokes.  $\rightsquigarrow$  *John prefers Mary to not smoke*

This suggests that the account offered for *believe* in 4.1 should be extendable to desiderative PTPs. Notice, however, that such PTPs are non-monotonic (see e.g. Asher 1987; Heim 1992; Villalta 2008; Lassiter 2011; Rubinstein 2012; Anand and Hacquard 2013 a.o.). (60a) does not entail (60b).

- (60) a. John *desired / wanted / wished* that Mary and Sue smoke.  
b. John *desired / wanted / wished* that Mary smokes.

To account for this non-monotonicity property, I adopt Heim's 1992 similarity-based account of desiderative predicates. The entry for *want*, for instance, is as in (61). (61) applied to a proposition  $p$  asserts that for all of the subject's doxastic alternatives  $w'$  the worlds most similar to  $w'$  in which  $p$  is true are more desirable to the subject in  $w$  than the worlds most similar to  $w'$  in which  $p$  is false.<sup>10</sup> Applied to (60a), for instance, (61) says that John believes that if Mary and Sue smoke he is in a more desirable world than if they do not smoke. The counterfactual component in (61) blocks entailment in both directions in (60). Crucially, (61) has the opinionatedness presupposition familiar from *believe* built in.

$$(61) \quad \llbracket \text{want} \rrbracket = \lambda p_{st}. \lambda x_e. \lambda w_s. [\forall w' \in \text{Dox}_{x,w}. \text{Sim}_{w'}(p) >_{x,w} \text{Sim}_{w'}(\neg p)] \vee \\ \frac{[\forall w' \in \text{Dox}_{x,w}. \text{Sim}_{w'}(\neg p) >_{x,w} \text{Sim}_{w'}(p)]}{\forall w' \in \text{Dox}_{x,w}. \text{Sim}_{w'}(p) >_{x,w} \text{Sim}_{w'}(\neg p)}$$

Consider now the ungrammatical (57b) with *want*. Its literal meaning is as in (62). Given the existential quantification over answers, the assertive component says that John prefers Mary smoking to her not smoking or he prefers the reverse.

$$(62) \quad \llbracket (57b) \rrbracket = \lambda w. \exists p \in Q' : [\forall w' \in \text{Dox}_{J,w}. \text{Sim}_{w'}(p) >_{J,w} \text{Sim}_{w'}(\neg p)] \vee \\ \frac{[\forall w' \in \text{Dox}_{J,w}. \text{Sim}_{w'}(\neg p) >_{J,w} \text{Sim}_{w'}(p)]}{\forall w' \in \text{Dox}_{J,w}. \text{Sim}_{w'}(p) >_{J,w} \text{Sim}_{w'}(\neg p)}$$

Now, since the two possible answers are the negations of each other, they make the same contribution to the presuppositional component. Each says that John either prefers Mary to smoke or he prefers the reverse. Thus the presupposition of (62) is equivalent to the assertion. Therefore the literal meaning of (57b) is trivial. Now, the negation in (58) has the same presupposition as (62). But the assertive component now requires that John have no preference among the possible answers. This contradicts the presupposition and thus (58) also has a trivial literal meaning. In other words, the order-based semantics of desiderative PTPs does not interfere with their neg-raising property, and they come out as non-rogative, as desired. This treatment

<sup>10</sup>The similarity relation among worlds and the notion of desirability employed in (60) are defined as in (i) and (ii), following again Heim (1992: 195ff.).

- (i)  $\text{Sim}_w(p) := \{w'' \in W : w'' \in p \text{ and } w'' \text{ resembles } w \text{ no less than any other world in } p\}$   
(ii) a. For any  $w, w', w'' \in W$ ,  $w' >_{\alpha,w} w''$  iff  $w'$  is more desirable to  $\alpha$  in  $w$  than  $w''$ .  
b. For any  $w \in W, X \subseteq W, Y \subseteq W$ ,  $X >_{\alpha,w} Y$  iff  $w' >_{\alpha,w} w''$  for all  $w' \in X, w'' \in Y$ .

can be extended to other neg-raising PTPs in (5) with an order-based semantics, such as *expect*, *fear* and *hope*.

## 6. Conclusion and outlook

In this paper I argued that embedding of polar interrogative clauses under PTPs involves an existential semantics, as suggested more generally by Spector and Egré (2015). This allowed me to account for the surprising context-dependence of the embedding of such clauses under *be certain* and other PTPs. Specifically, I proposed an exhaustification-based polarity system (Krifka, 1995; Chierchia, 2006, 2013) which leads to a contradiction for polar interrogatives with unnegated *be certain*. This system moreover has the immediate consequence that polar interrogatives can be embedded under factive PTPs even when not negated. The reason is that factivity avoids contradiction by exhaustification. This proposal also explains why seemingly non-veridical PTPs like *tell* show a limited kind of veridicality when embedding polar interrogatives. The reason is, again, that otherwise a contradiction would ensue. Finally, the existential semantics for embedding of polar interrogatives predicts that neg-raising PTPs—even those with an order-based semantics—always give rise to trivial meanings. That is, the system predicts such PTPs to never embed polar interrogatives.

The most important issue for future research now is to investigate how the proposed system can be extended to *wh*-interrogatives. First, the existential semantics assumed in this paper does not directly work with *wh*-interrogatives. It would give rise to too weak mention-some interpretations. Second and connected to this, the factivity presupposition assumed in the present paper does not automatically yield Strawson-equivalence in the case of *wh*-interrogatives embedded under factive PTPs. I.e., they should not be licensed contrary to fact. The consequence of this is that the lexical semantics for the PTPs themselves must be altered somewhat. For discussion of how this can be done, I refer the reader to Mayr (2017).

# Modal subordination of propositional anaphora: On the role of tense and the modal particle *ook* in contextual counterfactuals in Dutch<sup>1</sup>

A. Marlijn MEIJER — *Humboldt-Universität zu Berlin*

Sophie REPP — *Humboldt-Universität zu Berlin*

**Abstract.** This paper examines a variant of modal subordination that involves reference to propositions that have been introduced in the scope of a negative operator. In the dialogues under consideration, this kind of reference is most reliably established if the modal particle (MP) *ook* and past perfect morphology are present in the response, which contains the anaphor (Meijer 2016). We provide experimental evidence that supports this empirical claim and provide a theoretical explanation for the data. We assume that the discourses at issue involve contextual counterfactuals (CFs) whose antecedent may be positive or negative and provides the antecedent for the anaphor. CFs with a negative antecedent ‘doubt’ the truth of the previous utterance, whereas CFs with a positive antecedent do not. As a consequence, the MP, which presupposes that the epistemic modal base already entailed the previously uttered proposition, is incompatible with the former but not the latter type of CF (Meijer 2016). For the tense marking we propose that the effects are due to the local interpretation of the non-*fake* tense in the consequent of the CF (cf. Ippolito 2013).

**Keywords:** modal subordination, modal particles, propositional anaphora, counterfactuality

## 1. The phenomenon

Propositions can be targeted by demonstrative pronouns like English *that*, see (1), where the proposition denoted by a declarative clause is the referent that is picked up by *that* in the subsequent sentence. We may say that the first clause introduces a propositional discourse referent (e.g. Asher 1986, 1993; Geurts 1998). That referent is targeted by *that*. Krifka (2013) suggests that clauses with sentential negation introduce two propositional discourse referents: the negative proposition that is denoted by the entire clause, and the positive proposition that is denoted by the syntactic object below the negation. Evidence for this claim comes from data like (2). (2B) and (2B’) are possible discourse continuations of the negative assertion (2A). Both contain the pronoun *that*. In (2B), *that* refers to the negative proposition  $\neg\phi$ , *two plus two is not five*. In (2B’), *that* refers to the positive proposition  $\phi$ , *two plus two is five*. Note that (2B’) contains the modal verb *would*, whereas (2B) does not contain a modal verb.

(1) [John was out last night] <sub>$\phi$</sub> . Mary knew that <sub>$\phi$</sub> .

(2) A: Two plus two isn’t five.  $\equiv \neg\phi$  (Krifka 2013)  
B: Everyone knows that <sub>$\neg\phi$</sub> . B’: That <sub>$\phi$</sub>  would be a contradiction.

<sup>1</sup>We would like to thank Maribel Romero, Manfred Krifka and the audiences at Sinn und Bedeutung 21 and ConSOLE XXIV for discussion.

Reference to antecedents that are in the scope of negation or of intensional operators was first described for nominal anaphora by Roberts (1989), see (3a-b) and (4a-b). In the first utterance of these discourses, there is an indefinite that introduces a discourse referent in the scope of an intensional operator (*a book* in (3a)), or in the scope of negation (*a car* in (4a)). In the second utterance, (3b) and (4b), which both contain a modal verb (*will/would*), a pronoun refers back to the discourse referent that was introduced in the first utterance. (3b') and (4b') are minimal variants of (3b) and (4b) without a modal verb. These variants are not felicitous continuations of (3a) and (4a). Thus, in order to establish reference to a discourse referent below an intensional operator or negation in the previous utterance, a modal must be used.

- (3) a. If John bought [a book]<sub>i</sub>, he will be home reading it by now. (Roberts 1989:683)  
 b. It<sub>i</sub>'ll be a murder mystery. b'. # It<sub>i</sub> is a murder mystery.
- (4) a. John doesn't have [a car]<sub>i</sub>. (Roberts 1997:239)  
 b. It<sub>i</sub> would be in the garage. b'. # It<sub>i</sub> is in the garage.

The propositions denoted by the clauses in (3b) and (4b) are said to be *modally subordinated* to the propositions in (3a) and (4a) (Roberts 1989, 1997). The modal base of the modal in the second utterance is restricted: in (3) by the proposition in the antecedent of the conditional; in (4), by the accommodated counterfactual proposition *John bought a car*. In the restricted domain of the modal, the familiarity presupposition for the use of the respective pronoun is fulfilled because *a book* and *a car* are given in that domain. Roberts (1997) highlights that domain restriction across utterances can be compared with domain restriction in conditionals, where the antecedent restricts the domain of the consequent. So for instance (4b) can be paraphrased as *if John had a car, it would be in the garage*.

Going back to Krifka's example for anaphoric reference to a proposition under negation, the presence of *would* is not surprising from the perspective of modal subordination involving nominal anaphora. The example is an instance of modal subordination involving a propositional anaphor. However, interestingly, the presence of a modal does not always seem to be necessary to refer to a propositional discourse referent in the scope of negation, see (5). In the continuations (5B/B'), there is no modal verb. Both continuations are felicitous although they differ with respect to the reference of *that*, which seems to be due to the presence vs. absence of a negation. If there is a negation, as in (5B), *that* refers to the positive proposition  $\phi$ , *you won the jackpot*. If there is no negation, *that* refers to the negative proposition  $\neg\phi$ , *you did not win the jackpot*. Goodhue and Wagner (resubm.) suggest that these different interpretations are due to our world knowledge. Winning the jackpot is unlikely whereas not winning it is likely.

- (5) A: You didn't win the jackpot.  $\equiv \neg\phi$  (Goodhue and Wagner resubm.)  
 B: I didn't expect that <sub>$\phi$</sub> . B': I expected that <sub>$\neg\phi$</sub> .

Although a modal does not always seem to be necessary to refer to a proposition under negation, in certain contexts the presence of a modal does not seem to be sufficient. Consider the Dutch

discourses in (6) (Meijer 2016). (6A) is a negative assertion. (6B) is a felicitous continuation, in which the speaker uses a predicate of personal taste to express their opinion about what was stated in the assertion. As the difference between (6B/B') indicates, reference to the positive proposition with the demonstrative pronoun *dat* 'that' only is possible if in addition to a modal verb (here *zouden* 'would'), the MP *ook* (literally 'also') as well as a past participle (*geweest* 'been') are present (Meijer 2016). In (6B), which contains *ook* and the past participle *geweest*, *dat* refers to the positive proposition  $\phi$ , *Jan worked yesterday*. (6B') is infelicitous on the reading that involves reference to the non-negated proposition (Meijer 2016). It is worth pointing out here that (6B') is coherent if *dat* is interpreted as referring to  $\neg\phi$ . (7) illustrates that German seems to behave similarly regarding the anaphoric possibilities of the pronoun *das* 'that' in the presence vs. absence of the MP *auch* (lit. 'also') and the past participle *gewesen* 'been'.<sup>2</sup> In this paper, we will use the terms  $\phi$ -reference vs.  $\neg\phi$ -reference, in order to distinguish the two interpretations of *dat*, viz. as referring to  $\phi$  vs.  $\neg\phi$ .

- (6) A: Jan heeft gisteren niet gewerkt.  $\equiv \neg\phi$   
 Jan has yesterday not worked  
 'Jan didn't work yesterday.'
- B:  $\text{Das}_{\phi/\#-\phi}$  zou ook raar zijn geweest. B':  $\text{Dat}_{\# \phi / -\phi}$  zou raar zijn.  
 that MOD OOK strange be been that MOD strange be  
 'That would have been strange.' 'That would be strange.'
- (7) A: Hans hat gestern nicht gearbeitet.  $\equiv \neg\phi$   
 Hans has yesterday not worked
- B:  $\text{Das}_{\phi/\#-\phi}$  wäre auch komisch gewesen. B':  $\text{Das}_{\# \phi / -\phi}$  wäre komisch.  
 that BE.SBJV AUCH strange been that BE.SBJV strange

Note that similar to Roberts' cases of modal subordination involving nominal anaphora, (6B) and (7B) express conditional readings. Meijer (2016) calls such utterances *contextual counterfactuals*. Speaker B seems to accommodate an antecedent for a counterfactual (CF) conditional whose consequent is uttered overtly: *if Jan had worked yesterday, that would have been strange*. The antecedent of the CF provides the referent  $\phi$  which is picked up by *dat/das* in the consequent. Turning to (6B') and (7B'), we could assume that the accommodated CF plausibly is *if Jan hadn't worked yesterday, that would be strange*. Again, the antecedent of the CF provides the referent that is picked up by *dat/das* in the consequent, in this case this is  $\neg\phi$ . However, there is an important difference between the CFs that are accommodated in the (B)- vs. (B')-versions. In the (B)-versions, the second speaker accepts what the first speaker said as true: In the actual world Jan did not work. It is in the CF worlds that Jan worked. In the (B')-version, in contrast, the second speaker doubts what the first speaker said, i.e. it is not established as common ground that Jan did not work. Rather, the second speaker implicates that Jan did work.

<sup>2</sup>Some native speakers of German report that (7B') is not coherent for them even on a  $\neg\phi$ -reading. It seems that the midclause insertion of the conjunction *aber* 'but' improves (7B') as in *Das wäre aber komisch*. We assume that the improvement is due to *aber* overtly marking the contrast with the previous utterance – after all, speaker B' calls into doubt the utterance by the first speaker. See below for elaboration.

It is important to note at this stage that discourses involving predicates of personal taste only seem to enable  $\phi$ -reference if the predicate of personal taste is one of surprise or wonderment. Consider the response in (8B), which is minimally different from the one in (6B'): the predicate *normaal* 'usual' replaces the predicate *raar* 'strange'. A proposition whose truth one finds normal, i.e. expects to be true cannot be surprisingly or unexpectedly true. The discourse in (8) is incoherent – with any kind of reference. The same observation holds for German (not illustrated). We will not explore the role of the type of predicate of personal taste in this paper and restrict our discussion to predicates of surprise/wonderment (for details see Meijer 2016).<sup>3</sup>

- (8) A: Jan heeft gisteren niet gewerkt. B: #Dat $\phi$ / $-\phi$  zou ook normaal zijn geweest.  
 Jan has yesterday not worked that MOD OOK usual be been  
 'Jan didn't work yesterday.' 'That would have been normal.'

In the present paper, we will explore the marking that is required to establish  $\phi$ -reference in discourses involving responses with predicates of personal taste like (6B) and (7B) in more detail. The other cases of reference to a positive proposition in the scope of negation mentioned above are beyond the scope of this paper and must be left for future research. Also, we will be mainly focusing on Dutch. The goal of the paper is twofold. First, we will present quantitative evidence supporting Meijer's claims about the influence of the presence of the MP *ook* and the past participle *geweest* on establishing  $\phi$ -/ $-\phi$ -reference in responses like (6) (section 2). This quantitative verification is important because the judgments are somewhat subtle and sometimes puzzle native speakers. We will also see, however, that the empirical results offer some intricacies that merit some detailed discussion. Second, we will theoretically evaluate the experimental findings. For *ook* (section 4), we will largely follow Meijer's suggestion that the particle signals that the knowledge that is available to the speaker, already entailed the truth of the proposition that was asserted by the previous speaker before that assertion was made. Therefore, the accommodation of a CF that calls into question the truth of the utterance of the previous speaker – which is what seems to be happening with  $-\phi$ -reference – is incompatible with using the particle *ook* in that CF. With respect to the tense marking, Meijer suggests in her discussion of the occurrence of the past participle and *zouden*, that this combined marking fits a cross-linguistic pattern of establishing counterfactuality with multiple tense markers. However, she does not provide an explanation of the temporal marking in relation to the two anaphoric possibilities. Prima facie there is no obvious reason why the presence of a past participle in the consequent should result in  $\phi$ -reference whereas the absence of that participle should re-

<sup>3</sup>There are instances of  $\phi$ -reference which do not require the presence of *ook*. Consider (i) (Berry Claus, p.c.), where *ook* is not required for *dat* to refer to the proposition *Jan has won the final match*. In fact, if *ook* were present, (iB) would be slightly odd. Note that (i) is not a contextual CF, and cannot be paraphrased as one.

- (i) A: Jan heeft de laatste wedstrijd niet gewonnen.  $\equiv -\phi$   
 Jan has the final match not won  
 'Jan hasn't won the final match.'  
 B: Dat $\phi$  zou nodig zijn geweest om deel te nemen aan de finale.  
 that MOD required be been to part to take on the finale  
 'That would have been required for taking part in the final.'

sult in  $\neg\phi$ -reference. In section 4 we will propose an explanation for the tense marking in the contextual CFs in (6), building on the proposal for tense in CFs by Ippolito (2013).

## 2. Experiment

For the quantitative verification of the empirical observations made in Meijer (2016), we conducted a semantic forced choice experiment. The experiment tested discourses which consisted of a negative assertion uttered by one speaker, and a response by another speaker that involved a predicate of personal taste. There were four types of discourses, which differed in whether or not the response contained the MP *ook* and/or the past participle *geweest*. (9) is a sample item.

- (9) Willem en Elisabeth laten hun grote tuin herinrichten. Hiervoor hebben ze een tuinman ingehuurd. Ze spreken over de herinrichting van de tuin.  
 ‘Willem and Elisabeth are having their large garden redecorated. They hired a gardener to do this. They are talking about the redecoration of their garden.’
- W: De tuinman heeft het gras nog niet gezaaid.  
 The gardener has the grass still not sown.  
 ‘The gardener hasn’t sown the lawn yet.’
- E1: [–TENSE,–OOK] Dat zou raar zijn.  
 that would odd be
- E2: [–TENSE,+OOK] Dat zou ook raar zijn.  
 that would OOK odd be
- E3: [+TENSE,–OOK] Dat zou raar zijn geweest.  
 that would odd be been
- E4: [+TENSE,+OOK] Dat zou ook raar zijn geweest.  
 that would OOK odd be been

The participants in the experiment were asked to choose between one of two possible interpretations for Elisabeth’s responses in (10E1–E4), such that the anaphoric pronoun *dat* was interpreted as referring to the negative proposition  $\neg\phi$ , *the gardener has not sown the lawn yet*, or to the positive proposition  $\phi$ , *the gardener has sown the lawn (already)*,<sup>4</sup> which arguably were introduced in the utterance by Willem. As discussed in the previous section, Meijer (2016) observed that *dat* receives a  $\phi$ -interpretation in the response in discourses like (9) if both *ook* and the past participle *geweest* are present. Therefore we expect that in condition E4, participants should choose the interpretation where *dat* refers to  $\phi$ . In condition E1, in contrast, *dat* should not refer to  $\phi$  because the response neither contains *ook* nor *geweest*. So participants should choose the  $\phi$ -interpretation much less often for E1 than for E4. As for E2 and E3, Meijer

<sup>4</sup>The antecedent clause, uttered by the first speaker, contained the negative polarity item *nog* ‘yet’. This item cannot be part of the positive proposition, and most likely is replaced by the positive polarity counterpart *al* ‘already’ during the referential process (in a way to be explored by future research). This replacement does not seem to cause problems for anaphoric reference to positive/negative propositions: the materials used here have been adapted from earlier acceptability judgment studies on anaphoric reference involving response particles reported in Meijer, Claus, Repp and Krifka (2015) and in Claus, Meijer, Repp and Krifka (accepted), where the replacement did not seem to lead to degradedness.

(2016) observes that if only *geweest* or only *ook* are present in the response, that response is not fully coherent on the reading involving  $\phi$ -reference. For the forced choice between the  $\phi$ - and the  $\neg\phi$ -interpretation, this might either mean that participants choose randomly between these two interpretations, or that they still show a preference for one over the other. On the basis of the concrete meaning contributions that we propose for the past perfect morphology (section 3) and that Meijer proposes for *ook* (section 4), we expect for both E2 and for E3 a higher proportion of  $\phi$ -references than for E1. For E2, there should be a very high proportion of  $\phi$ -references – possibly as high as for E4 – because, as we will see below,  $\neg\phi$ -reference results in a presupposition failure for *ook*. For E3, the proportion of  $\phi$ -references might be a bit lower because the past tense morphology is ambiguous, see section 3 for details.

## 2.1. Method

24 native speakers of Dutch were recruited through Prolific Academics (<https://www.prolific.ac>) and received payment for their participation. The experiment had a 2x2 within-subjects design with the factors OOK (+/–*ook*) and TENSE (+/–past participle). There were 24 experimental items and 24 fillers from another experiment. Items were allocated to participants and conditions in a Latin square design. Each item was constructed as illustrated in (9). There was a scene-setting passage that introduced the interlocutors and the topic of the conversation. One of the interlocutors made a negative assertion, the other responded such that the response was one of the four conditions illustrated in (9). The predicates of personal taste used in the materials all expressed surprise. There were twelve such predicates: *gek* ‘crazy’, *raar* ‘odd’, *vreemd* ‘strange’, *uitzonderlijk* ‘extraordinary’, *merkwaardig* ‘remarkable’, *opvallend* ‘notable’, *eigenaardig* ‘peculiar’, *verbazingwekkend* ‘surprising’, *bizar* ‘bizarre’, *opmerkelijk* ‘remarkable’, *maf* ‘crazy’ and *apart* ‘unusual’. Each predicate was used twice. After having read the dialogue in (9), participants were given a choice between two paraphrases which were meant to reveal the  $\phi$ - vs.  $\neg\phi$ -interpretation of the response, see (10). The tense marking in the clause preceding the paraphrases matched the tense marking in the response, i.e. for conditions E1 and E2 the marking was *zou* plus infinitive, and for conditions E3 and E4 it was *zou* plus *hebben* ‘have’ plus past participle. The antecedent paraphrases always had past perfect tense marking. We will discuss this tense marking in section 3.

- (10) Elisabeth zou het raar {vinden<sub>E1/2</sub>/hebben gevonden<sub>E3/4</sub>},  
 ‘Elisabeth would {find<sub>E1/2</sub>/ have found<sub>E3/4</sub>} it weird,’
- als the tuinman het gras nog niet had gezaaid.  $\neg\phi$   
 if the gardener the grass yet not had sown  
 ‘if the gardener had not sown the lawn yet.’
  - als the tuinman het gras al had gezaaid.  $\phi$   
 if the gardener the grass already had sown  
 ‘if the gardener had sown the lawn already.’

For half of the participants, the first proposition was  $\neg\phi$ ; for the other half, it was  $\phi$ . After participants had chosen one of the paraphrases, the item disappeared from the screen. A verifi-

cation task followed. Participants read an assertion about the previous test item and judged its truth. Participants that scored at chance level on this task were excluded from the analysis.

## 2.2. Results

Figure 1 and Table 1 show the mean proportions of choice of the positive proposition, i.e. of  $\phi$ -reference, for the four conditions in the experiment. Descriptively, we may say that the individual effects of the *ook* and *geweest* was similar (each producing around 70%  $\phi$ -references), and that the most reliable way of establishing  $\phi$ -reference was a combination of the two markers. If no marker was present,  $\phi$ -reference was chosen not very often. The statistical analysis was carried out with linear mixed-effects models with a binomial logit function. The fixed factors were TENSE and OOK with contrast coding  $-1$  for  $-OOK$  and  $-TENSE$ , and  $+1$  for  $+OOK$  and  $+TENSE$ . Participants and items were random factors. The best models (forward selection) contained random participant slopes for OOK and random intercepts for items. The analysis revealed a main effect of TENSE ( $b = 2.96$ ,  $SE = 0.40$ ,  $t = 7.4$ ,  $p < .001$ ) and of OOK ( $b = 2.78$ ,  $SE = 0.50$ ,  $t = 5.6$ ,  $p < .001$ ).  $\phi$ -reference was chosen more often when the past participle was present, and it was chosen more often when the MP was present. There also was an interaction of the two factors ( $b = -1.32$ ,  $SE = 0.56$ ,  $t = -24$ ,  $p = .019$ ). The effect of the participle was smaller when *ook* was present than when it was not present.

| condition      | proportion | sd   |
|----------------|------------|------|
| [-TENSE, -OOK] | .278       | .449 |
| [-TENSE, +OOK] | .688       | .465 |
| [+TENSE, -OOK] | .708       | .456 |
| [+TENSE, +OOK] | .861       | .347 |

Table 1. The proportions of choice of the non-negative conditional clause and the standard deviation.

Figure 1. The mean proportion of choice of the non-negative conditional clause.

The experiment has shown that for  $\phi$ -reference, speakers prefer the presence of both the past participle *geweest* and the MP *ook*. However, even if only one of these markers is present  $\phi$ -reference is more likely than if none of these markers is present. In the following we will propose how these results can be accounted for.

## 3. Tense in contextual counterfactuals

The literature on CFs distinguishes between two major types of CFs: those with simple past morphology, and those with past perfect morphology, see (11a) and (b), respectively. The difference is also sometimes characterized as (11a) containing one *layer* of past morphology – in the antecedent (*be* + PAST) and in the consequent (WOLL + PAST) –, and (11b) containing

two layers of past morphology – additional *have* in antecedent and consequent (Iatridou 2000).<sup>5</sup> (12) shows that the same marking is present in Dutch. The finite verb *zou* in the consequent is the 3rd person past tense of the auxiliary *zullen* ‘will.INFINITIVE’.<sup>6</sup> Now crucially, both in English and in Dutch, the ‘actual tense’ in these examples, i.e. their temporal interpretation, seems to be different from what the morphological marking suggests. (11a) and (12a) seem to convey that it is not true that John is here at present and Jane is happy at present, whereas (11b) and (12b) seem to convey that it is not true at some relevant moment in the past that John was here and Jane was happy. So (11a) and (12a) are about worlds ‘contrary to the present’ whereas (11b) and (12b) are about worlds ‘contrary to the past’ (Iatridou 2000). It seems that there is one past too many both in the antecedent and in the consequent of the CFs. This ‘additional’ layer of past has been called *fake past* or *fake tense* (Iatridou 2000 and subsequent literature). The ‘remaining’ tense is the one that fits the actual temporal interpretation, i.e. present tense in (11a) and (12a) and past tense in (11b) and (12b).

- (11) a. If John were here Jane would be happy.  
       b. If John had been here Jane would have been happy.
- (12) a. Als Jan hier was, zou Anne gelukkig zijn.  
       if Jan here be.PAST will.PAST Anne happy be  
       b. Als Jan hier was geweest, zou Anne gelukkig zijn geweest.  
       if Jan here be.PAST been will.PAST Anne happy be been

The above observations have spurred various analyses where the fake past is assumed to trigger a CF reading either via a past interpretation or via a modal interpretation (see Schultz 2014 for a brief overview). Proposals also differ with respect to whether the fake tense outscopes the entire conditional or not. We will explore two past-as-past approaches with wide-scope fake tense here, viz. Arregui (2007) and Ippolito (2013), because these approaches address some complications that we will talk about instantly and that are relevant for the discussion of our experimental results. Terminology-wise, we will dub the tense outscoping the conditional *wide-scope* past/tense, and the tense that seems to be interpreted *in* the conditional clauses, i.e. present tense in (11a) and (12a) and past tense in (11b) and (12b), the *local* tense.

Now, an important challenge for the analysis of the local tense is the observation that the intuitions about the temporal interpretation in the above examples, although apparently clear, are

<sup>5</sup>We will not distinguish between present CFs and *future less vivid* (FLV) conditional sentences (cf. Iatridou 2000) here. The latter contain a telic rather than stative predicate in the antecedent, which has consequences for the interpretation of the present (future-oriented or not). We will see later that the type of predicate in general seems to play an important role in the temporal interpretation of CFs but we cannot discuss this issue in this paper.

<sup>6</sup>*Zullen* is traditionally characterized as a future auxiliary. Broekhuis and Verkuyl (2014) argue that *zullen* is purely modal and therefore is different from English WOLL. This debate is not immediately relevant for the present discussion. Furthermore, note that it is also possible to form a past perfect consequent without *zouden* in Dutch. In (i) the consequent contains the same morphology as the antecedent. We gloss over this here.

- (i) Als Jan hier was geweest, dan was An gelukkig geweest.  
       if Jan here was been then was An happy been

deceptive. As was observed in Dudman (1984) and subsequent literature (e.g. Ogihara 1999; Arregui 2007, 2009; Ippolito 2003, 2013), CFs with simple past marking cannot only be about the present but also about the future, and CFs with past perfect marking cannot only be about the past but also about the present and the future, see (13) from Dudman (1984). The data are equivalent in Dutch, which for reasons of space we cannot show here.

- (13) a. If Grannie missed the last bus tomorrow, she would walk home.  
 b. If Her Majesty had been here now, she would have been revolted.  
 c. If Grannie had missed the last bus on Friday (next Friday), she would have walked home. (*She is actually dead*)

Importantly for our discussion of  $\phi$ -reference, there are restrictions on the use of the morphological tense marking for certain temporal interpretations. Observe that the set of examples we have looked at so far does not include a CF with simple past marking that has a past interpretation. The following examples illustrate that even with an elaborate context, a simple past marking in antecedent and consequent (14b), only in the consequent (14c), or only in the antecedent (14d), is unacceptable if a past interpretation of both antecedent and consequent is intended (compare (14a)). (14b) and (14c), where the antecedent is marked with simple past, are generally unacceptable with a past interpretation of the antecedent. (14d) is ‘only’ infelicitous with the indicated past interpretation of the consequent. If we replace *last week* in the consequent of (14d) with *now* and imagine that Paul’s failure to turn up has created long-term sadness in Jane, (13d) is felicitous. Thus, it is clearly possible to combine a past perfect antecedent with a simple past consequent if the latter contains a non-past interpretation. Again, the data are parallel in Dutch.

- (14) Paul had announced for last week that he would be in London. His old friend Jane was looking forward to seeing him. However, Paul didn’t turn up, and Jane wasn’t happy.  
 a. If John had visited London last week Jane would have been happy (last week).  
 b. \*If Paul visited London last week Jane would be happy (last week).  
 c. \*If Paul visited London last week Jane would have been happy (last week).  
 d. #If Paul had visited London last week Jane would be happy (last week).

The restrictions on the tense morphology in an otherwise apparently fairly flexible tense marking system in CFs has received different kinds of analyses in the literature. As mentioned above, both Arregui (2007) and Ippolito (2013) assume that a layer of fake tense outscopes the conditional. The proposals differ with respect to the local tense in the conditional clauses (as well as with respect to the number of wide-scope past operators, see below). We will briefly describe the two proposals here.

Arregui (2007) sees the crucial difference between simple past vs. past perfect morphology as an aspectual rather than a tense difference. She suggests that simple past antecedents with eventive predicates contain a perfective operator, whereas antecedents with the past perfect (or those with a stative predicate) come with a perfect operator. The perfective operator introduces

a deictic event pronoun. The deictic nature of that pronoun creates the presupposition that the respective event is true in the actual world, i.e. that it has happened.<sup>7</sup> For instance, in contexts like (14), the presupposition *Paul visited London* is clearly violated: Paul was not in London. So a simple past antecedent is expected to be infelicitous. A past perfect antecedent, in contrast, is felicitous because the perfect operator does not come with a deictic event pronoun.

Turning to Ippolito (2013), we need to go in a bit more detail in order to be able to discuss our findings within her theory further below. Similarly to Arregui (2004, 2009), Ippolito assumes that a CF reading arises from the presence of a past operator that takes scope over the entire conditional. This past operator binds the time argument of the accessibility function of the modal WOLL. This function returns the set of worlds that have the same history as the evaluation world up to a time *t*, the *accessibility time*. At *t*, the truth of e.g. John having visited London has not been decided yet and what is called in the philosophical literature *branching* into different futures occurs only afterwards. The wide-scope past operator shifts the accessibility time to the past, which means that the worlds started branching into different futures at a time in the past. In addition to the accessibility time, there is another time that is important in Ippolito's account. This is the reference time, which is the time when presuppositions of the antecedent and the consequent are evaluated: the presuppositions must be entailed by the worlds that are historically accessible from the reference time. Since the set of possible worlds can only become smaller over time, and because the reference time cannot precede the accessibility time, the presuppositions eventually must be satisfied *at* the reference time. The default reference time is the utterance time. For illustration Ippolito discusses the following example. For someone to be in love they must be alive (cf. Musan 1997 for existence presuppositions of this kind). So, a presupposition of the antecedent in *If John were in love with Mary, he would ask her to marry him* is that John is alive in worlds that are historically accessible from the utterance time, and thus by extension at the utterance time. As a consequence, the utterance of this conditional after a statement like *John is dead* is infelicitous. However, if the same conditional appears with past perfect marking it is felicitous in this context. According to Ippolito, this effect is due to the past perfect introducing a second past tense operator that scopes over the entire conditional. The function of this operator is to shift the reference time to the past. As a consequence, the presuppositions of antecedent/consequent are evaluated for worlds that are historically accessible from a reference time that is before the utterance time. With respect to the example we just discussed, this means that the being-alive presupposition must be entailed by historically accessible worlds at that past reference time. Since there is a time in the past where worlds with a living John are still accessible the CF *If John had been in love with Mary, he would have asked to marry him* is felicitous if John is dead at the utterance time.

Now, in addition to the two wide-scope past operators, Ippolito assumes that the antecedent and the consequent each have 'local' deictic tense, which is always evaluated with respect to the utterance time. Such local deictic tenses are also assumed e.g. by Romero (2014). What is special about Ippolito's account is that the present perfect – due to a deficit in English morphology – may either signal the presence of the two wide-scope operators that we discussed, or the presence of the two wide-scope operators *plus* the presence of local past tense. The mor-

<sup>7</sup>See Arregui (2007: 247ff.) for cases where the speaker does not or cannot know whether the event has happened / will have happened.

phological deficit is that standard English does not have the morphology to express three layers of past. Therefore, Ippolito proposes the following structures for CFs:

(15) Simple past (a) and past perfect (b&c) CFs (Ippolito 2013: 96ff.)

- a. [PAST<sub>1</sub>[ WOLL [ PRESENT<sub>deictic</sub>  $\phi$ ] [PRESENT<sub>deictic</sub>  $\psi$ ]]]
- b. [PAST<sub>1</sub>[PAST<sub>2</sub> [ WOLL [ PRESENT<sub>deictic</sub>  $\phi$ ] [PRESENT<sub>deictic</sub>  $\psi$ ]]]
- c. [PAST<sub>1</sub>[PAST<sub>2</sub> [ WOLL [ PAST<sub>deictic</sub>  $\phi$ ] [PAST<sub>deictic</sub>  $\psi$ ]]]]]

In (15a) and (b), there is a deictic present tense in the antecedent and in the consequent of the conditional. This structure is not compatible with the examples in (14) above, because these all involve the adverb *last week*. The present tense indicates that we are evaluating an event that would have taken place now which is inconsistent with *last week*. Therefore, we must assume that the examples in (14) have the structure in (15c). A question that arises is how we can account for the felicitous minimal variant of (14d) in which we replaced *last week* in the consequent with *now*. According to Ippolito's structures in (15b) and (c), there would still be two past tense operators outscoping the entire conditional, because the antecedent occurs in the past perfect. Yet, intuitively, using a past perfect rather than a simple past in the consequent alters the interpretation of the conditional. At this point, we do not see how Ippolito's account can be altered, such that it can account for such 'mixed' CFs.

With this much in hand, let us now turn to our cases of  $\phi$ -reference /  $\neg\phi$ -reference in the experiment presented in section 2. Recall that the utterance of the first speaker in our discourses is a negative assertion stating that a certain event (e.g. one of the gardener sowing the lawn) has not taken place. We are assuming that this assertion is one about the past, which is the default interpretation of the present perfect in Dutch (Broekhuis and Verkuyl 2014).<sup>8</sup> Next, recall that we are assuming that the second speaker, who uses a contextual CF to evaluate the utterance of the first speaker, plausibly accommodates either the past perfect CF in (16B $\phi$ ) or the one in (16B $\neg\phi$ ).

- (16) A: The gardener hasn't sown the lawn yet.  
 B: Dat zou (ook) raar zijn (geweest), ...  
 that will.PAST OOK odd be been  
 $\phi$  ...als de tuinman het gras al had gezaaid.  
 ...if the gardener the grass already have.PAST sow.PERF  
 $\neg\phi$  ...als de tuinman het gras nog niet had gezaaid.  
 ...if the gardener the grass not yet have.PAST sow.PERF  
 'It would {be / have been} strange if the gardener had(n't) sown the lawn {yet / already}'

<sup>8</sup>There are differences between the Dutch present perfect and the English simple past but note that the Dutch present perfect can be used in sentences that contain a temporal modifier like *yesterday*, which is not possible with the English present perfect: \**John has gone to the cinema yesterday* vs. *John went to the cinema yesterday*. A thorough discussion of this issue is beyond the scope of this paper; we refer the reader to De Vuyst (1985).

Starting with the tense in the antecedent, recall from the introductory section that when accommodating a CF like the one in (16B $\phi$ ) the second speaker accepts what the first speaker said as true. In the actual world, the gardener hasn't sown the lawn, in the CF worlds he has sown the lawn. In Ippolito's terms, the CF worlds are historically accessible only from a reference time in the past, at which it was still possible for the gardener to sow the lawn. Therefore, there must be two past operators scoping over the conditional. As a consequence, the conditional antecedent in (16B $\phi$ ) must be marked with the past perfect. This is the tense morphology that we used in the paraphrases in the experiment for  $\phi$ -reference. On Arregui's account we expect past perfect marking as well because that marking comes with no presupposition concerning the actual existence of the event at issue – which is what is required in the above context: the context says that the event did not take place. Further below – when we discuss the tense marking in the consequent, which we argue can be captured best in Ippolito's account – we will suggest that the local deictic tense in the antecedent of (16B $\phi$ ) is past tense as well.

As for (16B $\neg\phi$ ), we said in the introductory section that the second speaker doubts what the first speaker said, viz. that the gardener hasn't sown the lawn. The second speaker implicates that the gardener has sown the lawn. What is interesting about this kind of CF is that intuitively, the present perfect marking in the antecedent of the conditional also seems to be allowed. That is the sentence that is uttered by the first speaker can form the antecedent of the contextual CF. In English, this would look as follows: *A: John did not work. B: If John didn't work...* Note that the preferred interpretation of the antecedent seems to be that of an antecedent in an indicative conditional. Thus, such a marking somehow reduces the 'degree' of counterfactuality of the sentence. An antecedent with past perfect marking seems to be better suited to express stronger counterfactuality (cf. Iatridou 2000; Ippolito 2013). For the present purposes we need to lay that issue aside. In the experiment, we chose past perfect marking for the antecedent of the paraphrases that we gave to the participants both for  $\phi$ -reference and for  $\neg\phi$ -reference because this choice enabled us to compare minimal pairs in the investigation of the tense marking in the consequent.

Turning to the tense in the consequent, the experiment revealed that morphological marking with the past perfect increased the chances that the demonstrative pronoun in the response was interpreted as having  $\phi$ -reference. As we saw above, the consequent of a CF with a past perfect antecedent in principle can occur with simple past marking or with past perfect marking, if the antecedent is overt. So in principle the choice of tense for the consequent is open.<sup>9</sup>

<sup>9</sup>Also observe that the choice between present perfect and past perfect does not seem to influence nominal reference under modal subordination, at least in examples like (iA). The indefinite *een dier* 'an animal', which occurs under negation in the first utterance, is felicitously picked up by the pronoun *het* 'it' in the second utterance, independently of the morphological marking in that utterance, which corresponds to the consequent in an accommodated CF.

- (i) Context: Paul gaat af en toe vroeg in de ochtend jagen. Rond het middaguur vraagt Anna, die Paul die dag nog niet gezien heeft, zich af of hij vanochtend heeft gejaagd.  
'Every now and then Paul goes hunting early in the morning. Around noon, Anna, who hasn't seen Paul today yet, is wondering if he was out hunting this morning.'
- A: Paul heeft geen dier<sub>i</sub> geschoten. Het<sub>i</sub> zou daar in de hoek {liggen/hebben gelegen}.
- Paul has NEG+a animal shot it would there in the corner lie /have lain
- 'Paul has not shot an animal. It would {be/have been} lying in the corner over there.'

Let us see how the accounts by Arregui (2007) and Ippolito (2013) can be applied to our findings about the consequent. Arregui (2007) designed her proposal for the antecedent in CFs but observes in a footnote (p. 224, n. 2) that the tense restrictions that she discusses for antecedents are essentially the same for consequents. She suggests that the latter also fit the proposal she makes but does not discuss any details. As we briefly mentioned above, a crucial question within Arregui's aspectual account is whether the consequent is eventive or stative. For eventives, the tense matters because they combine with the deictic event pronoun that is introduced by the perfective aspect. For statives, the tense does not matter because there is no event pronoun. The evaluating consequents in our examples, see (20), are stative. So tense should not matter. However, our experimental results seem to suggest it does. This is problematic for Arregui's account and we do not see a straightforward way of fixing the problem.

As we saw above, Ippolito (2013) assumes that there local tense in the antecedent and in the consequent of conditionals that receives a deictic interpretation. However, she also points out that it is not quite clear how the tense marking in the consequent can be related to the wide scope past operator(s), whose presence is signaled by the past perfect morphology in the antecedent, and which, as we saw above, we must assume is present in our discourses. Ippolito discusses a potential sequence-of-tense analysis (also cf. Romero 2014) for past perfect marking in the antecedent and the consequent. However, as we mentioned above, she does not consider 'mixed' CFs, i.e. CFs with a past perfect antecedent and with a simple past consequent in English (which would correspond to the present perfect in Dutch). To explain the results that we obtained in the experiment within Ippolito's proposal we will capitalize on the idea that the local tenses are interpreted deictically. Let us start with the preferred preference of the past participle for  $\phi$ -reference. Recall that our contextual CFs are responses to a negated assertion about the past. This assertion thus introduces a salient time in the past. It is a plausible to assume that a subsequent contextual CF will say something about this salient time. Thus, we assume that the consequent conveys that the speaker thinks that the worlds that are picked up by the propositional anaphor contain spatio-temporal regions that are specified for that salient time in the past, are strange – or rather *were* strange, because they are in the past. It is not very plausible to assume that the strangeness only applies at the time of speaking, which is what the absence of the past participle would signal.

Turning to the  $\neg\phi$ -reference, it seems that we may say exactly the same: the contextual CF is a response to a negative assertion about the past. As a consequence we might expect the presence of a past participle. However, recall that the CFs that are arguably accommodated in the two cases are different. In the case of  $\neg\phi$ -reference, the speaker doubts the truth of the previous utterance. So, the evaluative comment refers to the truth of the utterance just made rather than to past CF worlds on whose counterfactuality both speakers agree as in the case of  $\phi$ -reference. Since the truth of the utterance is at issue at the utterance time, the consequent preferably is marked without the past participle.

Linking these suggestions to Ippolito's structures for CFs in (15), we might say that  $\phi$ -reference has the structure in (15c). Both the antecedent and the consequent contain a local deictic past, with the entire conditional being in the scope of the two past operators that we argued for

above.  $\neg\phi$ -reference cannot straightforwardly be matched to Ippolito's structures because there seem to be different tenses in antecedent and consequent. Also, recall that the details of the interpretation of such doubting CFs still pose a number of questions that need to be addressed in future research.

With respect to the experimental results, the above suggestions explain why the presence of the past participle increases the proportions of  $\phi$ -reference. Still, recall that in condition E3, which contained a past participle but not the MP, there still was a non-negligible proportion of  $\neg\phi$ -choices. We may assume that speakers adopted a structure like (15b) when they made this choice. According to Ippolito past perfect marking is compatible with a local present tense interpretation: the past perfect may signal the presence of only the two wide scope past operators. An alternative, or additional explanation for the results for E3 might be that the contextual CFs with  $\phi$ -reference have a kind of default marking, which includes the MP *ook*. The experimental results suggest that this might indeed be the case because  $\phi$ -choices were most frequent if both the participle and the particle were present (condition E4). Hence, if one of the 'typical' markers is missing, slight incoherence might arise, which most likely influences the way participants interpreted the response. This issue needs to be investigated in future research in an acceptability study. Finally, recall that the proportion of  $\phi$ -choices was non-negligible when the past participle (and the MP *ook*) was absent (condition E1). Again, it is possible that some speakers do not find such utterances coherent (as is the case for German, see footnote 2). As a consequence they might have found it difficult to determine the meaning of the response. This issue also needs to be investigated in an acceptability study.

#### 4. The MP *ook*

In this section we will discuss the finding that the presence of the MP *ook* increased the proportion of  $\phi$ -references. We will generally follow the proposal by Meijer (2016) but deviate in some of the details. Meijer builds her analysis – which she provides for *ook* and its German cousin *auch* – on previous accounts of the German particle because descriptions of Dutch *ook* are scarce. We will employ the same strategy in our initial characterization of the particle but then focus on *ook*.<sup>10</sup> (17) shows an example of the MP *ook*. Speaker A notes that Peter

<sup>10</sup>Note that *ook* (as well as *auch*) is ambiguous between a MP and an additive focus particle reading. As a focus particle *ook* comes in two variants: unstressed and stressed. If it is unstressed it associates with a focus in its c-command domain, see (i). If it is stressed it associates with a focus that is outside its c-command domain, see (ii). Both variants come with the presupposition that there is an alternative in the context for which the predicate that holds for the focus constituent also holds for the alternative. Thus, in (i) and (ii) there must be someone in addition to Marie that Peter called. There are subtle differences between the two versions of the particle, see e.g. Krifka (1998) and Reis and Rosengren (1997) for analyses of stressed German *auch*.

- |     |                                                                                              |      |                                                                                              |
|-----|----------------------------------------------------------------------------------------------|------|----------------------------------------------------------------------------------------------|
| (i) | Peter heeft ook MARIE gebeld.<br>Peter has OOK Marie called<br>'Peter has also called Mary.' | (ii) | Peter heeft MARIE OOK gebeld.<br>Peter has Marie OOK called<br>'Peter has also called Mary.' |
|-----|----------------------------------------------------------------------------------------------|------|----------------------------------------------------------------------------------------------|

Focus particle(s) and the MP can be distinguished from each other by their prosody (the MP cannot be stressed) and their syntactic distribution. Most importantly for the present purposes, the focus particles but not the MP come with the above-mentioned presupposition. Our experimental materials (recall (9) in section 2) were such that that presupposition was not satisfied in the context. Neither did the scene-setting passage provide a focus alternative to *dat* (which would have been required for the stressed variant of *ook*), nor did it provide a focus

looks bad. Speaker B's response is to be read as conveying that Peter's looking bad was not unexpected to him, since Peter has been ill for a long time (cf. Karagjosova 2003 for *auch*).

- (17) A: Peter ziet er slecht uit. B: Hij is ook lang ziek geweest.  
 Peter looks there bad out he is OOK long ill been  
 'Peter looks bad.' 'Well, he has been ill for a long time.'

*Auch* has been claimed to indicate that a previously asserted proposition was expected to be true already (Thurmair 1989, Karagjosova 2003). As a consequence, with an *auch*-utterance, a speaker confirms the proposition asserted prior to the *auch*-utterance. Karagjosova (2003) notes that *auch*-utterances can be 'corrective', in the sense that speakers can use them to indicate to their interlocutor that the previous utterance did not even contain new information. Furthermore, she suggests that *auch* signals that the speaker has made some sort of inference, based on what s/he already knew (for instance, from Peter being ill for a long time, we can infer that he looks bad). She notes that *auch*-utterances often can be translated with *because*-constructions (e.g. *Peter looks bad because he has been ill for a long time* for (17B)). However, note that it is not actually possible to paraphrase contextual CFs using *because*, as the use of *auch* does not seem to be causal here. In line with this intuition, Bergmann and Repp (2015) provide experimental evidence suggesting that *auch* is not causal in the same way that the e.g. German markers *denn* 'because' and *eben* 'obviously' are. A recall experiment showed that *denn* and *eben* helped recalling information. This effect was not found for *auch*. Yet, the recall of information has been claimed to be aided by the presence of causal markers (e.g. Caron, Micko and Thüring 1988).

Meijer (2016) largely follows the theories by Thurmair (1989) and Karagjosva (2003), but offers a formal analysis of *auch* and *ook* as epistemic markers. Roughly, Meijer suggests that *auch/ook* presupposes that the proposition asserted in the previous utterance (proposition  $\phi_{-1}$ ) was already entailed by the epistemic modal base before it was asserted, as shown in (18). The epistemic modal base  $f(w)$  contains the propositions that describe the knowledge that has been established in a world  $w$  (Kratzer 1981).

- (18)  $\llbracket \text{ook}(\phi) \rrbracket^{c,w} = \phi$ ; defined if  $\cap f(w) \subseteq \phi_{-1}$  before  $\phi_{-1}$  was uttered

Applying (18) to (17), we can say that the knowledge available to B enabled him to infer that Peter was looking bad, before A asserted this. Specifically, B's world knowledge that *if one is ill for a long time, one looks bad* and the knowledge that Peter has been ill for a long time most likely are decisive here. Note that the dialog in (17) is still fine if A knows nothing about Peter's medical history, but does know that he looks bad. The fact that for A, the proposition that Peter looks bad does not have to be inferable in the way that *ook* signals that it is for B,

alternative to (*to be*) *strange* (which would have been required for the unstressed variant of *ook*). Furthermore, it is difficult to accommodate the presupposition of additive focus particles (Kripke 2009). Hence, we assume that it is highly unlikely that the participants in the experiment interpreted the word *ook* as a focus particle.

shows us that it need not be the context set that is the contextually salient body of knowledge, but it could also be the knowledge of the speaker.<sup>11</sup> However, in what Karagjosova calls the ‘corrective’ use of *auch*, it seems that the particle indicates that the speaker who is making the *auch*-utterance indicates to his/her interlocutor that s/he should have known already that this proposition was inferable. In such scenarios, it might be the context set that is the relevant body of information.

Meijer’s (2016) specific proposal for *auch* and *ook* is slightly different from what we are assuming here. It is couched in the framework by von Fintel and Gillies (2010) on *must*, where a distinction is made between two sets of propositions that are relevant for epistemic/evidential modality. The first set is the kernel. This set consists of propositions that the speaker takes to be true (propositions denoting world knowledge, direct observations and trustworthy knowledge). The second set is the intersection of the kernel: the modal base it determines. For *must*, roughly, the authors argue that it presupposes that its prejacent is entailed by the modal base that the kernel determines but that it is *not* in the Kernel. Meijer (2016) tentatively suggests that the MPs signal that the prejacent was entailed by the modal base, but remains agnostic about the presupposition *auch/ook* bear with respect to the kernel. For *ook*, Meijer points out that the kernel does not seem to play a role, since (17B) is felicitous, even if both speakers have seen that Peter looks bad and are aware of their mutual knowledge. For some speakers of German, the use of *auch* in such scenarios is marked, which suggests that for these speakers, the prejacent of *auch* cannot be in the kernel. Meijer (2016) therefore remains agnostic with respect to the role of the kernel in uses of *auch*. Since the kernel does not seem relevant for *ook*, we will stick to (18) and leave research into the use of *auch* in scenarios in which the prejacent is in the kernel for future research.<sup>12</sup>

Let us return to the use of *ook* in contextual CFs and to our experimental results. From the above suggestion for *ook*, it follows that if *ook* is used in response to a negative assertion the utterance that *ook* occurs in is interpreted as affirming this negative assertion. Such an affirmation is present in the CFs with  $\phi$ -reference but not in the CFs with  $\neg\phi$ -reference. Recall that in the latter the second speaker doubts what the first speaker said, viz. that  $\neg\phi$  is true. Hence, we predict that *ook* should not be felicitous with  $\neg\phi$ -reference. With respect to our experiment, this means that conditions with *ook* (E2, E4) should elicit a low proportion of  $\neg\phi$ -choices. This is what we found. However, recall that there still was a non-negligible proportion of choices for  $\neg\phi$  for contextual CFs that contain *ook*, but not *geweest* (E2). As we pointed out above, the most common, or preferred, way of establishing  $\phi$ -reference in contextual CFs is by including both the MP and the past participle. As we mentioned in the discussion on *geweest*, it could be that the lack of one of these markers made the response incoherent for some of the participants. Future research should investigate this matter in an acceptability judgment study.

<sup>11</sup>We are aware that some authors have argued against such an analysis of modal verbs (e.g. von Fintel and Gillies 2008) and we do not wish to enter this debate on modality. However, for the use of *ook* the data strongly suggest that it is the knowledge of the speaker that is relevant for a felicitous use of the MP.

<sup>12</sup>It seems that (18) holds too for those speakers of German who think that the German equivalent of (17) is fine even if both speakers are aware of their mutual knowledge of A’s assertion before A made this assertion.

## 5. Conclusion

In this paper we have argued that two important factors for establishing reference to a proposition in the scope of a negation in a previous utterance are the tense marking and the presence or absence of the MP *ook* (cf. Meijer 2016). We have provided experimental evidence for a certain class of evaluative utterances that supports this empirical claim. With Meijer (2016) we have assumed that these evaluative utterances are contextual CFs for which an antecedent is accommodated on the basis of the previous utterance. The antecedent that is accommodated either contains a negation or not, and it serves as the antecedent for the propositional anaphor in the consequent, i.e. decides whether the anaphor refers to the proposition in the scope of the negation  $\phi$  or the negated proposition  $\neg\phi$ . With Meijer (2016) we have argued that *ook* presupposes that the previous utterance could be inferred from previous knowledge and thus must be true. Since this presupposition is only satisfied in CFs with  $\phi$ -reference, the presence of *ook* is only compatible with such a reading. Furthermore, we have argued that  $\phi$ -reference is preferably marked with a past participle in the consequent because a local deictic past tense – which plausibly is the temporal interpretation of the consequent – requires past perfect tense morphology (Ippolito 2013).  $\neg\phi$ -reference in contrast, is compatible with a local deictic present tense in the consequent.

# The proper treatment of the wide scope *or* reading of the English *either ... or ...* construction<sup>1</sup>

Mioko MIYAMA — *University of Tokyo*

**Abstract.** The main concern of this paper is the availability of the wide scope *or* reading in the English *either ... or ...* construction and its interaction with the behavior of *either*. I propose that a hybrid analysis consisting of an ellipsis analysis (Schwarz, 1999), which directly arises from the requirement of *or* that it connect disjuncts of the same type, and a choice function analysis of *either* (cf. Winter (2001); Schlenker (2006) for a choice function analysis of *or*) explains the whole data set. I also discuss a prediction the present analysis makes and some remaining issues, including a data issue in which the judgments made by my informants differ from the ones observed in a previous study.

**Keywords:** disjunction, wide scope *or* reading, choice function, ellipsis.

## 1. Introduction

This paper focuses on the English *either ... or ...* construction, in which *either* can be overt or covert as presented in Larson (1985):

- (1)    a.    Mary is looking for a maid or a cook.  
       b.    Mary is looking for either a maid or a cook. (Larson, 1985: 218)

The proposal of this paper is that a hybrid analysis consisting of a choice function analysis of *either* (cf. Winter (2001); Schlenker (2006) for a choice function analysis of *or*) and an ellipsis analysis (Schwarz, 1999) straightforwardly explains the basic data concerning the (un)availability of the wide scope *or* reading.

The rest of the paper is organized as follows. In Section 2, I review the basic data set of the availability of the wide scope *or* reading and its interaction with *either*. The main proposal is given in Section 3, where it is shown that neither a pure ellipsis analysis nor a pure choice function analysis explains the data set in Section 2. I propose that a hybrid analysis which combines the ellipsis analysis and a choice function analysis of *either*, a modified version of the choice function analysis of disjunction, covers the whole data set introduced in Section 2. Section 4 concludes the paper and discusses some potential problems related to the predictions that the present analysis makes.

---

<sup>1</sup>I am grateful to Akira Watanabe and Noriko Imanishi for giving me helpful comments and suggestions. I also express my deep gratitude to Barbara Partee, who gave me important advices and suggestions to the very first version of this paper, without which the research would never have taken shape, and to Christopher Tancredi, who has also given me numerous invaluable comments to the later versions of this paper, without which the research would never have developed into the present version. I also thank the audience at *Sinn und Bedeutung* 21, especially Mats Rooth, for discussion and judgments. All remaining errors are my own.

## 2. The basic data set

As noted in Partee and Rooth (1983) as a problematic case and discussed in Rooth and Partee (1982) in more detail, when disjunction is combined with certain kinds of elements in a sentence, the sentence is (at least) three-ways ambiguous:

- (2) The department is looking for a phonologist or a phonetician. (Partee and Rooth, 1983: 374)
- a.  $\llbracket \text{look for} \rrbracket (\llbracket \text{a phonologist or a phonetician} \rrbracket) (d)$  (narrow scope *or de dicto* reading)
  - b.  $\exists x : \llbracket \text{a phonologist or a phonetician} \rrbracket (x), \llbracket \text{look for} \rrbracket (x) (d)$  (*de re* reading)
  - c.  $\llbracket \text{look for} \rrbracket (\llbracket \text{a phonologist} \rrbracket) (d) \vee \llbracket \text{look for} \rrbracket (\llbracket \text{a phonetician} \rrbracket) (d)$  (wide scope *or de dicto* reading)

There is a *de re* reading in (2b) according to which there is a specific person  $x$  who is either a phonologist or a phonetician, and the department is looking for him. (Since this reading does not affect the discussion in this paper, I disregard this reading hereafter.) The narrow scope *or de dicto* reading (the NS reading) is in (2a), and under this reading the department would be satisfied by finding either a phonologist or a phonetician. The “problematic” *de dicto* reading, which I am interested in, is described in (2c). On this reading, the department do not yet necessarily have a specific candidate in mind. They do already have in mind which of the two specialists they are going to look for, but the speaker forgot which it was. The reading becomes clearer when continued with “... but I don’t know which.” Thus the overall meaning is as if the disjunction is connecting two propositions, taking widest scope, even though the indefinite in each disjunct takes narrow scope. This is called the “wide scope *or*” reading (the WS reading) in Rooth and Partee (1982).

Larson (1985) observes that the possible readings of a sentence change when *either* comes into the structure. He states a generalization:

- (3) Larson’s (1985) generalization (Winter, 2000: 395):
- a. In *or* coordinations without *either*, as well as in *either... or...* coordinations with *either* undisplaced, the scope of *or* is confined to those positions where *either* can potentially appear.
  - b. When *either* is displaced it specifies the scope of *or* to be at that displaced position.

Thus, while when *either* is adjacent to the Disjunction Phrase both NS and WS readings are available (4), when *either* floats to a higher position the NS reading disappears (5).

- (4)
- a. Mary is looking for a maid or a cook.
  - b. Mary is looking for either a maid or a cook.
    - (i)  $\llbracket \text{look for} \rrbracket (\llbracket \text{a maid or a cook} \rrbracket) (m)$  (NS reading)
    - (ii)  $\llbracket \text{look for} \rrbracket (\llbracket \text{a maid} \rrbracket) (m) \vee \llbracket \text{look for} \rrbracket (\llbracket \text{a cook} \rrbracket) (m)$  (WS reading)
- (5)
- a. Mary is either looking for a maid or a cook.
  - b. Mary either is looking for a maid or a cook.

- c. Either Mary is looking for a maid or a cook.
- (i)  $?*\llbracket\text{look for}\rrbracket(\llbracket\text{a maid or a cook}\rrbracket)(m)$  (NS reading)
- (ii)  $\llbracket\text{look for}\rrbracket(\llbracket\text{a maid}\rrbracket)(m) \vee \llbracket\text{look for}\rrbracket(\llbracket\text{a cook}\rrbracket)(m)$  (WS reading)

Winter (2000) and Schlenker (2006) report data which at first glance look like an exception to Larson's (1985) generalization in (3), where disjunction can take wide scope over an island as in (6) and (9) but *either* cannot appear out of the island as in (8) and (11).<sup>2</sup> Note that *either* can appear inside the island and the disjunction can take either the narrow or wide scope as shown in (7) and (10).

- (6) If Bill praises Mary or Sue then John will be happy. (Winter, 2000: 403)
- a. If Bill praises Mary then John will be happy and if Bill praises Sue then John will be happy. (NS)
- b. If Bill praises Mary then John will be happy or if Bill praises Sue then John will be happy. (WS)
- (7) a. If Bill praises either Mary or Sue then John will be happy. (<sup>OK</sup> NS / <sup>OK</sup> WS)
- b. If Bill either praises Mary or Sue then John will be happy. (<sup>OK</sup> NS / <sup>OK</sup> WS)
- (8) \*Either if Bill praises Mary or Sue then John will be happy. (Winter, 2000: 403)
- (9) Students taking the exam have a choice of two options: Greek or Latin.
- a. Not a single student who picked some/a certain option (I don't remember which) passed the exam. (baseline; island-escaping indefinites)
- b. #Not a single student who picked at least one option (I don't remember which) passed the exam. (baseline; non-island-escaping indefinites)
- c. Not a single student who picked Greek or Latin (I don't remember which) passed the exam.
- (10) a. Not a single student who picked either Greek or Latin (I don't remember which) passed the exam.
- b. ?Not a single student who either picked Greek or Latin (I don't remember which) passed the exam.

<sup>2</sup>Larson, 1985: 245 reports that the scope of *or* actually is sensitive to CNP islands and *Wh* islands when *either* is not present as in (i) and (ii) (according to his claim, movement of the null operator in the position of *either* is sensitive to islands). Thus there seems to be a discrepancy in judgment.

- (i) John maintains the claim that Bill should resign or retire.
- a. John maintains [SHOULD (resign (b))  $\vee$  SHOULD (retire (b))]
- b. \*John maintains [SHOULD (resign (b))]  $\vee$  John maintains [SHOULD (retire (b))]
- (ii) John knows who should resign or retire.
- a. John knows  $p$ , where  $p$  is true &  $\exists x [p = \text{SHOULD}(\text{resign}(x)) \vee \text{SHOULD}(\text{retire}(x))]$
- b. ??[John knows  $p$ ]  $\vee$  [John knows  $q$ ], where  $p$  is true &  $\exists x [p = \text{SHOULD}(\text{resign}(x))]$ , and where  $q$  is true &  $\exists x [q = \text{SHOULD}(\text{retire}(x))]$

- (11) \*Either not a single student who picked Greek or Latin passed the exam. (Schlenker, 2006: 306)

The fact that sentences with *either* inside an island do have WS readings ((7), (10)) conforms to the generalization in (3a), since sentences with *either* in its base position can have the scope of *or* higher than the surface position of *either*. In contrast, it goes against the generalization in (3b), since floated *either* does not mark the exact scope of *or* but allows the scope of *or* to be in a higher position.

In this section we have seen Larson's (1985) generalization in (3), in which it is stated that (i) in sentences with no *either* or with *either* in its base position, *or* can take both the narrow scope and the wide scope, while (ii) in sentences with floated *either*, only the WS reading is available. We have also seen data reported by Winter (2000) and Schlenker (2006), in which *or* can take scope over an island but *either* cannot overtly appear outside the island. In the next section, we will see that a hybrid analysis, which combines Schwarz's (1999) ellipsis analysis and a version of a choice function analysis that slightly modifies a choice function analysis for disjunction suggested in previous studies, explains the data in this section neatly.

### 3. Proposal: A hybrid analysis

In this section, I introduce two previous analyses on the *either... or...* construction: the ellipsis analysis (Schwarz, 1999) and the choice function analysis of *or* (Winter, 2001; Schlenker, 2006). It is shown that although both analyses have advantages, they also have problems. I propose that the hybrid analysis which combines the two analyses with some modification covers the data set introduced in Section 2: (i) the ellipsis treatment of disjunction, which comes from the semantic requirement on *or* that it has to take two disjuncts of the same semantic type, explains the obligatory WS reading of the "floated *either*" sentences in (5), and (ii) the choice function analysis of *either*, which is a modified version of the choice function analysis of *or*, explains the ambiguity of sentences with no *either* or with *either* in its base position (4).

#### 3.1. The ellipsis analysis

The ellipsis analysis of Schwarz (1999) claims that "unbalanced disjunction" as in (12), in which in the surface form the disjuncts are not the same size under the assumption that the overt position of *either* marks the left edge of the first disjunct, is derived by ellipsis. The analysis correctly predicts that when *either* floats only the WS reading is available, since the underlying form involves balanced disjunction and directly corresponds to the WS reading.

- (12) a. John either ate rice or beans.  
       John either [<sub>VP</sub> ate rice] or [<sub>VP</sub> ate beans]  
       b. Either John ate rice or beans.  
       Either [<sub>IP</sub> John ate rice] or [<sub>IP</sub> ~~John~~ ate beans] (Schwarz, 1999: 351-352)

The ellipsis analysis can also explain the fact that the size of the second disjunct can be smaller

than the first one (13a) while the size of the first disjunct cannot be smaller than the second one (13b).

- (13) a. *either* [ $X_t$  or  $Y_\tau$ ] (where  $\tau$  is any semantic type)  
 Mary is either looking for a maid or a cook.  
 Mary either is looking for a maid or a cook.  
 Either Mary is looking for a maid or a cook.
- b. *either* [ $X_t$  or  $Y_\tau$ ] (where  $\tau \neq t$ )  
 #Mary is either a maid or looking for a cook.  
 \*John either Mary or saw Sue.

The ellipsis analysis is able to handle this fact since ellipsis is sensitive to the linear order of the elements under consideration. Specifically, ellipsis is applied to the second (non-initial) element, under identity of the deleted element with the initial element. Thus when the size of the second disjunct is smaller than the first one (13a), it is possible to assume that there is some elided material for the second disjunct, while when the size of the first disjunct is smaller than the second one (13b), we cannot claim that the first disjunct has undergone ellipsis, since ellipsis cannot be applied to the initial element. We successfully account for the difference in the acceptability between (13a) and (13b).<sup>3</sup>

Next, let me closely examine the nature of the ellipsis operation that is involved in deriving unbalanced disjunction. Specifically, I will examine whether the proposal can explain data beyond the simplest ones like (12), namely sentences such as (13).

- (14) John either cited a theory that Partee or Rooth invented.

(14) is an example of unbalanced disjunction which involves a Complex NP Island. According to the ellipsis analysis, its structure is as in (15), based on the assumption that unbalanced disjunction has a balanced structure in its underlying form. The surface form in (14) is derived by (i) eliding the embedded verb in the first disjunct and (ii) eliding everything but the embedded subject and verb in the second disjunct, as shown in (15). In the rest of this subsection, I investigate whether such a derivation is really possible.

- (15) John either [cited a theory that Partee ~~invented~~] or [~~cited a theory that~~ Rooth invented].

<sup>3</sup>Note that the ellipsis analysis have difficulty in accounting for the data of “R-*either*” in Den Dikken (2006), in which *either* seems to be “buried” inside the first disjunct.

- (i) John either ate rice or he ate beans. (Den Dikken, 2006: 690)

Larson (1985), who proposes a movement analysis of *either*, claims that sentences like (iia) involve an unbalanced disjunction of VP and CP as in (iib). The matrix subject moves out from the first disjunct and *either*, originally inside the DisjP, optionally moves leftwards.

- (ii) a. Mary either is driving to the airport or she is taking a cab.  
 b. Mary<sub>j</sub> either<sub>i</sub> is [<sub>DisjP</sub> t<sub>i</sub> or [<sub>VP</sub> t<sub>j</sub> driving to the airport] [<sub>CP</sub> she is taking a cab]].

Going back to the original argument of the ellipsis analysis proposed by Schwarz (1999), Schwarz (1999) claims that the ellipsis operation involved in the derivation of unbalanced disjunction (17) is in fact Gapping (16).

(16) Tom has a pistol and Dick ~~has~~ a sword.

(17) a. John either ate rice or ~~ate~~ beans.  
b. Either John ate rice or ~~John ate~~ beans. (Schwarz, 1999: 351-352)

As supporting evidence, he observes that Gapping and unbalanced disjunction behave similarly. For one thing, Gapping always targets the finite verb of the second conjunct, and sometimes extra material too, including subjects as in (18). This parallels the unbalanced disjunction data in (17).

(18) On Monday I bought a car and on Tuesday ~~I bought~~ a motorcycle. (Schwarz, 1999: 354)

For another, it is possible for Gapping to leave only one expression as in (19). This behavior also parallels (17).

(19) John bought a book yesterday, and a newspaper. (Schwarz, 1999: 354)

An important characteristic that Gapping and unbalanced disjunction have in common is that neither of them allows “dangling remnants,” where the first and second conjuncts/disjuncts are not parallel. In both (20) and (21), the second conjunct/disjunct has some extra material that the first conjunct/disjunct does not, and this leads to the degraded status of the sentences.

(20) \*Some talked about politics and others ~~talked~~ with me about music.  
(Schwarz, 1999: 356)

(21) a. ?Either [he invited you] or [~~he invited~~ me to a party].  
b. ??Either [this pissed Bill] or [~~this pissed~~ Sue off]. (Schwarz, 1999: 357)

According to Schwarz (1999), the reason why the sentences in (21) are less degraded than (20) is because what is prohibited from being left as a “dangling remnant” can be Right Node Raised from both the first disjunct and the second disjunct. Right Node Raising must take place in a disjunct-final position as in (21), thus having no ameliorating effect on (20) since the “dangling remnant” there is in a medial position.

Now let us return to (14) and see whether the derivation (15) is a possible one.

(14) John either cited a theory that Partee or Rooth invented.

(15) John either [cited a theory that Partee ~~invented~~] or [~~cited a theory that~~ Rooth invented].

As stated earlier, the surface form in (14) is derived by (i) eliding the embedded verb in the first disjunct and (ii) eliding everything but the embedded subject and verb in the second disjunct, as shown in (15). The second step, namely the deletion of elements in the second disjunct, can be explained with Gapping, given that Gapping can potentially leave only one element as in (19) and, in addition, the least embedded verb can potentially be the only material elided. In fact, as laid out in Johnson (2006) in detail, Gapping cannot target an embedded verb excluding the matrix verb as in (22), following the No Embedding Constraint (23).

- (22) \*Alfonse stole the emeralds, and I think that Mugsy ~~stole~~ the pearls. (Johnson, 2006: 412)

- (23) The No Embedding Constraint (Johnson, 2006: 412)  
Let A and B be conjoined or disjoined phrases, and  $\beta$  be the string elided in B whose antecedent is  $\alpha$  in A. Then  $\alpha$  and  $\beta$  must contain the highest verb in A and B.

The first step of deriving (14), namely eliding the embedded verb in the first disjunct, is also accounted for by claiming that the embedded verb, which is the rightmost element in the first disjunct, undergoes Right Node Raising. The claim is consistent with the observation that Right Node Raising has to target the conjunct/disjunct-final element as in (21). Furthermore, the data conform to the classic claim that Right Node Raising has to target constituents (cf. Postal (1974); Bresnan (1974) among others), which is shown by the contrast between (24a) and (24b). As can be observed from the difference in acceptability between (24a,b) and (25c), the elided material in the first disjunct in unbalanced disjunction also has to form a constituent as in (24a,b) and the sentence is degraded when it is not a constituent as in (25c).

- (24) a. He tried to persuade them, but he couldn't convince them, that he was right.  
b. \*He tried to persuade, but he couldn't convince, {them / the students} that he was right. (Bresnan, 1974: 615)
- (25) a. John either thinks that Mary talked yesterday ~~with Sue~~ or ~~thinks that Mary talked~~ today with Sue.  
b. John either thinks that Mary talked yesterday ~~about music~~ or today about music.  
c. ??John either thinks that Mary talked yesterday ~~with Sue about music~~ or today with Sue about music.

Now it has been shown that the ellipsis analysis of unbalanced disjunction, claimed to involve Gapping and Right Node Raising according to Schwarz (1999), successfully derives sentences like (14) with the underlying structure (15). I thus adopt the ellipsis analysis to account for the unbalanced disjunction examples. Further, to ensure that *either* occurs with *or*, I claim that *either* is syntactically required to take a DisjP as its argument and *or* inside the DisjP has to take two disjuncts of the same type/size (cf. Law of coordination of likes), thus motivating the ellipsis treatment when the surface form is unbalanced.

However, even though the ellipsis analysis explains very well the unbalanced disjunction data, it has a crucial problem that it does not have much to say about the availability of the WS

reading for sentences with *either* in its base position, adjacent to the DisjP. Recall that such sentences are ambiguous, having both NS and WS readings, as we have seen in (4) in Section 2.

- (26) a. Mary is looking for a maid or a cook.  
 b. Mary is looking for either a maid or a cook.  
 (i)  $\llbracket \text{look for} \rrbracket (\llbracket \text{a maid or a cook} \rrbracket) (m)$  (NS reading)  
 (ii)  $\llbracket \text{look for} \rrbracket (\llbracket \text{a maid} \rrbracket) (m) \vee \llbracket \text{look for} \rrbracket (\llbracket \text{a cook} \rrbracket) (m)$  (WS reading)

In such “balanced disjunction” examples, there is no motivation to posit ellipsis in the derivation of the sentences, and thus in the ideal case, ellipsis would not be involved in the derivation of these sentences. Thus the ellipsis analysis predicts that only the NS reading is possible. The ellipsis analysis on its own leaves unexplained the problem of the ambiguity of the sentence when *either* is in its base position.<sup>4</sup>

It is precisely this problem that the choice function analysis readily explains. I next turn to the details of the choice function analysis.

### 3.2. The choice function analysis of disjunction

In this section, I review the choice function analysis of disjunction suggested in Winter (2001) and Schlenker (2006). It is shown that the analysis can explain the ambiguity that sentences with *either* in its base position and the fact that the WS reading is available in sentences with the disjunction in an island. Winter (2001) suggests a (Skolem) choice function analysis for disjunction and claims that through existential closure over the choice function variable that the disjunction introduces, we obtain the WS reading as in (27).<sup>5</sup> This is basically applying the choice function analysis that he proposes for indefinites to disjunction.

- (27) If Bill praises Mary or Sue then John will be happy.  
 $\exists f [\text{CH}(f) \wedge [\langle \rangle^d (\min(M \cup S)) (\lambda x. \text{praise}'(x)(b') \rightarrow \text{happy}'(j'))]]$   
 $= \exists f [\text{CH}(f) \wedge [\langle \rangle^d (\{\{m'\}, \{s'\}\}) (\lambda x. \text{praise}'(x)(b') \rightarrow \text{happy}'(j'))]]$   
 $= \exists A \in \{\{m'\}, \{s'\}\} [(\lambda P. A \subseteq P) (\lambda x. \text{praise}'(x)(b') \rightarrow \text{happy}'(j'))]$   
 $= [\text{praise}'(m')(b') \rightarrow \text{happy}'(j')] \vee [\text{praise}'(s')(b') \rightarrow \text{happy}'(j')] \quad (\text{Winter, 2001: 159})$

<sup>4</sup>The fact that the ellipsis analysis predicts that *either* marks the exact scope of *or* becomes problematic again when we see data other than the basic ones in Section 4.

<sup>5</sup> $M$  and  $S$  are the quantifiers corresponding to the proper names *Mary* and *Sue* respectively (and thus can be connected by Generalized Disjunction as in (27)) and the notations  $m'$  and  $s'$  are the lexical denotations of *Mary* and *Sue* respectively. The operator  $\min$  (for the operation Minimum Sort) takes  $Q$ , a set of objects of type  $\tau$  (which is a boolean type) and gives back the set of minimal sets of  $Q$ , where a set  $A$  is a minimal set of  $Q$  iff  $A$  is in  $Q$  and every proper subset of  $A$  is not in  $Q$ .

(i)  $\min = \lambda Q_{\tau}. \lambda A_{\tau}. Q(A) \wedge \forall B \in Q [B \subseteq A \rightarrow B = A]$  (Winter, 2001: 53)

$\langle f \rangle^d$  is a distributive version of a choice function. The operator  $\langle \rangle^d$  lifts a choice function with the following definition.

(ii)  $\langle \rangle^d = \lambda g_{(et)(et)}. \lambda A_{et}. \lambda B_{et}. A \neq \emptyset \wedge g(A) \subseteq B$

Importantly, the choice function analysis has the obvious advantage that, since existential closure is not confined within islands, it successfully predicts the availability of the WS reading in sentences with no *either* or with *either* in its base position ((4), (6), (9)), even if the disjunction is inside an island. Furthermore, since existential closure can be applied to any node whose semantic type is *t*, the choice function analysis can account for the ambiguity that the sentences have; namely having both the NS and WS reading. Thus the choice function analysis neatly explains the ambiguity of sentences with no *either* or with *either* in its base position, which was a problem for the ellipsis analysis alone as we have seen in Section 3.1.

However, the choice function analysis has at least two problems. First, it has difficulty in deriving the WS reading for sentences with floated *either* since the analysis in itself does not have the machinery to derive the reading. In such sentences, the surface form is unbalanced disjunction, while the WS reading involves two propositional disjuncts as we can see from (5) repeated below.

- (28)
- a. Mary is either looking for a maid or a cook.
  - b. Mary either is looking for a maid or a cook.
  - c. Either Mary is looking for a maid or a cook.
    - (i)  $?*[[\text{look for}]([\text{a maid or a cook}]])(m)$  (NS reading)
    - (ii)  $[[\text{look for}]([\text{a maid}]])(m) \vee [[\text{look for}]([\text{a cook}]])(m)$  (WS reading)

Second, the choice function analysis of disjunction has a problem in the mechanism used to determine the position of the choice function variable, and it becomes visible when we closely inspect the unbalanced disjunction example (28a). The problem is, the choice function analysis of disjunction actually does not rule out the possibility of the choice function variable being introduced at a position lower than is actually allowed. Since, according to the choice function analysis of disjunction, the only thing that the disjunction does is to require that the two disjuncts be of the same size and to introduce a choice function variable just outside the DisjP, there is no way to determine the size of the DisjP and the position where the choice function variable is introduced just from the role of the disjunction. Thus, for example, the choice function analysis of disjunction wrongly predicts that we can place the choice function variable just above *[a maid or a cook]* in (28a). The requirements of the disjunction are fulfilled in this situation, conjoining two disjuncts of the same size and placing the choice function variable above the DisjP. This results in the narrow scope reading of the disjunction, which the sentence does not have.

Thus a pure choice function analysis also have problems. In Subsection 3.3, I propose that we need to combine the choice function analysis with the ellipsis analysis in order to solve the first problem, and in addition, we need to modify the choice function analysis so that *either*, not *or*, introduces the choice function variable in order to solve the second problem.

### 3.3. The hybrid analysis

In previous subsections, I have shown that the ellipsis analysis and the choice function analysis of disjunction both have advantages and problems. The ellipsis analysis is able to account for the obligatory WS reading of floated *either* examples, but it cannot explain the availability of the WS reading in sentences with *either* in its base position. The choice function analysis of disjunction can explain the ambiguity of sentences with *either* in its base position, but lacks the machinery to derive the WS reading in floated *either* examples and overgenerates the NS reading.

Now we can see that the problem of the ellipsis analysis and the first problem of the choice function analysis of disjunction are solved if we combine the two analyses. The first version of the hybrid analysis, “the ellipsis analysis + the choice function analysis of disjunction,” is given in (29). Below I give an overview of how the analysis can explain the basic data set. In sentences with no *either* or with *either* in its base position (30), where there is an ambiguity between narrow scope and wide scope *or*, no ellipsis is involved in the derivation of “balanced disjunction.” Thus there are multiple possible positions for Existential Closure which correspond to the multiple possible scope positions of *or*.

- (29) The ellipsis analysis + the choice function analysis of *or*
- a. *Either* syntactically requires a DisjP as its argument
  - b. *Or* semantically requires two disjuncts of the same semantic type
  - c. *Or* introduces a choice function variable
- (30) **Ambiguous between NS and WS *or***
- a. Mary is looking for a maid or a cook.
  - b. Mary is looking for either a maid or a cook.  
 $\Rightarrow$  **No ellipsis / Multiple possible positions of Existential Closure**  
 $[\exists f]$  Mary is looking for  $[\exists f]$  PRO to FIND  $f(\{a\text{ maid}, a\text{ cook}\})$  (cf. Larson et al. (1997))

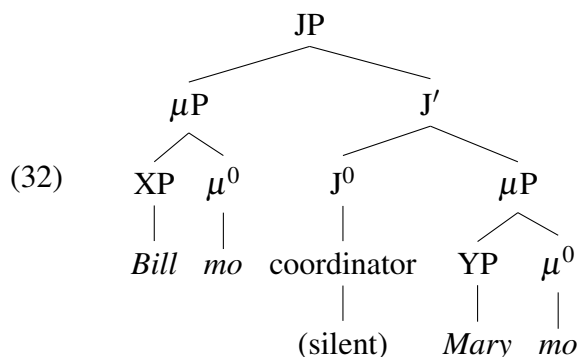

In sentences with floated *either* as in (31), where the WS reading is forced, *either* marks the left edge of the first disjunct and ellipsis is involved in the derivation. Since the choice function variable is introduced with the disjunction, Existential Closure is restricted to a position above the DisjP. Thus we can account for the fact that only the WS reading is available in the sentences.

- (31) **Unambiguous: only WS *or***
- a. Mary is either looking for a maid or a cook.
  - b. Mary either is looking for a maid or a cook.
  - c. Either Mary is looking for a maid or a cook.  
 $\Rightarrow$  **Involve ellipsis / Existential Closure possible only above DisjP**  
    - a. Mary is either looking for a maid or ~~looking for~~ a cook.
    - $\exists f$ . Mary is  $f(\{looking\text{ for a maid}, looking\text{ for a cook}\})$

- b. Mary *either* is looking for a maid or ~~is looking for~~ a cook.  
 $\exists f. \text{Mary } f(\{ \text{is looking for a maid}, \text{is looking for a cook} \})$   
 c. *Either* Mary is looking for a maid or ~~Mary is looking for~~ a cook.  
 $\exists f. f(\{ \text{Mary is looking for a maid}, \text{Mary is looking for a cook} \})$

The first version of the hybrid analysis seems to explain well the data set in Section 2. However, the second problem of the choice function analysis of disjunction, namely the analysis predicts that a NS reading is available for the “floated *either*” examples, remains. This problem arises because we have assigned the role of introducing the choice function variable to the disjunction. This is the point where the analysis needs refinement. What, then, has the role of introducing the choice function variable? The obvious alternative candidate is *either*, and this indeed seems to be the right choice to make. Observe that, in all of the examples we have seen in (30) and (31), the position where the choice function variable is placed actually coincides with the overt position of *either*. Thus I propose that the item that has the role of introducing the choice function variable is *either*, rather than *or*, and argue for a choice function analysis of *either*.

As for the semantic role of *or*, I assume that *or* forms a set consisting of the disjuncts (cf. Alonso-Ovalle (2006)) that serves as the argument of the choice function variable. I adopt the claim made by Mitrović and Sauerland (2014) for the syntactic structure and the semantic computation inside coordination. Mitrović and Sauerland (2014) give a decomposed structure (32) for the Japanese phrase involving conjunction *Bill mo Mary mo* ‘Bill and Mary.’

According to Mitrović and Sauerland (2014), languages can be classified into languages with an overt  $\mu$  head such as Japanese *mo*, which can be used as a quantificational particle or a focus particle, and languages with an overt J(unction) head such as English *and*, which can be used when the coordinated items are individuals and when the coordinated items are propositions. The semantics of the two heads is as in (33).

- (33) a.  $\llbracket \mu^0 \rrbracket (R_{\langle et \rangle}) (S_{\langle et \rangle}) = R \subseteq S$   
 b.  $\llbracket J^0 \rrbracket (Q_{I \langle ett \rangle}) (Q_{2 \langle ett \rangle}) = Q_I \cap Q_2$

With the help of the type-shifting operation from *e* to *et* at the XP/YP level, the individuals Bill and Mary are shifted to their characteristic properties and can combine with  $\mu^0$ . The overall denotation of JP in (32) is thus the set  $\{ \text{Bill}, \text{Mary} \}$ . Although the semantic difference between conjunction and disjunction needs to be clarified, I claim that the denotation of a DisjP is the

set of the disjuncts and adopt the claim of Mitrović and Sauerland (2014) that the denotation can be derived compositionally.

Other elements of the hybrid analysis, namely (29a) and (29b), are carried over, so the final version of the hybrid analysis is as in (34). I also claim that even in sentences where *either* is covert, the presence of *or* indicates that a phonetically null version of *either* is present in the structure, thus ensuring that the possible readings are the same as for sentences with overt *either*.<sup>6</sup>

- (34) The ellipsis analysis + the choice function analysis of *either*
- Either* syntactically requires a DisjP as its argument (= (29a))
  - Or* semantically requires two disjuncts of the same semantic type (= (29b))
  - Either* introduces a choice function variable
  - Or* semantically forms a set of the disjuncts that serves as the argument of the choice function variable

Below I show how interpretations are assigned for sentences with *either* in its base position (36) and with floated *either* (37). By claiming that *either* syntactically selects a DisjP and semantically introduces a choice function variable as in (35), we carry on the advantage of the choice function analysis and at the same time avoid the trouble of wrongly predicting a NS reading for the sentences in (31).

- (35)  $\llbracket \textit{either} \rrbracket = f: f \in D_{cf}$   
(where  $f$  is a choice function  $\text{Chf}(f)$  iff for all  $P$  in  $\text{dom}(f)$ :  $f(P) \subseteq P$ )
- (36) Mary<sub>i</sub> is looking for  $[_{TP} \text{PRO}_i \text{ TO FIND } [_{XP} \textit{either} [_{DisjP} \text{a maid or a cook}]]]$ .
- $\llbracket XP \rrbracket = \llbracket \textit{either} \rrbracket \llbracket DisjP \rrbracket$   
 $= f(\{\text{a maid, a cook}\})$
  - $\llbracket TP \rrbracket = \lambda w. \exists f. \text{Chf}(f) \ \& \ \text{Mary to find } f(\{\text{a maid, a cook}\}) \text{ in } w$
  - $\llbracket (36) \rrbracket = \lambda w'. \text{Mary is looking for } [\lambda w. \exists f. \text{Chf}(f) \ \& \ \text{Mary to find } f(\{\text{a maid, a cook}\}) \text{ in } w] \text{ in } w'$
- (37) Mary<sub>i</sub> is  $[_{XP} \textit{either} [_{DisjP} \text{looking for PRO}_i \text{ TO FIND a maid or looking for PRO}_i \text{ TO FIND a cook}]]]$ .
- $\llbracket XP \rrbracket = \llbracket \textit{either} \rrbracket \llbracket DisjP \rrbracket$   
 $= f(\{\lambda x. \lambda w'. x \text{ is looking for } [\lambda w. \text{Mary to find a maid in } w] \text{ in } w', \lambda x. \lambda w'. x \text{ is looking for } [\lambda w. \text{Mary to find a cook in } w] \text{ in } w'\})$

<sup>6</sup>A point that needs explanation if we are to argue for the presence of covert *either*/Op is that in a question, the possible readings differ as to whether there is overt *either* or not. When there is no overt *either*, the sentence is ambiguous between an Alternative Question (AltQ) reading and a Yes/No Question (YNQ) reading as in (ia), while sentences with overt *either* only have the YNQ reading as in (ib) and (ic) (although there seems to be some speaker variation). I leave this problem for future research.

- (i) a. Did Mary look for a maid or a cook? (AltQ / YNQ)  
b. Did Mary look for either a maid or a cook? (\*AltQ / YNQ)  
c. Did Mary either look for a maid or a cook? (\*AltQ / YNQ)

- b.  $\llbracket (37) \rrbracket = \exists f. \text{Chf}(f) \ \& \ f(\{\lambda x. \lambda w'. x \text{ is looking for } [\lambda w. \text{Mary to find a maid in } w] \text{ in } w', \lambda x. \lambda w'. x \text{ is looking for } [\lambda w. \text{Mary to find a cook in } w] \text{ in } w'\})$

In this section, I have shown that the hybrid analysis, which combines the choice function analysis of *either* with the ellipsis analysis, fully accounts for the basic data set in Section 2. In the next section, I discuss the predictions that the hybrid analysis makes and some data that are problematic at first sight.

#### 4. Conclusion and further issues

In this paper I have investigated the availability of the WS reading in the *either ... or ...* construction and its interaction with the behavior of *either*. It has been shown that the WS reading should be treated semantically, rather than syntactically. The rest of this section is devoted to discussion of a prediction that the choice function analysis of *either* + the ellipsis analysis makes and of some data beyond the basic data set that we have limited ourselves to up to this point. The data apparently go against the prediction, but it is shown that the data are indeed not problematic, pointing out judgment issues that have been overlooked previously.

A prediction that the present analysis makes is that *either* marks the “minimal possible scope” of *or*. I have claimed that *either* introduces a choice function variable and the scope of the variable is determined by the position of Existential Closure. Existential Closure should thus be able to occur at any type *t* position above *either*.

First consider (6)-(8), repeated in (38)-(40) below.

- (38) If Bill praises Mary or Sue then John will be happy. (Winter, 2000: 403)
- a. If Bill praises Mary then John will be happy and if Bill praises Sue then John will be happy. (NS)
- b. If Bill praises Mary then John will be happy or if Bill praises Sue then John will be happy. (WS)
- (39) a. If Bill praises either Mary or Sue then John will be happy. (<sup>OK</sup> NS / <sup>OK</sup> WS)
- b. If Bill either praises Mary or Sue then John will be happy. (<sup>OK</sup> NS / <sup>OK</sup> WS)
- (40) \*Either if Bill praises Mary or Sue then John will be happy. (Winter, 2000: 403)

As shown in (38) and (39), when a DisjP is inside an if-clause, which is an island, both the NS and WS readings are available, and the possible readings are the same in sentences with *either* inside the if-clause. As I have stated above, this is straightforwardly accounted for by the proposed analysis, since Existential Closure is not restricted within islands, and ellipsis that takes place inside the if-clause does not cause any problem. In contrast, (40) at first sight seems to go against the prediction that the choice function analysis makes. This is because, according to the analysis, there is no reason for the sentence to become unacceptable.

It may be possible to posit a restriction on ellipsis to avoid this difficulty, for example claiming that ellipsis is island-sensitive, but I would like to point out that there might be a problem in the data itself. Specifically, some native speakers that I have consulted (although the number is still small) suggested that (40) might be degraded for a syntactic reason rather than a semantic one. In particular, they felt that *either* coming next to *if* itself is bad, which indicates that the cause of the degradedness lies in this particular island. Indeed, at least one native speaker who reports that (40) has a syntactic problem judged (41) as grammatical, in which *either* is overtly outside other islands, such as a complex NP island (41a) and a *wh*-island (41b). Although the judgment has to be confirmed by a larger number of native speakers, this suggests that the overt position of *either* is not constrained by syntactic islands, and if this is the case, the data in (40) is not a problem for the present analysis.

- (41) a. John maintains *either* the claim that Bill should resign or retire.  
 b. John knows *either* who should resign or retire.

However, the problem of the degraded status of (40) remains. Why is it unacceptable even though the full version of the sentence (42) is acceptable?

- (42) Either if Bill praises Mary or if Bill praises Sue then John will be happy.

I have no concrete answer to this question, but I would like to suggest that the unacceptability does not come from island sensitivity but from a syntactic restriction on ellipsis inside questions. This is because there seems to be a connection between (40)&(42), disjoined *wh* questions (43) and disjoined Yes/No Questions (44). In all examples the elided versions are bad. Given that there are studies which claim that some conditionals are a kind of question (e.g. Starr (2014)), it might be the case that what makes (40), (43b), and (44b) unacceptable is the same restriction on ellipsis operative inside questions.

- (43) a. I need an answer to one of the two questions: Who came or who left?  
 b. \*I need an answer to one of the two questions: Who came or left?
- (44) a. I need an answer to one of the two questions: Did John come or did he leave?  
 b. \*I need an answer to one of the two questions: Did John come or leave?

Another point that apparently goes against the prediction of the present analysis that *either* marks the “minimal possible scope” of *or* is Larson’s (1985) generalization that we have seen earlier in this paper in (45b).

- (45) Larson’s (1985) generalization (Winter, 2000: 395):  
 a. In *or* coordinations without *either*, as well as in *either ... or ...* coordinations with *either* undisplaced, the scope of *or* is confined to those positions where *either* can potentially appear.  
 b. When *either* is displaced it specifies the scope of *or* to be at that displaced position.

Observe that the generalization in (45) states an imbalance in the semantic role of *either*: on the one hand, in sentences with no *either* or with *either* in its base position, *either* marks the minimal possible scope of *or* (45a), but on the other hand, in sentences with floated *either*, *either* marks the exact scope of *or* (45b). This imbalance between the positions of *either* would be a difficult problem to explain. However, some native speakers I have consulted do not agree with the “exact scope marking” nature of floated *either* but judge that floated *either* also marks the minimal possible scope of *or*.

Let us see the examples from Larson (1985). The sentences in (46) have embedded non-finite clauses. In sentences with no *either* (46a) or with *either* in its base position (46b), there are three possible readings: (A) *or* taking narrowest scope, below *look for*, (B) *or* taking scope at the embedded clause level, and (C) *or* taking widest scope at the main clause level. Larson’s (1985) judgment for (46c) and (46d) is that the position of floated *either* coincides with the scope of *or*, as given in the second line of the table. The judgment of some native speakers I have consulted, given in the third line of the table, differs crucially from Larson’s (1985) in the judgment of (46c). Specifically, they judge that both the (B) reading (the exact scope reading) and the widest scope reading of *or* are available. This shows that they judge that floated *either* marks not the exact scope of *or* but the minimal possible scope of *or*. Thus their judgment does not accord with (45).

- (46) Non-finite clauses (Larson, 1985: 221)
- a. Sherlock pretended [to be looking for a burglar or a thief].
  - b. Sherlock pretended [to be looking for either a burglar or a thief].  
 A. S. pretend to look for ((a burglar) or (a thief))  
 B. S. pretend [S. look for (a burglar) or S. look for (a thief)]  
 C. S. pretend to look for (a burglar) or S. pretend to look for (a thief).
  - c. Sherlock pretended [to either be looking for a burglar or a thief].
  - d. Sherlock either pretended [to be looking for a burglar or a thief].

|                       | (44a,b)                               | (44c)                        | (44d)               |
|-----------------------|---------------------------------------|------------------------------|---------------------|
| Larson (1985)         | <i>OK</i> A, <i>OK</i> B, <i>OK</i> C | *A, <i>OK</i> B, *C          | *A, *B, <i>OK</i> C |
| Other native speakers | <i>OK</i> A, <i>OK</i> B, <i>OK</i> C | *A, <i>OK</i> B, <i>OK</i> C | *A, *B, <i>OK</i> C |

If this intuition turns out to be correct, it makes it easier to account for the scope of *or* and its interaction with *either*, since we do not have to say, for example, that base-generated *either* has to move covertly to mark the scope of *or* while floated *either* overtly marks the scope of *or*, which Larson (1985) actually proposes. What is more, the uniform “minimal possible scope marking” nature of *either*, if it is real, fits very well with the choice function analysis argued for in this paper, confirming the prediction that the analysis makes, namely that *either* should mark the minimal possible scope of *or*. Thus there might be supporting evidence to further extend the analysis to data outside the basic data set. Note that the ellipsis analysis on its own predicts that *either* would mark the exact scope of *or*, lending further support not to adopt a pure ellipsis analysis but to combine it with the choice function analysis of *either*.

Before closing the section, let me briefly state another prediction of the present analysis related to the one discussed in this section: *either* marks the minimal scope of *or*, and what is more,

the scope of *or* must be unbounded. This is because, as far as I understand, there is no way to keep Existential Closure from taking place when the semantic type of the node is type *t*. The prediction that the scope of *or* must be unbounded is a falsifiable one, and I leave further investigation into this question for future research.

This section has discussed the predictions that the hybrid analysis makes, pointing out judgment issues that have been overlooked previously and opening up the possibility that the hybrid analysis can cover data outside the basic ones.

# ***Hillary Clinton is not Mitt Romney rich: Nouns modifying degree and dimension of adjectives***<sup>1</sup>

Charlie O'HARA — *University of Southern California*

**Abstract.** In loose English speech, speakers can be observed to use nouns to modify adjectives. This paper explores the four readings which this construction can attain, associated with four types of parameters typically associated with adjectives: degrees, judges, comparison classes, and dimensions. A formal analysis is put forth that derives all four phenomena by recentring pragmatic halos around the modifying noun.

**Keywords:** adjectives, degree, dimensions, comparison class, equative, alternatives.

## **1. Introduction**

Consider the sentence in (1).

- (1) Hillary Clinton is rich, but not Mitt Romney rich.

*Mitt Romney rich* is indicative of a construction that seems unique to varieties of English, where a noun phrase modifies the meaning of the following adjective. *Mitt Romney rich* can be ambiguous between several different readings.

- (2)
- a. How rich is Hillary Clinton?
  - b. Does Hillary Clinton care about poor people?
  - c. Mitt Romney's only inviting rich people to his birthday party, did he invite Hillary Clinton?

As an answer to the first question, (1) obtains the DEGREE READING: *Mitt Romney rich* means something similar to *as rich as Mitt Romney*. The second question obtains a DIMENSION READING, *Mitt Romney rich* means something like *rich in the way Mitt Romney is*. The third reading is a JUDGE READING, similar to *is considered rich by Mitt Romney*. A fourth reading is more difficult to obtain with the sentence in (1), but is more apparent in (3).

- (3) They are rich, of course [...], but not *New York City* rich.

Here we obtain a COMPARISON CLASS READING, *New York City rich* means something like, *rich for someone in NYC*.

---

<sup>1</sup>Thanks to Roumyana Pancheva, Barry Schein and Lauren Winans for patience, feedback and much helpful discussion on this project. I also would like to thank audiences at SuB21 and WCCFL34 for helpful questions, in particular Curt Anderson, Peet Klecha, Stephanie Solt, Ai Taniguchi, Alexis Wellwood, and Eva Wittenberg. Thanks to everyone who has been sending me examples they find in the wild of these constructions, for reminding me why I was interested in this project. All the ways this paper are good belong to them, all the ways it is bad belong to me.

## 2. Basic data

(4) a. Those are huge elephants. ([huge elephant]=**huge**∩**elephant**)  
 b. Those are Asian elephants. ([Asian elephant]≠**Asian**∩**elephant**)

(5) After the scandal, the actor was too *Osama Bin Laden famous* to hire.  $\nrightarrow$  too famous to hire.

### 2.1. Modifier-adjective positive requirement

Proceedings of *Sinn und Bedeutung* 21  
 Edited by Robert Truswell, Chris Cummins, Caroline Heycock, Brian Rabern, and Hannah Rohde

the referent of the modifier can be incompatible with the scale discussed.<sup>2</sup>

- (6) The salsa isn't spicy, but it is *my dad spicy*.

The Comparison Class reading does require compatibility with the adjective, but is fully grammatical even if the prototypical member of the comparison class referred to by the modifier does not satisfy the adjective in its positive form. Consider (7): one would be hard pressed to find a context where mansions were cheap, but we are able to get a comparison class reading where the house in question is cheap for a mansion. This reading, like *for*-phrases (Kennedy, 2007; Bale, 2008; Solt, 2011), does require that the subject is a member of the comparison class.

- (7) It isn't cheap, but it is *mansion cheap* and if you want a mansion that's as good as you're gonna get.

The degree reading does require that the positive sentence to be true to be grammatical, consider (8). This sentence does not work unless we are in some context where snails are considered fast.

- (8) #The animal was *snail fast*.

Further, I argue that the dimension reading requires this as well.<sup>3</sup> The sentence in (9) can obtain a meaning where the person in question is shorter than the speaker's threshold for *tall* but is a politically imposing figure, much like Napoleon (perhaps *tall in spirit*). While we may not consider Napoleon *tall*, in order to get this sort of reading, it is crucial that under some wordplay and metaphorical meaning Napoleon is "politically tall". For a non-tall individual with less culturally relevant jokes made comparing their physical height and their success or imposingness, this does not seem to work. Though James Madison is considered the father of the American Constitution, I have much more difficulty creating *James Madison tall*, as he was a short man.

- (9) They're not tall but they're *Napoleon tall*.

The different sorts of relationships required between the modifiers and the adjectives are summed up in the table in (10).

- (10) Required relationship between referent of modifier and scale of adjective

| <i>Reading</i> | Judge | CC | Degree | Dimension |
|----------------|-------|----|--------|-----------|
| Compatible     | ✗     | ✓  | ✓      | ✓         |
| Positive       | ✗     | ✗  | ✓      | ✓         |

<sup>2</sup>Of course, a context could exist where we have considered the flavor of our family members, in which case other readings of this sentence would be possible.

<sup>3</sup>However, it seems as if a subtype of dimension readings do not require it. In order to understand *tall in the way Napoleon is tall*, Napoleon must be tall in some way, but *I'm sick*, but *I'm blood pressure healthy* clearly does not require *blood-pressure* to be *healthy* but is grabbing a dimension directly.

## 2.2. Degree RMs

The degree reading of an RM (11a) can often be paraphrased as an equative (11b).

- (11) a. Mary is *Usain Bolt fast*.  
b. Mary is as fast as Usain Bolt.

However, these constructions differ in two important ways: a degree RM is more imprecise than an *exactly* reading of the equative; and the degree RM can create indirect comparisons using implicit comparison classes.

### 2.2.1. Implicit comparison classes

Unlike the equative, the degree RM can make indirect comparisons—comparing positions of the individuals on their relative scales—without any overt reference to comparison classes. While the typical equative (and comparative by parallel) construction involve comparison of individuals based upon their degrees on the same scale, sentences like (12) seem to compare individuals based on their degrees on distinct (but often related scales).

- (12) a. Marie Curie is smarter than Marilyn Monroe is beautiful. (Modified from Bale, 2011)  
b. John is taller for a man than Mary is for a woman. (Bale, 2011)  
c. Mary is as fast for a middle schooler as Usain Bolt is for an Olympian.

Several recent proposals attempt to explain these indirect equatives (Bale, 2006, 2008, 2011; Sassoon and van Rooij, 2016). Bale (2008) shows that these do differ from metalinguistic comparisons (13) (Embick, 2007; Morzycki, 2011) due to several distributional realities, notably, metalinguistic comparatives have a strong preference (if not a requirement) for the *more* morpheme over the *-er* morpheme.

- (13) Seymour is more intelligent than devious. (Bale, 2011)

Degree RMs, like (11b) are able to be true in the case that the indirect comparison seen in (12c) is true, which is not true for the equative without explicit comparison classes, (11b). While the equative can express such a meaning in an exaggerative context, in O'Hara (to appear) I argue that the Degree RM is not achieving these kinds of readings through exaggeration in the same way, as evidenced by the contrast in (14): the literal meaning of *Usain Bolt fast* is the meaning that was used in the first sentence, so *well not literally* contradicts the prior sentence.

- (14) Mary is {as fast as Usain Bolt/#*Usain Bolt fast*}. Well not literally...

In these comparison class indirect equatives, somehow the relative position of an individual within their own comparison class is being compared. Therefore, the realities of how we find an individual's relative position in their comparison class is rather important. Bale (2008) handles this by deriving a scale from a linear order of equivalence classes fromed by a relation

like *x is as ADJ as y*. Bale defines a universal scale where the equivalence classes of individuals from a given comparison class are evenly spaced.

Thus, if our comparison class for Mary involves six middle school runners, of whom Mary is the fastest, and no two runners are of equal speed; Mary is associated to the maximal possible universal scale degree ( $d_{\frac{6}{6}}$ ), the next runner is associated with  $d_{\frac{5}{6}}$  and so on, with the slowest runner being associated with degree  $d_{\frac{1}{6}}$ . Since Usain Bolt is the fastest man in the world, regardless of the size of the comparison class he is being considered in, Usain is going to be associated to the maximal degree,  $d_{\frac{n}{n}}$ . Therefore, Mary and Usain Bolt have the same degree on the universal scale,  $d_1$ .

However, this approach fails to capture a few intuitions present in indirect comparisons, as noted by Wellwood (2014). Consider Katie Ledecky, American Olympian who finished the 800m freestyle at the 2016 Olympics over a pool length ahead of her opponents. If Mary won her middle school race, but not so significantly, (15) is not as true.

(15) **F** Mary is as fast for a middle schooler as Katie Ledecky is for an Olympian.

Therefore, it seems not only the linear order of the equivalence classes must be preserved when comparing disparate scales, but also the distance between degrees. Sassoon and van Rooij (2016) handle this by formulating the scale *fast for a middle schooler* as the ratio from an individual's speed's deviation from the norm for middle schoolers, and the standard deviation for a middle schooler, (16).<sup>4</sup>

$$(16) \quad [[\text{fast for a middle schooler}]] = \lambda x : [[\text{mdschl}]](x) \cdot \frac{(\mu_{\text{fast}}(x) - \text{norm}(\mu_{\text{fast}}, [[\text{mdschl}]])}{\text{std}(\mu_{\text{fast}}, [[\text{mdschl}]])}$$

This formulation allows a finer comparison of diverse scales, allowing us to get the correct truth conditions for (15). Under such an interpretation, since Katie Ledecky surpasses the norm for her comparison class by a number of standard deviations, but in our context Mary surpassed the norm by less standard deviations for her comparison class. However, an additional issue could arise: Say Katie Ledecky surpassed the norm of her comparison class by exactly 5 standard deviations, and each standard deviation is relatively large, resulting in a change of race time by about a second. It is possible that Mary could also surpass the norm of her class by 5 standard deviations, but the standard of deviation for her class could be orders of magnitude smaller than Katie Ledecky's. In this case, we note that Katie Ledecky notably finishes before everyone else, but Mary finishes her race in a photo finish with all of the other members of her race, though Katie Ledecky would have the same degree of *fast for an Olympian* as Mary has for *fast for a middle schooler*. This seems potentially problematic, but it seems possible that the difference between these two situations is whether or not the deviation from the norm is observable to the speakers. Standard deviation (a purely mathematical/statistical measure) might not be sufficient.

<sup>4</sup>Solt (2011) uses median absolute deviation in a similar way while trying to define the positive construction.

Unlike the equative, the degree RM does not require an overt comparison class (through a *for*-phrase) to get these indirect, relative readings. I argue the difference here derives from the different ways the degree of the standard (i.e. that which the subject is being compared to, recently Katie Ledecky) is derived. The denotation of the equative involves the calculation of the maximal degree on some scale denoted by the adjective (potentially relativized by comparison classes) which the standard surpasses (17). In (17),  $S_{\text{FAST},C}$  represents some relevant scale related to *fast* for some comparison class  $C$ .

$$(17) \quad [[\text{as fast as Katie Ledecky}]] = \lambda x. \max(\lambda d. S_{\text{FAST},C}(d, x)) = {}^5 \max(\lambda d'. S_{\text{FAST},C'}(d', KL))$$

However, since by the very nature of an equative (or a comparative) we are comparing the individuals in question, there is a great preference to use a comparison class that includes both individuals; making an indirect comparison unlikely without overt morphology.

Degree RMs do not have clauses so rather than deriving the degree in the way an equative does, the RM simply selects some degree that is somehow associated to the standard and the adjective. The most salient degrees for a given individual will likely be in their most common comparison class; for Katie Ledecky, it is with the swimmers she raced against at the Olympics, so Mary as a middle schooler will not be part of the comparison class, and will therefore select a different comparison class that is contextually appropriate for her.

### 2.2.2. Imprecision

The equative is said to have two readings, the strong *exactly-as* reading, and the weak *at least as* reading. The degree RM seems to quantify over a different set of degrees than either of these readings.

- (18) a. STRONG EQUATIVE (*exactly*) as fast as Usain Bolt

- b. WEAK EQUATIVE (*at least*) as fast as Usain Bolt

- c. DEGREE RM *Usain Bolt fast*

The lower bound is apparent in sentences like (19); there must be some degrees of speeds slower than Usain Bolt's speed that still qualify as *Usain Bolt fast*.

- (19) a. How fast is Andre de Grasse?

<sup>5</sup>Here I denote an *exactly* reading of an equative, following Rett (2008) that this is basic; this relation would be  $\geq$  if an *at least as* reading is taken as basic (Schwarzschild, 2008). Neither are crucial for this point.

- b. Andre de Grasse is *Usain Bolt fast*, but he's not as fast as Usain Bolt.

Here, speakers may paraphrase *Usain Bolt fast* as being in the same speed tier as Usain Bolt, allowing for Andre de Grasse to have a lower speed than Usain Bolt, but still be *Usain Bolt fast*. This is actually a fact of the semantic relationship of *Usain Bolt fast* to *as fast as Usain Bolt*, rather than a pragmatic force trying to derive meaning from the sentence. If there was not a difference in semantics between the two phrases, (20) should be able to capture the same meaning, which it cannot.

- (20) #Andre de Grasse is as fast as Usain Bolt, but he's not *Usain Bolt fast*.

Further, we can see that there is in fact an upper bound on RMs unlike the *at least as* reading of the equative. Yao Ming, the former NBA player, is 7'6" tall. Given the same context, there are certain heights, such that someone is not *Yao Ming tall* but they are *as tall as Yao Ming*.

- (21) a. Speaker A: My friend Cody is super tall!  
 b. Speaker B: Are they as tall as Yao Ming?  
 c. Speaker A: Yes, in fact they're 15 ft tall!
- (22) a. Speaker A: My friend Cody is super tall!  
 b. Speaker B: Are they *Yao Ming tall*?  
 c. Speaker A: ??Yes, in fact they're 15 ft tall!

This arises from the same sense speakers have that the RM, *Yao Ming tall* refers to a tier of heights around Yao Ming's height. The RM gets a reading closer to *about as tall as Yao Ming* or *around Yao Ming's height*. The fact that this paraphrases to *about* suggests that the RM has a less precise reading than the equative when being evaluated upon the same scale. This is not a surprising result; the RM is a more marked construction than the equative (it is typologically rare, and rare within (particularly formal) English; the ambiguity of the many possible readings also makes the processing of RMs difficult), and marked constructions tend to have marked meanings, which in this case is the weaker, less precise meaning (Horn, 1984).

### 2.2.3. Distribution of Degree RMs

A final noteworthy property of Degree RMs is their distribution with overt degree morphology. Like the equative, this construction is unable to appear below other degree quantifiers (23)

- (23) a. #Mary is very/too/sorta Usain Bolt fast.  
 b. #Mary is more/as Usain Bolt fast than/as Jill.

On the other hand, degree RMs are available above gradable degree phrases, like *more* and *too* phrases.

- (24) a. Man be glad you're not Yao Ming—You're too tall for this room, but you're not (Yao Ming/way) too tall for this room.

- b. You're taller than Kevin, but you're not Yao Ming taller than Kevin, so the picture doesn't look too funny.

These distributional facts show that Degree RMs have the same distribution as degree quantifiers like the comparative, providing evidence that this construction is also a degree quantifier.

#### 2.2.4. Summary of Degree RMs

This section has shown evidence that degree RMs are able to quantify over degrees in a way that is somewhat different than the equative, or any other degree quantifier. Crucially, Degree RMs are able to capture indirect comparisons without any overt comparison class phrase. When Degree RMs do represent direct comparisons, they tend to be interpreted less precisely.

### 2.3. Judge RMs

While the degree of gradable adjectives is the most studied argument, it is not the only one available to adjectives. The degree which certain items receive on many adjectival predicates is dependent upon the *judge* or the individual doing the evaluation. Predicates of Personal Taste (Lasersohn, 2005) like *fun* are the most clear case—it's more surprising if two people ranked all the rides at an amusement park in order of funness exactly the same than if they disagree somewhere. This can be observed via faultless disagreement (Kölbel, 2003). In (25), the speakers do not contradict each other, because they are differing on the contextually determined judge of funness, rather than anything greater.

- (25) a. The roller coaster is more fun than the merry-go-round.
- b. No, the merry-go-round is more fun than the roller coaster.

This does not remain true, if the judge is overt, marked by either a *for* or a *to* phrase.

- (26) a. The roller coaster is more fun for/to me than the merry-go-round.
- b. #No, the merry-go-round is more fun for/to you than the roller coaster.

Thus, predicates of personal taste require a judge in order to be evaluated—whether this judge is supplied by a judge index of evaluation (Lasersohn, 2005) or as a thematic argument (Stojanovic, 2007; Bylinina, 2014), is not important for our purposes. This judge can be targeted by a Judge RM.

- (27) The roller coaster is more *me fun* than the merry-go-round.

Subjectivity is not limited to predicates of personal taste; adjectives not associated with objective physical scales, called evaluative by Bierwisch (1989), can be equally subjective. These adjectives include *smart*, *healthy*, *lazy*.

- (28) *Given Paulo is recovering a full body cast post-accident; and Daniel smokes 20 cigarettes a day and mostly eats fast food.*
- a. Paulo is healthier than Daniel.
  - b. No, Daniel is healthier than Paulo.

Sassoon (2013); Bylinina (2014) argue that the source for this subjectivity can come from the multidimensionality of *healthy*; *healthy* quantifies over a variety of scales (blood pressure, mobility, amount of aortic plaque, etc.), and which scales receive which priority/weight is dependent on the context and the speaker.

Unlike predicates of personal taste, *for* and *to* phrases cannot overtly supply a judge argument here, without prosodic breaks setting off the phrase.<sup>6</sup> However, verbs like *find* can supply the judge here.

- (29) a. I find Paulo healthier than Daniel.  
b. Paulo is healthier, to me, than Daniel.

A Judge RM is able to capture these subjective versions of these evaluative adjectives as well.

- (30) a. I don't care what the doctor says, Paulo is more *me healthy* than Daniel.

Finally, even simple objective unidimensional adjectives like *tall* or *rich* appear to be judge-dependent in the positive.

- (31) a. Hillary Clinton is rich.  
b. No, Hillary Clinton is not.

This seems to simply be an issue of where the standard degree supplied by the null POS morpheme, lies relative to Hillary Clinton's degree of wealth. Since this is based on the contextual standard degree, this sort of judge dependence is available in the positive, *very* constructions, and *sorta* constructions, but not in more objective constructions, like the comparative. Again, speakers differ on whether overt *to*-phrases can supply the judge here, but verbs like *find* definitely can.

- (32) a. I find Hillary Clinton rich.  
b. Hillary Clinton is rich to me.

The Judge RMs are again able to supply the judge for these sort of constructions, given appropriate context.

- (33) *Given Mitt Romney is inviting only people he considers rich to a party.*  
a. Hillary Clinton did not get an invite. She's rich, but not *Mitt Romney rich*.

<sup>6</sup>Speakers may differ in acceptability of these phrases in these contexts; Bylinina (2014) seems to suggest that these comma intonation *for*-phrases are only possible sentence initially; however, several consultants and myself allow them in a variety of positions; and even sometimes without such a clear intonation contrast from with predicates of personal taste.

Exactly how the judge-dependence for each of these types of constructions may differ (see Bylinina, 2014), but the Judge RMs seem to be able to capture these readings regardless.

## 2.4. Comparison Class RMs

Particularly in the positive construction, comparison classes are also a critical part of evaluating adjectives. Identifying the standard necessarily involves identifying the set which the individual is being compared to.

- (34) The rock climbing wall in Maggie Daley Park is tall.

Whether the rock climbing wall in Maggie Daley Park in Chicago is considered tall, depends on what it is being compared to. At 40 ft tall, it is one of the tallest things in Maggie Daley Park, it is taller than the average rock climbing wall, but it is also not very tall in comparison to things in downtown Chicago. Depending on which class we use—things in MDP, rock climbing walls, or things in downtown Chicago—the height at which things are considered tall is different, perhaps 20ft, 35ft, and 600ft. This comparison class can be made explicit using a *for*-phrase.

- (35) The rock climbing wall in MDP is tall for {a thing in the park/a rock climbing wall/a thing in Chicago}

These comparison classes can also be overtly noted using a Comparison Class RM.

- (36) The rock climbing wall isn't *thing in Chicago tall*, but it is *rock climbing wall tall*.

As discussed in Section 2.2.1, comparison classes are available in degree constructions other than the positive as well. In indirect comparatives, overt comparison classes can be used to compare relative difference from the norm for each class as in (37). Comparison Class RMs may also be available, though they feel degraded (and might be metalinguistic) here (38).

- (37) Usain Bolt is faster for an Olympian than Mary is for a child.

- (38) (?)Usain Bolt is more *Olympian fast* than Mary is *child fast*.

## 2.5. Dimension RMs

Where the other three types of RMs interact with adjectives in ways that resemble relatively well-studied concepts, the degree, judge, and comparison class; the dimension RMs interact with a less well-understood aspect of adjectives: the scale upon which they are evaluated. Morzycki (2012) argues that there many adjectives encode several different dimensions in their lexical encoding. In (39), *big* seems to be being evaluated over distinct senses.

- (39) a. The US is bigger than Canada (Population)

- b. Canada is bigger than the US (Area)

(40) **dimensions(big)** = {size-by-population, size-by-area, size-by-importance, ...}

Somehow, the dimensions the adjective is evaluated upon must be selected by context, Morzycki suggests that degree quantifiers like POS existentially quantify over these dimensions: something is big in the case that some dimension of big exists so that the thing surpasses the standard on that dimension.<sup>7</sup> This set of dimensions clearly must be able to be contextually restricted: when speaking about land, the population dimension is not selectable.

As discussed in the section on Judge RMs, Sassoon (2007, 2013) discusses a variety of adjectives that seem to quantify over the dimensions in a different way than *big*. In order to be *healthy*, one must be healthy on all relevant dimensions; i.e. blood pressure, mobility, etc.

Thus many adjectives have multiple dimensions available to them. Specific dimensions can be picked out overtly using a *with regard to* phrase.

- (41) a. Japan is bigger with regard to population than Canada.  
b. Tara is healthier with regard to blood pressure than I.

RMs are capable of accomplishing the same thing.

- (42) a. Japan is more population big than Canada.  
b. Tara is more blood pressure healthy than I.

Both of the above constructions are able to shift the dimension of an adjective by referencing the dimension in question directly; but the dimension can also be restricted in a different way by *like* or *in the way* phrases, or Dimension RMs.

- (43) a. Nigeria is big like Japan, not big like Canada.  
b. Nigeria is big in the way Japan is, not the way Canada is.  
c. Nigeria is *Japan big*, not *Canada big*.

Given appropriate context, *big like Japan* means the same thing as *big with regard to population*. However, these constructions seem to be capable of picking out any dimension of the adjective which the modifying individual has a salient (usually large) degree on.

In fact, it is possible in this way to refer to dimensions that are not necessarily quantified over by the adjective typically. For an example, consider that Yao Ming and Andre the Giant were both

<sup>7</sup>Some difficulties might arise for such an account. I have checked with several other speakers, who seem to share the intuition that while (39a) seems to work, (i) is less licit out of the blue, contra to what would be expected if *big* here was simply selecting the **size-by-population** dimension.

(i) ?Japan is bigger than Canada.

This suggests somehow the area dimension has some sort of primacy, only allowing the population dimension out of the blue if the area dimension is ambiguous or at least close.

exceptionally tall men, but Yao Ming is skinner and Andre the Giant is broader. If presented with a giraffe and an elephant of the same height, speakers have little difficulty identifying who is *Yao Ming tall* and who is *Andre the Giant tall*. (or *tall like Yao Ming*, or *tall in the way Yao Ming is*)

- (44) a. The giraffe is *Yao Ming tall*.  
b. The elephant is *Andre the Giant tall*.

*Tall* is typically thought of as a prototypically monodimensional measurable adjective. The scale over which it is evaluated is typically the same in all contexts: height. In this context, *Yao Ming tall* paraphrases to something like *tall in a slender way*. We can see that this slenderness dimension is not quantifiable over by *tall*; we are unable to access it using a *with regard to* phrase (45).

- (45) # The giraffe is tall with regard to slenderness.

Yet, there are strong restrictions to which sorts of dimensions can be selected here. The dimension must be properties of the Yao Ming's tallness, not simply properties of Yao Ming. Yao Ming is rich and successful, and even given an equally tall but poorer person: Lonnie, *Yao Ming tall* cannot mean tall and rich, and *Lonnie tall* cannot mean tall and poor.

The distinction here comes from other evidence about what dimensions are part of the lexical encoding of *tall*. While plain *tall* does not allow paraphrases of *tall in a slender way* in the same way *healthy* can be paraphrased as *healthy with regards to blood pressure*, evidence that *tall* encodes some information about slenderness, rather than wealth is available from prototypical uses of *tall*.

First consider two cups of the same height, one slender and one as wide as it is tall. If *the tall cup* is referred to, speakers identify the slender cup as *the tall cup*. While slenderness is not typically part of the scale quantified over when identifying *tall*, it can be made accessible here. Wealth is not available in this way; given two people of the same height, one clearly rich, and one clearly poor, speakers will be left confused by reference to *the tall person*.

The second evidence comes from slack regulators and other constructions which strengthen utterances, or make them more prototypical. One of these (which we will return to later, as it seems somewhat related to RMs), referred to as lexical cloning, contrastive focus reduplication, or identical constituent compounding, where a word or phrase is copied in order often achieving a more prototypical meaning (Ghomeshi et al., 2004). Given a building that is 300 ft tall, but 2000 ft long and wide, we can imagine the sentence in (46a). The same sort of result can be seen with typical intensifying slack regulators like *exactly*, *precisely* and *really*.

- (46) a. I guess that building is tall, but it's not *TALL* tall.  
b. That building is not *really/exactly/precisely* tall.

The prototypical tall thing's (or perhaps building here) height exceeds its other dimensions,

allowing for a slenderness dimension to be accessed here. Thus it seems, somewhere in the lexical encoding these additional dimensions are available. It seems notable here that though prototypically tall things are slender, the polarity of this slenderness dimension is not fixed in the ways the dimensions of *big* and *healthy* are. *Tall in a slender way* and *tall in a broad way* are both valid, but *big in a populous way* and *healthy in a physically fit way* seem less strange than their counterparts *big in a unpopulous way* and *healthy in a physically unfit way*. If these counterparts do exist, they refer to something like *healthy even though very unhealthy in this one dimension*, suggesting individuals must be very healthy on the remaining dimensions to make up for that. It is possible that even *tall in a broad way* is defined this way, as *tall even though not slender*, evidence from this arises from the fact that it is easier to generate *tall in a slender or skinny way* from a reference that is tall in a skinny way than to generate *tall in a broad way* without defining it in opposition to *tall in a slender way*: *telephone pole tall* is easy to understand, in comparison to *Great Wall of China tall*.

These dimension RMs are able to appear below degree morphology, and seem incompatible above degree morphology.

- (47) a. The giraffe is more *Yao Ming tall* than the elephant.  
 b. #The giraffe is *Yao Ming taller* than the elephant.

A worthwhile question is whether or not *Yao Ming tall* is truthfully gradable, or if this is a metalinguistic comparative in (47a). Exactly how to probe this distinction seems difficult: most of the diagnostics that differentiate metalinguistic and true comparatives (Morzycki, 2011) do not occur here. McCawley (1998) notes that only metalinguistic comparatives allow displacement of the comparative morpheme, which does not seem to be possible here.<sup>8</sup>

- (48) a. Your problems are legal more than financial.  
 b. The giraffe is *Yao Ming tall* more than the elephant.

## 2.6. Data summary

All four types of RMs can appear with a variety of adjectives, more widely than might be expected: Degree RMs can appear with typically gradable predicates like *tall*, but they are also available for adjectives with minimal or maximal standards (Kennedy and McNally, 2005) like *coked-up businessman awake* or *arrow straight*. Judge RMs can appear with predicates of personal taste, but also multidimensional adjectives, and almost all adjectives in a positive construction. Comparison Class RMs are equally able to appear seemingly with any gradable adjective. Finally, dimension RMs appear with conventionally multidimensional adjectives like

<sup>8</sup>However, it may be that this property of comparing predicates rather than subjects, identifying metalinguistic comparatives that compare individuals seems more difficult, and I'm not certain works here; seeming to get a different frequency sense in (ib).

- (i) a. The coffee there is more coldbrew than when I make it.  
 b. (?)The coffee there is coldbrew more than when I make it.

*healthy*, ambiguous adjectives like *big* but also a variety of adjectives that have been typically thought of as simple and unidimensional like *tall*.

### 3. Analysis

In this section, I propose a uniform semantics for RMs that can handle all of these meanings. Each type of RM restricts the meaning of the predicate to a meaning more closely associated with the reference. Here we will see this can be captured by recentering the pragmatic halo (Lasnik, 1999) denoted by the predicate.

Morzycki (2011); Anderson (2016) capture compositional semantic imprecision using pragmatic halos consisting of alternatives (Hamblin, 1973; Kratzer and Shimoyama, 2002). Under this Hamblinized approach, the denotation of an adjective like *tall* is as in (49)

$$(49) \quad \llbracket \text{tall} \rrbracket^{d',C} = \{f_{\langle d,et \rangle} : f \approx_{d',C} \lambda d \lambda x. \text{tall}(d)(x)\}$$

Here, following Morzycki (2011), the  $\approx_{d,C}$  relation is a similarity relation, stating that iff  $\alpha \approx_{d,C} \beta$ , given the similarity scale given in context  $C$ ,  $\alpha$  is similar to  $\beta$  at least to the degree  $d$ . Here, the degree of similarity is the contextual degree of precision. Morzycki (2011) and Anderson (2016) make use of this degree (using a typeshift PREC) to capture metalinguistic comparatives (which are argued to be evaluated on the dimension of precision) and precision intensifiers and attenuators. Here rather than manipulating the degree of precision, RMs select one of these alternatives that is best associated with the reference and recenters the halo.

Take *American Football Player healthy*, a dimension RM which seems to select a scale of evaluation of *healthy* that unfortunately prioritizes physical fitness over limiting brain damage. Under Sassoon (2007)'s representation, *healthy* typically denotes universal quantification over the dimensions of health. However, within our pragmatic halo, alternatives that ignore specific dimensions will be available (much like how, as shown by Anderson (2016), *everyone is here* can be uttered by a professor when a few students are missing (p. 23)).

$$(50) \quad \begin{array}{ll} \text{a.} & \llbracket \text{healthy} \rrbracket^{d',C} = \{f_{\langle d,et \rangle} : f \approx_{d',C} \lambda d. \lambda x. \forall g \in \mathbf{dimension(healthy)} : [g(d)(x)]\} \\ \text{b.} & \llbracket \text{healthy} \rrbracket^{8,C} = \left\{ \begin{array}{l} \lambda d. \lambda x. \forall g \in \mathbf{dim(healthy)} : [g(d)(x)], \\ \lambda d. \lambda x. \forall g \in (\mathbf{dim(healthy)} - \mathbf{brain health}) : [g(d)(x)], \\ \lambda d. \lambda x. \forall g \in (\mathbf{dim(healthy)} - \mathbf{cholesterol}) : [g(d)(x)], \\ \text{etc.} \end{array} \right\} \end{array}$$

Given this loose denotation for *healthy*, the RM must simply select the appropriate dimension. This is accomplished using a null operator RM which selects an element of the predicate its modifying that is associated ( $\propto$ ) with the reference.<sup>9</sup>

$$(51) \quad \begin{array}{ll} \text{a.} & \llbracket \text{RM} \rrbracket^{d',C} = \lambda x_p \lambda S_\tau : \exists s \in S[s \propto_{d,C} x].s \\ \text{b.} & \llbracket \text{NFL player RM} \rrbracket^{d',C} = \lambda S_\tau : \exists s \in S[s \propto_{d,C} \mathbf{NFL player}].s \end{array}$$

<sup>9</sup>Often this association is the ability of the reference to directly satisfy the predicate, but particularly with judge RMs, this is not possible.

- c.  $\llbracket \text{NFL player healthy} \rrbracket^{d',C} = \{f_{\langle d,et \rangle} : f \approx_{d',C} \lambda d. \lambda x. \forall g \in (\text{dim}(\text{healthy}) - \text{BrainHealth}) : [g(d)(x)]\}$

One of the reasons selecting a dimension on more unidimensional adjectives like *tall* seems harder is due to the structure of the pragmatic halos for *tall*. Whereas *healthy* at its most precise universally quantifies across all dimensions of healthiness, the additional dimensions of *tall* are less critically related. The alternative selected by *Yao Ming tall*, of tall in a slender way, is only available in very imprecise readings uses of *tall*. Even given the cups having the same height,

- (52) The skinny glass is sorta taller than the fatter one.

Anderson (2016) argues that *sorta* expands the pragmatic halo of the predicate it modifies, selecting a degree of precision close to but lower than the standard degree of precision. Thus, the degree of precision must be lower to allow the RM to select any nontrivial dimensions. Earlier we saw that these dimensions are stored in the adjective and are also accessed in the most precise and prototypical readings. I claim that these additional dimensions are available as presuppositions to the most precise meaning of *tall*. If something is not saliently skinny enough, we cannot call it *tall*, but even on high level of precision, wide things are not *less tall* than things which have lower degrees of height than them.

- (53) a. #The Pentagon is tall tall.  
b. The telephone pole is tall tall.  
c. #The telephone pole is more tall tall than the Pentagon

It is not surprising that dimensions referenced in the presupposition of the lexical entry of an adjective are somehow similar to the most precise form of the lexical entry, but it also makes sense that these are less similar than subsets of dimensions like what we explored with *healthy*.

The purpose of the  $\propto$  associated relation appears when we attempt to capture comparison class and judge RMs. Consider *fun*, which as a predicate of personal taste contains a judge argument somewhere in its denotation. I will presume a relativist approach here, but noncritically.

- (54) a.  $\llbracket \text{fun} \rrbracket^{d',C,J} = \{f_{\langle d,et \rangle} : f \approx_{d',C} \lambda d. \lambda x. \text{fun}_J(d)(x)\}$

The pragmatic halo here will include functions which are not exactly *fun*—like *exciting*—but will more importantly include *fun* scales that are ordered by different judges. The association function in the RM can note the association of a judge to the function to which they are the judge.

- (55) a.  $\llbracket \text{fun} \rrbracket^{d',C,J} = \left\{ \begin{array}{l} \lambda d. \lambda x. \text{fun}_J(d)(x), \\ \lambda d. \lambda x. \text{exciting}_J(d)(x), \\ \lambda d. \lambda x. \text{fun}_{\text{me}}(d)(x), \\ \lambda d. \lambda x. \text{fun}_{\text{you}}(d)(x), \\ \text{etc.} \end{array} \right\}$

$$b. \llbracket \text{me fun} \rrbracket^{d',C,J} = \{f_{\langle d,et \rangle} : f \approx_{d',C} \lambda d. \lambda x. \text{fun}_{\text{me}}(d)(x)\}$$

Reference to the judge is made again in the positive construction when setting the standard. Assuming a denotation as follows for the POS morpheme, if the RM attaches above the POS morpheme, it can select the correct form.

$$(56) \quad \begin{aligned} a. \llbracket \text{POS} \rrbracket^{d',C,J} &= \lambda G_{\langle d,et \rangle} \lambda x. \exists d [G(x)(d) \wedge d! > \text{norm}_J(G)] \\ b. \llbracket \text{POS tall} \rrbracket^{8,C,J} &= \left\{ \begin{array}{l} \lambda x. \exists d [\text{tall}(d)(x) \wedge d! > \text{norm}_J(\text{tall})], \\ \lambda x. \exists d [\text{tall}(d)(x) \wedge d! > \text{norm}_{\text{me}}(\text{tall})], \\ \lambda x. \exists d [\text{tall}(d)(x) \wedge d! > \text{norm}_{\text{you}}(\text{tall})], \\ \lambda x. \exists d [\text{tall}(d)(x) \wedge d! > \text{norm}_{\text{Mitt Romney}}(\text{tall})], \\ \text{etc.} \end{array} \right\} \\ c. \llbracket \text{Mitt Romney POS tall} \rrbracket^{d',C,J} &= \{g_{\langle e,t \rangle} : g \approx_{d',C} \lambda x. \exists d [\text{tall}(d)(x) \wedge d! > \text{norm}_{\text{Mitt Romney}}(\text{tall})]\} \end{aligned}$$

This predicts that *Mitt Romney rich* is ungradable, and therefore incompatible with degree morphology. This is caused by putting the judge dependence in the positive morpheme: if that assumption is false, judge dependence must be lower and possible with RMs everywhere it is possible with overt *for* and *to* phrases. It is difficult to probe for data that tests this in particular because on these adjectives judge-dependence does not change the ordering of the degrees but only the location of the norm, making *more Mitt Romney rich* and *more rich* coextensive.

Comparison classes work the same way; reference to comparison classes is part of the positive morpheme, (or perhaps somewhere lower in order to capture indirect comparisons, see Sassoon and van Rooij, 2016). Regardless, some alternatives will be something like “has a degree on this scale surpassing the standard for comparison class C on this scale”, and the comparison class RM simply selects the alternative with the appropriate comparison class.

Degree RMs are less obvious. Consider the denotation of a gradable predicate, like *fast*. This is made up of a set of alternatives, which are each sets of predicates given different degrees (57b).

$$(57) \quad \begin{aligned} a. \llbracket \text{fast} \rrbracket^{8,C,J} &= \left\{ \begin{array}{l} \lambda d. \lambda x. \text{fast}(d)(x), \\ \text{etc.} \end{array} \right\} \\ b. \lambda d. \lambda x. \text{fast}(d)(x) &= \left\{ \begin{array}{l} \lambda x. \text{fast}(\text{5mph})(x), \\ \lambda x. \text{fast}(\text{6mph})(x), \\ \text{etc} \end{array} \right\} \end{aligned}$$

Here, the RM selects an element from this set rather than the set of alternatives. A degree that is associated with an individual like Usain Bolt may be his most famous speed (27.7 mph), or using a less measured set of degrees, it could be something like a very high degree. This ambiguity between the exact speed and the relative speed is what allows the ambiguity between direct and indirect comparisons discussed previously. The set of alternatives for *Usain Bolt fast* include a variety of degree near but not equal to Usain Bolt's degree of speed.

$$(58) \quad a. \llbracket \text{Usain Bolt fast} \rrbracket^{d',C,J} = \{f_{\langle e,t \rangle} : f \approx_{d',C} \lambda x. \text{fast}(\text{27.7mph})(x)\}$$

#### 4. Conclusion

Thus, RMs can be formulated as recentring pragmatic halos, capturing all the four readings discussed in this paper. This approach is able to capture these constructions, but also should be extendible to a variety of similar seeming constructions with different categories of predicates. The lexical cloning construction (*salad salad* or *tall tall*, Ghomeshi et al., 2004) would be a subtype of this: the alternative most associated with the predicate itself would be the most precise alternative, and this semantically vacuous recentring of the halo could cause a change in the degree of precision. Other related forms are: Judge RMs on the precision variable (59a), dimension RMs on nouns (59b) or verbs (59c). Further work must be done to investigate the full range of RMs in English.

- (59) a. *Given Sam is known to be imprecise*: Is everybody there, or is it just *Sam everybody*?  
 b. The biggest bird is like an *ostrich bird* not a *eagle bird* so it can't fly.  
 c. My son can swim, but he can only *baby swim*, so he's not going out on a boat.

# One *many*, many readings<sup>1</sup>

Doris PENKA — *University of Konstanz*

**Abstract.** This paper pursues a unified analysis of the different readings that the so-called quantifier *many* gives rise to. Adopting a degree-based semantics account, *many* is decomposed into a gradable cardinality predicate and the positive operator POS. The different readings are argued to result from different scope of POS and association with focus. This improves on alternative accounts, which either employ more than one lexical entry for *many* or do not specify a compositional implementation.

**Keywords:** quantifier decomposition, degree semantics, positive operator

## 1. Introduction

It is well known that the quantifier *many* gives rise to several readings. Partee (1989) distinguishes the so-called cardinal and proportional reading of *many*. Under the cardinal reading, a sentence with *many* is true iff the number of individuals that fall in the intersection of the restrictor and the nuclear scope counts as large in the given context. Sentence (1) under the cardinal reading, for instance, is true in a scenario where the number of students who took Intro to Semantics is considered large, e.g. compared to other courses or compared to previous years.

- (1) Many students took Intro to Semantics.

Under the proportional reading, sentence (1) can be paraphrased as ‘A high proportion of all the students took Intro to Semantics’ and comes out as true if the ratio of the number of students taking Intro to Semantics to the total number of students counts as high in the given context. Under the proportional reading, the truth of a sentence does not only depend on the number of individuals in the intersection, but also on the number of individuals in the denotation of the NP. In contrast to the cardinal reading, we also learn something about the students who did not take Intro to Semantics, namely that their number is small.

Besides the cardinal and proportional reading, Westerståhl (1985) noted an additional reading of *many*. This reading is illustrated by his celebrated sentence (2), which is intuitively considered true in the scenario in (3) (describing the actual state of affairs at the time Westerståhl’s paper was written), but false both under the cardinal and proportional reading – neither the absolute number 14 can be considered large nor the ratio of 14 to millions of Scandinavians.

- (2) Many Scandinavians have won the Nobel Prize in literature.

- (3) Of a total of 81 Nobel Prize winners in literature, 14 come from Scandinavia.

---

<sup>1</sup>I would like to thank audiences at Sinn und Bedeutung 21 and at the University of Konstanz for valuable comments and suggestions. I am grateful in particular to Maribel Romero, Bernhard Schwarz, Anthea Schöller and Sven Lauer for helpful discussion. The research reported here was undertaken while being a research fellow of the Zukunftskolleg at the University of Konstanz.

Intuitively, sentence (2) is true in the scenario in (3) because 14 out of a total of 81 Nobel Prize winners in literature is considered a high proportion. In this case the relevant proportion is determined not with respect to the NP denotation, but with respect to the denotation of the VP. Since this reading can be paraphrased as ‘Many of the Nobel Prize winners in literature are Scandinavians’, with the arguments of *many* reversed in comparison to the sentence (2), this reading has become known as the reverse reading.

One way of coping with this three-way ambiguity would be to employ three different lexical entries for *many*, each corresponding to one of the readings discussed above. In the framework of Generalized Quantifier Theory (GQT), we would then have the following determiners:<sup>2</sup>

- (4) a.  $\llbracket \text{many}_{\text{CARD}} \rrbracket = \lambda P. \lambda Q. |P \cap Q| > n$ , where  $n$  is a large number CARDINAL  
 b.  $\llbracket \text{many}_{\text{PROP}} \rrbracket = \lambda P. \lambda Q. |P \cap Q| : |P| > k$ , where  $k$  is a large fraction PROPORTIONAL  
 c.  $\llbracket \text{many}_{\text{REV}} \rrbracket = \lambda P. \lambda Q. |P \cap Q| : |Q| > k$ , where  $k$  is a large fraction REVERSE

The lexical entry for *many*<sub>REV</sub> in (4c) is particularly noteworthy, as pointed out by Westerståhl (1985). Since it makes reference to the cardinality of the VP denotation, it violates the Conservativity Universal (Barwise and Cooper, 1981; Keenan and Stavi, 1986). According to this semantic universal, determiners in natural languages are conservative, which means that the extension of the second argument of a determiner counts only insofar as it overlaps with the extension of the first argument, corresponding to the restrictor. But for reverse *many* in (4c), the entire extension of the second argument enters into the truth conditions.

Even leaving aside the issue of non-conservativity raised by the lexical entry for reverse *many*, there are obvious reasons to be dissatisfied with the meaning rules in (4). Employing a separate lexical entry for each reading is not very insightful and a more parsimonious way of dealing with the ambiguity that *many* gives rise to would be welcome.

The aim of the present paper is to explore a unified analysis in which the different readings are derived from a single lexical entry of *many*. Recent advancements in semantic theory give reasonable hope to such an endeavor. There is a growing body of work that decomposes the expressions GQT labels as quantifiers into smaller meaningful parts and derives the interpretations these expressions give rise to in a fully compositional way (Hackl, 2000, 2009 among many others). The analysis developed in the present paper builds in particular on Romero (2015, 2016), who shows that the reverse reading can be explained under the assumption that the so-called quantifier *many* is the positive form of a gradable determiner *many*, which is analysed in a degree-based semantic framework in analogy to gradable adjectives. While the present paper follows Romero in adopting a degree semantics account and her analysis of the positive operator, the goal of the investigation is to take the analysis a step further and derive all three readings from a single lexical entry in a compositional manner. The key idea is that *many* itself is a gradable cardinality predicate that combines with the positive operator POS,

<sup>2</sup> Cardinal *many* has also been treated as a cardinality predicate rather than as a genuine quantifier (Hoeksema, 1983; Partee, 1989, among others). Motivation for this comes from the observation that cardinal *many* patterns with indefinites and other so called weak determiners in terms of distribution in existential *there*-sentences and in subject position of individual-level predicates (Milsark, 1977); see section 4.2. We will use a version of this cardinality predicate analysis that makes the parallel between *many* and gradable adjectives transparent.

and the different readings result from different scope of POS (cardinal vs. proportional readings) and (free) association with focus (regular vs. reverse readings).

The paper is organized as follows: Section 2 lays out the ingredients that go into the analysis: on the one hand *many* as gradable cardinality predicate, on the other the semantics of degree operators, in particular of the positive operator. The analysis is presented in Section 3, showing how the different readings can be derived using these ingredients. Section 4 takes a closer look at reverse readings. In Section 5 it is shown how distributional restrictions on the different readings can be explained in terms of the proposed analysis. Section 6 concludes.

## 2. Ingredients of the analysis

In the analysis I propose, what has been labeled quantifier *many* is analysed as the positive form of a gradable cardinality predicate. There are thus two ingredients that go into the analysis, each having been motivated and proposed independently. The first is the assumption that *many* is not a determiner, but rather a gradable cardinality predicate. The second is the semantics of degree operators, specifically the semantics of the positive operator.

### 2.1. *Many* as a gradable cardinality predicate

Since *many* shows an obvious analogy to gradable adjectives – it can be put in the comparative form *more* as well as in the superlative *most* – it has also been proposed that it should be analysed in analogy to gradable adjectives (Schwarz, 2006; Hackl, 2009, among many others). In this type of analysis, *many* is a cardinality predicate with the semantics in (5).<sup>3</sup>

$$(5) \quad \llbracket \text{many} \rrbracket = \lambda d. \lambda x. |x| \geq d$$

The lexical entry in (5) follows the usual semantics assumed for gradable adjectives (e.g., Heim, 2001) and is formulated in analogy to that of gradable adjectives like *high* in (6). Note in particular that this semantics for gradable adjectives is downward monotonic, in the sense that a specific individual is not only associated with a single degree, but with a set of degrees: *high* is a relation between an individual  $x$  and all degrees up to  $x$ 's exact height, i.e. all degrees contained in the interval  $(0, \text{HEIGHT}(x)]$ .

$$(6) \quad \llbracket \text{high} \rrbracket = \lambda d. \lambda x. \text{HEIGHT}(x) \geq d$$

The dimension that *many* targets is that of cardinality. In a mereological framework of plural semantics (Link, 1983), *many* relates a plural individual with the number of atomic parts it consists of, i.e.  $|x|$  is the cardinality of  $\{y: \text{atom}(y) \ \& \ y \leq x\}$ .<sup>4</sup>

Under this view, *many* is a predicate rather than a determiner. Quantificational force, therefore, has to come from somewhere else. I adopt the common assumption that there is a

<sup>3</sup> I use a semantics in which the cardinality measure function is part of the meaning of *many*. There are, however, reasons to believe that the measure function is separate and not lexically contained in *many* (see Solt, 2009, 2015). For the purpose of the present paper, nothing hinges on this difference.

<sup>4</sup> I will sometimes sloppily talk about the cardinality of a plurality.

phonetically empty determiner  $\emptyset$  with the semantics of an existential quantifier. I assume that  $\emptyset$  is present whenever *many* occurs without an overt determiner.<sup>5</sup>

Just as gradable adjectives, *many* can combine with a range of degree operators: when it combines with the comparative operator it surfaces as *more*, and as *most* when it combines with the superlative operator (Bresnan, 1973; Hackl, 2000, 2009). In the cases we are interested in, where *many* occurs without a overt degree modifier, a phonetically empty positive operator POS is assumed. Before we discuss the semantics of POS in detail, let us first look at degree operators more generally.

## 2.2. Scope of degree operators and association with focus

In order to introduce some key features of degree operators, which will be put to use in the analysis of *many*, let us first look at the semantics of superlatives and the influential analysis in Heim (1999). The analysis starts out from the observation that superlatives are ambiguous between absolute and relative readings (Szabolcsi, 1986). Consider the following sentence.

- (7) John climbed the highest mountain.

Under the absolute reading, (7) is true iff John climbed a mountain higher than any other relevant mountain. In a situation where we are talking about mountains in Scotland, for instance, (7) under the absolute reading is tantamount to saying that John climbed Ben Nevis. Under the relative reading, (7) is true iff John climbed a higher mountain than any other relevant person. It could be true even if John climbed a mountain of rather modest height, as long as no other person under consideration climbed a higher mountain. Put differently, whereas the heights of mountains are at stake under the absolute reading, the mountain climbing achievements of people are being considered under the relative reading.

In the relative reading, focus plays an important role in determining truth-conditions. This is illustrated in the following contrast:<sup>6</sup>

- (8) a. BILL got the best grade in semantics.  
b. Bill got the best grade in SEMANTICS.

(8a), with focus on the subject, is true in a situation where out of all the students taking semantics, Bill's grade is the best. If focus is on *semantics*, in contrast, the sentence describes a situation where out of all the courses Bill took, his best grade is in semantics.

To account for the ambiguity of superlatives and the role focus plays, Heim (1999) proposes the following analysis: Superlatives are formed by a superlative operator *-est* which is semantically a quantifier over degrees. This operator is restricted by a covert variable *C*, which provides a comparison class and is resolved contextually. If focus is present and makes

<sup>5</sup> It has been observed that *many* can be accompanied by an overt definite article, as in *Jane regrets the many mistakes she has made*. This is in line with the view that *many* is a predicate rather than a determiner. See Solt (2009, 2015) for detailed discussion of the distribution of *many*.

<sup>6</sup> I use capital letters to indicate semantic focus independently of its intonational realisation.

available alternatives, these alternatives are factored in when  $C$  is resolved and  $C$  has to be a subset of the focus alternatives. In the terms of Beaver and Clark (2008), this means that *-est* shows free association with focus. The lexical entry in (9) is proposed by Heim to factor in the contribution of focus in the usual way via the squiggle operator following Rooth (1992).

$$(9) \quad \llbracket \text{-est } C \rrbracket = \lambda D_{\langle d, t \rangle}. \exists d [D(d) \ \& \ \forall D' \in C [D' \neq D \rightarrow \neg D'(d)]]$$

Note that in this lexical entry for *-est*, the comparison class  $C$  is a set of degree properties (type  $\langle \langle d, t \rangle, t \rangle$ ).<sup>7</sup> Being a quantifier, *-est* undergoes QR and can take local scope, i.e. internal to the host DP, or raise to a DP-external position to take non-local scope. Crucially, it is assumed that the material in the scope of *-est* determines the relation relative to which individuals are compared, which means that the members of  $C$  must have the same form as the LF sister of *-est*. With these assumptions, the two readings of superlatives discussed above can be derived as resulting from different scope of *-est*.

The absolute reading obtains from an LF where *-est* takes local scope inside its host DP, as shown in (10).<sup>8</sup>

- (10) a. LF: John climbed [<sub>DP</sub> the [2 [ [-est  $C$ ] [1 [ $t_2$   $t_1$ -high mountain]]]]]  
 b. climb( $j$ ,  $\iota x$  [  $\exists d$  [mountain( $x$ ) & HEIGHT( $x$ )  $\geq d$  &  
 $\forall D' \in C$  [  $D' \neq [\lambda d'. x \text{ is a } d'\text{-high mountain}] \rightarrow \neg D'(d)]$ ]]]  
 c.  $C = \{ \lambda d'. \text{Ben Nevis is a } d'\text{-high mountain, } \lambda d'. \text{Ben Macdui is a } d'\text{-high mountain, } \lambda d'. \text{Braeriach is a } d'\text{-high mountain, ...} \}$

In this configuration, the heights of contextually relevant mountains are compared. This is so because in the LF, the sister of *-est* is [1 [ $t_2$   $t_1$ -high mountain]]. In consequence, the members of the comparison class  $C$  are all of the form ' $\lambda d'. x$  is a  $d'$ -high mountain'. Following Szabolcsi (1986), it is assumed that  $x$  ranges over contextually relevant individuals to which the property of being a  $d'$ -high mountain can be felicitously applied, i.e. mountains. Under the downward monotonic semantics for *high* in (6), the members of  $C$  are sets of degrees consisting of all the degrees up to the respective mountain's height, e.g.  $C$  in (10c) contains the intervals (0, HEIGHT(Ben Nevis)], (0, HEIGHT(Ben Macdui)], *etc.* The denotation of the entire superlative DP is then the unique individual that figures in the member of  $C$  with the greatest maximum, i.e. the mountain whose height is the greatest.

Relative readings obtain from an LF where *-est* takes non-local scope and its LF sister does not only comprise the DP but crucially also the focused constituent. Now we also have to factor in the contribution of focus. In the relative reading of example (7) focus is on the subject, as indicated in (11).<sup>9</sup>

<sup>7</sup> In fact,  $C$  has to be a set of degree property intensions, i.e. of type  $\langle \langle s, \langle d, t \rangle \rangle, t \rangle$ . This is necessary in order to distinguish different degree properties that happen to have the same extensions. For now, I use the extensional version for the sake of readability, but I will return to this issue in footnote 11.

<sup>8</sup> This derivation assumes that landing sites for QR can be created inside DPs by PRO-movement (see Heim and Kratzer, 1998, chap. 8).

<sup>9</sup> Following Szabolcsi (1986), I assume that the definite article is interpreted as an indefinite in relative readings of superlatives.

- (11) a. LF: [ [-est C] [1 [JOHN climbed A  $t_I$ -high mountain]]  $\sim C$ ]  
 b.  $\exists d [\exists x [\text{climb}(j,x) \ \& \ \text{mountain}(x) \ \& \ \text{HEIGHT}(x) \geq d \ \& \ \forall D' \in C [D' \neq [\lambda d'. \text{John climbed a } d'\text{-high mountain}] \rightarrow \neg D'(d)]]]$   
 c.  $C \subseteq \{\lambda d'. \text{John climbed a } d'\text{-high mountain, } \lambda d'. \text{Bill climbed a } d'\text{-high mountain, } \lambda d'. \text{Sam climbed a } d'\text{-high mountain, } \dots\}$

As before, the form of the members of  $C$  is determined by the material inside the LF sister of *-est*. In addition, the squiggle operator adds the constraint that  $C$  has to be a subset of the focus alternatives, which are of the form ' $\lambda d'. x$  climbed a  $d'$ -high mountain', with  $x$  ranging over contextually relevant individuals. This results in a comparison class  $C$  comparing relevant persons in terms of the height of the mountains they climbed. Since the truth conditions in (11b) are fulfilled iff the maximum of the degree set given by ' $\lambda d'. \text{John climbed a } d'\text{-high mountain}$ ' is higher than the maximum of any other degree set in  $C$ , the sentence comes out as true iff John climbed a higher mountain than any other relevant person.

In summary, the ambiguity of superlatives between absolute and relative readings can be analysed as a scope ambiguity of the superlative operator *-est*. In relative readings, focus affects truth conditions.

### 2.3. The positive operator POS

Building on Schwarz (2010), Romero (2015) argues that the properties discussed in the preceding subsection for the superlative operator also hold of the phonetically empty positive operator POS. Motivation for this comes from the observation that adjectives in the positive give rise to an ambiguity between absolute and relative readings, too. This is illustrated in the following example discussed by Schwarz (2010).

- (12) Mia has an expensive hat.

Under the absolute reading, (12) can be paraphrased as 'Mia has a hat that is expensive for a hat'. Here the price of Mia's hat is compared to the price of hats in general. Under the relative reading, which can be paraphrased as 'Mia has a hat that is expensive for somebody like Mia to have', Mia is compared to other persons in terms of the expensiveness of their hats. Romero (2015) proposes that this ambiguity can be derived from DP-internal vs. DP-external scope of POS in analogy to absolute and relative readings of superlatives. She moreover argues that the positive form of adjectives shows the same kind of focus sensitivity as the superlative. Therefore, crucial features of the analysis of *-est* carry over to the analysis of POS. These are summarized in (13).

- (13) The positive operator POS:
- (i) The positive operator POS is restricted by a covert variable  $C$  providing a comparison class, which is resolved contextually.
  - (ii) The effects of focus are factored in when  $C$  is resolved (free association with focus in Beaver and Clark's 2008 terms).
  - (iii) POS can take local (DP-internal) or non-local scope (DP-external).
  - (iv) The material in the scope of POS determines the form of the members of  $C$ .

To implement this analysis, I use the following lexical entry for POS, which is parallel to that of *-est* in (9).

$$(14) \llbracket \text{POS } C \rrbracket = \lambda D_{\langle d, t \rangle}. \exists d [D(d) \ \& \ d > \theta_C]$$

POS requires the degree property  $D$  serving as its argument to hold to a degree exceeding a contextual standard. The standard is computed by the function  $\theta$ , which maps a comparison class  $C$  to a degree, taking into account the distribution of values in  $C$  (see Solt, 2011a). As for superlatives, I assume that the comparison class  $C$  is a set of degree properties.

With these assumptions, the two readings of sentence (12) above can be derived in the following way. The absolute reading is derived from an LF where POS takes DP-internal scope, as shown in (15).

- (15) a. LF: Mia has  $[\text{DP a } [2 [\text{POS } C] [1 [t_2 \text{ } t_1\text{-expensive hat} ]]]]$   
 b.  $\exists x [\text{have}(m, x) \ \& \ \exists d [\text{hat}(x) \ \& \ \text{Expensiveness}(x) \geq d \ \& \ d > \theta_C]]$   
 c.  $C = \{ \lambda d'. h_1 \text{ is a } d'\text{-expensive hat, } \lambda d'. h_2 \text{ is a } d'\text{-expensive hat, } \dots \}$

In this configuration, the LF-sister of POS is  $[1 [t_2 \text{ } t_1\text{-expensive hat} ]]$  and consequently, the members of  $C$  are of the form ' $\lambda d'. x \text{ is a } d'\text{-expensive hat}$ ', with  $x$  ranging over hats. The contextual standard that the semantics of POS refers to is determined relative to this comparison class, i.e. relative to the price of hats in general.

In the absolute reading of (12), the price of Mia's hat is compared to the price of hats owned by persons comparable to her, e.g., 3-year-old girls. This reading is derived from an LF where POS takes DP-external scope and focus is on the subject, as shown in (16). In analogy to the derivation of the relative reading of superlatives discussed above,  $C$  is a subset of the focus alternatives, which are of the form ' $\lambda d'. x \text{ has a } d'\text{-expensive hat}$ ', with  $x$  ranging over contextually relevant individuals.

- (16) a. LF:  $[[\text{POS } C] [1 [\text{MIA has a } t_1\text{-expensive hat} ]]] \sim C]$   
 b.  $\exists d [\exists x [\text{have}(m, x) \ \& \ \text{hat}(x) \ \& \ \text{Expensiveness}(x) \geq d] \ \& \ d > \theta_C]$   
 c.  $C \subseteq \{ \lambda d'. \text{Mia has a } d'\text{-expensive hat, } \lambda d'. \text{Emma has a } d'\text{-expensive hat, } \lambda d'. \text{Hannah has a } d'\text{-expensive hat, } \dots \}$

Romero (2015) further observes that in relative readings, the focus associate of POS can not only be external to the host DP, as in (16), but that it can also be internal to the host DP. She discusses example (17), which has a reading under which it is true in the scenario in (18).

- (17) (For what he has been giving her, now) Rockefeller gave Kate an inexpensive CAR.  
 (18) Scenario: Rockefeller just gave Kate a very expensive car. Still, his present compares poorly to his previous astronomically expensive presents (e.g. apartment in Manhattan, island in the Pacific, etc.)

The relevant reading of (17) can be paraphrased as 'Rockefeller gave Kate a car and this present is inexpensive compared to his other presents to her'. The comparison class is thus

made up of sets of degrees to which other presents that Rockefeller gave Kate are inexpensive. We get this comparison class from an LF where POS takes DP-external scope while the focus associate is *car* inside the host DP, as shown in (19).

- (19) a. LF: [ [POS C] [1 [Rockefeller gave Kate a  $t_I$ -inexpensive CAR]]  $\sim$  C]  
 b.  $\exists d [\exists x [\text{give}(r,k,x) \ \& \ \text{car}(x) \ \& \ \text{Expensiveness}(x) \leq d] \ \& \ d < \theta_C]$   
 c.  $C \subseteq \{\lambda d'. \text{Rockefeller gave Kate a } d'\text{-inexpensive car,}$   
 $\lambda d'. \text{Rockefeller gave Kate a } d'\text{-inexpensive apartment in Manhattan,}$   
 $\lambda d'. \text{Rockefeller gave Kate a } d'\text{-inexpensive island in the Pacific, ...}\}$

Let us now apply this analysis of the positive operator to the cases of quantifier *many* under the assumption that we are dealing with the positive form of a gradable cardinality predicate.

### 3. Analysis

This section proposes an analysis of the quantifier *many*, where it is decomposed into three different components: *many* itself is treated as a gradable cardinality predicate, which combines with the phonetically empty positive operator. Quantificational force comes from a covert existential quantifier. It is shown that the different readings of *many* discussed in Section 1 can be derived under the assumptions about the semantics of *many* and the positive operator POS introduced in the previous section. The different readings are argued to result from different scope of POS and association with focus.

#### 3.1 Cardinal reading

Cardinal readings are in a way the default readings that arise under the present analysis. With the assumptions introduced in the preceding section, cardinal readings result from an LF where POS takes DP-external scope. This is illustrated in (21) for sentence (20).

- (20) Many students took Intro to Semantics.

- (21) a. LF: [POS C] [1 [ [DP  $\emptyset$  [ $t_I$ -many students]] took Intro to Semantics]]  
 b.  $\exists d [\exists x [\text{students}(x) \ \& \ |x| \geq d \ \& \ \text{take}(x, \text{Intro-to-Semantics})] \ \& \ d > \theta_C]$   
 c.  $C = \{\lambda d'. d'\text{-many students took Intro to Semantics, } \lambda d'. d'\text{-many students took Intro to Syntax, } \lambda d'. d'\text{-many students took Intro to Phonology, ...}\}$

In the in LF (21a) [POS C] is extracted out of the host DP and takes sentential scope. The value of the comparison class  $C$  is contextually resolved, possibly restricted by focus. Assuming that the number of students taking Intro to Semantics is assessed with respect to the number of students in other comparable courses,  $C$  might look as shown in (21c). According to the truth conditions in (21b), the sentence then comes out as true iff the number of students taking Intro to Semantics exceeds the number that would be expected on the basis of other comparable courses. This is similar to the meaning one would get using the determiner *many*<sub>CARD</sub> in (4), but differs from the analysis in GQT-style in one important respect: we are now more explicit regarding the standard relative to which the number of students is

considered large. It is computed on the basis of a comparison class, which is (partly) determined by the compositional semantics.

### 3.2 Proportional reading

We just saw that DP-external scope of POS yields cardinal readings of *many*. I now show that the proportional reading of *many* can be obtained from an LF where POS takes DP-internal scope.<sup>10</sup> Following the analysis of the proportional reading of *most* in Hackl (2009), I assume that in this configuration the comparison class  $C$  consists of the cardinalities of the pluralities denoted by the NP sister of *many*. In example (22), for instance, pluralities consisting of books on the reading list are compared in terms of how many atomic parts they have.

(22) John read many books on the reading list.

- (23) a. LF: John read  $[\emptyset [2 [\text{POS } C] [1 [t_2 t_1\text{-many books on the reading list}]]]]$   
 b.  $\exists x [\text{read}(j,x) \ \& \ \exists d [|x| \geq d \ \& \ \text{books-otrl}(x) \ \& \ d > \theta_C]]$   
 c.  $C = \{\lambda d'. x \text{ are } d'\text{-many books on the reading list: } x \text{ is a plurality consisting of books on the reading list}\}$

In the LF (23a), the sister of  $[\text{POS } C]$  is  $[1 [t_2 t_1\text{-many books on the reading list}]]$ . Thus, the members of  $C$  all have the form ' $\lambda d'. x$  are  $d'$ -many books on the reading list'. In analogy to absolute readings of superlatives, it is assumed that  $x$  ranges over individuals to which the property of being  $d'$ -many books on the reading list can be felicitously applied. Following Hackl (2009), I assume that  $C$  consists of the cardinalities of all the pluralities in the denotation of 'books on the reading list'. In order to see what it means that a certain degree exceeds a standard computed relative to this comparison class, let us inspect the values in  $C$  and their distribution more closely. Assuming for illustration, that there are eight books on the reading list,  $b_1, b_2, \dots, b_8$ , the pluralities in the denotation of 'books on the reading list' and their cardinalities are shown in (24). Consequently,  $C$  in this case looks as in (25).

|                                                                                                                                                        |                     |
|--------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| (24) $b_1, b_2, \dots, b_8,$                                                                                                                           | 8 of cardinality 1  |
| $b_1 \oplus b_2, b_1 \oplus b_3, b_1 \oplus b_4, \dots, b_7 \oplus b_8,$                                                                               | 28 of cardinality 2 |
| $b_1 \oplus b_2 \oplus b_3, \dots, b_6 \oplus b_7 \oplus b_8,$                                                                                         | 56 of cardinality 3 |
| $b_1 \oplus b_2 \oplus b_3 \oplus b_4, \dots, b_5 \oplus b_6 \oplus b_7 \oplus b_8,$                                                                   | 70 of cardinality 4 |
| $b_1 \oplus b_2 \oplus b_3 \oplus b_4 \oplus b_5, \dots, b_4 \oplus b_5 \oplus b_6 \oplus b_7 \oplus b_8,$                                             | 56 of cardinality 5 |
| $b_1 \oplus b_2 \oplus b_3 \oplus b_4 \oplus b_5 \oplus b_6, \dots, b_3 \oplus b_4 \oplus b_5 \oplus b_6 \oplus b_7 \oplus b_8,$                       | 28 of cardinality 6 |
| $b_1 \oplus b_2 \oplus b_3 \oplus b_4 \oplus b_5 \oplus b_6 \oplus b_7, \dots, b_2 \oplus b_3 \oplus b_4 \oplus b_5 \oplus b_6 \oplus b_7 \oplus b_8,$ | 8 of cardinality 7  |
| $b_1 \oplus b_2 \oplus b_3 \oplus b_4 \oplus b_5 \oplus b_6 \oplus b_7 \oplus b_8$                                                                     | 1 of cardinality 8  |

- (25)  $C = \{ \lambda d'. b_1 \text{ are } d'\text{-many books on the reading list,}$   
 $\lambda d'. b_2 \text{ are } d'\text{-many books on the reading list, } \dots,$   
 $\lambda d'. b_1 \oplus b_2 \oplus b_3 \oplus b_4 \oplus b_5 \oplus b_6 \oplus b_7 \oplus b_8 \text{ are } d'\text{-many books on the reading list} \}$

<sup>10</sup> See Krasikova (2011) and Solt (2011b) for similar proposals.

Note that the distribution of values in  $C$  shows a particular pattern, as indicated in (24): Because there are 8 pluralities of cardinality 1, the set of degrees with maximum 1 is represented 8 times; there being 28 pluralities of cardinality 2, the set of degrees with maximum 2 is represented 28 times, and so on.<sup>11</sup> In general, if there are  $n$  atomic individuals of a certain kind, the number of pluralities with cardinality  $k$  is given by the binomial coefficient  $\binom{n}{k}$ . The distribution of values in a comparison class representing the cardinalities of the pluralities in the NP denotation corresponds to a bell curve, as illustrated in Figure 1.

**Figure 1:** Distribution of values in a comparison class representing the cardinalities of the pluralities in the NP denotation

Given this distribution of values in  $C$ , the standard for ‘many’ness relative to  $C$ ,  $\theta_c$ , is likely to be located somewhere in the rightmost third of the area enclosed by the curve, as indicated in Figure 1. In effect, the truth conditions in (23b) express that John read a plurality of books whose cardinality is high relative to the cardinalities of the members of the power set of the set of books on the reading list. This mirrors the meaning assigned to proportional *many* by the analysis in the framework of Generalized Quantifier Theory, but crucially without making reference to actual proportions.

### 3.2 Reverse reading

For the derivation of the reverse reading, I follow Romero (2015, 2016) and assume that it is the role that focus plays in determining the comparison class that gives the impression of a

<sup>11</sup> In this case, it is crucial that the comparison class consist of intensional degree properties.  $C$  in (25) should more accurately be rendered as in (i):

- (i)  $C = \{ \lambda w. \lambda d'. b_1 \text{ are } d'\text{-many books on the reading list in } w, \\ \lambda w. \lambda d'. b_2 \text{ are } d'\text{-many books on the reading list in } w, \dots, \\ \lambda w. \lambda d'. b_1 \oplus b_2 \oplus b_3 \oplus b_4 \oplus b_5 \oplus b_6 \oplus b_7 \oplus b_8 \text{ are } d'\text{-many books on the reading list in } w \}$

Using intensional degree properties is crucial to ensure that the degree properties corresponding to different pluralities with the same number of atomic elements are not equivalent. Note that e.g. (i-a) and (i-b) are different degree properties. Although the pluralities do not differ across worlds regarding the number of atomic elements, the degree properties (ii-a) and (ii-b) differ with respect to the worlds at which they are defined and are thus not equivalent (e.g., (ii-a) would be undefined at world  $w_{29}$  if the individual  $b_1$  does not exist in  $w_{29}$ ).

- (ii) a.  $\lambda w. \lambda d'. b_1 \oplus b_2$  are  $d'$ -many books on the reading list in  $w$   
 b.  $\lambda w. \lambda d'. b_3 \oplus b_4$  are  $d'$ -many books on the reading list in  $w$

‘reverse’ reading. But in contrast to Romero, under the present analysis the reverse reading is derived as a special case of a cardinal reading.

As noted by Herburger (1997), the reverse reading is facilitated by placing focus on (part of) the NP sister of *many*. In Westerståhl’s (1985) famous example focus is on ‘Scandinavians’, as indicated in (26).

(26) Many SCANDINAVIANS have won the Nobel Prize in literature.

Because focus alternatives are factored in when the comparison class  $C$  is computed, focusing *Scandinavians* has an important effect on the truth-conditions. Consider the LF (27) that we get for sentence (26) under the assumption that POS takes DP-external scope.

- (27) a. LF:  $[[\text{POS } C] [1 [\emptyset [t_I\text{-many SCANDINAVIANS}]] \text{ have won the NP}] \sim C]$   
 b.  $\exists d [\exists x [\text{Scandinavians}(x) \ \& \ |x| \geq d \ \& \ \text{won}(x, \text{NP})] \ \& \ d > \theta_C]$   
 c.  $C \subseteq \{ \lambda d'. d'\text{-many Scandinavians have won the NP,}$   
      $\lambda d'. d'\text{-many Mediterraneans have won the NP,}$   
      $\lambda d'. d'\text{-many Eastern Europeans have won the NP, ... } \}$

This configuration is parallel to the adjectival case in (19) discussed in Section 2.3 above. Because  $[\text{POS } C]$  takes sentential scope and the comparison class  $C$  is a subset of the focus alternatives triggered by focus on *Scandinavians*, we get the comparison class  $C$  in (27c). With this comparison class, different world regions are compared in terms of the number of Nobel Prize winners they have produced. The truth conditions in (27b) are fulfilled in case the number of Nobel Prize winners from Scandinavia is large compared to the number of Nobel Prize winners from other parts of the world. This is the case if the Scandinavians make up a significant proportion of all the Nobel Prize winners, as is the case in the scenario in (3), discussed in Section 1, where 14 out of a total of 81 Nobel Prize winners in literature come from Scandinavia (although this is in fact hard to say unless we know where the other 67 winners come from).

Before closing this section, I would like to add a remark regarding conservativity. Westerståhl’s (1985) example triggered a lot of discussion in the semantics literature, because it has been regarded as a counter-example to the generalization that determiners in natural languages are always conservative (Barwise and Cooper, 1981; Keenan and Stavi, 1986). Under the approach taken here *many* is not a determiner, so the question whether *many* obeys conservativity does not even arise.

To summarize, this section showed that the different readings can be derived under a single lexical entry of *many* as a cardinality predicate that combines with the positive operator POS. The proportional reading is derived from an LF where POS takes DP-internal scope. When POS takes DP-external scope, cardinal readings result. Reverse readings are a special case of cardinal readings that arise if (part of) the NP-sister of *many* is focused.

#### 4. A closer look at reverse readings

Above, the reverse reading was argued to arise as a special case of a cardinal reading, where the NP sister of *many* is focused. We now compare the truth conditions derived for the reverse reading in (27) above to the ones derived from a determiner *many*<sub>REV</sub> in GQT-style, and to the truth conditions derived under the analysis of Romero (2015, 2016).

Let us first compare the truth conditions derived under the present analysis to the truth conditions in (28b) obtained from a GQT-style analysis with the determiner *many*<sub>REV</sub> with the lexical entry in (28a).

- (28) a.  $\llbracket \text{many}_{\text{REV}} \rrbracket = \lambda P. \lambda Q. |P \cap Q| : |Q| > k$ , where  $k$  is a large fraction  
 b.  $| \{x: \text{Scandinavian}(x)\} \cap \{x: \text{NP-winner}(x)\} | : | \{x: \text{NP-winner}(x)\} | > k$

Comparing (28b) and the truth conditions derived under the present analysis in (27b) above, a difference can be noted concerning the question whether it makes a difference where the non-Scandinavian Nobel Prize winners come from. In (27b) the number of Nobel Prize winners per world region enters into the computation of the standard relative to which a number counts as ‘many’. The nationality of the non-Scandinavian Nobel Prize winners can therefore make a difference to the truth conditions. For (28b), in contrast, it does not seem to matter where the Nobel Prize winners who are not Scandinavians come from, since it only relates the number of Scandinavian Nobel Prize winners to the total number of Nobel Prize winners.

But we have to keep in mind a further difference between the present analysis and the one in GTQ-style concerning the question how the standard for ‘many’-ness is determined. While the present analysis holds that the comparison class, which is partly determined by the grammar, plays a crucial role in computing this standard, the GTQ-style analysis is vague and just assumes that the threshold value  $k$ , above which a fraction counts as large, is determined by the context. Depending on the assumptions we make about what contextually given facts are taken into account in determining the standard, the conditions under which (28b) is true get more similar to the truth conditions in (27b). If we assume that the decision what counts as a large proportion of a set  $S$  is also influenced by the composition of  $S$ , then the nationality of the non-Scandinavian Nobel Prize winners becomes again relevant: if we are aware that Scandinavia has produced more Nobel Prize winners than most other parts of the world, the proportion of Scandinavian Nobel Prize winners to the total number of Nobel Prize winners is probably considered large. To conclude, it is not straightforward to compare the truth conditions derived under the two types of analyses, as long as the GTQ-style analysis is vague about how the contextual standard is determined.

We now turn to the analysis of Romero (2015, 2016). Following Hackl (2000), Romero analyses *many* as a gradable determiner, i.e. a determiner with an extra degree argument. But in contrast to Hackl, Romero employs two different lexical entries for *many*, *MANY*<sub>CARD</sub> for cardinal readings and *MANY*<sub>PROP</sub> for proportional readings, as shown in (29).

- (29) a.  $\llbracket \text{MANY}_{\text{CARD}} \rrbracket = \lambda d_d. \lambda P_{\langle e, t \rangle}. \lambda Q_{\langle e, t \rangle}. |P \cap Q| \geq d$ , where  $d$  ranges over natural numbers  
 b.  $\llbracket \text{MANY}_{\text{PROP}} \rrbracket = \lambda d_d. \lambda P_{\langle e, t \rangle}. \lambda Q_{\langle e, t \rangle}. (|P \cap Q| : |P|) \geq d$ , where  $d$  ranges over fractions between 0 and 1 or percentages

For the derivation of the reverse reading, Romero uses the proportional determiner  $\text{MANY}_{\text{PROP}}$ . Leaving intact the rest of the analysis from above, which was in fact borrowed from Romero, the reverse reading results from an LF where POS takes DP-external scope and the NP sister of *many* is focused. Combining this with the proportional determiner  $\text{MANY}_{\text{PROP}}$  yields the truth conditions in (30b) where the standard is determined relative to a comparison class  $C$  that looks like (30c).

- (30) a. LF:  $[[\text{POS } C] [1 [[t_I\text{-MANY}_{\text{prop}} \text{ SCANDINAVIANS } ] \text{ have won the NP}]] \sim C ]$   
 b.  $\exists d [ | \{x: \text{Scandinavian}(x)\} \cap \{x: \text{NP-winner}(x)\} | : | \{x: \text{Scandinavian}(x)\} | \geq d \ \& \ d > \theta_C ]$   
 c.  $C \subseteq \{ \lambda d'. (| \{x: \text{Scand.}(x)\} \cap \{x: \text{NP-winner}(x)\} | : | \{x: \text{Scandinavian}(x)\} |) \geq d', \lambda d'. (| \{x: \text{Mediterranean}(x)\} \cap \{x: \text{NP-winner}(x)\} | : | \{x: \text{Mediterranean}(x)\} |) \geq d', \lambda d'. (| \{x: \text{Eastern Europ.}(x)\} \cap \{x: \text{NP-winner}(x)\} | : | \{x: \text{Eastern Europ.}(x)\} |) \geq d' }$

With this comparison class, different world regions are compared with respect to the number of Nobel Prize winners in relation to the total number of inhabitants of that region. That yields a crucial difference to the truth conditions derived under the present proposal in (27) above: in (30) not only the number of Nobel Prize winners from a certain region is taken into account, but also the size of the overall population. In effect, the smaller the total population of a region is, the fewer Nobel Prize winners are sufficient to make the corresponding sentence true. Cohen (2001) and Romero (2015) argue that this move is necessary to adequately capture the truth conditions of the sentence. Contrasting the truth conditions of the minimally different sentences in (31), Cohen (2001: 48) remarks: “It may be sufficient for as few as two or three Andorrans to have won the Nobel Prize in literature for [(31b)] to be true; but such a small number would not be enough for the truth of [(31a)].”

- (31) a. Many SCANDINAVIANS have won the Nobel Prize in literature.  
 b. Many ANDORRANS have won the Nobel Prize in literature.

Different intuitions, however, have been reported regarding the precise conditions under which Westerstähl’s Nobel Prize winner-sentence is true, and in particular regarding the question whether the total number of individuals in the NP denotation is taken into account. According to Eckardt (1999:175), it does not matter: “The sentence is even true if the nation in question is the biggest on earth, and the ratio of winners per nation is even rather bad.”

Given these diverging intuitions about the truth conditions of Westerstähl’s example, without an in depth empirical investigation it is impossible to decide whether an adequate semantics for the reverse reading of a sentence of the form *many A are B* does indeed have to make reference to the proportion  $| A \cap B | : | A |$ . But I would like to point out a possibility how to accommodate the impression that the total number of individuals in the NP denotation matters to the truth conditions of Westerstähl’s example, if it turns out to be correct. So far, we have made only one specific assumption about the function  $\theta$  determining the contextual standard to which POS makes reference, namely that it does so on the basis of a comparison class  $C$ . And one position would indeed be that the context dependency of the truth conditions of sentences with positive forms of adjectives all boils down to the comparison class  $C$ : once  $C$  is fixed, the standard is also fixed. Under this view,  $\theta_C$  always yields the same degree for all contexts (for discussion of a contextually-stable threshold function  $\theta$  used in the semantics

of *many* see Fernando and Kamp, 1996; Schöller and Franke, 2015). But an alternative view could maintain that  $\theta_C$  is itself context-dependent, i.e. what value  $\theta$  yields for the same  $C$  might differ from context to context. If we assume such a contextually-variable function  $\theta_C$  considerations about how many Nobel Prize winners one would expect to come from a certain region could enter into the computation of the standard for ‘many’ness, such that the standard would be higher for populous parts of the world than for parts with smaller population.

In any case, there are examples that clearly have a reverse reading where the total number of individuals in the NP denotation does not matter. A case in point is sentence (32a), which can be paraphrased as ‘A high proportion of the things Peter got for his birthday are books’. Corresponding truth conditions are derived from an LF where POS takes DP-external scope and the comparison class  $C$  is restricted by focus on the NP sister of *many*, as in (27) above. In general, attributing reverse readings to focus effects can account for types of reverse readings that the GQT-style analysis cannot accommodate. This is the case in (32b), where focus is inside the temporal modifier. The sentence has a reading under which a sensible person could still board an airplane, namely that most airplanes that crash do so when landing. This reading can be derived with the tools the present analysis makes available, namely by letting the focus inside the temporal modifier restrict the comparison class  $C$ , which will then compare the number of crashes in different stages of a flight.

- (32) a. Tom got many BOOKS for his birthday.  
       b. Many airplanes crash when LANDING.

A fact supporting the view that the reverse reading arises as a cardinal reading rather than a proportional reading comes from the observation that the reverse reading arises in the same grammatical contexts as cardinal readings, and is impossible in contexts where only proportional readings are available. The grammatical constraints governing the distribution of the different readings is the topic of the next section.

## 5. Distributional restrictions of the different readings

It is well known that the cardinal and proportional reading of *many* are restricted to certain grammatical contexts, as are the interpretations of other so-called weak quantifiers, like cardinal numerals and *some* (Milsark, 1977; Partee, 1989 among many others). When a *many*-phrase serves as the subject of an individual-level predicate, as in (33a), only the proportional reading is available. For *many*-phrases as subject of stage-level predicates and objects, in contrast, both the cardinal and the proportional reading is possible, cf. (33b) and (33c). *Many*-phrases in *there* sentences, finally, receive only the cardinal reading, cf. (33d).

- |                                           |                                          |
|-------------------------------------------|------------------------------------------|
| (33) a. Many Huskies have blue eyes.      | #cardinal reading, ✓proportional reading |
| b. Many students took Intro to Semantics. | ✓cardinal reading, ✓proportional reading |
| c. Carl invited many semanticists.        | ✓cardinal reading, ✓proportional reading |
| d. There are many children in the garden. | ✓cardinal reading, #proportional reading |

Under the present analysis of *many*, a possible way to handle the distribution of cardinal and proportional readings in the spirit of Diesing (1992) would be the following. Let us assume,

following Diesing, that genuine quantifiers are obligatorily interpreted at the level of IP, while a default existential closure operator binds any unbound (individual) variables at the level of vP. At LF, subject of stage-level predicates and objects can either occupy their base generated position inside vP, or, if they are genuine quantifiers, move to the level of IP. Subjects of individual-level predicates are base generated at the level of IP, whereas subjects of *there*-sentences are obligatorily interpreted vP-internally. Combining these assumptions with the present analysis, the quantificational force of *many*-phrases can come from different sources, depending on their structural position. Keeping the assumption from above that there is a phonetically empty existential determiner  $\emptyset$ , *many*-phrases that are interpreted at the level of IP involve  $\emptyset$ . In contrast, *many*-phrases that occupy a vP-internal position at LF get their existential force from the default existential closure operator.

We can account for the observed restrictions on the readings of *many* if we make a further assumption about the possible interpretation sites of the positive operator POS. Assume that the positive operator POS cannot move out of the restrictor of the genuine quantifier  $\emptyset$ , while being a degree quantifier, it has to be interpreted at the IP-level and thus raise above the existential closure operator if it originates from a vP-internal *many*-phrase.<sup>12</sup> With this assumption, there is a one-to-one correspondence between the reading and the source of the quantificational force of a *many*-phrase: since under the present analysis the proportional reading corresponds to DP-internal scope of POS, it results from a *many*-phrase involving  $\emptyset$ . The cardinal reading, corresponding to DP-external scope of POS, results from a vP-internal *many*-phrase that is subject to existential closure.

The pattern shown in (33) above now follows. Since *many*-phrases as subjects of individual-level predicates occupy a position at the IP-level, they obligatorily involve  $\emptyset$ .<sup>13</sup> This in turn means that POS can only be interpreted DP-internally, resulting in the proportional reading. *Many*-phrases as subjects of stage-level predicates and objects, in contrast, can occupy different positions at LF. If they involve  $\emptyset$ , they are interpreted at the IP-level, resulting in the proportional reading. Additionally they can also be interpreted vP-internally, in which

<sup>12</sup> This claim should not be restricted to POS, but should rather hold of degree operators in general. While it is difficult to judge whether this restriction also holds for the comparative operator *-er*, because scope of *-er* relative to  $\exists$  does not make a truth-conditional difference, there is evidence that it applies to *-est*. First, it is well known that proportional *most* is a so-called strong determiner, i.e. *most*-phrases cannot occur in *there*-sentences. Second, only the proportional reading seems to be available for *most*-phrases as subjects of individual-level predicates. The different readings of *most* thus seem to show the same distributional restrictions as the readings of *many*. Under the analysis of Hackl (2009), where the proportional reading of *most* results from an LF where the superlative operator *-est* takes DP-internal scope, the restrictions of *most* would also follow from the present assumptions about the correspondence between the source of quantificational force and the scope options of degree operators.

<sup>13</sup> More precisely, *many*-phrases interpreted at the IP-level are assumed to involve  $\emptyset$  if they receive an existential interpretation. They can also be interpreted generically, as is well known from bare plurals. The generic cardinal reading (de Hoop, 1992) is illustrated in sentence (i), which expresses a statement about all groups of people reaching a considerable number.

- (i) Many people don't fit into this room.

The comparison with readings available for bare plurals raises the question why the phonetically empty existential determiner  $\emptyset$  does not seem to be available for bare plurals. Speculating on possible reasons goes beyond the scope of the present paper.

case POS raises above the existential closure operator, giving rise to the cardinal reading. For *many*-phrases in *there*-sentences, only a vP-internal position is possible, making only the cardinal reading available. The structures assumed to underlie the proportional and the cardinal reading are schematized in (33).

- (34) a. [IP [DP Ø [[POS C] [ 1 ... *t*<sub>I</sub>-many ... ]]] ... ]                      proportional reading  
       b. [IP ... [[POS C] [ 1 ... ∃<sub>x</sub> [vP ... *t*<sub>I</sub>-many *x* ... ]]]]                      cardinal reading

Let us now turn to the reverse reading. Herburger (1997) observes that the reverse reading is restricted to the same grammatical contexts as the cardinal reading. As illustrated in the following paradigm, the reverse reading cannot arise with individual-level predicates, whereas it is possible with stage-level predicates as well as for objects, and is perfectly available in *there*-sentences.

- (35) a. Many COOKS know how to make a soufflé.  
       #‘A high proportion of the people that know how to make a soufflé are cooks.’  
       b. Many COOKS applied.  
       ‘A high proportion of the applicants are cooks.’  
       c. Carl interviewed many COOKS.  
       ‘A high proportion of the people Carl interviewed are cooks.’  
       d. There are many speakers of Basque THAT ARE CITIZENS OF SPAIN.  
       ‘A high proportion of Basque speakers are citizens of Spain.’

Under the present analysis, this distribution of the reverse reading is entirely expected, since the reverse reading is derived as a special instance of the cardinal reading, i.e. POS taking DP-internal scope, in which (part of) the NP-sister of *many* is focused. Under the assumption from above that the cardinal reading arises from the configuration in (33b), a *many*-phrase is predicted to give rise to the reverse reading only if it is interpreted in a vP-internal position, which is subject to existential closure. Under the analysis of Diesing (1992), a vP-internal interpretation is obligatory for subjects of *there*-sentences, possible for objects and subjects of stage-level predicates, but impossible for subjects of individual-level predicates. This accounts for the distribution of the reverse reading.

## 5. Conclusion

This paper explored a uniform analysis of the so-called quantifier *many*, where *many* is decomposed into a gradable cardinality predicate and the positive morpheme POS. It was shown that the various readings that have been observed for *many* can be derived under this analysis. The different readings were argued to arise from different scope of POS and free association with focus. The proportional reading is generated from an LF where POS takes DP-internal scope. If POS takes non-local scope, cardinal readings are derived, with reverse readings being a special case arising from association with focus. This improves on existing accounts, which either employ more than one lexical entry for *many* (Romero 2015, 2016) or do not specify a compositional implementation (Solt 2009).

Under the present analysis, *many* always operates on a cardinality scale, which means that the degrees *many* takes as arguments are invariably natural numbers. This contrasts with the view

that proportional *many* operates on a scale of proportion, i.e. that the degrees it takes as arguments are rational numbers between 0 and 1, or alternatively percentages (Solt, 2018). More work is needed to investigate whether the kind of data that seem to require a scale of proportion can be accommodated under the present analysis.

The analysis presented in this paper contributes to the enterprise of quantifier decomposition. In the spirit of Hackl (2000, 2009), it is shown that ambiguities that are puzzling from a GQT perspective follow if expressions that appear to be quantifying determiners are decomposed and analysed with the tools made available in a degree-semantic framework.

## I want to, but...

Milo PHILLIPS-BROWN<sup>1</sup> — *Massachusetts Institute of Technology*

**Abstract.** I want to see the concert, but I don't want to take the long drive. Both of these desire ascriptions are true, even though I believe I'll see the concert if and only if I take the drive. Yet they, and *strongly conflicting desire ascriptions* more generally, are predicted incompatible by the standard semantics, given two standard constraints. There are two proposed solutions. I argue that both face problems because they misunderstand how what we believe influences what we desire. I then sketch my own solution: a *coarse-worlds* semantics that captures the extent to which belief influences desire. My semantics models what I call *some-things-considered* desire. Considering what the concert would be like, but ignoring the drive, I want to see the concert; considering what the drive would be like, but ignoring the concert, I don't want to take the drive.

**Keywords.** Desire ascriptions, strongly conflicting desire ascriptions, coarse worlds, some-things-considered desire.

### 1. Introduction

I want to pass, but I don't want to study; I want to eat pizza, but I don't want heartburn; I want to see the concert, but I don't want to take the long drive. These are pairs of *strongly conflicting desire ascriptions*. Standard accounts of 'want' wrongly predict that they're incompatible.

Say that 'A wants p' and 'A wants q' *conflict* when A believes that p will obtain only if q does not. Say that 'A wants p' and 'A wants q' *strongly conflict* when A believes that p will obtain if and only if q does not.

Here's an example. The Who are performing tonight, and Al's parents are deciding whether to take the long drive to the concert. Al knows that he'll see the concert only if he takes the drive, and he knows that he'll see the concert if he takes the drive. Al loves The Who, but he gets very carsick, and the drive isn't at all worth it. Al begs his parents to not take the drive.

- (1) Al wants to see the concert.
- (2) But Al doesn't want to take the long drive.<sup>2</sup>

Intuitively, both (1) and (2) are true, even though they strongly conflict (Al believes that (p) he'll see the concert if and only if it's not the case that (q) he doesn't take the drive).

Strongly conflicting desire ascriptions are common. Yet all of the standard semantics, given

---

<sup>2</sup>I'll be talking about the prominent, neg-raising reading of (2): Al wants not to take the long drive.

two standard constraints, predict that strongly conflicting desire ascriptions are incompatible. The standard semantics form a class: they all treat ‘want’ like a deontic modal.<sup>3,4</sup> I can’t show here that all contemporary, deontic modal-style semantics for ‘want’, with the two constraints, make strongly conflicting desire ascriptions incompatible. What I can do is give a feel for the problem with a case study: a best-worlds semantics for ‘want’.<sup>5</sup>

I am not the first to notice that (merely) conflicting *desires* are puzzling, or that (merely) conflicting desire *ascriptions* are a problem for *some* of the standard semantics.<sup>6</sup> I’m focusing on strongly conflicting desire ascriptions—and by extension, strongly conflicting desires—because strongly conflicting desire ascriptions pose a problem for *all* of the standard semantics, given the two standard constraints. Two non-standard accounts have been developed that make strongly conflicting desire ascriptions compatible (each drops one of the two constraints). But, I argue, each faces problems elsewhere. Both misjudge the extent to which what we believe influences what we desire. The first non-standard account, like the standard account, overestimates it. The second non-standard account underestimates it.

After discussing the problem and the two proposed solutions, I sketch my own: a *coarse worlds* semantics, designed to model what I call *some-things-considered* desire. My account gives an intuitive characterization of how our desires lead to strongly conflicting desire ascriptions, and it accurately reflects the extent of belief’s influence on desire.

## 2. Case study: a best-worlds semantics for ‘want’

We have a modal base  $f$  and an ordering source  $g$ . Both take a world  $w$  and an agent  $A$  as arguments (and a time, strictly speaking). The modal base returns a set of worlds. The ordering source returns a set of propositions.<sup>7</sup> (I’ll sometimes use ‘modal base’ and ‘ordering source’ to refer to the functions and sometimes to refer to their values.) The ordering source determines a preorder  $\preceq_{g(A,w)}$  on worlds, and  $\text{BEST}(A, w, f, g)$  is the subset of  $f(A, w)$  that is minimal according to  $\preceq_{g(A,w)}$ .<sup>8</sup> Here is the form of the semantics:

*Best-worlds semantics.*  $\llbracket A \text{ wants } p \rrbracket^{w,f,g} = 1$  iff  $\forall u \in \text{BEST}(A, w, f, g): \llbracket p \rrbracket^{u,f,g} = 1$ .

<sup>3</sup>These semantics include: an “other things equal” semantics (Heim, 1992), a variant of a best-worlds semantics (Portner, 1997), an “absolute preference” semantics (Geurts, 1998), a decision-theoretic semantics (van Rooij, 1999; Levinson, 2003; Lassiter, 2011), a contrastive semantics (Villalta, 2008). Deontic modal analogs are given by, e.g. Goble (1996), Lassiter (2011) (decision-theoretic); Jackson (1985), Cariani (2013) (contrastive). A caveat: a semantics with a probability function makes desire ascriptions incompatible not when  $A$  merely believes that  $p$  will obtain if and only if  $q$  does not, but when she is *certain* of it.

<sup>4</sup>There’s another prominent approach to ‘want’, traditional in the philosophy literature, and recently proposed by Condoravdi and Lauer (2016) (Moltmann (2013) has a related approach). Roughly: ‘ $A$  wants  $p$ ’ is true iff  $A$  has a desire that is satisfied in all and only the  $p$ -worlds. Strongly conflicting desire ascriptions are compatible on this approach, but it has its own problems (see Fara (2013) and Braun’s (2015) reply to Fara).

<sup>5</sup>Kratzer (1981), Giorgi and Pianesi (1997), von Fintel (1999).

<sup>6</sup>See e.g. Davis (1984), Jackson (1985), van Rooij (1999), Levinson (2003).

<sup>7</sup>I’m roughly following von Fintel in presenting the best-worlds semantics.

<sup>8</sup> $u \preceq_{g(A,w)} v$  iff  $\{p \in g(A, w) : v \in p\} \subseteq \{p \in g(A, w) : u \in p\}$ .  $\text{BEST}(A, w, f, g) = \{u \in f(A, w) : \neg \exists v \in f(A, w), v \preceq_{g(A,w)} u\}$ . On this definition, ‘best’ means ‘none better’. I make the limit assumption (Lewis, 1973), which entails that  $\text{BEST}(A, w, f, g)$  is non-empty if  $f(A, w)$  is non-empty.

This is just the form. We need to say what the modal base and ordering source are.

Start with the modal base. Which worlds are in the modal base when we evaluate  $\lceil A \text{ wants } p \rceil$ ? In other words, whether  $\lceil A \text{ wants } p \rceil$  is true depends on whether  $p$  is true in certain worlds. Which? Presumably not *all* worlds. Say that I want sushi. Somewhere out there in the total space of worlds eating sushi carries a lifetime prison sentence, yet worlds where it does are irrelevant to my desire. They're not possibilities that I take seriously. I believe that eating sushi is legal, so worlds where it isn't don't figure into my desire for sushi.

Along these lines, Stalnaker suggests that "wanting something is preferring it to certain relevant alternatives, the relevant alternatives being those possibilities that the agent believes will be realized if he does not get what he wants" (Stalnaker, 1984: p. 89). You might translate this thought into the semantics by identifying the modal base with the set of worlds compatible with what the agent believes—the agent's belief set.<sup>9</sup> And indeed it's standard to identify the modal base with the belief set, or a close relative.<sup>10</sup> (The modal base actually can't *always* be the belief set (Heim, 1992). In particular, it can't be the belief set when the agent either believes  $p$  or believes  $\neg p$ . I won't discuss such cases, so we'll only need to settle what the modal base is like when the agent believes neither  $p$  nor  $\neg p$ .)

*Constraint: belief set modal base.*  $\llbracket A \text{ wants } p \rrbracket^{w,f,g}$  is defined only if  $f(A, w) = A$ 's belief set in  $w$  (when  $A$  in  $w$  believes neither  $p$  nor  $\neg p$ ).

What about the ordering source? On what basis does it rank the worlds for desire ascriptions? On the basis of the agent's desires. That much is universally accepted. What's not quite universally accepted, although still standardly assumed, is that the ordering source ranks worlds based on the agent's *total desire state*.<sup>11</sup> An ordering source ranks worlds based on the agent's total desire state when it contains *every* proposition that counts in favor of a world in the agent's eyes. (When it contains *some* such propositions, it ranks worlds based on *part* of her desire state.)

*Constraint: unique (total desire) ordering source.*  $\llbracket A \text{ wants } p \rrbracket^{w,f,g}$  is defined only if  $g(A, w)$  represents  $A$ 's total desire state in  $w$ .

Combining the semantics with the two constraints gives us:

*Simplified, informal truth conditions.*  $\lceil A \text{ wants } p \rceil$  is true iff  $p$  is true in all of the best worlds in  $A$ 's belief set, as ranked by  $A$ 's total desire state.

Let's see why these truth conditions make strongly conflicting desire ascriptions incompatible.

<sup>9</sup>Heim (1992) also uses the presupposition behavior of 'want' to motivate using the belief set.

<sup>10</sup>E.g. Heim (1992), Giorgi and Pianesi (1997), Portner (1997), Geurts (1998), von Stechow (1999), Giannakidou (1999), van Rooij (1999), Levinson (2003), Lassiter (2011), Pearson (2016) all identify the modal base with the belief set or a close relative (at least when  $A$  believes neither  $p$  nor  $\neg p$ ).

<sup>11</sup>So far as I know, only Levinson (2003) and Crnič (2011) have denied that the ordering source ranks worlds based on the agent's total desire state. Everyone else accepts it (some implicitly, others explicitly).

### 2.1. Predicting that strongly conflicting desire ascriptions are incompatible

Al believes that he'll see the concert if and only if he takes the drive, which will make him sick.

- (1) Al wants to see the concert.
- (2) Al doesn't want to take the long drive.

(1) and (2) are both true. But that's not what we predict. If (1) and (2) are both true, then the truth conditions say that Al both sees the concert and doesn't take the drive in the best worlds in his belief set. But Al believes that he'll see the concert if and only if he takes the drive: there aren't any worlds in his belief set where Al both sees the concert and doesn't take the drive.<sup>12</sup>

More generally, we predict that all strongly conflicting desire ascriptions are incompatible: 'A wants  $p$ ' and 'A wants  $q$ ' are both true if and only if among the possibilities that A takes seriously (the worlds in A's belief set), the best are those where  $p$  and  $q$  both obtain. But by definition, if 'A wants  $p$ ' and 'A wants  $q$ ' conflict, then A believes that  $p$  will obtain if and only if  $q$  does not—she doesn't take seriously the possibility that  $p$  and  $q$  will both obtain. The agent's beliefs are making strongly conflicting desire ascriptions incompatible—they're influencing the modal base too much.

### 2.2. Two ways to make strongly conflicting desire ascriptions compatible

Given the belief set modal base and unique ordering source constraints, the best-worlds semantics wrongly predicts that strongly conflicting desire ascriptions are incompatible. There are two obvious ways to make things right: drop the unique ordering source constraint or drop the belief set modal base constraint. Both have been proposed, and both do make strongly conflicting desire ascriptions compatible. But, as I argue in sections §3 and §4, both face problems elsewhere. These problems stem from a misunderstanding of how what we believe influences what we desire.

## 3. Drop the unique ordering source constraint?

Intuitively speaking, what is happening when Al wants to see the concert *and* wants to avoid the drive? What is happening when an agent wants two things and believes that one will come about if and only if the other does not? Maybe the agent has conflicting values. Al values hearing good music. He also values avoiding sickness. When Al believes that one of these values will be realized if and only if the other is not, desire ascriptions strongly conflict. You might base your account of 'want' on this picture of values by saying that desire ascriptions are true or false *relative to a value*. Relative to Al's value of having hearing good music, (1), 'Al wants to see the concert', is true; relative to his value of avoiding sickness, (2), 'Al doesn't want to take the drive', is true.

<sup>12</sup>This amounts to a contradiction if we assume what's entirely plausible: that Al's beliefs are consistent, in which case there will be best worlds in his belief set (see footnote 8 for details).

To implement truth relative to a value in our semantics, we need to represent some things that the agent values without representing them all. In other words, we need to enable ordering sources to represent only part of the agent's desire state: we need to drop the (unique) total-desire ordering source constraint. Levinson (2003) and Crnić (2011) propose to do this by letting the ordering source vary by context:<sup>13</sup>

*Constraint: variable (partial-desire) ordering source.*  $\llbracket A \text{ wants } p \rrbracket^{w,f,g}$  can be defined even if  $g(A, w)$  represents just some part of A's desire state in  $w$ .

Both (1) and (2) need true readings. What does that take? The variable ordering source view says that in a given conversation, there are multiple ordering sources that different contexts determine, multiple ordering sources that are *available* for evaluating a given desire ascription in a given conversation. A desire ascription has a true reading when evaluated against an ordering source that is available for evaluating that ascription.

Suppose that there are two ordering sources available for evaluating (1) and (2). One of them,  $g_1$ , represents Al's value of hearing good music; the other,  $g_2$ , represents his value of avoiding sickness. In Al's belief set, Al sees the concert in the  $g_1$ -best worlds, giving (1) a true reading, while in the  $g_2$ -best worlds, Al doesn't take the drive, giving (2) a true reading.

The crux of the variable ordering source view is: extra ordering sources, extra readings. Before, at most one of two strongly conflicting desire ascriptions could have a true reading, and now both can. However, along with these extra readings that we want, we get others that we don't.

### 3.1. Overgeneration threatens the variable ordering source view

Consider:

(3) Al wants to take the drive.

(3) has no true reading here: Al is kicking and screaming, begging to not go. But the variable ordering source view has just said that there's an available ordering source,  $g_1$ , which gives (3) a true reading. Because  $g_1$  makes (1) true, it ranks concert-worlds best in Al's belief set. Yet the concert-worlds *are* the drive-worlds in his belief set, so  $g_1$  ranks drive-worlds best in Al's belief set: (3) is true relative to  $g_1$ . We've overgenerated.

<sup>13</sup>Three things to note. First, neither Levinson nor Crnić give a best-worlds semantics (Levinson's semantics is decision-theoretic, and Crnić is noncommittal among the deontic-modal-style semantics). My objection to the variable ordering source view in §3.1 also applies to the other deontic-modal-style semantics. Second, van Fraassen (1973) and von Fintel (2012) propose an analog of the variable ordering constraint for 'ought'. Third, instead of having ordering sources vary by context, you could build extra orderings into the semantics. Let  $\mathcal{G}$  be a set of ordering sources.  $\llbracket A \text{ wants } p \rrbracket^{w,f,\mathcal{G}} = 1$  iff  $\exists g \in \mathcal{G} : \forall u \in \text{BEST}(A, w, f, g) : \llbracket p \rrbracket^{u,f,g} = 1$ .  $\llbracket A \text{ wants } p \rrbracket^{w,f,\mathcal{G}}$  is defined only if, for every  $g \in \mathcal{G}$ ,  $g(A, w)$  represents at least some of A's desire state in  $w$ . (For analogous approaches to 'ought', see e.g. Horty (2003), von Fintel (2012), and Cariani (2013).) This view makes strongly conflicting desire ascriptions compatible, but it's susceptible to the objection to the variable ordering source view that I give in §3.1.

(If the concert were enjoyable enough to be worth the drive, we could get a true reading of (3): Al might say to his parents that he wants to take the drive to convince them to go to the concert. This is not the case as we've set it up though.)

We can't conclude that the variable ordering source view is wrong. Because it posits variability in a contextual parameter, it is flexible. Maybe it can give principled constraints according to which  $g_1$  is *not* available for evaluating (3), even though it is available for evaluating (1). With such constraints, we wouldn't overgenerate. For now, I'll operate as if we don't have such constraints, and I'll return to the issue in §7.

### 3.2. Lesson

Because we've continued to use the belief set modal base, the agent's beliefs continue to influence the modal base too much. Al believes that he'll see the concert if and only if he takes the drive—in his belief set, the concert-worlds are the drive-worlds. The ordering source draws only on worlds in the modal base—only on worlds in the belief set—so it can't distinguish the concert from the drive. We need to lessen the influence of the agent's beliefs on the modal base.

## 4. Drop the belief set modal base constraint?

A natural way to lessen the influence of the agent's beliefs on the modal base is to let the modal base contain worlds outside of the agent's belief set:

*Constraint: beyond-belief set modal base.*  $\llbracket A \text{ wants } p \rrbracket^{w,f,g}$  can be defined when  $f(A, w)$  contains worlds outside of A's belief set in  $w$  (even if A in  $w$  believes neither  $p$  nor  $\neg p$ ).

If we adopt the beyond-belief set modal base constraint, we again make unacceptable predictions, although now we'll do so because the agent's beliefs influence the modal base too *little*.

If we want our modal base to reach beyond the belief set, we need to give a principled answer to the question *which worlds outside of the belief set are in the modal base?* Villalta gives a principled answer.<sup>14</sup> Let's look at what she says.

### 4.1. Villalta's answer

We know that if the modal base is the belief set, at most one of two strongly conflicting desire ascriptions can be true: if  $\llbracket A \text{ wants } p \rrbracket$  and  $\llbracket A \text{ wants } q \rrbracket$  are both true, then  $p$ -and- $q$ -worlds are best in the belief set, but if  $\llbracket A \text{ wants } p \rrbracket$  and  $\llbracket A \text{ wants } q \rrbracket$  strongly conflict, there aren't any  $p$ -and- $q$ -worlds in the belief set. If the modal base isn't the belief set, there can be  $p$ -and- $q$ -worlds in the modal base: there is no *structural* obstacle to two strongly conflicting desire ascriptions

<sup>14</sup>The other authors who propose a beyond-belief set modal base are Asher (1987), Anand and Hacquard (2013), and Rubinstein (2017). Anand and Hacquard adopt Villalta's view, Asher doesn't specify which worlds are outside of the belief set, and although Rubinstein says in a particular case which worlds are outside the belief set, she doesn't give a principled answer to the question of which worlds outside the belief set are in the modal base.

both being true. Nonetheless, if we use Villalta's modal bases, most desire ascriptions come out false, strongly conflicting or not.

Villalta's semantics is contrastive, so her modal bases are built out of the contextually salient contrast class. If  $p$ ,  $q$ , and  $r$  make up the contrast class for  $\lceil A \text{ wants } p \rceil$  in a given context, then the modal base is the union of  $p$ ,  $q$ , and  $r$ .

Consider (1), 'Al wants to see the concert', evaluated against a contrast class that's just *Al sees the concert* and *Al doesn't see the concert*. If (1) is true, the best worlds in this set must all be concert-worlds. (This is what's predicted by both the best-worlds semantics and Villalta's.<sup>15</sup>) It just can't be, though, that all of the best worlds in this set are concert-worlds. The possible ways for Al to *not* see the concert are too varied. In some worlds where he doesn't see the concert, The Who perform in his living room. In others, John Lennon and George Harrison have been resurrected from the dead, The Beatles are reunited, and *they* perform in Al's living room.<sup>16</sup>

When we evaluate  $\lceil A \text{ wants } p \rceil$ , we can't concern ourselves with *every* way that  $p$  and the relevant contrast propositions can come about. If we do, only rarely will all of the best worlds be  $p$ -worlds. With Villalta's modal bases, most desire ascriptions will come out false. The agent's beliefs are influencing the modal base too *little*: doxastically outrageous possibilities have nothing to do with our desires. This is how we motivated the belief set modal base in the first place: worlds where I'm imprisoned for eating sushi have nothing to do with my desire for eating sushi, just as worlds where Lennon and Harrison are resurrected have nothing to do with Al's desire to go to the concert.

We need a principled answer to the question *which worlds outside of the belief set are in the modal base?* Villalta's answer doesn't succeed, but that doesn't mean that no answer could. I'll now suggest a different answer and two ways to flesh it out. Neither succeeds.

#### 4.2. A simple, incomplete answer

The problem with the belief set modal base was that (1), 'Al wants to see the concert', and (2), 'Al wants to take the drive', couldn't both be true because there aren't worlds in Al's belief set where he both sees the concert and doesn't take the drive. There's an obvious fix: take Al's belief set and add worlds just like those in his belief set, except that in the new worlds, Al sees the concert *and* doesn't take the drive. Of course, Al most desires going to the concert without taking the drive, so these concert-no-drive-worlds are best in the new modal base. If the new modal base is available for evaluating both (1) and (2), then both have true readings.

But consider a different case. Jo is ill. Her doctors may give her antibiotics—whether she wants them or not. Jo herself wouldn't choose to have them. She believes that she can't be cured.

<sup>15</sup>See p. 479, where Villalta defines her preference relation: it is effectively a best-worlds approach.

<sup>16</sup>The problem isn't with the *Al sees the concert/Al doesn't see the concert* contrast class. If it were instead e.g. *Al sees the concert/Al stays home*, there would still be worlds where The Who perform in his living room.

(4) Jo wants the doctors to give her antibiotics.

(4) has no true reading. Yet we can give (4) a true reading with a modal base that goes outside of the agent's belief set: take Jo's belief set and add worlds just like those in her belief set, except that in the new worlds, she gets antibiotics *and* is cured. Of course, being cured is better than not, so these *antibiotics-cured-worlds* are best in the new modal base. If the new modal base is available for evaluating (4), then (4) is wrongly predicted to have a true reading.

The agent's beliefs are again influencing the modal base too little. Jo doesn't want to be given antibiotics *because* she believes they can't cure her: if the modal base contains worlds where she is cured by antibiotics, we'll make the wrong predictions about her attitude towards antibiotics.

The simple, incomplete answer is simple because it gives us a simple way to build a modal base to make (1) and (2) compatible. The simple, incomplete answer is incomplete because it doesn't tell us why we get to add concert-no-drive-worlds to Al's belief set but not antibiotics-cured-worlds to Jo's. It doesn't give us a complete, principled answer to the question *which worlds outside of the belief set are in the modal base?* I'll now make two attempts to complete the incomplete answer. Both fail.

#### 4.2.1. An attempt at completing the simple, incomplete answer: conjunction-introduction

Here's a more complete answer—a *conjunction-introduction* answer: when 'A wants p' and 'A wants q' are both true and there aren't any *p-and-q-worlds* in A's belief set, then the modal base is A's belief set, plus some *p-and-q-worlds*. This answer delivers Al's belief set, plus concert-no-drive-worlds (because both 'Al wants to see the concert' and 'Al doesn't want to take the drive' are true), but it doesn't deliver Jo's belief set, plus antibiotics-cured-worlds (because 'Jo wants antibiotics' is not true), just as we wanted. However, there are two problems.

First, the conjunction-introduction answer is itself incomplete: it works backwards from what the right predictions are to what the modal base must be. We want to go the other way around. We want to give a principle for generating the modal base that yields the right predictions.

Second, the conjunction-introduction answer is not in general true. There is a kind of case of strongly conflicting desire ascriptions where the conjunction-introduction answer simply makes the wrong predictions. Consider Lu, who believes that she may be served one of two drinks tonight: either a champagne or a port. Lu is big fan of both. She says:

(5) I want to drink the champagne.

(6) I also want to drink the port. (I'm excited to see what they serve!)

(7) But of course I don't want to drink the champagne *and* the port. That would ruin both.

(5) and (6) are true, and there aren't any champagne-and-port-worlds in Lu's belief set. The conjunction-introduction answer tells us to add to Lu's belief set worlds where she drinks

port *and* champagne, banking on these conjunction worlds being best in the new modal base. They're not. Drinking champagne and port would ruin both! The conjunction worlds are *worst* in the new modal base.<sup>17</sup> (5) and (6) are wrongly predicted false.

#### 4.2.2. A different attempt at completing the simple, incomplete answer: partly belief-based

We've seen that if we want to use a modal base that's not the belief set, we risk the agent's beliefs influencing the modal base too little. We don't have to throw out the baby with the bath water, though. We can use a modal base that's not the belief set and still use the agent's beliefs to influence the modal base to *some* extent.

Think of the belief set as the set of worlds that an agent thinks are viable candidates for actuality. All worlds outside the belief set are unviable candidates. Nonetheless, some worlds outside of the belief set are less viable than others. According to Al, worlds where Lennon and Harrison are resurrected are unviable candidates for actuality, as are worlds where Al sees the concert without driving. Both kinds of worlds are outside of his belief set. Nonetheless, Al thinks that worlds where Lennon and Harrison are resurrected are *less* viable candidates than worlds where Al sees the concert without driving. Put another way: Al would be less surprised to learn that he could see the concert without driving than he would be to learn that Lennon and Harrison were resurrected.

You might use viability to complete the incomplete answer. Here's a *partly belief-based* answer to the question *which worlds outside the belief set are inside the modal base?* Worlds that the agent thinks are unviable candidates for actuality can be inside the modal base, but worlds that the agent thinks are *too* unviable can't be inside the modal base.

We want the partly belief-based answer to give (1), 'Al wants to see the concert', and (2), 'Al doesn't want to take the drive', true readings without giving (4), 'Jo wants the doctors to give her antibiotics', a true reading. We want to allow the modal base that is Al's belief set, plus concert-no-drive-worlds, but disallow the modal base that is Jo's belief set, plus antibiotics-cured-worlds. So we'd need it to be that Al thinks that concert-no-drive-worlds are *more* viable candidates for actuality than Jo thinks antibiotics-cured-worlds are. But we can just suppose that this isn't the case. We can suppose that Jo would be *less* surprised to learn that she could be cured with antibiotics than Al would be to learn that he could see the concert without driving.

#### 4.3. Lesson

In trying to reduce the influence of the agent's beliefs on the modal base by letting the modal base contain worlds outside of the agent's belief set, we make wrong predictions. And we do so *because* we have reduced the influence of the agent's beliefs too much. The possibility that The Who perform in Al's living room is irrelevant to Al's desire to see the concert *because* Al

<sup>17</sup>The conjunction-introduction answer also fails when the prejacent of two true desire ascriptions are impossible (Davis (1984), Fara (2013) give such cases). Van Rooij (1999) and Levinson (2003) also point out that 'want' is not closed under conjunction.

believes that he can only see The Who perform if he sees the concert; the possibility that Jo is cured by antibiotics has nothing to do with Jo's desire to not be given antibiotics *because* she believes that antibiotics can't cure her; the possibility that Al drinks port with champagne has nothing to do with his desire to drink port, and champagne, respectively, *because* he believes that he won't drink them together. Doxastic impossibilities are irrelevant to the agent's desires.

If our modal bases for desire ascriptions contain possibilities that are irrelevant to the agent's desires, we shouldn't expect to make the right predictions—we shouldn't expect to make the right predictions if we adopt the beyond-belief set modal base constraint.

## 5. Interim summary

The standard, deontic modal-style semantics for 'want', given the two standard constraints, make strongly conflicting desire ascriptions incompatible. We've seen the incompatibility, and the problems with dropping either of the two standard constraints, within the best-worlds semantics.

If we keep the best-worlds semantics—or any of the standard deontic-modal style semantics—we're in a bind. With the belief set modal base constraint, the agent's beliefs are too influential: in Al's belief set, the concert-worlds are the drive-worlds, and so ordering sources (variable or not) can't distinguish the concert from the drive. Yet without the belief set modal base constraint, the agent's beliefs aren't influential enough: doxastic impossibilities are irrelevant to our desires. To make strongly conflicting desire ascriptions compatible without going wrong elsewhere, the agent's beliefs should influence the modal base some, but not too much. To properly capture the influence of the agent's beliefs on the modal base, I propose a new semantics.

## 6. A sketch of a coarse worlds semantics

Here's a hypothesis about *desire*—a hypothesis about how much our beliefs influence our desires—that makes strongly conflicting desire ascriptions compatible: in situations like Al's, the agent *considers* how the world will be in certain respects, but *ignores* how it will be in others.

Al can consider how things would be at the concert but ignore how they'd be during the drive. When Al considers *what the concert would be like*, what's good about the concert—he'd hear good music—comes to the fore. When Al ignores *what it would take to get to the concert*, what's bad about what it would take to get to the concert—he'd get carsick from the drive—does not come to the fore. In other words, when Al considers what the concert would be like, but ignores what it would take to get to the concert, *Al wants to go to the concert*. Similarly, when Al considers what the drive would be like, what's bad about the drive—carsickness—comes to the fore. When Al ignores what he would do if he took the drive, what's good about what he would do if he took the drive—experience good music—does not come to the fore. In other words, when Al considers what the drive would be like, but ignores what he would do if he took the drive, Al doesn't want to take the drive.

This is a picture of *some-things-considered* (other-things-ignored) desire. Desire is not a *two-place* relation between an agent and a proposition, but rather a *three-place* relation between an agent, a proposition, and what the agent is considering. You don't desire *p simpliciter*. You desire *p* considering some things and ignoring others.

It will help to say a little more about considering. We'll model considering *p* with a *question* that bears on *p*. Formally, I'll take a question to be a partition on the total space of worlds, a partition whose cells are the exhaustive answers to the question (Hamblin, 1958):<sup>18</sup> e.g., the question *q?* is represented with  $\{q, \neg q\}$ .

Say that a set of propositions  $\Pi$  *bears on a proposition p* iff *p* is entailed by some member of  $\Pi$  or  $\neg p$  is entailed by some member of  $\Pi$ .

Take the question that asks both *does Al go to the concert?* and *does Al hear good music?* This question is  $\{\text{concert} \wedge \text{good music}, \text{concert} \wedge \neg \text{good music}, \neg \text{concert} \wedge \text{good music}, \neg \text{concert} \wedge \neg \text{good music}\}$ , and it bears on the proposition *Al goes to the concert*. We can use this question, call it ' $\Pi_1$ ', to represent considering going to the concert because its answers tell us about the concert, and in this case, also about not going to the concert. What about ignoring? To ignore something is to not consider it. We model ignoring *p* with a question that can't tell us about either *p* or  $\neg p$ —with a question that doesn't bear on *p*. So, for example, we can model ignoring the proposition *Al takes the drive* with  $\Pi_1$  because  $\Pi_1$  doesn't bear on *Al takes the drive*.

We're not interested merely in modeling Al considering what the concert would be like, but also in modeling what Al believes the concert would be like—after all, ways for the concert to be that Al believes are impossible are irrelevant to his desires. We need to fit the agent's beliefs in our picture of considering and ignoring. We need to model what the agent believes about a given question. An agent's beliefs about a given question eliminate answers to that question. Take again  $\Pi_1$ , and suppose that Al believes that he'll hear good music if and only if he goes to the concert. Al's beliefs are incompatible with certain answers to  $\Pi_1$  ( $\text{concert} \wedge \neg \text{good music}$ ,  $\neg \text{concert} \wedge \text{good music}$ ), and compatible with others ( $\text{concert} \wedge \text{good music}$ ,  $\neg \text{concert} \wedge \neg \text{good music}$ ).

Following Yalcin (2016), we'll call the set of answers to  $\Pi_1$  that are compatible with Al's beliefs, Al's  $\Pi_1$ -*relative belief state*. More generally:

A's *belief set* in *w* is the set of worlds compatible with what A believes in *w*.

Where  $\Pi$  is a question, A's  $\Pi$ -*relative belief state* in *w* is the set of answers to  $\Pi$  compatible with what A believes in *w*:  $\{p \in \Pi : p \cap \text{A's belief set in } w \neq \emptyset\}$ .<sup>19</sup>

Yalcin has motivated the existence of question-relative belief states by arguing that they can help us solve certain problems that go under the name 'the problem of logical omniscience'.

<sup>18</sup>I don't think much turns on whether we use a partition approach to questions. I'm using it for concreteness.

<sup>19</sup>I'm defining question-relative belief states slightly differently from Yalcin, who thinks that agents' beliefs can't be represented with a belief *set*. This difference isn't important to my view.

Here, I'll take for granted that agents have question-relative belief states.

The answers to a question are propositions. To better understand my semantics, it will help to think of these propositions as *coarse worlds*. A coarse world is coarse in the sense that it does not decide the truth value of every proposition. Where defined, every proposition, or its negation, is *true* at a given (non-coarse) world. But not every proposition, or its negation, is *entailed* by a given coarse world.<sup>20</sup> I will use a bold '*p*' to indicate that you should think of the proposition *p* as a coarse world.

Back to some-things-considered desire. The term 'considering' is a little misleading: it suggests something *episodic*. I don't mean it that way. In order for Al to want to see the concert—considering what the concert would be like, but ignoring what the drive would be like—there doesn't need to be, or have been, an *episode* of Al considering what the concert would be like. Compare: in order for Al to believe that he'd hear good music at the concert, there doesn't have to be, or have been, an episode of Al believing that he'd hear good music at the concert.

On the picture of some-things-considered desire, desire is a relation between an agent, a proposition, and what the agent is considering—more precisely, a relation between an agent, a proposition, and a question-relative belief state. Coarse worlds in questions decide the truth values of some propositions, but not others, and that's helpfully understood as the agent considering some propositions, but not others. I said, speaking loosely, that considering what the concert would be like, but ignoring what the drive would be like, Al wants to go to the concert. Strictly speaking, what I mean is that there is some question  $\Pi$  that bears on what the concert would be like, but not on what the drive would be like, and the desire relation holds between Al, the proposition *Al goes to the concert*, and Al's  $\Pi$ -relative belief state.

What is  $\Pi$ ? The question-relative belief states that figure into our desire relations are complex. Whether Al desires to go to the concert depends on what he believes about a whole host of propositions: does Al hear good music? do The Who perform? which songs? does Al have fun? how much fun? how long is the concert? how loud? where does Al sit? will it be crowded? And so on. A question that bears on all of those propositions has a great many answers—many more than the four that e.g.  $\Pi_1$  has. To make the semantics easier to understand, though, we'll consider how it works with toy questions. So in place of the true question that bears on all of these propositions about the concert, we'll use the question that asks just *does Al go to the concert?* and *does Al hear good music?* We'll use  $\Pi_1$ .

## 6.1. The semantics

The picture of some-things-considered desire adds an extra relatum to the desire relation—a question-relative belief state. To give a semantics that represents some-things-considered desire, we need to add an extra parameter—a question. Compare:

*Old truth conditions, informally.* 'A wants *p*' is true iff *p* is *true* in all of the best

<sup>20</sup>'Coarse worlds' comes from Yalcin (2011). See also Humberstone (1981).

(non-coarse) worlds in A's belief set, as ranked by A's total desire state.

*New truth conditions, informally.*  $\lceil A \text{ wants } p \rceil$  is true with respect to  $\Pi$  iff  $p$  is *entailed* by all of the best coarse worlds in A's  $\Pi$ -relative belief state, as ranked by A's total desire state.

Two strongly conflicting desire ascriptions can both be true: each with respect to a different question.

Recall that Al's  $\Pi_1$ -relative belief state is  $\{\text{concert} \wedge \text{good music}, \neg \text{concert} \wedge \neg \text{good music}\}$ . There are two coarse worlds here: one where he goes to the concert and hears good music, and one where he doesn't go to the concert and doesn't hear good music. Hearing good music is better than not hearing good music, so he goes to the concert in the best coarse world in his  $\Pi_1$ -relative belief state. If  $\Pi_1$  is available for evaluating (1), 'Al wants to see the concert', then (1) has a true reading.

We'll now use a second toy question,  $\Pi_2$ . Let  $\Pi_2$  ask both *does Al take the drive?* and *does Al get carsick?*—i.e.  $\Pi_2 = \{\text{drive} \wedge \text{sick}, \text{drive} \wedge \neg \text{sick}, \neg \text{drive} \wedge \text{sick}, \neg \text{drive} \wedge \neg \text{sick}\}$ . Now suppose that Al believes that he'll get carsick if and only if he takes the drive: Al's  $\Pi_2$ -relative belief state is  $\{\text{drive} \wedge \text{sick}, \neg \text{drive} \wedge \neg \text{sick}\}$ . There are two coarse worlds here: one where he takes the drive and gets sick, and one where he doesn't take the drive and doesn't get sick. Not being sick is better than being sick, so he doesn't take the drive in the best coarse world in his  $\Pi_2$ -relative belief state. If  $\Pi_2$  is available for evaluating (2), 'Al doesn't want to take the drive', then (2) has a true reading.

Let's state the semantics precisely. Before, the modal base was a function from an agent and world to a set of worlds. Now, it's a function from an agent, a question, and a world to a set of coarse worlds. The ordering source is still a function from worlds to sets of propositions (although the way that it orders possibilities differs slightly from before—see just below).<sup>21</sup>

$$\llbracket A \text{ wants } p \rrbracket^{w,f,g,\Pi} = 1 \text{ iff } \forall q \in \text{BEST}(A,w,f,g,\Pi): q \subseteq \llbracket p \rrbracket^{f,g,\Pi}.$$

$\llbracket A \text{ wants } p \rrbracket^{w,f,g,\Pi}$  is defined only if:

- (i) *Constraint: unique (total desire) ordering source.*  $g(A,w)$  represents A's total desire state in  $w$ .
- (ii) *Constraint: question-relative belief state modal base.*  $f(A,\Pi,w) = A$ 's  $\Pi$ -relative belief state in  $w$  (when A believes neither  $p$  nor  $\neg p$  in  $w$ ).

These are not the only constraints we'll need (see below), but let's look at them first.

The question-relative belief state modal base constraint prevents the problem with the beyond-belief set modal base view. The problem was that the modal base contained worlds incompatible with the agent's beliefs—worlds irrelevant to the agent's desires. The problem was that the agent's beliefs influenced the modal base too little. But if the modal base is the agent's question-

<sup>21</sup>Dandelet (ms) proposes a similar, situations-based semantics for 'want'.

relative belief state, then the modal base doesn't contain any *coarse worlds* incompatible with the agent's beliefs. The agent's beliefs *don't* influence the modal base too little.

The unique (total desire) ordering source is just what we had before.  $g(A, w)$  is the set of all propositions that A cares about. What's different is the way that the ordering source ranks possibilities. Before, the ordering source ranked (non-coarse) *worlds* on the basis of *which propositions those worlds make true*.

Old ordering:  $u \preceq_{g(A, w)} v$  iff  $\{p \in g(A, w) : v \in p\} \subseteq \{p \in g(A, w) : u \in p\}$ .

Now, the ordering source ranks *coarse worlds* on the basis of *which propositions those coarse worlds entail*.<sup>22</sup>

New ordering:  $q \preceq_{g(A, w)} r$  iff  $\{p \in g(A, w) : r \subseteq p\} \subseteq \{p \in g(A, w) : q \subseteq p\}$ .

We can now verify that (1) is true relative to  $\Pi_1$ . To simplify things, suppose Al just cares about hearing good music and avoiding sickness:  $g(Al, w)$  is  $\{good\ music, \neg sick\}$ .<sup>23</sup> Al's  $\Pi_1$ -relative belief state is  $\{concert \wedge good\ music, \neg concert \wedge \neg good\ music\}$ . There is a single concert-coarse-world in Al's  $\Pi_1$ -relative belief state,  $concert \wedge good\ music$ , and it entails a proposition in  $g(Al, w)$ ,  $good\ music$ . But the no-concert-coarse-world in Al's  $\Pi_1$ -relative belief state,  $\neg concert \wedge \neg good\ music$ , entails neither  $good\ music$  nor  $\neg sick$ , so the concert-coarse-world is ranked best within Al's  $\Pi_1$ -relative belief state: (1) is true relative to  $\Pi_1$ .<sup>24</sup> The explanation for why (2) is true relative to  $\Pi_2$  goes along similar lines.

## 6.2. A comparison with the variable ordering source view

I propose:

*Constraint: question-relative-belief-state-bearing-on-prejacent.*  $\llbracket A\ \text{wants}\ p \rrbracket^{w, f, g, \Pi}$  is defined only if A's  $\Pi$ -relative belief state in  $w$  bears on  $p$ .

This constraint prevents the immediate overgeneration problem that threatens the variable ordering source view. The variable ordering source view gives (1) a true reading with an available ordering source,  $g_1$ , which ranks concert-worlds best in Al's belief set. But given that in Al's belief set, the concert-worlds are the drive-worlds,  $g_1$  ranks drive-worlds best: without further constraints on which ordering sources are available, the variable ordering source view incor-

<sup>22</sup>Two things to note. First, Cariani et al. (2013) have a related approach to 'ought'. Second, 'BEST' needs to be adjusted:  $BEST(A, w, f, g, \Pi) = \{q \in f(A, \Pi, w) : \neg \exists r \in f(A, \Pi, w), r \prec_{g(A, w)} q\}$  (compare with footnote 8).

<sup>23</sup>Note that simplifying in this way wouldn't help the variable ordering source view. It faces overgeneration regardless of which propositions Al cares about.

<sup>24</sup>Note that the coarse world  $concert \wedge good\ music$  contains (non-coarse) worlds where Al gets sick, as well as (non-coarse) worlds where he does not. The presence of (non-coarse) worlds where Al get sick doesn't matter to how  $concert \wedge good\ music$  is ranked. The ordering source ranks coarse worlds *only* on the basis of which propositions those coarse world entail: since  $concert \wedge good\ music$  contains both sick-worlds *and* no-sick-worlds, it does not entail that Al gets sick.

rectly predicts that (3), ‘Al wants to take the drive’, has a true reading.

My view gives (1) a true reading with an available question,  $\Pi_1$ , where concert-coarse-worlds are best within Al’s  $\Pi_1$ -relative belief state. Unlike  $g_1$ ,  $\Pi_1$  doesn’t give (3) a true reading: Al’s  $\Pi_1$ -relative belief state,  $\{concert \wedge good\ music, \neg concert \wedge \neg good\ music\}$ , does not bear on the prejacent of (3): neither member of this set entails either *Al takes the drive* or *Al doesn’t take the drive*. In other words, considering what the concert would be like, but ignoring the drive, it’s neither the case that Al wants to take the drive nor that he doesn’t want to take the drive: he is *ignoring* the drive. This is captured by the question-bears-on-the-prejacent constraint: (3) is *undefined* with respect to  $\Pi_1$ .

In §7, I say more about how my view compares to the variable ordering source view.

### 6.3. The agent’s beliefs don’t influence the modal base too *much*

We’ve seen that the agent’s beliefs don’t influence question-relative belief state modal bases too *little*. They also don’t influence question-relative belief state modal bases too *much*.

Al’s beliefs influence the belief *set* modal base too much because within Al’s belief set the concert-worlds are *coextensive* with the drive-worlds. We don’t have such coextension in question-relative belief state modal bases: the questions involved in question-relative belief states are partitions over the set of all worlds, partitions over the entire space of metaphysically possible worlds. (They are *not* partitions over the agent’s belief set.) Take Al’s  $\Pi_2$ -relative belief state,  $\{drive \wedge sick, \neg drive \wedge \neg sick\}$ . The drive-coarse-world here, *drive*  $\wedge$  *sick*, is coextensive with another coarse world just in case that coarse world is *metaphysically equivalent* to *drive*  $\wedge$  *sick*. But the proposition *drive*  $\wedge$  *sick* is not metaphysically equivalent to any coarse world where Al goes to the concert (i.e. it’s not metaphysically equivalent to any proposition that entails that Al goes to the concert).

The key here is that considering merely whether he’ll take the drive and whether he’ll get sick, and ignoring the concert, Al ignores the relationship between the drive and the concert. Even though Al believes that he’ll see the concert if and only if he takes the drive, that belief makes no difference to which coarse worlds are in his  $\Pi_2$ -relative belief state. Al’s  $\Pi_2$ -relative belief state is the set of coarse worlds in  $\Pi_2$ ,  $\{drive \wedge sick, drive \wedge \neg sick, \neg drive \wedge sick, \neg drive \wedge \neg sick\}$ , that are compatible with his beliefs. Only certain of Al’s beliefs make a difference to which of these coarse worlds are compatible with his beliefs. Although Al believes the proposition *concert iff drive*, that proposition is *compatible* with every coarse world in  $\Pi_2$ , so his belief in *concert iff drive*, doesn’t affect which coarse worlds are in his  $\Pi_2$ -relative belief state. Some of the agent’s beliefs influence the modal base—a belief influences the modal base if it’s incompatible with an answer to the relevant question. But not all of an agent’s beliefs are incompatible with answers to a given question, so not all of the agent’s beliefs influence the modal base. The agent’s beliefs influence the modal base some, but not too much.

## 7. Conclusion

The standard semantics, given two standard constraints, make strongly conflicting desire ascriptions incompatible. There are two proposed solutions—the variable ordering source view, and the beyond-belief set modal base view—each of which drops one of constraints. I’ve argued that the beyond-belief set modal base view is misguided: possibilities incompatible with an agent’s beliefs are irrelevant to what she desires. I have not taken such a strong stance against the variable ordering source view. I pointed out that as long as we keep the belief set modal base in a non-coarse worlds framework, ordering sources can’t distinguish propositions that must be distinguished, which means that the variable ordering source view overgenerates *without further constraints* on which ordering sources are available. No further constraints have been given. That doesn’t mean they couldn’t be given in a principled way, although I’m pessimistic.

I’ve sketched my own way to make strongly conflicting desire ascriptions compatible: a coarse-worlds semantics based on a picture of some-things-considered desire. My view has two principal merits. First, the picture of some-things-considered desire gives an intuitive explanation of why our *desires* strongly conflict, a picture that my formalism captures. Second, what we learned by looking at the two proposed solutions was that the problem with strongly conflicting desire ascriptions stems from the extent to which our beliefs influence our desires. A solution to the problem needs belief to influence desire some, but not too much, and mine does.

A *complete* solution to the problem will allow us not just to say that some, but not all, beliefs influence desire. It will also identify, in a principled way, *which* beliefs influence which desires. I have already done some identifying (e.g. Al’s desire to go to the concert is influenced by his beliefs about what the concert would be like, but not by his beliefs about what the drive would be like). Nonetheless, I have only given a sketch of my semantics—not a complete solution. I have not given a complete, principled answer to the question *which questions are available for evaluating a given desire ascription?* To properly answer that question I need further constraints—beyond those I have given—on which questions are available. Without such constraints, my account will overgenerate. This means that I have not shown that my view has a decisive advantage over the variable ordering source view. But I hope to have shown that the some-things-considered desire framework—and so the coarse-worlds framework—is a powerful one for identifying which beliefs influence which desires. Developing further constraints within this framework is the most important task for future work.

Here are two other issues that I hope to pursue in future work.

First, any adequate account of ‘want’ needs to address certain invalid inferences that Villalta noted.<sup>25</sup> She pointed out that Heim’s semantics wrongly validates inferences like:

- (8)    a.    Cy wants to pass.
- b.    Cy believes that he’ll pass if and only if he studies.
- c.    So, Cy wants to study.

---

<sup>25</sup>Pettit (1991) noted similar inferences.

It's not just Heim's semantics that validates such inferences. Any semantics that uses (an analog of) the belief set modal base constraint wrongly predicts that 'want' is *closed under believed extension*. On my view, both (8a) and (8b) can be true in a given context *c*, while (8c) is not true but *undefined* with respect to the question that *c* determines. The further constraints I just mentioned are constraints on definedness conditions: understanding what these constraints are can shed light on why closure inferences fail.<sup>26</sup>

Second, although I've shown my idea for a coarse worlds semantics within the best-worlds framework, the best-worlds framework is not essential. I've used it not because I think it is the right framework for 'want'—it has its limitations—but because the Kratzer-style ranking on (non-coarse) worlds extends transparently to a ranking on coarse worlds (the ordering source ranks (non-coarse) worlds on the basis of the propositions those (non-coarse) worlds make true, and it ranks coarse worlds on the basis of the propositions those coarse worlds entail). Coarse worlds can be implemented within other semantics, too. Within a given semantics, we replace (non-coarse) worlds with coarse worlds and adjust accordingly. The implementations will be different within different semantics. (For example, some semantics use a probability distribution over worlds, and that distribution will have to be extended to coarse worlds.) The point is that a coarse worlds semantics—within the best-worlds framework or not—is a promising approach to strongly conflicting desire ascriptions.

# Paradigm-induced implicatures of TAM markers: The case of the Daakaka distal<sup>1</sup>

Kilu VON PRINCE — *Humboldt-Universität zu Berlin*

**Abstract.** The distal TAM-marker in the Oceanic language Daakaka (Vanuatu) refers to events in the actual past as well as the counterfactual past, present and future. It comes with a cessation interpretation similar to English simple past statives and similar to markers of (dis)continuous past in other languages. For English and Tlingit, it has been argued that this cessation interpretation is a pragmatic implicature rather than part of the lexical semantics. I will argue that in Daakaka, too, the cessation interpretation is the result of an implicature, but that this can only be understood if the modal dimensions of the TAM markers are taken into consideration.

**Keywords:** Oceanic, TAM, tense, modality, implicatures, cessation, discontinuity

## 1. Introduction

Discontinuous past markers have been described for a wide variety of languages from diverse families and areas. Plungian and van der Auwera (2006: 317) therefore suggest that “[d]iscontinuous past can thus be analyzed as a special cross-linguistically valid type of past tense marking.” Plungian and van der Auwera (2006) assume that the discontinuity interpretation can be a lexical feature of past markers and that discontinuous past is therefore a distinct category from regular past.

However, Cable (2017) suggests that the discontinuity interpretation of past markers in some languages is not a built-in part of their lexical semantics, but rather the result of pragmatic reasoning, similar to Altshuler and Schwarzschild (2012)’s analysis of cessation implicatures in English simple past.

The Daakaka distal adds an interesting complication to this picture. Although its discontinuity interpretation can also be shown to be context-dependent and thus non-lexical, it defies the typological generalizations by Cable (2017), who suggests that discontinuous past markers occur exclusively in languages with optional tense marking.<sup>2</sup>

In Daakaka, however, TAM marking of finite clauses is obligatory. While we will see that this observation itself is not a great obstacle to applying Cable (2017)’s analysis, I will discuss several aspects of his theoretical approach that are problematic and at odds with established assumptions.

---

<sup>1</sup>I would like to thank the people of Ambrym for their precious collaboration, in particular Tio Bang, Chief Filip and his family of Emyotungan and Donatien and Catherine Merané of Sesivi, Manfred Krifka for discussions, as well as three anonymous reviewers and the participants at Sinn und Bedeutung 2016 in Edinburgh. This work has partly been funded by the DFG (PR1516/2-1) and by the Volkswagen Foundation

<sup>2</sup>Note that this is not fully supported by Plungian and van der Auwera (2006). They cite Washo and systems with a binary remoteness distinction or a pluperfect as possible counterexamples.

I will argue that the discontinuity implicature of the Daakaka distal can only be understood if we consider its modal as well as its temporal meaning.

## 2. Background

Daakaka is an Oceanic language of Vanuatu, spoken by about one thousand people on the island of Ambrym and the small diaspora in Vanuatu's cities Port Vila and Luganville. Its basic word order is SVO and it has a fairly strictly developed system of lexical classes (von Prince, 2015). All data come from my own fieldwork. The bulk of the data comes from the corpus I created during a language documentation project between 2009 and 2012. Referenced examples refer back to the corpus, which is published in The Language Archives (TLA) and which I constantly work on to make it more consistent and more accessible.

## 3. TAM markers in Daakaka

Finite clauses in Daakaka have to contain a TAM marker. They typically cliticize to the preceding subject agreement marker or to the subsequent verb. With third-person singular subjects and non-human subjects, there is no subject agreement marker and the TAM marker will be realized as a monosyllabic word with a vowel determined by the subsequent verb instead. The following two examples show the realis marker:

- (1) *waawu, na=m pyane swa kemyas kyun.*  
 grandparent 1SG=REAL roast one only just  
 "grandmother, I have only roasted one."<sup>3</sup> (5401)

- (2) *ulilir mu du-ru yen bwili wye*  
 prawn REAL REDUP-stay in hole.of water  
 "Prawns live in fresh water ponds" (1775)

The TAM markers form a rather close-knit unit with the subject-agreement marker and the verb. The only thing that can interfere between them are auxiliaries and some aspectual particles. The main temporal-modal contrasts of the system are instantiated by the markers in table 1.

In addition, there are two other markers, which play a less important role in the context of this article:

- *too* is used exclusively for embedded polarity questions about the episodic past or present as in *I don't know whether she has arrived already*.

<sup>3</sup>ATT – attributive linker; COMP – complementizer; CONT – continuous aspect; COP – copula; COS – change of state; DEF – definite; DEM – demonstrative; DISC – discourse marker; DIST – distal TAM; EX – exclusive; IMPF – imperfective; IN – inclusive; LOC – locative; MED – medial; MOD – assertion marker; POSS – possessive; POT – potential; PROX – proximate; REAL – realis; REDUP – reduplication; RES – resultative suffix; TOP – topic marker; TRANS – transitivizer.

|                    | enclitic   | proclitic   | monosyllabic  |
|--------------------|------------|-------------|---------------|
| Positive Realis    | = <i>m</i> | <i>mw</i> = | <i>mwe/mV</i> |
| Negative Realis    |            |             | <i>to</i>     |
| Positive Potential | = <i>p</i> | <i>w</i> =  | <i>wV</i>     |
| Negative Potential | = <i>n</i> |             | <i>nV</i>     |
| Distal             | = <i>t</i> | <i>t</i> =  | <i>tV</i>     |

Table 1: The main TAMP markers of Daakaka (cf. von Prince, 2015)

- *bwet* has the same temporal-modal implications as the realis marker, with the additional information that an event constitutes a new development.

The positive realis marker is by far the most frequent in my corpus. It is used to talk about the contextually determined actual past and present. In fictional settings, where the actual present is shifted to a fictional world, the realis marker is also used throughout. The potential markers are used to talk about future developments relative to the matrix clause or relative to the utterance context; they can also refer to epistemic possibilities of the present (but not the past). In the following discussion, we will contrast the distal marker with the realis marker in particular. First, however, let us have a closer look at the distal and its various functions.

#### 4. The distal TAM marker

##### 4.1. Discontinuous past

As we have seen in the previous section, TAM markers in Daakaka are obligatory in finite sentences. In this section, we will explore the distal marker in more detail and see how it corresponds to the category of a discontinuous past marker as observed by Plungian and van der Auwera (2006) and Cable (2017).

Plungian and van der Auwera (2006) suggest the following typical properties for discontinuous past markers.

- (3) a. They are idle past markers: In the majority of event descriptions of the past, they are *not* used.
- b. They are mostly used with imperfective predicates, in which case they denote states that do not extend to the present moment.
- c. When they occur with perfective event descriptions, they express that the result of an action does not hold at the time of speaking.

I will show now that all these criteria apply to Daakaka. I will start with the observation that the realis is the standard marker to refer to past events. In my corpus, there are over 8400 matches for the realis marker as opposed to just over one thousand occurrences of the distal. And only in a minority of those cases where the distal marker is used does it clearly express a discontinuous past. Most of the texts in the corpus are narratives about the actual or fictional past, and in both cases, the realis marker is the most frequent form throughout. The following beginning of a story illustrates this:

- (4) *bili na sa wotop mwe pa,*  
time COMP TOP breadfruit REAL bear.fruit  
“when the breadfruit tree bore fruit,” (5443)
- (5) *te gee ma ka t-en sivi ye=Ø vyan te vyan du ane*  
DISC flying.fox REAL say and-3S.POSS lorikeet 3D=POT go DISC go stay eat  
*wotop*  
breadfruit  
“the flying fox suggested to the lorikeet that they go to eat breadfruit” (5444)
- (6) *ye=m vyan ma ge=tak, du en-en vyan te*  
3D=REAL go REAL be.like=PROX stay REDUP-eat go DISC  
“they went like that and they were eating, when...” (5445)

Having established that the default marker for the actual past is the realis marker, I will now turn to the distal marker in unembedded environments where it refers to events or states of the actual past. These cases almost always involve a discontinuity interpretation.

In accordance with (3b), most of those cases involve stative predicates and then induce the interpretation that something used to be the case but is no longer the case. A typical example is given in (7), where the stative predicate is *dyanga* (not exist). The speaker talks about the millipede being an alien species which only arrived on Ambrym recently.

- (7) *dereli, nge te dyanga teve nyem, nge bwet dakap me kyun*  
millipede 3S DIST lack side.of 1PL.EX 3S COS recently come just  
“the millipede didn’t use to be with us [here], it just came recently” (2203)

Another example illustrates the use of the distal with the imperfective auxiliary *du* to talk about the habitual, discontinuous past.

- (8) *te t=i seli swa na yap myató nyoo ya=t du gene meerin*  
DISC DIST=COP road one COMP old.man old 3P 3P=DIST IMPF make long.time  
“[spear throwing] was a tradition the old ones used to perform long ago” (5201)

As required by generalization (3c), the distal marker can also function as a discontinuous past marker in the context of perfective event descriptions; as expected, it then usually expresses that the result of an action does not hold at the speech time. The following example is from a story about a group of people who want to cultivate a new patch of bush for food crops. But a mischievous *lisepsep* (a dwarf-like creature with magical powers) makes the trees grow back as they were before. When they come back to visit the next day, one person expresses their astonishment that the tree they had cut down is whole again: The result of the cutting no longer holds.

- (9) *swa mwe ka, nye nenyu na=t me te te lee en=tak*  
one REAL say 1S yesterday 1S=DIST come DISC cut tree DEF=PROX  
“one said: ‘I cut this tree yesterday’ (lit. ‘I had come and cut this tree’)” (3074)

In addition to the properties by Plungian and van der Auwera (2006), Cable (2017) adds suggests the following generalization:

[...] there does not appear to be any language with an obligatory discontinuous past marker; that is, in every language with a putative “discontinuous past”, the marker in question does not have to be used in contexts supporting a cessation inference.

This, too, is the case in Daakaka. Thus the following two sentences come from two different versions of the same story, recorded at different occasions. They are almost identical, except for two things:

1. The main TAM marker in (10) is a realis marker, as opposed to the distal marker in (11).
2. The sentence with the realis marker in (10) contains the temporal adverbial *meerin* “a long time ago”.

(10) *meerin* nya ye *mw=i* bivian na *mu* vu ten  
 long.time 3D 3D REAL=COP friend COMP REAL good very  
 “before, [the rat and the cat] used to be good friends” (0912)

(11) *pus myane tomo*, nya ye *t=i* bivian *tu* vu ten  
 cat with rat 3D 3D DIST=COP friend DIST good very  
 “the cat and the rat, they used to be very good friends” (4597)

This shows that distant and discontinuous past can be referred to by the realis marker as well as the distal. Without further specification however, the default interpretation of the realis marker is a reference to the utterance time or the topic time (which are identical at the very beginning of a story). An expression like *meerin* (“a long time ago”) can help to get the intended, non-default reference to the past.

In sum, this section has shown that the Daakaka distal marker can clearly be identified as a discontinuous past marker by the criteria brought forward in the literature.

#### 4.2. Other functions of the distal

Other than marking the discontinuous actual past, the distal is also instrumental for talking about counterfactuality. It is the only marker in the language that can be used in the context of counterfactual developments in the past or present. This reference is available in matrix clauses, if the context makes a counterfactual interpretation plausible:

(12) *Nye na bwe dimyane ka ebya-ok we pwer kyun*, [*na=t ka pini or.*]  
 1SG 1SG CONT want MOD wing-3S.POSS POT stay just 1SG=DIST fly fill place  
 “I wish I had wings, I would fly around everywhere.”

Counterfactual interpretations can of course also be found in conditionals:

- (13) *[tati, saka w=i vyaven en=tak te] [saka ko=t esi*  
 dad MOD.NEG POT=COP woman DEM=PROX Glossdisc MOD.NEG 2SG=DIST see  
*nye]*  
 1SG  
 “father, if it had not been for this woman, then you would never have seen me again”  
 (4856)

Complement clauses of verbs of thinking, wishing and saying can also be headed by the distal to signal that the prejacent is not asserted by the speaker:

- (14) *te ma ka ti mini sye swa yen kava*  
 DISC REAL say DIST drink something one in kava  
 “and he (wrongfully) said he had drunk something in the kava.”

In sum, we have seen that, outside of the protasis of temporal and conditional clauses, the distal marker can refer to the discontinuous actual past, or to the counterfactual past, present or future. Within the protasis of temporal and conditional clauses, it may also refer to the future. However, by far the most frequent environment for the distal to occur is the protasis of temporal and conditional clauses. In (15), the distal expresses a reference to the episodic past:

- (15) *[or ka te myaek] te mwe me vyan te syu ane apyaló-ten*  
 place MOD DIST be.night DISC REAL come go DISC land TRANS ship-native  
 “at night, he went and sat down in the canoe” (4723)

Within this environment, its interpretation and distribution crucially differs from matrix clauses in several respects:

1. It occurs with non-stative predicates as the norm, not as the exception.
2. There is no discontinuity effect.
3. It does not necessarily refer to past events. It can also refer to the generic present and to the future.

Of course, point 2 is also crucial for the hypothesis that the discontinuity reading is not part of the lexical definition of the distal marker, but comes in as an implicature. In the following example, the distal marker does not refer to the past at all, but rather to the generic present. Accordingly, there is no discontinuity reading here. Someone could have an appetite for eating doves right now, nothing to the contrary is implicated by this sentence.

- (16) *[ka vyanten te dimyane ka wa ane maa] te mwe gene kuo*  
 COMP person DIST want MOD POT eat dove DISC REAL make trap  
 “When someone wants to eat dove, they make a trap” (0523)

The example in (17) illustrates a reference to the episodic future. It is uttered by a small bird in a story where this bird wants to steal breadfruits from the magical creature known as *lisepsep*.

- (17) [*ka lisepsep te me*], *te nye ka na=p ka*  
 COMP lisepsep DIST come DISC 1S MOD 1S=POT fly  
 “if the lisepsep comes, then I will fly away.” (4496)

This kind of temporal reference is only ever available for the distal in the protasis of temporal and conditional clauses. It is not only absent in matrix clauses, but also from complement clauses, relative clauses and adverbial clauses. Usually, temporal and conditional clauses are introduced by the complementizer *ka*, but even if *ka* is not there, clauses headed by the distal can often only be interpreted as temporal or conditional:

- (18) [*ki=t me a=tak*] *ka na w=ane kimim*  
 2P=DIST come LOC.DEM=PROX MOD 1S POT=eat 2P  
 “if you come here, then I will eat you!” (3133)

- (19) [*ko=t kii-kuwu*] *te mu kuo*  
 2S=DIST dig-RES.out DISC REAL run  
 “when you dig it out, it runs away” (6104)

For reasons of space, I cannot give a full account of why these temporal references become available for the distal exclusively in these environments. I will argue below that they are covered by the lexical definition of the distal, but typically blocked by pragmatic defaults and via its contrast to the realis and potential markers. In this particular context, however, this contrast is partially removed because the realis marker in particular is not allowed in this environment.

Concluding this section, we have seen that the functions of the distal marker go far beyond a reference to the discontinuous past. In the right context, it can also refer to counterfactual scenarios. And in the protasis of temporal and conditional clauses, a reference to the future and present also becomes available.

## 5. Previous approaches to discontinuity interpretations

### 5.1. Altshuler and Schwarzschild (2012)

Altshuler and Schwarzschild (2012) discuss the cessation implicature of English simple past with stative predicates. For example, in the given context in (20), B’s utterance implicates that Scotty is no longer anxious:

- (20) A: How is Scotty doing?  
 B: He was anxious.

Their analysis relies on two assumptions: One about the semantics of stative predicates, and one about the contrast of English simple past to English simple present. I will argue in this section that the cessation implicature for the distal cannot be derived in the same way that Altshuler and Schwarzschild (2012) propose for English simple past. One important empirical difference that already foreshadows this conclusion is that the discontinuity reading for the Daakaka distal also applies to non-stative predicates, in contrast to English simple past. The theoretical reasons for

this difference are however interesting enough to deserve some exploration. Let us first briefly review the proposal by Altshuler and Schwarzschild (2012). One fundamental assumption is that stative sentences have the following temporal profile:

(21) Temporal Profile of Statives:

For any tenseless stative clause  $\phi$ , if  $\phi$  is true at moment  $m$ , then there is a moment  $m'$  preceding  $m$  at which  $\phi$  is true and there is a moment  $m'$  [sic] following  $m$  at which  $\phi$  is true.

The notions of simple past and simple present could then be formalized as follows:<sup>4</sup>

(22) English simple present, as applying to statives:

$$\llbracket \text{PRES} \rrbracket = \lambda w_0 \lambda t_0 \lambda p. \exists t. t = t_0, p(t)(w_0)$$

(23) English simple past, as applying to statives:

$$\llbracket \text{PAST} \rrbracket = \lambda w_0 \lambda t_0 \lambda p. \exists t. t < t_0, p(t)(w_0)$$

It follows from these assumptions that a stative clause in the present tense logically implies the corresponding sentence in the past tense, but not vice versa.

- (24) a. *Scotty is anxious* implies  
b. *Scotty was anxious*

(25)  $\llbracket (24a) \rrbracket = \exists t. t = t_0, \text{anxious}(\text{scotty})(t)(w_0)$ , assuming (21)

$$\vdash \exists t \exists t'. t = t_0, t' < t, \text{anxious}(\text{scotty})(t)(w_0), \text{anxious}(\text{scotty})(t')(w_0)$$

$$\vdash \exists t. t < t_0, \text{anxious}(\text{scotty})(t)(w_0) = \llbracket (24b) \rrbracket$$

This means that simple present and simple past in English are scalar alternatives. When an utterance is part of a set of scalar alternatives, it implicates the negation of its stronger alternatives. In the case of English tenses, the use of the simple past in a stative description can therefore give rise to the implicature that the prejacent is not true in the present. This same mechanism would not translate straightforwardly to the Daakaka data though, because of the difference between the Daakaka realis and the English present tense. If we only look at the purely temporal usage of the distal and realis markers for the moment, without considering counterfactuals and other modal environments, we might conclude that they only differ from English past and present in that the realis marker also applies to past events in addition to present ones. This idea is spelled out below:

<sup>4</sup>Here, I am glossing over the reference time concept, which ensures that the cessation implicature does not arise in contexts that are explicitly about the past as in the following context:

- (i) a. There was a book on the table.  
b. It was in Russian.

I am also glossing over the authors' assumption that tenseless clauses can be true at intervals, which would be compatible with the following slightly different formalization:

(ii)  $\llbracket \text{PRES} \rrbracket = \lambda w_0 \lambda t_0 \lambda p \lambda I. \exists t. t = t_0, p(I)(w_0), t \in I$

(26) Daakaka distal (first suggestion, to be rejected):

$$\llbracket \text{DIST} \rrbracket = \lambda w_0 \lambda t_0 \lambda p. \exists t. t < t_0, p(t)(w_0)$$

(27) Daakaka realis (first suggestion, to be modified):

$$\llbracket \text{REAL} \rrbracket = \lambda w_0 \lambda t_0 \lambda p. \exists t. t \leq t_0, p(t)(w_0)$$

Let us assume for a moment that these definitions were correct. Then, the distal and the realis would in fact form a scale, since the distal would imply the realis. But this means that the distal would be the stronger expression, the realis marker would be weaker. Therefore, using the distal would not generate an implicature via its contrast to the realis marker. So the above picture cannot be entirely correct. Furthermore, we have seen that the realis marker can refer to the actual past and present and essentially nothing else. Therefore, the definition in (27) cannot be too far off the mark. We will have to reconsider the definition of the distal marker instead.

We will see later on that the definition of the distal marker has to be extended to include also counterfactual developments. However, we cannot extend it to include the actual present. If we did, the realis marker would end up as the stronger alternative to the distal. But then we would no longer get a temporal contrast between the two and would no longer expect the distal to refer to the actual world at all. Therefore, the cessation implicature cannot be derived purely from a scalar contrast. The same problem is faced by Cable (2017), which is the second approach we are going to review.

## 5.2. Cable (2017)

At first glance, the approach by Cable (2017) does not appear to work for Daakaka because it is based on the assumption that the discontinuity interpretation is a consequence of the optionality of tense marking. Quoting from the abstract of Cable (2017):

I develop an account of the cessation inference in Tlingit, whereby it arises from the optionality of the past-tense marker in question. I argue that this account should be extended to all putative instances of “Discontinuous Past”, since it would capture the fact that putative cases of “Discontinuous Past” only ever arise in optional tense languages.

Daakaka is a straightforward counterexample to the above generalizations. The Daakaka TAM markers have modal and, to a lesser extent, aspectual implications as well as temporal ones. In that sense, it could be argued that they are not tense markers at all. However, the same goes for most markers that have been labeled as tense markers; thus, indicative tense forms in European languages have usually different modal implications from subjunctive ones. And markers from other languages that appear to have essentially the same modal-temporal interpretations as the realis marker have been labeled as non-future tense markers.

In short, Daakaka is a language that requires any finite clause to be marked by a morpheme from a small paradigm of TAM markers. And the meanings of these markers have temporal

implications as well as modal and, to a lesser extent, aspectual ones. Daakaka can therefore be said to have obligatory tense marking. It is definitely not an optional-tense language in the sense intended by Cable (2017).

However, a closer look reveals that Cable (2017) is still potentially relevant for the puzzle at hand. In fact, what is crucial for Cable (2017)'s analysis is not the optionality of tense marking, but the presence of a non-future tense that contrasts with the marker expressing discontinuous past. And the Daakaka realis marker may well be described as a marker of non-future tense – with the additional modal restriction to actual developments. It turns out that the facts reported by Cable (2017) for Tlingit appear very similar to Daakaka. There are two theoretical reasons why I will still not adopt Cable (2017)'s analysis here:

1. One of the pragmatic principles he assumes appear to directly contradict Gricean reasoning. As a result, the analysis predicts that speakers should choose the weakest possible tense marker, contradicting standard pragmatic reasoning according to which weaker expressions are blocked by their stronger alternatives.
2. If we adopt only the definitions for the distal and the realis (non-future) without the above pragmatic principles, we would predict that the realis, as the weaker alternative, should not be used whenever the distal can felicitously be used instead. This is however not the case.

Let us start with the second point, since it also directly builds on the observations we have made in the previous section. There, we have reviewed the following assumptions:

1. The realis marker refers to actual events of the past or present.
2. The distal marker refers to actual events of the past.

I have already foreshadowed that my analysis will abandon the second of these assumptions. If these assumptions were true, then the distal and the realis would be scalar alternatives, with the distal being the stronger alternative of the two. I have argued above that this setup cannot provide us with an explanation for the discontinuity reading in the style of Altshuler and Schwarzschild (2012), because the elements in this scale are in the wrong order: Altshuler and Schwarzschild (2012) can derive their cessation implicature because the present (in combination with statives) is the stronger element; but in our case, the past, or distal, is stronger.

Not only would this situation under standard pragmatic assumptions fail to get us the desired discontinuity implicature, however. It would also make false predictions. Thus, since you should always choose the strongest assertable candidate of a scale, it should be infelicitous to use the realis marker in a situation where the distal marker could also have been used. But we have seen that this happens without any restrictions. The relevant example pair is repeated below, showing the realis in a context that clearly supports a discontinuity inference:

- (10) *meerin nya ye mw=i bivian na mu vu ten*  
 long.time 3D 3D REAL=COP friend COMP REAL good very  
 “before, [the rat and the cat] used to be good friends” (0912)

- (11) *pus myane tomo, nya ye t=i bivian tu vu ten*  
 cat with rat 3D 3D DIST=COP friend DIST good very  
 “the cat and the rat, they used to be very good friends” (4597)

Furthermore, if the realis and the distal were true scalar alternatives, using the realis should in fact implicate the negation of the (stronger) utterance with the distal. In other words, the use of the realis should then have the implicature that something is the case in the present, but was not the case in the past. But this effect cannot be observed, as also illustrated by (10). The situation in Tlingit is virtually identical with respect to the considerations at hand, and yet Cable (2017) proposes that the discontinuity interpretation of the Tlingit past still pragmatically derives from its contrast to non-future tense. The key element in this proposal is the following pragmatic principle for production:

- (28) (Cable, 2017: (36)): Make the topic time as large as possible.

According to this principle, if you can possibly use an expression that covers both the speech time and a time prior to that, you should always do that. This would of course directly reverse the pragmatic defaults worked out so far. It would also seem to contradict the Gricean principle of Quantity, which has previously been assumed to operate also on the interpretation of tenses (Smith et al., 2007; Mucha, 2015).

It will remain to be seen which pragmatic principles guide the choice and interpretation of TAM markers cross-linguistically, and this is still a very new field with much left to discover. But this initial assessment should at least have convinced us that there is room for doubt when it comes to Cable (2017)’s assumption in (28). And that looking for an alternative approach may be worthwhile.

In sum, we have seen that a simple, elegant solution that merely appeals to scalar alternatives along the lines of Altshuler and Schwarzschild (2012) is not feasible for the Daakaka system. The same problem is faced by Cable (2017), who introduces a somewhat counterintuitive pragmatic principle to solve it. In the following section, I will propose an alternative route, which harnesses the power of established pragmatic principles by looking beyond the merely temporal meanings of the distal and taking into account its modal implications.

## 6. The modal dimension

### 6.1. Fundamental observations and assumptions

If we only take into account the purely temporal reference of the distal and realis markers, the distal would appear to have the narrower definition and be the stronger of two scalar alternatives. Given that, it would seem puzzling that its use has any implicatures at all. In this section, I will argue that the distal in fact has a much wider reference than the realis and they are not scalar alternatives. This becomes clear when we also take into account the modal dimension.

We have seen in section 4.2 that the distal not only refers to the discontinuous actual past. It is also the only option in the language to talk about counterfactual scenarios in the past and

present. And in the context of conditional and temporal clauses, it can also refer to future eventualities. The counterfactual use of the distal in particular is fairly typical cross-linguistically for markers of discontinuous past. As Plungian and van der Auwera (2006) write:

The use of the discontinuous past markers within hypothetical or counterfactual conditionals (the boundary between them is not always very neat, cf. Comrie 1986 and Athanasiadou and Dirven 1997 for more detail) is widely attested, including, as far as we can judge, almost all Creole and West African systems, witness Wolof (30a).

The relation between the past and the counterfactual has been observed early and explored by many, prominently including Fleischman (1989); Iatridou (2000), to name just two. I will here propose a new approach to this relation, whose implications go far beyond the scope of this paper. While I will not be able to explore all its logical constraints and consequences in this context, it will suffice to define and model the meaning of the distal including both its temporal and its modal dimensions and thus allow us to move forward with the analysis of the discontinuity interpretation.

The main ingredient for my analysis is the branching-times structure that is a very well-established tool for exploring the relation between time/tense and modality (e.g. Dowty, 1977; Thomason, 1984; Condoravdi, 2002; Laca, 2012; Ippolito, 2013).

My basic definition of the branching structure follows Thomason (1984):

- (29) Definition Branching Times: A branching-times frame  $\mathfrak{A}$  is a pair  $\langle I, < \rangle$ , where
- a.  $I$  is a non-empty set of indices  $i$ ;  $<$  is an ordering on  $I$  such that if  $i_1 < i$  and  $i_2 < i$ , then either  $i_1 = i_2$ , or  $i_1 < i_2$ , or  $i_2 < i_1$ .
  - b. A **branch** through  $i$  is a maximal linearly ordered subset of  $I$  containing  $i$ .
  - c. An index  $i_1$  is called a **predecessor** of  $i_2$  iff  $i_1 < i_2$ ; it is a **successor** of  $i_2$  iff  $i_2 < i_1$

I propose here a major theoretical innovation to this approach. Thomason (1984) and everyone else working with branching times, to the best of my knowledge, has only ever considered the definition in (29) as a way to define historical accessibility. This is why quantification over branching times has always been restricted to those branches that are identical up to the actual present. Thus, in the toy model represented in the following figure, if  $i_2$  is the actual present, then quantification is restricted to branches  $b_3, b_4$ .

It is also possible to quantify over all six branches  $b_1, \dots, b_6$ , if one shifts the perspective backwards to  $i_1$ . However, it is not possible to quantify exclusively over  $b_1, b_2, b_5, b_6$ , because from  $i_2$  they are not accessible at all, and from the perspective of  $i_1$  the precedence relation cannot distinguish them from  $b_3$  and  $b_4$ . The decision to restrict quantification in this way was originally well motivated, since the model was designed to define historical accessibility. However, I propose to not treat the branching structure itself as an accessibility relation but as an ordering relation on the set of indices that allows for the definition of various temporal-modal domains.

Figure 1: A branching-times structure. Relative to  $i_2$ , the solid line represents the actual past, the dashed lines the possible futures and the dotted lines counterfactual developments.

The precedence relation generates the following three-way distinction between modal-temporal domains relative to the contextually defined actual present  $i_c$ :

- (30) a. the actual (past or present):  $\{i | i \leq i_c\}$   
 b. the counterfactual (past, present or future):  $\{i | i \not\leq i_c, i_c \not\leq i\}$   
 c. the possible (future):  $\{i | i_c < i\}$

## 6.2. Definitions and derivation

I propose that natural language expressions can refer to any of the three domains in (30) to the exclusion of the others, as well as to subsets and combinations of them. We have seen that the distal can refer to all temporal-modal domains except for the actual present. The following definition captures this observation:<sup>5</sup>

- (31)  $\llbracket \text{DIST} \rrbracket^{g,c} = \lambda i : i \neq i_c . i$ , where  $i_c$  is the contextually defined actual present (by default the index of utterance).

We can now also take the definition of the realis in (27) and re-cast it in the newly developed terms:<sup>6</sup>

- (32)  $\llbracket \text{REAL} \rrbracket^{g,c} = \lambda i : i \leq i_c . i$

These definitions are illustrated in figure 2.

The definition of the distal is strongly reminiscent of Iatridou (2000)'s Exclusion Feature for English simple past. At the same time, its grounding in a branching-times structure makes it directly comparable to the realis marker. We can now see that the distal marker and the realis marker are not really scalar alternatives at all. Their meanings overlap, but neither fully

<sup>5</sup>I adopt the standard assumption that tense expressions place presuppositional restrictions on pronominal tenses, though nothing hinges on this decision at this point. I recommend Bochnak (2016) for a concise and recent overview.

<sup>6</sup>Also compare with the proposal by Krifka (2016) for the very similar realis marker in the neighbouring language Daakie.

Figure 2: The temporal modal domains of the realis marker (dashed outline) and the distal marker (solid outline).

includes the other. At the same time, we can see that the definition of the distal is much less restrictive. The distal marker is less informative than the realis marker. This is well in line with the observation that the default way to talk about the actual past is to use the realis marker, not the distal. Linking back to the previous discussion, we can still not operationalize a scalar contrast between the realis and the distal as in Altshuler and Schwarzschild (2012). But in contrast to Cable (2017) we can now see that the past (distal) marker is the less informative of the two and I suggest that we can get some leverage out of this difference for deriving the discontinuity interpretation.

To account for the interpretation of the distal, we will need to appeal both to an interpretation principle and to a production principle, just as Altshuler and Schwarzschild (2012) and Cable (2017) do. Altshuler and Schwarzschild (2012) could simply appeal to the Gricean maxim of Quantity. Cable (2017) posited the production principle cited in (28) to reverse the effects of the maxim of Quantity. With the definitions in (31) and (32), we can once again appeal to Quantity as the driving force behind the discontinuity interpretation. Even though the realis and the distal are not scalar alternatives, one is clearly more restrictive than the other. This difference in restrictiveness can be understood in at least two ways – in terms of the domains referred to and in terms of quantities of indices. Out of the three different domains identified in (30), the realis only includes one, while the distal cuts across all three. Quantities of indices are not trivially measured since I understand the branching-times structure as a concept the scope and granularity of which change dynamically and which contains potentially infinite numbers of indices. But to compare the distal with the realis, consider that in the domain of actual indices, the distal contains only a single index less than the realis. So in any situation that allows for more than a single moment of future and/or more than a single counterfactual index, the quantity of indices referred to by the realis is smaller than that referred to by the distal. For my proposal to be as concrete as possible, I suggest the following principle:

- (33) **Simplicity Principle of Production (SPP):** Always choose the TAM marker quantifying over the narrowest possible modal-temporal domain.

This principle is a straightforward extension of Gricean Quantity to TAM expressions and in direct contradiction to Cable (2017)'s principle in (28).

To derive the interpretation of the distal, I also need to adapt an interpretation principle that, by default, a TAM expression is understood to the world and time of utterance. In the context of tense semantics, a hierarchy of defaults has already been suggested in the literature:

- (34) **Simplicity Hierarchy of temporal references** (cf. Mucha 2015: 69, following Smith et al. 2007):  
present > past > future

I propose to extend this hierarchy to the modal dimension of TAM meanings in the following way:

- (35) **Simplicity Hierarchy of Modal-Temporal Domains:**  
actual present > actual past > possible futures > counterfactual past/present/futures

I can at this point not explore whether the counterfactual past, present and futures are internally ranked, or how this hierarchy might look. For our purposes, it should suffice to say that reference to counterfactual worlds is less preferred relative to reference to the actual past and present and to the possible futures.

With these definitions and principles in place, we can now walk through the pragmatic process that generates the discontinuity interpretation:

1. The speaker uses the distal marker.
2. Let us assume that nothing in the context suggests that counterfactual events are relevant.
3. By (35), the default interpretation for the distal marker is a reference to the actual past.
4. But if the speaker wants to talk about the actual past, she should just have used the realis, by principle (33).
5. Then, the violation of (33) triggers the discontinuity implicature.

Thus, by defining the modal implications of the distal marker in terms that make them directly comparable to the realis marker, we can operationalize the Gricean principle of Quantity to derive the discontinuity implicature.

## 7. Conclusion

The Daakaka distal matches the cross-linguistic criteria for a marker of discontinuous past. Contrary to the hypothesis by Plungian and van der Auwera (2006), its discontinuity reading is probably not lexically derived, but a pragmatic function of its contrast to the realis marker. Contrary to the generalization by Cable (2017), Daakaka is not an optional-tense language. I have argued that the discontinuity reading of the distal marker cannot derive from a scalar contrast to the realis marker and that in fact the implicature would be quite puzzling if we only take into account the temporal dimensions of its meaning. However, if we also consider its modal dimension, we can still appeal to the Gricean maxim of Quantity to derive the discontinuity implicature.

# Saving monotonic modals with ranked ordering sources<sup>1</sup>

Dee Ann REISINGER — *Johns Hopkins University*

**Abstract.** In this paper, I argue that Jackson (1985)’s Professor Procrastinate (PrP) problem is not inconsistent with a quantificational semantics for deontic modals. In particular, the apparent inability to infer *ought*( $\phi$ ) from *ought*( $\phi \wedge \psi$ ) is because the modals in the two sentences are interpreted with respect to two distinct ordering sources, and these contexts differ in the relative ranking that they assign to different priorities. I show how formalisms for modeling contextual priority rankings—particularly the ordered merging operation (Katz et al., 2012) and ranked ordering sources (Reisinger, 2016)—account for the PrP problem and argue that ranked ordering sources better account for priority-sensitive modals in embedded contexts.

**Keywords:** modality, ordering semantics, monotonicity.

## 1. Introduction

The main data point I consider in this paper is the Professor Procrastinate (PrP) problem, raised by Jackson (1985) to argue against the distributivity of *ought* over conjunction in deontic logic. The problem takes place in the following scenario.<sup>2</sup>

Professor Procrastinate is the leading researcher in her field, and accordingly she has been invited to review a book on that topic. A review written by Prof. Procrastinate will be significantly more valuable to the scholarly community than one written by anyone else. Unfortunately, she has a habit of putting off her work, and if she accepts the invitation, she is extremely unlikely to finish the review on time. If she declines, then the editor will find someone else to write the review, and this would be a better outcome than no review at all.

In this scenario, Jackson judges (1) to be true and (2) to be false.

- (1) Prof. Procrastinate ought to accept and write the review.
- (2) Prof. Procrastinate ought to accept.

On this basis, he argues that the inference from *ought*( $\phi \wedge \psi$ ) to *ought*( $\phi$ ) is invalid, where in this case  $\phi$  is *Prof. Procrastinate accepts* and  $\psi$  is *Prof. Procrastinate writes the review*. Lassiter (2011) moves this problem from deontic logic to natural language semantics as part of his argument that deontic modals are not upward monotonic. This is a critical argument against a standard quantificational semantics for modals, which predicts that modals are upward monotonic, but the argument only goes through if the modals in (1) and (2) quantify over the same set of possible worlds, which in Kratzer (1991)’s semantics corresponds to interpretation

---

<sup>1</sup>I want to thank Kyle Rawlins, Aaron Steven White, Justin Bledin, Paul Smolensky, and Daniel Lassiter for their suggestions, feedback, and encouragement at various stages of this project.

<sup>2</sup>This version of the PrP scenario is based more closely on Lassiter (2011)’s presentation, which, along with Jackson and Pargetter (1986), simplifies the original description of the PrP problem from Jackson (1985).

with respect to the same conversational backgrounds. I will argue in this paper that these sentences are interpreted under two different *ordering sources*, and that these ordering sources encode different relative rankings of priorities. Hence, the PrP problem is consistent with a quantificational modal semantics that can encode this contextual priority ranking difference.

I begin in Section 2 by reviewing the PrP problem in more detail, and in Section 3 I outline how the problem challenges standard quantificational accounts of modality. In Section 4, I present a solution to the PrP problem in which (1) and (2) are interpreted under ordering sources encoding different priority rankings. This solution motivates comparing different formalisms for encoding priority rankings, and hence I show in Section 5 that an embedded modification of the PrP problem supports Reisinger (2016)'s *ranked ordering source* account over the *ordered merging operation* from Katz et al. (2012). Finally, in Section 6, I consider additional data with implications for how contextual priorities are encoded and suggest applications of priority ranking formalisms to other questions in modal semantics.

## 2. The Professor Procrastinate problem

First, I take a closer look at the readings of the PrP problem sentences (1) and (2) in this scenario. Recall that the three possible outcomes in the PrP scenario, in decreasing order of desirability, are

- that Prof. Procrastinate accepts the invite and, against all odds, actually writes the review;
- that she declines the invite, and someone else writes the review; and
- that she accepts the invite and fails to write the review.

Furthermore, if she accepts the invite, it is much more likely that she will not write the review than that she will. In this scenario, Jackson (1985) judges (1) to be true. This intuition is straightforward, as accepting the invitation and writing the review leads to the most desirable outcome. To understand why he judges (2) to be false, we need to remember that by far the most likely consequence of accepting the invite is that no review gets written—the *least* desirable outcome—even though accepting is also a prerequisite for the *most* desirable outcome.

This is not the only reading for (2), however. One could also judge the sentence to be true if one also holds Prof. Procrastinate responsible for overcoming her procrastination habit. This contrast is clarified by the continuations in (3)

- (3)    a.    Prof. Procrastinate ought not to accept. If she does, she almost certainly won't write the review. (Jackson's intended reading)  
           b.    Prof. Procrastinate ought to accept. And she better actually write the review if she does!

Hence, the PrP problem places at least two empirical constraints on a theory of natural language modals. First, the theory must account for both the truth of (1) and the falsity of (2); I show

in the next section that this constraint is not trivial to satisfy with a standard quantificational modal semantics. Second, it should be flexible enough to allow both readings in (3).

### 3. The challenge for quantificational semantics

In this section, I review why, as Lassiter (2011) points out, the PrP problem challenges standard quantificational accounts of modality and outline how that challenge can be resolved.

First, recall the doubly relative modal semantics developed by Kratzer (1981, 1991), in which a modal expression is evaluated with respect to a pair of *conversational backgrounds*—functions from possible worlds to sets of propositions—supplied by context. One conversational background is the *modal base*, commonly denoted by  $f$ , which maps a world  $w$  to a set of relevant facts or body of information in  $w$ . The other is the *ordering source*, denoted by  $g$ , which maps  $w$  to a set of norms, desires, laws, goals, or so on, depending on the type of ordering source. The denotation of a necessity<sup>3</sup> modal like *ought* is given in (4).

$$(4) \quad \llbracket \text{ought} \rrbracket^{w@,f,g} = \lambda p_{\langle s,t \rangle} . \forall w \in \max_{g(w@)} (\cap f(w@)) : p(w)$$

In this denotation,  $\max_P(W)$  denotes the maximal worlds in  $W$  according to the preorder  $\leq_P$ , which ranks a world  $u$  above another world  $v$  if every proposition in  $P$  satisfied by  $v$  is also satisfied by  $u$ :

$$(5) \quad v \leq_P u \text{ iff } \forall p \in P : p(v) \rightarrow p(u)$$

What is important for the current discussion is that the truth of  $\llbracket \text{ought} \rrbracket^{w@,f,g}(p)$  depends on whether  $p$  holds throughout a contextually determined domain of quantification that depends on the world of evaluation  $w@$  and the conversational backgrounds  $f$  and  $g$ . This is enough to show that the modal semantics in (4) is upward monotonic in its prejacent. That is, if  $p$  and  $q$  are propositions such that  $p \subseteq q$ , then  $\llbracket \text{ought} \rrbracket^{f,g}(p)$  implies  $\llbracket \text{ought} \rrbracket^{f,g}(q)$ . For if all worlds in the domain of quantification are in  $p$ , then by assumption they are also in  $q$ . Because  $p \wedge q \subseteq p$  for any  $p$  and  $q$ , distribution over conjunction follows as a special case of monotonicity. Thus, *assuming a fixed choice of conversational backgrounds*, this semantics cannot account for the simultaneous truth of (1) and falsity of (2), which are reproduced as (6) and (7), respectively.

(6) Prof. Procrastinate ought to accept and write the review.

(7) Prof. Procrastinate ought to accept.

One reaction to this problem is to adopt a modal semantics that does not license monotonic inferences. For example, Lassiter (2011) proposes a scalar semantics for deontic and bouletic modals in which  $\text{ought}(p)$  is true if, given some probability measure on propositions and a utility random variable, the expected utility conditioned on  $p$  being true exceeds a contextually provided threshold. Such a semantics is non-monotonic in either direction. In particular, the expected utility conditioned on some  $p \wedge q$  may exceed a threshold even if the expected utility

<sup>3</sup>For now, I gloss over the distinction between weak and strong necessity modals.

conditioned on  $p$  alone does not if the worlds in  $p \wedge \neg q$  have sufficiently low utility and high probability.

An alternative strategy, which I pursue in this paper, is to argue that the contextual parameters used to interpret (6) and (7) are not actually the same. If the two sentences are interpreted under different conversational backgrounds, then their modal quantification domains will also generally differ, and hence there is no reason to expect any particular logical relation between them to hold.

Nevertheless, if there is a difference in contextual parameters used to interpret (6) and (7), it is not obvious what that difference is. If the modal bases differ, then there should be a difference in the relevant facts or body of information used to interpret the sentences. If the ordering sources differ, then some criteria by which an outcome is judged to be desirable, morally good, or legally permissible must differ. Thus, the burden falls on the proponent of this solution to explicitly describe this contextual difference; I do this in the next section.

#### 4. Solving the problem with priority ranking

I now propose a solution to the PrP problem that relies on what I will call *priority rankings* on ordering sources. First, I lay out a simple model of the PrP scenario and establish some notation for the rest of the paper. Next, I motivate the concept of priority rankings and show how it solves the PrP problem by blocking the inference from (6) to (7) with their intended readings. I then discuss a couple of ways to implement it formally in a quantificational modal semantics.

##### 4.1. A model of the PrP scenario

Let *Accept* be the proposition that Prof. Procrastinate accepts the invitation to write the review, let *ProfWrite* be the proposition that she writes the review, and let *OtherWrite* be the proposition that someone else writes the review. Additionally, let *Focused* be the proposition that Prof. Procrastinate is in the right state of mind, is sufficiently organized, and so on such that she would be able to complete the review if she accepted the invitation.

These propositions are sufficient to characterize the possible outcomes in the PrP scenario as well as their causes. For example, we can capture that someone else will write the review exactly if Prof. Procrastinate rejects the invite ( $OtherWrite \leftrightarrow \neg Accept$ ), that the outcome of accepting the invitation depends on whether she procrastinates or not ( $Accept \rightarrow (ProfWrite \leftrightarrow Focused)$ ), and so on. These background facts that are relevant to interpreting the modals in (6) and (7) are captured by the modal base  $f$ , which should contain these propositions when evaluated at the actual world.

These propositions are also sufficient to define certain orderings on possible worlds that are relevant to the PrP scenario. One such ordering, which I denote  $\leq_{DES}$ , captures the relative goodness or desirability of worlds. In this case, the worlds in which Prof. Procrastinate writes

the review are ranked above those in which someone else writes the review, which in turn are ranked above those in which no one writes the review. Note that these outcomes exhaust all possibilities given the modal base.

$$(8) \quad \neg \text{ProfWrite} \wedge \neg \text{OtherWrite} <_{DES} \text{OtherWrite} <_{DES} \text{ProfWrite}$$

Another, simpler ordering  $\leq_{LH}$  captures the relative likelihood of events. In particular, given Prof. Procrastinate's poor work habits, it is more likely that she is not focused than that she is:

$$(9) \quad \text{Focused} <_{LH} \neg \text{Focused}$$

Both of these orderings will need to be derived from appropriate ordering sources, but I leave these details to Section 4.3.

Note also that the valuation of every proposition in this scenario is completely characterized by the valuations of *Accept* and *Focused*. That is, knowing whether each of these two propositions is true in a world is enough to know the truth value of every relevant proposition in that world. Thus, there are four relevant equivalence classes of possible worlds, which I will denote  $AF$ ,  $\neg AF$ ,  $A\neg F$ , and  $\neg A\neg F$ . This model is summarized in Table 1.

| World          | <i>ProfWrite</i> | <i>OtherWrite</i> | <i>DES</i> rank | <i>LH</i> rank |
|----------------|------------------|-------------------|-----------------|----------------|
| $AF$           | ✓                | ✗                 | 3               | 1              |
| $\neg AF$      | ✗                | ✓                 | 2               | 1              |
| $A\neg F$      | ✗                | ✗                 | 1               | 2              |
| $\neg A\neg F$ | ✗                | ✓                 | 2               | 2              |

Table 1: The equivalence classes of possible worlds in the PrP scenario. The first three columns give the valuations of all relevant propositions in the model, and the last two give the rankings of the equivalence classes according to the orders  $\leq_{DES}$  and  $\leq_{LH}$  where higher ranks are more desirable or likely, respectively.

#### 4.2. The concept of priority ranking

One way to characterize the intuitive challenge of the PrP scenario is that it puts two competing sets of priorities or constraints into conflict. In this case, the constraint that outcomes be as desirable as possible conflicts with the constraint that outcomes be realistic or attainable. If this conflict is resolved in different ways, then the outcomes that best satisfy the competing constraints will also change. In particular, if a modal's domain of quantification depends on how such a conflict is resolved, then its truth conditions will also depend on that resolution.

This intuition motivates the concept of *priority ranking* in the interpretation of modals. At a high level, if two potentially conflicting priorities are used to compute the set of maximal possible worlds in a modal's domain of quantification, then we defer to the higher-ranked priority when the two priorities conflict. More formally, since the Kratzer's modal semantics makes use

of preorders over possible worlds, suppose that we have two such preorders  $\leq_A$  and  $\leq_B$ . Then using the order  $\leq_{A*B}$  defined in (10) corresponds to ranking  $\leq_A$  over  $\leq_B$ .<sup>4</sup>

$$(10) \quad u \leq_{A*B} v \text{ iff } u <_A v \text{ or } (u \cong_A v \text{ and } u \leq_B v)$$

That is,  $\leq_{A*B}$  orders worlds by first consulting  $\leq_A$  and then only falling back to  $\leq_B$  if  $\leq_A$  is indifferent. To see how priority rankings help us solve the PrP problem, first consider the possible rankings of  $\leq_{DES}$  and  $\leq_{LH}$  from the previous section. These orders are summarized in Figure 1.

Figure 1: The orders  $\leq_{DES}$  and  $\leq_{LH}$  along with their possible priority rankings.

In all of the optimal worlds under  $\leq_{DES*LH}$  (and in fact under  $\leq_{DES}$ ), Prof. Procrastinate accepts the invitation and writes the review. In all of the optimal worlds under  $\leq_{LH*DES}$ , Prof. Procrastinate does not accept the invitation. Thus, if the modals in (11) and (12) are interpreted using the world orderings  $\leq_{DES*LH}$  and  $\leq_{LH*DES}$ , respectively, we recover Jackson's judgments on these sentences despite using a quantificational semantics for *ought*.

(11) Prof. Procrastinate ought to accept and write the review.

(12) Prof. Procrastinate ought to accept.

Additionally, priority rankings neatly account for the different readings in (13) that were pointed out in Section 2. In particular, the first sentence in (13a) is true under the ordering  $\leq_{LH*DES}$ , and the one in (13b) is true under  $\leq_{DES*LH}$  (or in fact under  $\leq_{DES}$ ).

- (13) a. Prof. Procrastinate ought not to accept. If she does, she almost certainly won't write the review.  
 b. Prof. Procrastinate ought to accept. And she better actually write the review if she does!

Not only does a priority ranking account have the formal degrees of freedom to account for both of these readings, but it does so in a way that reflects the intuitive difference between them. In particular, the reasoning that would cause someone to utter (13a) places high weight on the likelihood that desirable outcomes actually occur ( $\leq_{LH*DES}$ ), and the rationale for (13b) must

<sup>4</sup>Here I use  $u \cong_A v$  as an abbreviation for  $u \leq_A v$  and  $v \leq_A u$ . In the special case where  $\leq_A$  is a *partial* order,  $u \cong_A v$  reduces to  $u = v$ .

be willing to overlook ( $\leq_{DES* LH}$ ) or even disregard ( $\leq_{DES}$ ) the low probability of a desirable outcome. Thus, a priority-ranking-based account can meet both of the empirical challenges raised by the PrP problem.

### 4.3. Implementing priority rankings in Kratzer's semantics

In the preceding discussion, I have shown how a Kratzerian modal semantics that has access to the priority ranking preorders  $\leq_{LH*DES}$  and  $\leq_{DES*LH}$  can account for the PrP problem. Nevertheless, in Kratzer's semantics, modals are not directly parametrized by a preorder over possible worlds. Rather, a world preorder is derived from an ordering source as described in Section 3. Thus, in this section, I review formalisms from Katz et al. (2012) and Reisinger (2016) that derive priority ranking preorders from conversational backgrounds and show how they model the PrP scenario.

#### 4.3.1. Ordered merging

The first of these formalisms is the *ordered merging operation* from Katz et al. (2012), the first proposed formalism for implementing priority rankings over ordering sources in a Kratzerian semantics. The operation, denoted by  $*$ , is a binary operation on sets of propositions with the following property: If  $P$  and  $Q$  are sets of propositions that induce preorders  $\leq_P$  and  $\leq_Q$ , then  $P * Q$  is a set of propositions that induces the preorder  $\leq_{P*Q}$  that ranks  $\leq_P$  over  $\leq_Q$ . For completeness, the definition of  $*$  is in (14), though the preceding property of  $*$  is enough for the current discussion.

$$(14) \quad P * Q = \\ P \cup \{q \wedge \bigwedge P \mid q \in Q\} \cup \{q \vee \bigvee P \mid q \in Q\} \cup \{(q \wedge P_n) \vee P_{n+1} \mid 0 < n < |P|, q \in Q\} \\ \text{where } P_k = \bigvee_{\substack{R \subseteq P \\ |R|=k}} \bigwedge R$$

The operation is extended from sets of propositions to ordering sources in the natural way:  $(g_1 * g_2)(w) = g_1(w) * g_2(w)$ .

To see how this operation applies to the PrP problem, I define two ordering sources,  $g_{DES}$  and  $g_{LH}$ , that induce the orders  $\leq_{DES}$  and  $\leq_{LH}$  when evaluated at  $w_@$ .

$$(15) \quad g_{DES}(w_@) = \{ProfWrite, \neg ProfWrite \rightarrow OtherWrite\} \\ g_{LH}(w_@) = \{\neg F\}$$

After some work, we can compute the ordered merge of these sets of propositions:<sup>5</sup>

$$(16) \quad g_{LH}(w_@) * g_{DES}(w_@) = \{\neg F, P \wedge \neg F, P \vee \neg F, (\neg P \rightarrow O) \wedge \neg F\}$$

Indeed, the order that  $g_{LH} * g_{DES}$  induces is exactly  $\leq_{LH*DES}$  from the previous section. Similarly,  $\leq_{DES*LH}$  is induced by  $g_{DES} * g_{LH}$ , which is computed below.

<sup>5</sup>*ProfWrite* is abbreviated *P*, and *OtherWrite* is abbreviated *O*

$$(17) \quad g_{DES}(w@) * g_{LH}(w@) = \{P, \neg P \rightarrow O, \neg F \wedge P, \neg F \vee P \vee O, P \vee (\neg F \wedge O)\}$$

Thus, the ordered merging operation can account for each of the PrP problem readings by using the ordering source  $g_{LH} * g_{DES}$  or  $g_{DES} * g_{LH}$  as appropriate.

#### 4.3.2. Ranked ordering sources

An alternative formalism that captures priority rankings is Reisinger (2016)'s *ranked ordering sources*. In contrast to the ordered merging operation previously described, which involves no modification to Kratzer's semantics, ranked ordering sources require minor changes to the way ordering sources induce preorders on possible worlds.

In particular, ranked ordering sources are functions from possible worlds to *partially ordered* sets (posets) of propositions. Equivalently, they can be thought of as pairs  $(g, \prec)$ , where  $g$  is a conventional (unordered) conversational background, and  $\prec$  is a function that maps  $w$  to a partial order on the set of propositions  $g(w)$ . For any two propositions  $p, q \in g(w)$ , the statement  $p \prec_w q$  can be read as “ $q$  has higher priority than  $p$ .” When discussing ranked ordering sources, the term *priority order* will refer to the ordering  $\prec$ .

Intuitively, propositions ranked higher by the priority order have greater weight in determining the preorder on possible worlds. This intuition is formalized in (18).<sup>6</sup>

$$(18) \quad u \leq_{P, \prec} v \text{ iff } \forall p \in P : (p(u) \wedge \neg p(v)) \rightarrow (\exists q \in P : q(v) \wedge \neg q(u) \wedge p \preceq q)$$

That is, for each ordering source proposition  $p$  that would rank  $u$  above  $v$ , there is another proposition  $q$  that ranks  $v$  above  $u$  and that has higher priority than  $p$ .

With these definitions, it is simple to specify a model of the PrP scenario. Let  $g_{LH}(w@)$  be defined as before (with a trivial priority order), and let  $g_{DES}(w@) = \{ProfWrite, OtherWrite\}$ , where  $OtherWrite \prec_{w@} ProfWrite$ ; note that this captures the fact that *ProfWrite* is a better outcome than *OtherWrite* using the partial order structure of  $g_{DES}$ , whereas the previous formalism had to do so using a material conditional. As before,  $g_{LH}(w@)$  and  $g_{DES}(w@)$  induce the preorders  $\leq_{LH}$  and  $\leq_{DES}$ , respectively, via the order defined in (18).

To derive priority rankings on ranked ordering sources, Reisinger (2016) introduces the priority join operation  $\sqcup$ , which can be thought of as an extension of the ordered merge operation  $*$  to partially ordered sets. Given two ranked ordering sources  $(g, \prec)$  and  $(h, \prec')$ , their priority join  $(g, \prec) \sqcup (h, \prec')$  is  $(g \cup h, \prec^\sqcup)$ , where  $\prec^\sqcup$  is defined in (19) and where the  $\min_w$  and  $\max_w$  operators compute which of a pair of ordering sources has lower or higher priority ranking in a given possible world  $w$ .<sup>7</sup>

<sup>6</sup>In the special case where  $\prec$  is a total order, then computing the maximal worlds under  $\leq_{P, \prec}$  is equivalent to optimization in the sense of Optimality Theory (Prince and Smolensky, 2008), where the output candidates are possible worlds, and the constraints are the propositions in  $P$  ordered by  $\prec$ .

<sup>7</sup>This formulation of the priority join differs slightly from the one in Reisinger (2016), where the join takes a third contextual parameter determining the priority ranking at each possible world. In the current formulation, these priority rankings are assumed to be specified by each possible world.

$$(19) \quad p \prec_w^{\sqcup} q \text{ iff } p, q \in g_{\max}(w) \text{ and } p \prec_w^{\max} q \text{ or} \\ q \in g_{\max}(w) \text{ and } p \in g_{\min}(w) - g_{\max}(w) \text{ or} \\ p, q \in g_{\min}(w) - g_{\max}(w) \text{ and } p \prec_w^{\min} q$$

$$\text{where } (g_{\min}, \prec^{\min}) = \min_w((g, \prec), (h, \prec')) \text{ and} \\ (g_{\max}, \prec^{\max}) = \max_w((g, \prec), (h, \prec'))$$

That is, there are two ways for  $p$  to have lower priority than  $q$ . The first and third clauses say that if  $p$  has lower priority than  $q$  in either of the operand ordering sources, then it also has lower priority in the join. The second clause says that  $p$  has lower priority than  $q$  if  $p$  and  $q$  are members of the lower and higher priority ranked operands, respectively. Intuitively, the join  $(g, \prec) \sqcup (h, \prec')$  “glues” one of the partial orders on top of the other, depending on which ordering source has higher priority in a given world.

To see how this applies to the PrP problem, let  $g = g_{LH} \sqcup g_{DES}$ . If  $g_{LH}$  has higher priority than  $g_{DES}$  in  $w@$ —that is, if  $\max_{w@}(g_{LH}, g_{DES}) = g_{LH}$ —then  $g(w@)$  has the following priority order:  $OtherWrite \prec_w ProfWrite \prec_w \neg F$ . The reader can check that this ranked ordering source induces the preorder  $\leq_{LH*DES}$ . Alternatively, in a world  $w$  where  $g_{DES}$  has higher priority, the priority order is  $\neg F \prec_{w@} OtherWrite \prec_{w@} ProfWrite$ , and in this case  $g(w)$  induces the preorder  $\leq_{DES*LH}$ . In both cases, the priority relation within  $g_{DES}$  is left intact. This join is represented schematically in Figure 2.

$$(\leq_{LH}) \quad (\leq_{DES}) \quad (\leq_{LH*DES}) \quad (\leq_{DES*LH})$$

$$\neg F \quad \sqcup \quad \begin{array}{c} P \\ | \\ O \end{array} = \begin{array}{c} \neg F \\ | \\ P \\ | \\ O \end{array} \quad \text{or} \quad \begin{array}{c} P \\ | \\ O \\ | \\ \neg F \end{array}$$

Figure 2: Possible values of the priority join  $(g_{LH} \sqcup g_{DES})(w@)$ , depending on the priority ranking of  $g_{LH}$  and  $g_{DES}$  at  $w@$ . In parentheses above each poset of propositions is the world preorder that it induces.

Thus, ranked ordering sources and the priority join operation, like the ordered merging operation in the previous section, are a way to implement a priority ranking solution to the PrP problem in Kratzer’s modal semantics. In the next section, I discuss some differences between these two formalisms.

## 5. Priority rankings in embedded contexts

Many of the differences between the ordered merging and ranked ordering source implementations of priority rankings are purely formal. For example, the ordered merge operation implements priority rankings without any modification to Kratzer’s ordering semantics, whereas ranked ordering sources capture priority rankings with intuitively transparent formal represen-

tations; compare the priority joins in Figure 2 with the merged ordering sources in (16) and (17).

Nevertheless, there is at least one difference that has empirical consequences. In an ordered merging account, the priority ranking is fixed by the choice of ordering source, which in turn is presumably determined by the context of utterance. For example,  $g_{LH} * g_{DES}$  and  $g_{DES} * g_{LH}$  are two different ordering sources that encode two different priority rankings relating  $g_{LH}$  and  $g_{DES}$ . In contrast, the priority join  $g_{LH} \sqcup g_{DES}$  allows the priority ranking to vary with the world of evaluation. This difference is significant in sentences like (20), where a priority-sensitive modal (*ought*) is in an embedded context that shifts the world of evaluation (the complement of *thinks*).

(20) Prof. Procrastinate ought not to accept, but Kat thinks that she ought to.

In particular, (20) has a reading under which Kat and the speaker agree on the facts behind the PrP scenario, including the relative likelihood and utility of outcomes, but differ in the kind of moral reasoning used to determine what Prof. Procrastinate should do. In other words, (20) can entail that the speaker and Kat disagree on how to prioritize the outcome feasibility and desirability.

The ordered merging account in Section 4.3.1 does not predict that (20) has this reading. I assume here that *think* has the standard neo-Hintikka denotation in (21), where  $Dox_x(w@)$  is the set of worlds doxastically accessible from  $w@$  by entity  $x$ .

(21)  $\llbracket \text{think} \rrbracket^{f,g,w@} = \lambda p_{\langle s,t \rangle} . \lambda x_e . \forall w \in Dox_x(w@) : p(w)$

We can model the fact that Kat and the speaker agree on the relevant facts of the PrP scenario with the conditions in (22), that the modal base, likelihood ordering source, and desirability ordering source all have the same values in Kat's doxastically accessible worlds as in the world of evaluation.

(22)  $\forall w \in Dox_{Kat}(w@) :$   
 a.  $f(w) = f(w@)$   
 b.  $g_{LH}(w) = g_{LH}(w@)$   
 c.  $g_{DES}(w) = g_{DES}(w@)$

From this it follows that  $(g_{LH} * g_{DES})(w)$  and  $(g_{DES} * g_{LH})(w)$  agree with their values at  $w@$  for all  $w$  in  $Dox_{Kat}(w@)$ , and hence the domains of quantification for both instances of *ought* in (20) are the same. Thus, this account predicts that (20) is a contradiction regardless of which priority ranking is used to interpret it, since the first conjunct requires all worlds in the domain of quantification to be  $\neg A$  worlds while the second requires them to be  $A$  worlds.

In contrast, a ranked ordering source account makes no such prediction. In particular, suppose that  $g_{LH}$  has higher priority than  $g_{DES}$  in  $w@$  and that the reverse is true for each  $w$  in  $Dox_{Kat}(w@)$ . Then  $g_{LH} \sqcup g_{DES}$  induces the preorder  $\leq_{LH*DES}$  (with maximal worlds  $\neg A \neg F$ ) at

$w@$  and  $\leq_{DES* LH}$  (with maximal worlds  $AF$ ) within  $Dox_{Kat}(w@)$ , and hence both conjuncts of (20) are predicted to be true under the priority join.

Thus, on the basis of sentences like (20), I argue that we need accounts of priority rankings that, like ranked ordering sources, allow relative priority to vary with the world of evaluation.

## 6. Further implications and future directions

In this section, I begin by pointing out additional empirical and theoretical consequences of the priority ranking solutions to the PrP problem, particularly in comparison to non-monotonic alternatives, by focusing on the possible readings of *ought*(*Accept*), which has been taken by Jackson (1985) and others in the literature to be false. I then conclude by drawing connections between priority rankings and a variety of related topics in the modality literature for further investigation.

### 6.1. Revisiting Jackson's judgment

First, I claim that Lassiter (2011)'s scalar semantics for deontic modals alluded to in Section 3 accounts for the possible readings of (23) very differently from either of the quantificational priority ranking analyses.

(23) Prof. Procrastinate ought to accept.

A simplified version of Lassiter's semantics for *ought* is given in (24), where I use  $\mathbb{E}(p)$  to denote the expected utility conditioned on a proposition  $p$  given some probability and utility functions on possible worlds and  $\theta$  is a contextually determined threshold.

(24)  $\llbracket \text{ought} \rrbracket^\theta = \lambda p_{\langle s, t \rangle} . \mathbb{E}(p) \geq \theta$

Even in this form, there are clear differences between the scalar and priority ranking accounts for (23). First, since the PrP scenario is reasonably modeled by assuming at least that  $\mathbb{E}(\text{Accept} \wedge \text{ProfWrite}) > \mathbb{E}(\text{Accept})$ , there are three different regimes that  $\theta$  can fall in. If  $\theta \leq \mathbb{E}(\text{Accept})$ , then both *ought*(*Accept*) and *ought*(*Accept*  $\wedge$  *ProfWrite*) are true, and if  $\theta > \mathbb{E}(\text{Accept} \wedge \text{ProfWrite})$ , both *ought* statements are false. Finally, if  $\theta$  is between these two expected utility values, then *ought*(*Accept*  $\wedge$  *ProfWrite*) is true while *ought*(*Accept*) is false, exactly as judged by Jackson (1985).

Thus, the only way for someone to judge (23) as true is that the standard for things one ought to do,  $\theta$ , be sufficiently low, assuming that person correctly understands the PrP scenario. In contrast, under a priority ranking account, (23) can be judged true by someone who uses a different (perhaps normatively irrational) mode of moral reasoning that discounts the role of outcome plausibility.

Lassiter also posits additional conditions on the threshold  $\theta$  in order to, among other goals, differentiate between strong necessity, weak necessity, and possibility modals in a scalar framework. For weak necessity modals like *ought*,  $\theta$  must be significantly greater than the expected utility of some set of relevant alternatives to the prejacent. In the case of (23), the relevant alternative is  $\neg\textit{Accept}$ . But since  $\mathbb{E}(\textit{Accept}) < \mathbb{E}(\neg\textit{Accept})$  in the PrP scenario, this implies that any  $\theta$  low enough to make (23) true will also violate this constraint. Thus, this stronger version of Lassiter's analysis predicts that (23) *cannot* be judged true by a competent speaker of English who correctly understands the PrP scenario.

These distinct analyses of (23) are difficult to distinguish empirically as it is difficult to ensure that an informant has a correct understanding of the scenario. Nevertheless, I suspect that an account that requires (23) to be false in the PrP scenario *for semantic reasons* too strongly encodes rational norms of decision making under uncertainty into the meaning of natural language modals.

Additionally, the ordered merging and ranked ordering source accounts tell slightly different stories about the conditions under which (23) can be judged true. Using the ordered merging operation, there are two possible merged ordering sources that encode two possible priority rankings,  $g_{LH} * g_{DES}$  and  $g_{DES} * g_{LH}$ , and (23) is false under the former and true under the latter. Using the priority join operation, however, there is only a single ordering source,  $g_{LH} \sqcup g_{DES}$ , that encodes a priority ranking relation between likelihood and desirability, and whether the sentence is true or not depends on which priority ranking holds in the world of evaluation (although note that the sentence is true under  $g_{DES}$  alone). This difference is subtle, but it bears on disagreement data like the dialogue in (25), where I assume A and B are both speakers who agree on the likelihood and desirability of outcomes in the PrP problem.

- (25) A: Prof. Procrastinate ought to accept the invitation, right?  
 B: No! She really ought not to. She wouldn't write the review if she did.

If the difference between A's and B's position is just a matter of which ordering source is used to interpret the modal, as it would be using the ordered merging account, then this disagreement is odd, as A and B are asserting two mutually compatible propositions. On the other hand, under a priority join analysis, A and B disagree about whether *ought*(*Accept*) is true under the ordering source  $g_{LH} \sqcup g_{DES}$ . That is, since the priority ranking between  $g_{LH}$  and  $g_{DES}$  is a matter of fact in a given possible world, A and B can debate which kind of world they are actually in. Thus, to the extent that a dialogue like (25) can occur without some kind of misunderstanding between the participants, I argue that the priority join is a better model of this kind of disagreement.

## 6.2. Priority rankings in other domains

Although in this paper and in Reisinger (2016), I have primarily motivated priority rankings through the study of deontic modals under conditions of uncertainty, there are a variety of other topics in modal semantics where formalisms similar to priority rankings have been applied or where they are likely to be appropriate.

One such topic, which was one of the motivations for the ordered merging operation in Katz et al. (2012) as well as one of Lassiter (2011)'s main empirical targets, is the study of gradable modal expressions, such as modal expressions appearing with degree modifiers or in comparative constructions. In a ranked ordering source framework, it is tempting to paraphrase a sentence like (26a) with an expression like (26b), where  $\prec$  is the priority order for a deontic ordering source.

- (26) a. It is more illegal to commit murder than to jaywalk.  
 b.  $\lambda w_s. \neg \text{Jaywalk} \prec_w \neg \text{Murder}$

Thus, it may be desirable for a modal degree semantics that makes use of ordering sources, such as the one proposed by Portner and Rubinstein (2016), to be consistent with such priority order paraphrases (or vice versa).

Additionally, similar formalisms in which multiple ordering sources contribute to a modal domain of quantification with different degrees of priority have been proposed to model other phenomena. For example, von Stechow and Iatridou (2008) explain why weak necessity modals are logically weaker than strong necessity modals in terms of an additional ordering source, called a *secondary* ordering source, that is used to further winnow down a weak necessity modal's domain of quantification after the primary ordering source has already been applied. This is equivalent to optimizing under a priority ranked pair of ordering sources in which the primary ordering source is ranked above the secondary. Furthermore, Rubinstein (2012) shows that the difference between primary and secondary ordering sources corresponds to a difference in discourse commitments by conversational participants. In particular, primary ordering sources are those that are collectively committed to by all participants, whereas secondary ordering sources may only be committed to by the speaker. Thus, if the primary/secondary distinction can be modeled using priority rankings, it is natural to wonder whether similar discourse constraints apply to priority rankings more generally.

## 7. Conclusion

In this paper, I have addressed a potent objection to a quantificational semantics for natural language modals raised by the Professor Procrastinate problem. Although this problem has been proposed as evidence against any upward monotonic modal semantics, I have shown that adding a *priority ranking* as an additional contextual degree of freedom circumvents this argument. I have shown how this solution can be implemented using two related formalisms, the *ordered merging operation* of Katz et al. (2012) and Reisinger (2016)'s *ranked ordering sources*, and argued that data involving modals embedded under attitude verbs better accord with the latter. Finally, I have argued that priority rankings are not merely a stopgap measure to save quantificational modals from this one objection, as they have additional empirical and theoretical implications that differ from non-monotonic alternatives and may be applicable to several other areas of research in modal semantics.

# The distributive ignorance puzzle<sup>1</sup>

Floris ROELOFSEN — *University of Amsterdam*

Wataru UEGAKI — *Leiden University*

**Abstract.** We observe that verbs like *wonder* do not just imply that their subject does not know the answer to the embedded question, but a stronger form of ignorance, which we call *distributive ignorance*. This is not predicted by existing work on the semantics of *wonder*, and we argue that it cannot be straightforwardly derived as a pragmatic inference either. We consider two possible semantic accounts, and conclude in favor of one on which the lexical semantics of *wonder* involves exhaustification w.r.t. structural alternatives as well as sub-domain alternatives of its complement.

**Keywords:** *wonder*, ignorance, inquisitive semantics, exhaustivity.

## 1. Introduction

This paper is concerned with clause-embedding predicates such as *wonder*, *investigate* and *be curious*. These predicates have two things in common. First, in terms of selectional restrictions, they only take interrogative clauses as their complement, not declarative ones:

- (1) The doctor **is wondering** what the patient ate / \*that the patient ate.
- (2) The doctor **is investigating** what the patient ate / \*that the patient ate.
- (3) The doctor **is curious** what the patient ate / \*that the patient ate.

Second, in semantic terms, they each imply, roughly, that their subject is *ignorant* with respect to the issue expressed by the complement and *interested* in resolving this issue.

We will refer to predicates with these two properties as INQUISITIVE PREDICATES,<sup>2</sup> and we will be concerned in this paper with the kind of ignorance that they imply on the part of their subject. Our starting point is a simple but novel empirical observation: when an inquisitive predicate takes an alternative question as its complement, it implies ignorance about all the alternatives introduced. For instance, *John wonders whether Ann, Bill, or Carol arrived* implies that John is ignorant as to whether Ann arrived, as to whether Bill arrived, and as to whether Carol arrived. We will show that this DISTRIBUTIVE IGNORANCE implication is not predicted by existing work on the semantics of *wonder*, even if we take pragmatic strengthening into account. We will then consider two ways of accounting for distributive ignorance: one directly encodes it in the lexical entry for *wonder*, the other derives it as a consequence of a lexicalized

---

We gratefully acknowledge financial support from the Netherlands Organisation for Scientific Research (NWO), the Japan Society for the Promotion of Science (JSPS), and the European Research Council (ERC, grant agreement number 680220).

<sup>2</sup>For Karttunen (1977), the class of inquisitive predicates also includes speech act predicates such as *ask* and *inquire*. We will leave such predicates out of consideration here since they do not semantically imply that the subject is ignorant (although this is often pragmatically implicated). In particular, in examples where the subject is a teacher or a quiz master, it is clear that she need not be ignorant about the answer to the embedded question.

exhaustive inference. We will argue that the exhaustivity-based account is preferable, since it better accounts for distributive ignorance when the complement is a *wh*-question or a polar disjunctive question rather than an alternative question. Throughout, we will focus on the case of *wonder*, but the arguments apply to other inquisitive predicates as well.

The paper is structured as follows: §2 briefly reviews existing work on the semantics of *wonder*; §3 introduces the distributive ignorance puzzle; §4 considers a *pragmatic* account, and the challenges it faces; §5 specifies two *semantic* approaches, and §6 attempts to tease these two apart with additional empirical observations.

## 2. Background on the semantics of *wonder*

Our theoretical point of departure here is the semantics for *wonder* proposed by Ciardelli and Roelofsen (2015), henceforth C&R.<sup>3</sup> Informally, the idea behind this account is that *wondering*  $\varphi$  amounts to (i) not knowing an answer to the issue expressed by  $\varphi$ , and (ii) entertaining the issue expressed by  $\varphi$ . To make this idea more precise, C&R develop a formal framework called *inquisitive epistemic logic* (IEL), combining notions from standard epistemic logic and inquisitive semantics. We will briefly review the relevant features of the framework, and then spell out the proposed semantics for *wonder*.

**Information states and sentence meanings** An INFORMATION STATE is modeled in epistemic logic as a set of possible worlds, namely those worlds that are compatible with the information available in the state. The MEANING OF A SENTENCE, whether declarative or interrogative, is modeled in inquisitive semantics as a set of information states, those states where (i) the information conveyed by the sentence is established, and (ii) the issue raised by the sentence is resolved. For instance:

- $\llbracket \text{Bill left} \rrbracket = \{s \mid \forall w \in s : \text{Bill left in } w\}$
- $\llbracket \text{Did Bill leave} \rrbracket = \{s \mid \forall w \in s : \text{Bill left in } w\} \cup \{s \mid \forall w \in s : \text{Bill did not leave in } w\}$
- $\llbracket \text{Who left} \rrbracket = \{s \mid \exists d \in D : \forall w \in s : d \text{ left in } w\}$  [mention-some]

The meaning of a sentence in inquisitive semantics is always non-empty and closed under subsets: if  $s \in \llbracket \varphi \rrbracket$  and  $s' \subset s$  then  $s' \in \llbracket \varphi \rrbracket$  as well (for motivation of these constraints on sentence meanings, see Ciardelli et al., 2015). The maximal elements of  $\llbracket \varphi \rrbracket$  are called the ALTERNATIVES in  $\llbracket \varphi \rrbracket$ , denoted  $\text{ALT}(\varphi)$ . For instance:

- $\text{ALT}(\text{Bill left}) = \{\{w \mid \text{Bill left in } w\}\}$
- $\text{ALT}(\text{Did Bill leave}) = \{\{w \mid \text{Bill left in } w\}, \{w \mid \text{Bill didn't leave in } w\}\}$
- $\text{ALT}(\text{Who left}) = \{\{w \mid d \text{ left in } w\} \mid d \in D\}$  [mention-some]

<sup>3</sup>For a closely related account see Uegaki (2015), and for comparison of the two see Theiler et al. (2016). For earlier informal discussions of the semantics of *wonder*, see Karttunen (1977) and Guerzoni and Sharvit (2007).

**Modal operators, informally** IEL has two basic modal operators. Informally, (i) an agent *knows*  $\varphi$  iff her current information state  $\sigma_a$  is a member of  $\llbracket \varphi \rrbracket$ , i.e., one where the issue expressed by  $\varphi$  is resolved, and (ii) an agent *entertains* the issue expressed by  $\varphi$  iff every information state in her inquisitive state is a member of  $\llbracket \varphi \rrbracket$ , i.e., every state that resolves the issues that she entertains is one where the issue expressed by  $\varphi$  is resolved. The semantics of *wonder* is defined in terms of these two basic modal operators. Informally, an agent *wonders* about  $\varphi$  iff she doesn't know  $\varphi$  but does entertain the issue expressed by  $\varphi$ .

(4) a.  $\llbracket A \rrbracket := \{s \mid \forall w \in s : A \in V(w)\}$  for any atomic sentence  $A \in \mathcal{P}$   
b.  $\llbracket \neg \varphi \rrbracket := \{s \mid \forall t \in \llbracket \varphi \rrbracket : s \cap t = \emptyset\}$   
c.  $\llbracket \varphi \wedge \psi \rrbracket := \llbracket \varphi \rrbracket \cap \llbracket \psi \rrbracket$   
d.  $\llbracket \varphi \vee \psi \rrbracket := \llbracket \varphi \rrbracket \cup \llbracket \psi \rrbracket$   
e.  $\llbracket K_a \varphi \rrbracket := \{s \mid \forall w \in s : \sigma_a(w) \in \llbracket \varphi \rrbracket\}$   
f.  $\llbracket E_a \varphi \rrbracket := \{s \mid \forall w \in s : \Sigma_a(w) \subseteq \llbracket \varphi \rrbracket\}$

$$(5) \quad w \models \varphi \iff \{w\} \in \llbracket \varphi \rrbracket$$
$$(6) \quad \begin{array}{ll} \text{a. } w \models K_a \varphi & \iff \sigma_a(w) \in \llbracket \varphi \rrbracket \\ \text{b. } w \models E_a \varphi & \iff \Sigma_a(w) \subseteq \llbracket \varphi \rrbracket \end{array}$$

As anticipated above the *wonder* modality in IEL,  $W$ , is defined in terms of the basic modal operators  $K$  and  $E$ , as in (7). This means that it has the truth-conditions specified in (8):

$$(7) \quad W_a\varphi := \neg K_a\varphi \wedge E_a\varphi$$

$$(8) \quad w \models W_a\varphi \iff \sigma_a(w) \notin \llbracket \varphi \rrbracket \wedge \Sigma_a(w) \subseteq \llbracket \varphi \rrbracket$$

IEL can be extended into a compositional, type-theoretic framework (cf., Ciardelli et al., 2017). English *wonder* can then be translated into the formal language of this framework as follows:

$$(9) \quad \ulcorner \text{wonder} \urcorner = \lambda Q_{\langle \text{st}, \text{t} \rangle} \lambda x_e. W_x(Q)$$

For a full sentence involving *wonder* we then get the following:<sup>4</sup>

- (10) a.  $\ulcorner \text{John wonders whether Ann or Bill arrived.} \urcorner = W_j(A \vee B)$   
 b.  $w \models W_j(A \vee B) \iff \sigma_j(w) \notin \llbracket A \vee B \rrbracket \wedge \Sigma_j(w) \subseteq \llbracket A \vee B \rrbracket$   
 c. John's current information state doesn't resolve the question whether  $A$  or  $B$ , but every information state that resolves the issues that he entertains is one in which the question whether  $A$  or  $B$  is resolved.

Before closing this background section it is worth mentioning that C&R's semantics predicts that *wonder* does not license declarative complements, assuming that the meaning of a declarative complement always contains a single alternative. Namely, whenever  $W$  applies to a sentence whose meaning contains a single alternative, it yields a contradiction.

### 3. Problem: distributive ignorance

C&R's semantics of *wonder* faces an empirical problem. Consider the following example:

- (11) **Situation** John has three students, Ann, Bill and Carol. He is waiting for all of them to arrive at a lab meeting. Someone knocks at the door, but John knows that it can't be Carol because she has just emailed him that she will be late.

**Example** John wonders whether Ann, Bill or Carol arrived. (Judgment: *False*)

The above example is judged false in the given situation. The sentence is true only if John's information state is compatible with *every alternative* expressed by the complement, i.e., the sets of worlds in which Ann arrived, Bill arrived, and Carol arrived, respectively. Moreover, John's information state should not entail any of these alternatives. Together, this means that the truth of (11) requires that, for each alternative, John is *ignorant* as to whether it holds.

<sup>4</sup>For simplicity, we assume here that the embedded alternative question *whether Ann or Bill arrived* is translated into IEL as  $A \vee B$ , disregarding the fact that alternative questions presuppose that exactly one of the disjuncts holds. This simplification does not affect the arguments that we will make.

Figure 1: The meaning of the complement, John's inquisitive state  $\Sigma_j$ , and John's information state  $\sigma_j$  in (11). Recall that  $\Sigma_j$  and  $\llbracket A \vee B \vee C \rrbracket$  are downward-closed; the figures only depict their maximal elements.

More generally, for any individual-denoting DP  $x$  and any alternative question  $\varphi$ , the sentence  $x$  *wonders*  $\varphi$  implies that  $x$  is ignorant about each of the alternative answers to  $\varphi$ . We refer to this requirement in the meaning of *wonder* as the DISTRIBUTIVE IGNORANCE requirement. Later, we will discuss in detail what this requirement looks like in examples with *wh*-questions and polar questions. For now, however, let us focus on explaining why the distributive ignorance requirement that arises with alternative questions is a problem for C&R's account.

To see this, consider the example in (11) again. C&R's semantics incorrectly predicts that (11) is *true* in the given situation. This is so since John's current information state does not resolve the question of whether  $A$ ,  $B$  or  $C$ , but every information state that resolves the issues that he is entertaining, i.e., every element of his inquisitive state, is one that does resolve the question whether  $A$ ,  $B$  or  $C$ . Formally, we have the following:

$$(12) \quad \ulcorner \text{John wonders whether Ann, Bill or Carol arrived.} \urcorner = W_j(A \vee B \vee C)$$

$$(13) \quad w \models W_j(A \vee B \vee C) \iff \sigma_j(w) \notin \llbracket A \vee B \vee C \rrbracket \text{ and } \Sigma_j(w) \subseteq \llbracket A \vee B \vee C \rrbracket$$

The meaning of the complement, John's inquisitive state  $\Sigma_j$ , and his information state  $\sigma_j$  are as follows in the given situation (see Figure 1 for graphical representations):

- $$\begin{aligned}
 (14) \quad & \text{a. } \llbracket A \vee B \vee C \rrbracket = \llbracket A \rrbracket \cup \llbracket B \rrbracket \cup \llbracket C \rrbracket && \text{(meaning of the complement)} \\
 & \text{b. } \Sigma_j = \{s \mid s \in \llbracket A \rrbracket \cup \llbracket B \rrbracket \text{ and } \forall t \in \llbracket C \rrbracket : s \cap t = \emptyset\} && \text{(John's inquisitive state)} \\
 & \text{c. } \sigma_j = \{w \mid (w \in \llbracket A \rrbracket \text{ or } w \in \llbracket B \rrbracket) \text{ and } w \notin \llbracket C \rrbracket\} && \text{(John's information state)}
 \end{aligned}$$

Thus, the truth conditions in (13) are indeed met in the given situation, since (14c) is not a member of (14a) while (14b) is a subset of (14a). This prediction is incorrect.

## 4. A pragmatic account and its challenges

### 4.1. The distributive ignorance requirement as a conversational implicature

Prima facie, one may think that the distributive ignorance requirement could be explained pragmatically, while retaining C&R's semantics for *wonder*. A possible pragmatic derivation of the requirement would go as follows. The speaker of (11) could have uttered another sentence with a *shorter disjunction*, such as the one in (15):

(11) John wonders whether Ann, Bill or Chris arrived.

(15) John wonders whether Ann or Bill arrived.

The alternative in (15) would have been a simpler, presumably still relevant, way to describe John's state. Thus, we could derive the negation of (15) as an implicature, which has the following truth conditions:

$$(16) \quad w \models \neg W_j(A \vee B) \iff \sigma_j \in \llbracket A \rrbracket \cup \llbracket B \rrbracket \text{ or } \Sigma_j \not\subseteq \llbracket A \rrbracket \cup \llbracket B \rrbracket$$

Distributive ignorance can be derived from this implicature, together with the assumed literal meaning of the sentence. Namely, the ignorance condition in the literal meaning implies that  $\sigma_j \notin \llbracket A \rrbracket \cup \llbracket B \rrbracket$ . Therefore, for the implicature to hold it must be the case that  $\Sigma_j \not\subseteq \llbracket A \rrbracket \cup \llbracket B \rrbracket$ . But the 'entertainment' condition in the literal meaning says that  $\Sigma_j \subseteq \llbracket A \rrbracket \cup \llbracket B \rrbracket \cup \llbracket C \rrbracket$ . This allows us to conclude that  $\Sigma_j \cap \llbracket C \rrbracket \neq \{\emptyset\}$ , which in turn implies that John's information state,  $\sigma_j$  must be compatible with  $\llbracket C \rrbracket$ . Following the same line of reasoning for the other disjuncts, we can derive that  $\sigma_j$  has to be compatible with  $\llbracket A \rrbracket$  and with  $\llbracket B \rrbracket$  as well. At the same time,  $\sigma_j$  cannot entail any of  $\llbracket A \rrbracket$ ,  $\llbracket B \rrbracket$  and  $\llbracket C \rrbracket$ , due to the ignorance condition in the literal meaning. Thus, we derive that John has to be ignorant w.r.t.  $\llbracket A \rrbracket$ ,  $\llbracket B \rrbracket$ , and  $\llbracket C \rrbracket$ .

Thus, we see that the distributive ignorance requirement of (11) can be derived as a pragmatic inference. However, there are empirical features of the distributive ignorance requirement which, at face value, do not seem to be in line with the traditional Gricean conception of pragmatic implicatures. Below, we describe three such empirical features.

### 4.2. Challenges for the pragmatic account

#### 4.2.1. Non-monotonicity of *wonder*

First of all, due to the non-monotonicity of C&R's semantics for *wonder*, the sentence in (15) is actually not stronger than the original sentence in (11). For instance, (15) is true while (11) is false when John's inquisitive state is as follows:

$$(17) \quad \Sigma_j = \{s \mid s \in \llbracket A \rrbracket \cup \llbracket B \rrbracket \text{ and } s \in \llbracket C \rrbracket\}$$

Since quantity implicatures under the traditional Gricean conception arise only with respect to *strictly stronger* alternatives, the fact that (15) is not strictly stronger than (11) suggests that the inference cannot be treated as a traditional quantity implicature.

One might suggest that the ignorance condition in the semantics of *wonder* could be treated as a presupposition, and that (15) would then indeed asymmetrically entail (11) if we only consider their assertive component, which would consist in the entertainment condition. However, we submit that the ignorance condition of *wonder* is part of its assertive meaning, given that it does not exhibit the projection behavior of presuppositions. The following examples show that it does not project out of (a) negation, (b) polar questions, and (c) the attitude predicate *doubt*, as evidenced by the fact that the underlined continuations are perfectly felicitous.

- (18) a. The detectives are not wondering whether Ann stole the jewels.  
           They already know that she did.  
       b. A: Are the detectives wondering whether Ann stole the jewels?  
           B: No, they already know that she did.  
       c. Bill doubts that the detectives are wondering whether Ann stole the jewels.  
           He believes that they already know that she stole them.

This contrasts with the behavior of attitude-verb meanings whose presuppositional status is undisputed. For example, the factive presupposition of *know* does exhibit the typical projection behavior, as shown by the oddness of the contradicting continuations in the following examples (in order to become felicitous, these continuations need a marker of presupposition denial such as *actually* or *in fact*).

- (19) a. The detectives don't know that Ann stole the jewels.  
           #She didn't steal them.  
       b. A: Do the detectives know that Ann stole the jewels?  
           B: No, they don't. #She didn't steal them.  
       c. Bill doubts that the detectives know that Ann stole the jewels.  
           #He doesn't believe that she stole them.

#### 4.2.2. Obligatoriness

The second challenge for a pragmatic account of distributive ignorance is its *obligatory* nature. The following example indicates that distributive ignorance cannot be canceled, contrary to what would be expected under a traditional Gricean approach.

- (20) John wonders whether Ann, Bill or Carol arrived.  
       # In fact, he already knows that Carol is still at home, but he doesn't know yet whether Ann or Bill arrived.

At this point, it should be mentioned that not all Gricean analyses of implicatures predict cancellability as a necessary feature. In particular, Lauer (2014) points out that Gricean pragmatics predicts that an obligatory implicature arises if an utterance of an expression *necessarily* makes a more preferred expression salient. Lauer (2014) argues that this is exactly the case with the ignorance implicature of unembedded disjunctions since an utterance of the form  $\alpha$  or  $\beta$  necessarily makes each disjunct salient (see also Westera, 2017).

It is conceivable that Lauer's analysis can be applied to the distributive ignorance requirement of *wonder*, correctly capturing its obligatory nature within a pragmatic approach. However, such an analysis would still face the non-monotonicity issue discussed above, and would also have difficulty capturing the *locality* of distributive ignorance, to which we turn next.

#### 4.2.3. Locality

The distributive ignorance requirement of *wonder* is local, in the sense that it takes scope below operators that are syntactically above *wonder*. The following example illustrates this:

- (21) **Situation** There is a crime with three suspects, Ann, Bill, and Carol. There are five detectives investigating the case; one has already ruled out Carol but is still wondering whether it was Ann or Bill. The others don't know anything yet.

**Example** Exactly four detectives are wondering whether it was Ann, Bill, or Carol.  
(Judgment: *true*)

The judgment that this example is *true* can only be accounted for if the distributive ignorance requirement takes scope below the subject quantifier *exactly four detectives*. If the distributive ignorance requirement is derived as a global pragmatic implicature, the sentence would be predicted to be *false*. Here's why: the literal meaning of the given sentence would be that exactly four detectives are such that (i) they don't know whether it was Ann, Bill, or Carol, and (ii) every information state they want to be in resolves the issue of whether it was Ann, Bill, or Carol. This is *false* in the situation above since all five detectives meet these conditions. Adding implicatures to the literal meaning of the sentence could only strengthen it and could thus not make it true in the given situation.

The following example further strengthens our claim that distributive ignorance scopes locally:

- (22) **Situation** There is a crime with three suspects, Ann, Bill, and Carol. There are three detectives investigating the case.
- Detective 1 has ruled out Ann but still wonders whether it was Bill or Carol.
  - Detective 2 has ruled out Bill but still wonders whether it was Ann or Carol.
  - Detective 3 has ruled out Carol but still wonders whether it was Ann or Bill.<sup>5</sup>

<sup>5</sup>We thank Benjamin Spector for drawing our attention to this type of situations.

**Example** Every detective is wondering whether it was Ann, Bill, or Carol.  
(Judgment: *false*)

The judgment that this example is *false* makes sense if the distributive ignorance requirement takes scope under *every detective*. On the other hand, a global derivation of the pragmatic inference would predict the sentence to be *true*. Here's why: the predicted implicatures would be as follows:

- (23) a. It is not the case that every detective wonders whether it was Ann or Bill.  
b. It is not the case that every detective wonders whether it was Bill or Carol.  
c. It is not the case that every detective wonders whether it was Carol or Ann.  
and so on...

These implicatures are all *true* in the given situation. The presence of detectives 1 and 2 makes (23a) true. The presence of detectives 2 and 3 makes (23b) true. The presence of detectives 1 and 3 makes (23c) true.

The locality of distributive ignorance is a challenge for the pragmatic approach since pragmatic maxims are traditionally assumed to apply globally, i.e., to the sentence as a whole.<sup>6</sup> Certain apparently local implicatures have been explained within pragmatic approaches that are essentially Gricean in nature (see, e.g., Franke, 2009). It is possible that such pragmatic theories could ultimately derive local distributive ignorance implicatures with *wonder* as well. However, it is not immediately clear, to us, how this may be achieved.

We have seen, then, that a 'conservative' approach, which maintains C&R's semantics for *wonder* and tries to derive the distributive ignorance requirement pragmatically, encounters a number of challenges. However, this is of course not the only possible approach. Another option is to reconsider C&R's semantics of *wonder* and see if it could be adapted so as to derive the distributive ignorance requirement directly, without pragmatics. Clearly, such an approach would directly predict the obligatory and local nature of the distributive ignorance requirement. Moreover, it would steer clear of the non-monotonicity issue that the pragmatic approach faces. This is the route that we will take in the remainder of this paper.

<sup>6</sup>Locality also distinguishes *wonder* from other predicates, such as *believe*. Although *believe* also implies distributive ignorance when taking a referential subject, as illustrated in (i) below, examples with quantificational subjects reveal that this implication is not local, as illustrated in (ii) and (iii).

- (i) John believes that it was Ann, Bill, or Carol. (implies distributive ignorance)  
(ii) Exactly four detectives believe that it was Ann, Bill, or Carol. (*false* in (21))  
(iii) Every detective believes that it was Ann, Bill, or Carol. (*true* in (22))

This contrast between *wonder* and *believe* suggests that distributive ignorance with *wonder* is a local implication associated with the semantics of the predicate itself while distributive ignorance with *believe* is a global pragmatic implicature that arises regardless of the embedding predicate.

## 5. Two semantic accounts

We will consider two ways to adapt C&R's semantics. The first (§5.1) directly strengthens the ignorance requirement in the lexical semantics of *wonder*. The second (§5.2) leaves C&R's basic entry for *wonder* intact, but additionally assumes that the semantics of the verb involves an *exhaustivity operator*, just like the semantics of *only*.<sup>7</sup> The main difference between these two accounts is that on the former, *wonder* remains sensitive only to the semantic content of the clause that it combines with, while on the second, due to the exhaustivity operator, it becomes sensitive to the formal structure of its complement clause as well. In §6 we will attempt to tease these two accounts apart based on data involving polar questions and *wh*-questions.

### 5.1. Directly encoding strong ignorance

In C&R's semantics of *wonder*, the ignorance condition is encoded as  $\neg K_a \varphi$ . That is, the subject's information state must not be contained in any alternative in  $\llbracket \varphi \rrbracket$ . This is a relatively weak notion of ignorance. A natural way to strengthen it would be to require that, in addition, the subject's information state should be compatible with every alternative in  $\llbracket \varphi \rrbracket$ . Let us introduce a new modal operator, *I*, which expresses this strong form of ignorance:

$$(24) \quad w \models I_a \varphi \iff \forall \alpha \in \text{ALT}(\varphi) : \sigma_a(w) \not\subseteq \alpha \text{ and } \sigma_a(w) \cap \alpha \neq \emptyset$$

Using this strong ignorance operator, we can then re-define the *wonder* modality in IEL:

$$(25) \quad W_a \varphi := I_a \varphi \wedge E_a \varphi$$

This analysis directly encodes the distributive ignorance requirement in the lexical semantics of *wonder*. Clearly, the local and obligatory nature of the requirement are straightforwardly captured in this way.

### 5.2. Strong ignorance via exhaustivity

We now consider a more indirect account, which supplements C&R's entry for *wonder* with a built-in exhaustivity operator. We will assume that this exhaustivity operator is sensitive to the formal structure of the complement clause, rather than just its semantic content, because an account involving a purely semantic exhaustivity operator would be difficult to distinguish from the account specified above.

For any two natural language expressions  $\varphi$  and  $\varphi'$ , we write  $\varphi' \lesssim \varphi$  iff  $\varphi'$  is formally simpler

<sup>7</sup>Yet another possible analysis would be one involving an exhaustivity operator in the syntax (Chierchia et al., 2012) rather than in the lexical semantics of *wonder*. However, on such an approach additional assumptions would be needed about the distribution of this operator, in order to account for the locality and obligatory nature of the distributive ignorance requirement. For now, we leave this possible analysis out of consideration.

than  $\varphi$  in the sense of Katzir (2007), i.e., iff  $\varphi'$  can be obtained from  $\varphi$  by deleting constituents or replacing them with other constituents of the same syntactic category, taken either from the lexicon or from  $\varphi$  itself.

The exhaustivity operator that we will assume takes an expression  $\varphi$  and a set of formal alternatives  $A$ , and strengthens  $\varphi$  by negating every  $\psi \in A$  that is not entailed by  $\varphi$ :

$$(26) \quad \mathbf{EXH}_A(\varphi) := \varphi \wedge \bigwedge \{ \neg \psi \mid \psi \in A \text{ and } \varphi \not\models \psi \}$$

Using this exhaustivity operator, the semantics of *wonder* can be formulated as follows:<sup>8</sup>

$$(27) \quad \ulcorner \text{wonder } Q \urcorner = \lambda x. \mathbf{EXH}_{\{W_x(\ulcorner Q' \urcorner) \mid Q' \lesssim Q\}} W_x(\ulcorner Q \urcorner)$$

The formal alternatives for exhaustification are expressions of the form  $W_x \ulcorner Q' \urcorner$ , where  $Q'$  is grammatically simpler than the original complement  $Q$ . As a result of exhaustification,  $x$  *wonders*  $Q$  negates those formal alternatives that are not entailed by  $W_x(\ulcorner Q \urcorner)$ .<sup>9</sup> The obligatory and local nature of the distributive ignorance requirement follow from this analysis as well.

To see the account at work, consider the following sentence:

$$(28) \quad \text{Every detective wonders whether } A, B \text{ or } C.$$

For concreteness, let us assume that the complement in this sentence has the following structure (as far as we can see, all other reasonable assumptions about the structure of alternative questions are compatible with our argument as well):

$$(29) \quad [\text{whether } [A \text{ or } [B \text{ or } C]]]$$

Further assume that *or* is translated as  $\vee$  and that *whether* is semantically vacuous but syntactically requires at least one occurrence of *or* in its scope—if no such occurrence is overtly present, as in a polar question, there must be a covert *or not* (cf., Guerzoni and Sharvit, 2014; though again, other assumptions about the syntax-semantics interface of alternative questions would be compatible with our argument as well, as far as we can tell).

This structure can be simplified by eliminating either one or two of the disjuncts; in the latter case *whether* has to be eliminated as well. Such simplifications yield the following structures:

<sup>8</sup>Since the exhaustivity operator is structure-sensitive, our entry for *wonder* has to be syncategorematic.

<sup>9</sup>We could assume that formal alternatives are only negated if they are innocently excludable (IE), in order to avoid potential contradictions arising from exhaustification (Fox, 2007):

(i)  $\mathbf{EXH}_A(\varphi) := \varphi \wedge \bigwedge \{ \psi \mid \psi \in \mathbf{IE}(\varphi, A) \}$

(ii)  $\mathbf{IE}(\varphi, A) := \bigcap \{ A' \subseteq A \mid A' \text{ is a maximal subset of } A \text{ s.t. } \{ \neg \varphi' \mid \varphi' \in A' \} \cup \{ \varphi \} \text{ is consistent} \}$

However, we keep the simpler formulation in (26) since there would be no contradiction arising from the negation of non-weaker alternatives in the examples under consideration.

(30) [whether [A or B]] [whether [B or C]] [whether [A or C]] A B C

Thus, the sentence in (28) receives the interpretation in (32), which means that it is correctly predicted to be false in the scenario described in (22).<sup>10</sup>

(31) 「Every detective wonders whether A, B or C」

$$= \forall x : \mathbf{detective}(x) \rightarrow \mathbf{EXH}_{\{W_x(\ulcorner Q' \urcorner) \mid Q' \lesssim \text{whether } A, B \text{ or } C\}} W_x(A \vee B \vee C)$$

$$(32) = \forall x : \mathbf{detective}(x) \rightarrow \left( \begin{array}{l} W_x(A \vee B \vee C) \\ \wedge \neg W_x(A \vee B) \\ \wedge \neg W_x(B \vee C) \\ \wedge \neg W_x(C \vee A) \\ \wedge \neg W_x(A) \\ \wedge \neg W_x(B) \\ \wedge \neg W_x(C) \end{array} \right)$$

## 6. Teasing the two semantic accounts apart

We will now try to tease the two semantic accounts apart, by considering cases where *wonder* takes a polar question or a *wh*-question as its complement, rather than an alternative question. We will consider polar disjunctive questions like *whether-or-not Ann or Bill arrived* (§6.1), plain *wh*-questions like *which of the students arrived* (§6.2), ones where the domain of quantification is explicitly listed, as in *which of Ann, Bill, and Carol arrived* (§6.3), and ones where the domain specification involves a numeral, as in *which of John's three students arrived* (§6.4).<sup>11</sup>

### 6.1. Polar questions involving a disjunction

Distributive ignorance is observed also when *wonder* takes a polar disjunctive question complement, as in the following example:<sup>12</sup>

(33) John wonders whether-or-not Ann or Bill arrived.

That is, (33) implies that John is ignorant as to whether Ann arrived and as to whether Bill arrived. This is expected under the exhaustivity-based account, since the following complements are structurally simpler alternatives for the complement in (33):

<sup>10</sup>The last three conjuncts in (32) are tautologous, so they could in principle be left out. We do display them here just for transparency.

<sup>11</sup>We should note that the judgments reported in this section are based on introspection and discussion with a small number of native speakers. More systematic empirical work will be needed to obtain a more reliable picture of the relevant data.

<sup>12</sup>We use *whether-or-not* here, rather than just *whether*, in order to make sure that the complement is read as a polar question, and not as an alternative question. The relevant observation, however, applies just as well to complements headed by plain *whether*, interpreted as polar questions.

- (34) a. whether-or-not Ann arrived.  
b. whether-or-not Bill arrived.

Thus, (33) is predicted to imply, through exhaustivity, that  $\neg W_j(A \vee \neg A)$  and  $\neg W_j(B \vee \neg B)$ . It follows from this that John must be ignorant as to whether Ann arrived. To see this, first suppose that John believes that Ann did arrive. This is incompatible with the basic ignorance requirement of (33). Now suppose that John believes that Ann did not arrive. Then, the basic ignorance and entertain conditions of (33) are satisfied only if John is wondering whether Bill arrived. But this is incompatible with the implication  $\neg W_j(B \vee \neg B)$ . So, John must be ignorant as to whether Ann arrived. Similarly, ignorance as to whether Bill arrived follows as well.

In contrast, on the direct account it is wrongly predicted that (33) may be true even if John already knows that Ann did not arrive, or similarly, if he already knows that Bill did not arrive.

## 6.2. Plain *wh*-questions

When *wonder* takes a plain *wh*-question as its complement, as in (35-37), the distributive ignorance requirement seems to be absent.

- (35) *Situation: as in (11).*  
John wonders which of his students arrived. (true)
- (36) *Situation: as in (21).*  
Exactly four detectives are wondering which of the suspects did it. (false)
- (37) *Situation: as in (22).*  
Every detective is wondering which of the suspects did it. (true)

If the distributive ignorance requirement were present in the same way as in our earlier examples involving alternative questions, (35) should be judged false, (36) true, and (37) false. The actual judgments, however, seem to be the opposite.

This contrast is expected under the view that the distributive ignorance requirement is a result of exhaustification w.r.t. structurally determined alternatives. After all, complements like *whether Ann or Bill arrived* count as structural alternatives for *whether Ann, Bill or Carol arrived*, but not for *which of his students arrived*. As a consequence, strong ignorance is predicted to arise with alternative questions but not with *wh*-questions.

On the other hand, the contrast is puzzling if the mechanism responsible for the distributive ignorance requirement is only sensitive to the semantic properties of the complement, as on the direct account. After all, it is hard to distinguish between alternative questions and *wh*-questions in terms of purely semantic properties.

One may attempt to derive the contrast on this approach from the assumption that *wh*-questions, unlike alternative questions, may involve *implicit domain restriction*. That is, (35-37) could be taken to involve the following implicit domain restrictions:

- (38) John wonders which of his students [except Carol] arrived.
- (39) Exactly four detectives are wondering which of the suspects [that they are still suspecting] did it.
- (40) Every detective is wondering which of the suspects [that he is still suspecting] did it.

If this is indeed what is going on, the data is compatible with the direct account. For instance, it would then be predicted that (39) is false in the given scenario because all five detectives satisfy the distributive ignorance requirement with respect to the suspects that they are still suspecting. And similarly for the other examples.

However, on such an account it remains to be explained why the assumed implicit domain restrictions seem to be *obligatory*. Prima facie, one would expect that implicit domain restriction is optional, and that various restrictions would be possible, not just the ones explicated in (38-40). The case of (36)/(39) would be especially puzzling, because this sentence is judged *false* in the given context. Under the assumption that implicit domain restriction is optional, the Charity Principle would favor an interpretation *without* domain restriction in this case, because under such an interpretation the sentence would be *true* in the given scenario. However, the only interpretation that seems to be available is one on which the sentence is false.

### 6.3. *Wh*-questions with listed domain of quantification

Now consider the following variants of (35-37), where the quantificational domain is explicitly listed.

- (41) *Situation: as in (35).*  
John wonders which of Ann, Bill and Carol arrived. (false)
- (42) *Situation: as in (36).*  
Exactly four detectives are wondering which of Ann, Bill and Carol did it. (true)
- (43) *Situation: as in (37).*  
Every detective is wondering which of Ann, Bill and Carol did it. (false)

We see that ‘list *wh*-questions’ pattern with alternative questions rather than with plain *wh*-questions. This is again expected on the structure-sensitive exhaustivity-based account, because we have that *which of Ann and Bill arrived*  $\lesssim$  *which of Ann, Bill and Carol arrived*.

Under the direct account, ‘list *wh*-questions’ are also expected to pattern with alternative questions under the assumption that they do not permit implicit domain restriction. This assumption

seems quite natural, so the examples in (35-37) arguably do not present any new challenges for the direct account. However, as discussed above, it remains puzzling why plain *wh*-questions would obligatorily involve a specific kind of domain restriction.

An interesting hybrid between plain *wh*-questions and list *wh*-questions, as suggested to us by Brian Buccola, is the following:

- (44) **Situation** A certain linguistics department has one full professor (Jones), three associate professors (A, B, and C), and three assistant professors (X, Y, and Z). Jones is a phonologist and has a question about semantics, which he thinks only a real semanticist could possibly answer. The only semanticists in the department are A and C (both associate professors).

**Example** Jones wonders which assistant or associate professor could answer his question. (false)

What is required for (44) to be true is that Jones considers at least one assistant professor and at least one associate professor possibly capable of answering his question (for instance, the sentence would be true if, in addition to A and C, Y were a semanticist as well). On the other hand, it is not required that Jones considers *all* assistant and associate professors possibly capable of doing so.

This is straightforwardly accounted for on the exhaustivity-based account, because we have that *which assistant professor* and *which associate professor* are structural alternatives for *which assistant or associate professor*. On the other hand, it is not so clear that the direct account could generate this prediction in a principled way. If we assume that implicit domain restriction is blocked in (44), just as in alternative questions and list *wh*-questions, then the predicted ignorance requirement would be too strong: Jones would have to be ignorant about all assistant and associate professors. If we assume that implicit domain restriction can apply freely, then the predicted ignorance requirement would be too weak: it would be predicted that the sentence is true even if Jones knows that none of the assistant professors are semanticists, as in the given context. So, some intermediate constraint on domain restriction would be needed, and it is not clear how such a constraint could be justified.

#### 6.4. *Wh*-questions with numerical domain specification

Now consider the following variants of (35-37), where the domain of quantification is specified using a numeral. This has been argued in previous work to strongly disfavor, or even completely block, implicit domain restriction (Chemla, 2009; Geurts and van Tiel, 2016).

- (45) *Situation: as in (35).*  
John wonders which of his three students arrived. (false)

- (46) *Situation: as in (36).*  
 Exactly four detectives are wondering which of the three suspects did it. (true)
- (47) *Situation: as in (37).*  
 Every detective is wondering which of the three suspects did it. (false)

We see that ‘numerical *wh*-questions’ pattern like alternative questions and list *wh*-questions, and unlike plain *wh*-questions. This is predicted by the direct account, under the assumption that numerical *wh*-questions don’t allow for implicit domain restriction, just like alternative questions and list *wh*-questions.

On the other hand, the contrast between numerical *wh*-questions and plain *wh*-questions is not immediately accounted for under the exhaustivity-based account, because the structural alternatives for numerical *wh*-questions do not include ones such as *whether Ann or Bill arrived*, which would be necessary to derive the distributive ignorance requirement from exhaustivity.

There is, however, a possible extension of the exhaustivity-based account formulated above, which does capture the contrast between numerical *wh*-questions and plain *wh*-questions. This extension incorporates a number of ideas from Chierchia’s (2013) work on different types of indefinites (plain, NPI, free choice) and their interaction with exhaustification. We will briefly review these ideas and then return to the case of numerical *wh*-questions.

First, Chierchia assumes that indefinites and other quantifiers always come with a domain variable  $D$ , whose value is contextually determined. For instance, a sentence like *Some students arrived* is analyzed as  $\exists x \in D. S(x) \wedge A(x)$ , involving existential quantification over a contextually given domain  $D$ . This assumption is quite widespread, though not everyone agrees that implicit domains should be represented syntactically.

Second, Chierchia proposes that sentences involving a quantifier with domain variable  $D$  generate so-called *sub-domain alternatives*, which involve quantification over a subdomain  $D' \subseteq D$ . For instance, the sub-domain alternatives of *Some students arrived* are  $\exists x \in D'. S(x) \wedge A(x)$ , for any  $D' \subseteq D$ . Crucially for us, Chierchia proposes that these sub-domain alternatives can serve as input for exhaustivity operators, alongside structurally determined alternatives. Whether they actually play this role depends on whether they are *activated*. Chierchia proposes that the sub-domain alternatives generated by plain indefinites are only optionally activated. On the other hand, the sub-domain alternatives of specially marked indefinites (such as *any* and *ever*) are obligatorily activated, and therefore must always serve as input for an exhaustivity operator. This has certain interpretational consequences, and also accounts for the restricted distribution of such marked indefinites. For instance, the ungrammaticality of a sentence like *Any students arrived* is accounted for by the fact that exhaustification w.r.t. the sub-domain alternatives generated by *any* yields a contradiction in this case. On the other hand, in *John didn’t expect any students*, exhaustification w.r.t. sub-domain alternatives does not yield a contradiction.

Now let us return to the contrast between plain *wh*-phrases (e.g., *which of his students*) and numerical *wh*-phrases (e.g., *which of his three students*). Extending Chierchia’s ideas to *wh*-

phrases, it would be natural to assume that (i) *wh*-phrases always come with a domain variable and generate sub-domain alternatives, (ii) the sub-domain alternatives generated by plain *wh*-phrases are only optionally activated, but (iii) the sub-domain alternatives generated by specially marked *wh*-phrases, such as numerical ones, are obligatorily activated and therefore must serve as the input for an exhaustivity operator.

Given this, it is natural to assume that the exhaustivity operator in the lexical semantics of *wonder* is not only sensitive to structurally determined alternatives for the complement clause, but also to its sub-domain alternatives, when activated. Using  $SDA(Q)$  to denote the set of activated sub-domain alternatives generated by  $Q$ , this can be implemented as follows:

$$(48) \quad \ulcorner \text{wonder } Q \urcorner = \lambda x. \mathbf{EXH} \underbrace{\{W_x(\ulcorner Q' \urcorner) \mid Q' \lesssim Q\}}_{\text{structural alternatives}} \cup \underbrace{\{W_x(\varphi) \mid \varphi \in SDA(Q)\}}_{\text{sub-domain alternatives}} W_x(\ulcorner Q \urcorner)$$

Under this treatment of *wonder*, we get exactly the desired predictions. For instance, (45) now implies, due to exhaustification w.r.t. sub-domain alternatives, that John is *not* wondering which of Ann and Bill arrived. This implication is false in the given context, so the sentence as a whole comes out false as well. And similarly for (46) and (47).

Thus, while the exhaustivity-based account needs to be further worked out and tested on a broader range of empirical data, it seems to be able to capture some interesting contrasts, and to have an advantage over the direct account in that it does not rely on particular constraints on implicit domain restriction which would seem difficult to motivate independently.

## 7. Conclusion

If an inquisitive predicate like *wonder* takes an alternative question as its complement, it implies that its subject is ignorant about each of the alternatives introduced by the question. This implication, which we call the distributive ignorance requirement, is not predicted by previous work on the semantics of *wonder*. Furthermore, a pragmatic approach to deriving distributive ignorance faces a number of challenges (non-monotonicity, obligatoriness, and locality). We thus considered two semantic accounts: one that directly encodes a strong form of ignorance in the meaning of *wonder* and the other based on a built-in exhaustivity operator.

To tease apart these two semantic accounts, we looked at four types of questions as the complement of *wonder*: polar questions involving a disjunction, plain *wh*-questions, *wh*-questions with a listed domain of quantification and *wh*-questions with a numerical domain specification. The fact that the distributive ignorance requirement is absent with ‘plain’ *wh*-questions but present with polar questions involving a disjunction and ‘list’ *wh*-questions suggests that the distributive ignorance requirement is sensitive to the structure of the complement. This is expected on the exhaustivity-based account, which comes with a structure-sensitive notion of alternatives (Katzir, 2007). Furthermore, although at first sight the presence of distributive ignorance with ‘numerical’ *wh*-questions seemed unexpected under the exhaustivity-based account, we proposed that it could be accounted for by incorporating exhaustification w.r.t.

sub-domain alternatives (Chierchia, 2013). On the other hand, in order to capture the contrasts between the different types of *wh*-questions, the ‘direct’ account would have to invoke particular constraints on implicit domain restriction. Given that such constraints seem difficult to motivate independently, we conclude that the exhaustivity-based approach is more promising.

## Hierarchical structure and local contexts<sup>1</sup>

Jacopo ROMOLI — *Ulster University*

Matthew MANDELKERN — *Massachusetts Institute of Technology*

**Abstract.** We use antecedent-final conditionals to formulate a challenge to parsing-based theories of local contexts, and associated theories of presupposition projection and triviality, like the one given in Schlenker 2009. We show that a theory like Schlenker’s predicts that the local context for the antecedent of an antecedent-final conditional will entail the negation of the conditional’s consequent. It thus predicts that presuppositions triggered in the antecedent of antecedent-final conditionals will be filtered if the negation of the consequent entails the presupposition. But this is wrong: *John isn’t in Paris, if he regrets being in France* intuitively presupposes that John is in France, contrary to this prediction. Likewise, parsing-based approaches to triviality predict that material entailed by the negation of the consequent will be felt to be redundant in the antecedent of the conditional. But this is wrong: *John isn’t in Paris, if he’s in France and Mary is with him* is intuitively felicitous, contrary to this prediction. Importantly, given that the material in question appears in sentence-final position in antecedent-final conditionals, both incremental (left-to-right) and symmetric versions of parsing-based theories of local contexts make the same problematic predictions here. In Mandelkern and Romoli 2017, we discuss one solution to this problem, given within a broadly parsing-based pragmatic approach. In this paper, we explore an alternate direction: incorporating attention to hierarchical structure into the calculation of local contexts. We sketch several possible implementations and point to some of the possibilities and challenges for a hierarchical approach to local contexts.

**Keywords:** presupposition projection, conditionals, parsing, linear order, hierarchical order, local contexts, triviality, incrementality.

### 1. Introduction

Schlenker (2008, 2009), building on previous observations by Soames (1989) and Heim (1990), questions the explanatory power of traditional dynamic approaches to presupposition projection, posing an explanatory challenge for any theory of presupposition projection as follows:

#### **Explanatory Challenge for Presupposition Projection:**

Find an algorithm that predicts how any operator transmits presuppositions once that operator’s syntax and classical semantics have been specified.

(Schlenker 2009)

This challenge has sparked a debate which has led to a variety of new theories, both static

---

This paper is a companion of Mandelkern and Romoli 2017, which explores the same puzzle but provides a different solution to it, and therefore shares some material in introducing the puzzle.

(Schlenker 2009; George 2008; Fox 2008, 2012; Chemla 2010) and dynamic (Chierchia 2009; Rothschild 2008, 2011).

One aspect of this debate is whether the algorithm for predicting presupposition projection should be based on parsing, a process which takes as input a string of linguistic items, and thus will be sensitive to the linear order of the elements of the sentence in question; or on the compositional calculation of meanings, a process which takes as input a syntactic structure, and thus is sensitive to the hierarchical structure of the sentence. This debate, in turn, bears on the more general question whether presupposition calculation should be thought of as a pragmatic post-compositional phenomenon, in the sense of Chierchia et al. 2012, or as part of compositional semantics, as in more traditional dynamic approaches like that of Heim 1983.

In this paper, we will explore antecedent-final conditionals. We will argue that antecedent-final conditionals with presupposition triggers in the antecedent present a challenge to parsing-based accounts of presupposition projection, as well as to theories of triviality that build on those accounts. We will focus in particular on the predictions of Schlenker (2009), who uses a parsing-based approach to reconstruct the notion of a local context, and then builds theories of presupposition projection and triviality on top of his theory of local contexts in a straightforward way.<sup>2</sup>

To briefly sketch the problem: the parsing-based approaches to presupposition projection which we will consider come in both symmetric and asymmetric versions. Both versions, however, predict that presuppositions triggered in the antecedent of antecedent-final conditionals will be filtered (i.e. will not project) if the negation of the consequent entails the presupposition. But this is the wrong prediction; for instance, (1) presupposes that John is in France, contrary to this prediction.

(1) John isn't in Paris, if he regrets being in France.

Likewise, parsing-based approaches to triviality predict that material entailed by the negation of the consequent of an antecedent-final conditional will be redundant in the antecedent of the conditional. But, again, this is wrong; for instance, (2) is felicitous, contrary to these predictions.

(2) John isn't in Paris, if he's in France and Mary is with him.

In Mandelkern and Romoli 2017, we lay out a solution to this problem which allows us to maintain a parsing-based pragmatic approach with the caveat that, in calculating local contexts, we take into account material presupposed by the surrounding strings; we show that, together with a semantics for the conditional on which the conditional presupposes the antecedent to be compatible with the context set, this approach avoids the present problem. This approach

<sup>2</sup>As we discuss in Mandelkern and Romoli 2017, however, the problems extend to other parsing-based accounts, including those which make use of a trivalent valuation instead of local contexts (e.g. Fox 2008, 2012) as well as pragmatic parsing-based theories like Schlenker 2008.

requires a substantial shift in the formulation of the symmetric algorithm for calculating local contexts, however.

In this paper, we will take these puzzles in a different direction. In particular, we explore whether these puzzles motivate an approach to local contexts which takes account of hierarchical structure, rather than linear order. We will discuss two ways this might go. The first derives local contexts from an algorithm much like Schlenker's, but which is built on hierarchical structures rather than strings. The second builds on more traditional approaches in dynamic semantics, augmenting these approaches with hierarchical constraints. Our discussion will be somewhat inconclusive: we believe that both approaches have merits which make them worth careful exploration, but both also face substantial challenges.

The remainder of the paper is organized as follows. In the rest of this introduction, we introduce Schlenker (2009)'s algorithm for computing local contexts. In Section 2, we lay out the problem for presupposition projection from antecedent-final conditionals, and in Section 3, the problem for triviality. In Section 4, we discuss our first pass at a hierarchical approach to local contexts, building on Schlenker's system. In Section 5, we discuss our second pass at a hierarchical approach, an attempt to incorporate attention to hierarchical structure into traditional dynamic systems. We conclude in Section 6.

### 1.1. A parsing-based theory of local contexts and presupposition projection

Schlenker (2009) addresses the explanatory challenge for presupposition projection by using a parsing-based algorithm to reconstruct the notion of a local context in a static, bivalent semantics.<sup>3</sup> In this section, we summarize Schlenker's theory of local contexts and presupposition projection; those familiar with the theory should skip to the next section.

The basic intuition motivating Schlenker, which is similar to the intuition motivating trivalent theories of presuppositions (Peters 1979; Beaver and Krahmer 2001; George 2008; Fox 2008, 2012), is that as we evaluate a sentence against some contextual information, we try to minimize our effort by evaluating the sentence only in those worlds of the context that “matter” for the evaluation. Further, we assume (at least initially) that the interpreter evaluates expressions of a sentence proceeding left-to-right. Before evaluating an expression, the interpreter will choose the smallest domain she needs to take into consideration in evaluating such expression. This smallest domain is the local context for the expression.

Thus, for example, as we evaluate a conditional like *If A then B<sub>p</sub>* (where B<sub>p</sub> is a sentence B which presupposes  $\llbracket P \rrbracket$ ), as we proceed left-to-right, we will evaluate the consequent only in those worlds of the context in which the antecedent is true.<sup>4</sup> This is because we know that in

<sup>3</sup>Schlenker's approach is parsing-based in the sense we gave above: its input is a string, rather than a syntactic structure. We remain neutral on the connection of a theory like his to theories of parsing in general.

<sup>4</sup>We use sans serif capital letters as sentence variables, and italics to set off a linguistic example in running text. We move freely between talking of presuppositions as sentences and as propositions. Where P is a linguistic item,  $\llbracket P \rrbracket^c$  is the meaning (intension) of P at context C (a non-empty set of possible worlds); we often omit reference to the context for readability. We use ‘C’ throughout to refer to the global context, and sometimes use ‘C’ as a

those worlds in which the antecedent is false, the sentence as a whole is true irrespective of the value of the consequent, and thus we can ignore those worlds (assuming here that *If ... then* expresses the material conditional; we revisit this assumption in Mandelkern and Romoli 2017). But we cannot ignore any worlds where  $\llbracket A \rrbracket$  is true, since we must check whether the consequent is true at those worlds to see whether the sentence as a whole is true. This means that the local context for  $B$  in *If A then B* is  $C \cap \llbracket A \rrbracket$ .

We can then formulate a theory of presupposition in this framework as follows: we say that a sentence  $S$  is assertable in a context  $C$  only if, for every expression  $B_p$  in  $S$ ,  $\llbracket P \rrbracket$  is entailed by  $B_p$ 's local context in  $S$ . We then say that a sentence presupposes anything that is entailed by every context where it can be asserted. This means that the predicted presupposition of *If A then B* is  $A \rightarrow P$ : in other words, *If A then B* is assertable at  $C$  only if  $A \rightarrow P$  holds at every world in  $C$ .<sup>5</sup> This approach correctly predicts that a sentence like (4) presupposes only the tautology that if John used to smoke he used to smoke:

(3) If John used to smoke, he stopped smoking.

But—as Schlenker (2008, 2009) and Chierchia (2009), building on Heim 1990; Soames 1979 and others, discuss—antecedent-final conditionals pose a problem for the asymmetry encoded in this algorithm. (4), like (3), appears to have only a trivial presupposition, but this is not predicted by the incremental left-to-right algorithm, which only considers material to the left of the presupposition trigger.

(4) John stopped smoking, if he used to.

Intuitively, we would like material on the right of the presupposition trigger to count in this case. In response to these data, Schlenker (2009) proposes a symmetric version of his algorithm, which works on the entire sentence, rather than proceeding left-to-right: it considers both material on the left and the right of the expression to be evaluated. The result is that the symmetric local context for  $B$  in a conditional with the form *B, if A* is  $C \cap \llbracket A \rrbracket$ ; thus we predict that a conditional like (4) has no presupposition, as desired.

Schlenker makes these intuitive ideas precise as follows. First, the incremental, left-to-right version:

---

corresponding linguistic item whose intension is the global context.

<sup>5</sup>With  $\rightarrow$  standing for the material conditional. Notice that for some cases, the predicted conditional presuppositions of conditionals appear too weak. This is the so-called Proviso Problem (Geurts 1996 and much subsequent work; see Schlenker 2011 among others for recent discussion). This problem is orthogonal to the one we discuss here, however. Although the problem we raise for presupposition projection, like the Proviso Problem, stems from a gap between the observed projection and what is predicted, there is a crucial structural difference: in Proviso cases, the gap is between observed presuppositions with the form  $\llbracket P \rrbracket$ , and predicted presuppositions with the form  $\llbracket A \rightarrow P \rrbracket$ . It is possible that a principled story can be told about how we move from the latter to the former (and indeed just such a story has been told in the literature; see Mandelkern 2016 for citations and criticism). By contrast, in the cases we raise here, the gap is between observed presuppositions with the form  $\llbracket P \rrbracket$ , and a predicted trivial presupposition—i.e. a presupposition of  $\top$ . It is much harder in this case to see how a strengthening story would help: there is no obvious principled way to get from  $\top$  to  $\llbracket P \rrbracket$ .

**Definition 1.1.** Local Contexts, Incremental Version:<sup>6</sup>

The *incremental local context* of expression  $E$  in syntactic environment  $a\_b$  and global context  $C$  is the strongest  $\llbracket Y \rrbracket$  s.t. for all sentences  $D$  and good finals  $b'$ ,  $a(Y \wedge D)b' \leftrightarrow_c aDb'$ .

In addition to this incremental algorithm, Schlenker (2009) also defines a symmetric version, which applies as a dispreferred rescue strategy:

**Definition 1.2.** Local Contexts, Symmetric Version:<sup>7</sup>

The *symmetric local context* of expression  $E$  in syntactic environment  $a\_b$  and global context  $C$  is the strongest  $\llbracket Y \rrbracket$  s.t. for all sentences  $D$ :  $\mathbf{a}(Y \wedge D)\mathbf{b} \leftrightarrow_c \mathbf{a}D\mathbf{b}$ , where  $\mathbf{a}$  and  $\mathbf{b}$  are derived from  $a$  and  $b$  by removing any presupposition material.

This symmetric algorithm is like the incremental version except for two features. First, it takes into account all material in the sentence, regardless of whether it precedes or follows the expression to be evaluated: this is what makes it symmetric. Second, it ignores presuppositions in the surrounding material. The reason for this second feature is that, as Rothschild (2008) and Beaver (2008) point out, without it, the symmetric algorithm incorrectly predicts that on a symmetric parse, presuppositions can cancel each other out. Thus we would predict e.g. that a sentence like (5), with the form  $A_p$  and  $B_p$ , should not presuppose  $p$ .

- (5) The King of France is bald and the King of France is tall.

But this is wrong; to see that (5) presupposes that there is a king of France, note that this inference projects when (5) is embedded in the antecedent of a conditional, as in (6):

- (6) If the King of France is bald and the King of France is tall, there will be no diplomatic incident.

Analogous data can be generated with disjunction (see Rothschild 2008). This problem is avoided by the algorithm given above, according to which we ignore the presuppositional material of  $a$  and  $b$  when calculating the local context of the constituent between  $a$  and  $b$ .

Notice that if we are evaluating an expression  $D$  which appears sentence-final, the symmetric and incremental local context of  $D$  are identical. This is important for our purposes: it follows that for the data we are concerned with in this paper—the antecedents of antecedent-final conditionals—the incremental and symmetric versions of the algorithm will make the same predictions.

<sup>6</sup>We restrict our attention here to a propositional fragment; for a general version, see Schlenker 2009. The good finals of an expression are all strings that can grammatically follow that expression. ' $\leftrightarrow_c$ ' is material equivalence modulo a context  $C$ .

<sup>7</sup>This formulation assumes that it is possible to “delete” a sentence’s presuppositions from the sentence. It is not obvious to us that this is possible, but we set aside this issue here. See Mandelkern and Romoli 2017 for further discussion.

## 2. The problem for presupposition projection

To work up to our puzzle, consider first a conditional with a presupposition trigger in the antecedent, as in (7).

(7) If  $A_p$  then B.

Here the incremental and symmetric algorithms for calculating local contexts make different predictions, since the trigger appears sentence-initial. The incremental algorithm predicts that (7) presupposes P. The symmetric one, on the other hand, takes into consideration the material following  $A_p$  in evaluating it.  $\llbracket B \rrbracket$ -worlds would make the whole sentence true regardless of the value of the antecedent; thus we only need to consider  $\llbracket \neg B \rrbracket$ -worlds in evaluating  $A_p$ .<sup>8</sup> In particular we must consider every  $\llbracket \neg B \rrbracket$ -world in the context. Thus the symmetric local context of  $A_p$  in (7) is  $C \cap \llbracket \neg B \rrbracket$ , and so the predicted presupposition of the symmetric algorithm is  $\neg B \rightarrow P$ .

Schlenker (2009); Chemla and Schlenker (2012) and Rothschild (2011) discuss whether the prediction of the symmetric algorithm for (7) is correct. But this discussion is complicated by the fact that the symmetric algorithm is taken to be a dispreferred interpretive strategy, making it hard to see how to evaluate this prediction.

We can avoid this complication, however, by considering the antecedent-final counterpart of (7), in (8).

(8) B, if  $A_p$ .

Here the incremental and the symmetric algorithms make the same predictions, since in both versions of the algorithm the material on the left of the trigger is taken into account, and there is no material to the right of the trigger in this case. This allows us to avoid difficult questions about the relation between an incremental and symmetric algorithm,<sup>9</sup> and directly evaluate the plausibility of a parsing-based algorithm of either form.

Both algorithms predict that at the point at which we process A, we only need to consider  $\llbracket \neg B \rrbracket$ -worlds of C, because  $\llbracket B \rrbracket$ -worlds would make the sentence true regardless of the value of the antecedent. Therefore the incremental and symmetric local context for A in (8) is  $C \cap \llbracket \neg B \rrbracket$ . Thus the predicted presupposition of (8), for both the incremental and symmetric approach, is  $\neg B \rightarrow P$ .

But this prediction is problematic. It follows from this prediction that if the negation of the consequent of an antecedent-final conditional entails the presupposition of the antecedent, the sentence will be presuppositionless. Schematically, a case like (9), where  $\llbracket P^+ \rrbracket$  entails  $\llbracket P \rrbracket$ , is thus predicted to presuppose nothing.

<sup>8</sup>We sometimes use ‘ $\neg$ ’ and other logical connectives as abbreviations for the corresponding natural language connectives. We leave our derivations of local contexts at the present level of informality; the reader can check them for herself, or refer to Schlenker 2009.

<sup>9</sup>On which see Schlenker 2008, 2009; Chemla and Schlenker 2012 and Rothschild 2011.

- (9)  $\neg P^+$ , if  $A_p$ .

This prediction, however, does not match intuitions. To see this, consider first the conditionals in (10a), (11a), and (12a). They appear to presuppose that John is in France, that he is sick, and that he is a linguist, respectively, as predicted by the incremental parsing approach.

- (10) a. If John regrets being in France, he isn't in Paris.  
       b. John isn't in Paris, if he regrets being in France.
- (11) a. If John's wife is happy that he is sick, he doesn't have cancer.  
       b. John doesn't have cancer, if his wife is happy that he is sick.
- (12) a. If John is happy he is a linguist, he isn't a semanticist.  
       b. John isn't a semanticist, if he is happy that he is a linguist.

Consider now the corresponding antecedent-final conditionals in (10b), (11b), and (12b), which have the form of (9). Intuitively these have the same presuppositions as the antecedent-initial versions. The problem is that the symmetric and incremental versions of the algorithm both predict that (10b), (11b), and (12b) have no presuppositions.<sup>10</sup>

Both the symmetric and incremental parsing-based algorithms given in Schlenker 2009 thus apparently make the wrong predictions for antecedent-final conditionals with a presupposition trigger in the antecedent: they predict that, when the conditional has the form of (9), its presupposition will be filtered, whereas the presupposition in fact projects.

### 3. The problem with triviality

The parsing-based theory of local contexts can be straightforwardly extended to a theory which predicts when a sentence strikes us as trivial or redundant. We show in this section that the problem raised in the last section extends to this theory.

Reconstructing the notion of local context allows Schlenker (2009) to connect his theory to a general theory of triviality, a theory with roots in Stalnaker 1978 (see also Singh 2007; Fox 2008; Chierchia 2009; Mayr and Romoli 2016 among others).<sup>11</sup> Given the account of local contexts sketched above, we say that a sentence  $S$  is infelicitous if, for any part  $E$  of  $S$ ,  $\llbracket E \rrbracket$  is entailed or contradicted by its local context.

This approach correctly predicts that a sentence like (13) should be infelicitous, since it has a part, namely *he is in France*, whose content is entailed in its local context (whether we calculate it incrementally or symmetrically):

<sup>10</sup>In other words, that all three have trivial presuppositions: respectively, that if John is in Paris, then he is in France; that if John has cancer, then he is sick; and that if John is a semanticist, then he is a linguist.

<sup>11</sup>A theory of triviality can also be formulated in terms of equivalence to simplifications of the sentence, in the sense of Katzir 2007, to which one can add an incremental component (see Mayr and Romoli 2016; Meyer 2013 and Katzir and Singh 2013 for discussion). The problems discussed here extend to this approach as well.

(13) #If John is in Paris, he is in France and Mary is with him.

Similarly, this approach predicts that (14) should not be assertable, given that *he is in Paris* is contradictory in its local context.

(14) #If John isn't in France, he is in Paris and Mary is with him.

So far so good. Now consider the predictions of the parsing-based algorithm for antecedent-final conditionals. Recall in particular that the local context of the antecedent of an antecedent-final conditional like *B, if A* is predicted by both the incremental and symmetric algorithms to be  $C \cap \llbracket \neg B \rrbracket$ . The theory of triviality under discussion thus predicts that if  $\llbracket A \rrbracket$  is entailed or contradicted by  $C \cap \llbracket \neg B \rrbracket$ , the sentence should not be assertable. Both the symmetric and incremental algorithms thus predict that a sentence with the form

(15)  $\neg P^+$ , if P and Q.

will be infelicitous, since P will be redundant. But this is wrong. To see this, consider first the antecedent-initial conditionals in (16a) and (17a).

(16) a. If John is in France and Mary is with him, then he's not in Paris.  
b. John isn't in Paris, if he is in France and Mary is with him.

(17) a. If John is sick and his wife is happy that he is sick, then he doesn't have cancer.  
b. John doesn't have cancer, if he is sick and his wife is happy that he is sick.

We judge these conditionals to be perfectly felicitous. Now consider the antecedent-final versions, in (16b) and (17b). We judge these versions to be equally felicitous. However, the parsing-based theory of triviality (on both its incremental and symmetric versions) wrongly predicts that the antecedent-final versions will be infelicitous, since both have material that is locally redundant (*he is in France* and *he is sick*, respectively).

#### 4. Hierarchical transparency

Antecedent-final conditionals thus present a puzzle for parsing-based approaches to local contexts. In Mandelkern and Romoli 2017, we present a solution to this puzzle which stays largely within the bounds of the parsing-based framework. Here we will explore two alternate solutions, both of which reject parsing-based approaches in favor of approaches which track hierarchical structure rather than linear order. As we will discuss, while both approaches show promise in relation to our data and others discussed below, both also face serious challenges that remain open at this stage.

The first solution, which we call a *hierarchical transparency* approach, retains the basic idea of Schlenker's algorithm: namely, that the local context for an expression in a certain environment is the strongest meaning which *adds nothing* to that environment; i.e. the strongest meaning which is *transparent* in that environment. Crucially, we depart from Schlenker, however, in

implementing this idea with an algorithm that takes into account hierarchical structure, rather than linear order.

Before sketching the algorithm and how it might help with our case, let us quickly review some further data which will provide independent evidence for the hierarchical transparency approach. The first come from Ingason 2016, which explores triviality judgments regarding relative clauses in head-final languages, in particular Korean and Japanese. In brief, Ingason shows that triviality judgments track hierarchical structure, *not* linear order. To see the point, consider first the contrast between (18a) and (18b). (18a) is felicitous, while (18b) is infelicitous. This is just as predicted by the theory of triviality introduced above, since the local context for *is a man* will entail *is a man* in (18b), but not (18a).

- (18) a. John met a man who is an uncle.  
b. #John met an uncle who is a man.

These sentences are in English, a head-initial language, where hierarchical structure and linear order of relative clauses correspond. It turns out that when we look at head-final languages like Korean and Japanese, however, where hierarchical structure comes apart from linear order, judgments about triviality track hierarchical structure, *not* linear order. Here is Ingason's data from Korean:

- (19) a. Mary-nun [[accesi-in] sengin namca-lul] mannassta.  
Mary-TOP [[mister-ADN] adult male-ACC] met.  
'Mary met an adult man who is a mister/uncle.'  
b. #Mary-nun [[sengin namjcaa-in] aaccessi-lul] mannassta.  
Mary-TOP [[adult male-ADN] mister-ACC] met.  
'Mary met a mister/uncle who is an adult male.'

A theory of triviality based on linear order, like the one introduced above, will wrongly predict that (19b) is felicitous, since *uncle* cannot be part of the local context of *adult male*, as it follows *adult male* in the linear order of the sentence. By contrast to the predictions of a theory like that, these data seem to show that triviality judgments track hierarchical order in some sense, rather than linear order.

The second data point we will introduce here concerns presupposition projection, and comes from Chung 2017. Chung notes that Korean is a SOV language, and thus that the attitude verb generally follows its complement clause in terms of linear order. If the calculation of local contexts were sensitive to linear order, then, the local contexts for the complements of attitude verbs would be given by the global context, just as for unembedded material. But this is not what happens; presuppositions rather project just as they do in English, where the complement of an attitude verb follows the verb. For instance, (20) is not felt to presuppose that Mary used to smoke, contrary to what we would predict if the local context for the second attitude ascription was calculated based on linear order:

- (20) John-un Mary-ka kotunghakkyo ttay tampay-lul pi-ess-ess-tako  
John-TOP Mary-NOM high school time cigarette-ACC smoke-PERF?-PAST-COMP

mit-ø-ko, (John-un) Mary-ka cikum-to keysokhayse tambay-lul  
 believe-PRES-CONJ John-TOP Mary-NOM now-also continuously cigarette-ACC  
 pi-n-tako mit-nun-ta.  
 smoke-PRES-COMP believe-PRES-DECL.  
 ‘John believes that Mary smoked in high school, and he believes that she continues to smoke.’

This suggests that, just as in the case of triviality judgments, our calculation of local contexts needs to track hierarchical structure, not linear order. We will sketch an approach which modifies Schlenker’s algorithm so that it takes into account hierarchical structures, rather than linear order.<sup>12</sup> We will show how this kind of approach answers to the motivations just sketched, and then explore whether it also affords a solution to our puzzle from antecedent-final conditionals.

The idea is simple: to derive the local context for an expression, we look at that expression’s place in its LF, and we look at what we could add to that place in the LF, so that however the LF is completed, the LF’s denotation remains the same. There are different ways to flesh out what we mean by ‘however the LF is completed’. We will interpret this as meaning however we replace the material in that expression, or material which is structurally “below” it, in the sense of being asymmetrically c-commanded by it. This seems to us like a reasonable way of fleshing out the relevant notion, though it is worth noting that the basic idea could be implemented in a variety of other ways which are well worth exploring.

More formally, for any LF  $L$  and node  $\alpha$  in  $L$ , let us define a *good-completion* of  $L$  at  $\alpha$  as any well-formed LF which is identical to  $L$  except that any clause dominated or asymmetrically c-commanded by  $\alpha$  may be replaced by new material.<sup>13</sup> For any sub-tree  $Y$ , let a *Y-good-completion* of  $L$  at  $\alpha$  be any good completion of  $L$  at  $\alpha$  such that  $\alpha$  is replaced by a subtree beginning with  $[Y$  [and  $\_$ ]. Thus for instance (22) is a good-completion of (21) at  $\alpha$ , and (23) is a [John [came  $\_$ ]-good-completion of (21) at  $\alpha$ .

<sup>12</sup>We’ll focus only on the incremental version, since in the symmetric version, the predictions will be essentially equivalent to Schlenker’s approach.

<sup>13</sup>Why asymmetric c-command, instead of c-command? Consider an attitude ascription with the form  $[John$  [believes  $[A]]]$ . If we formulated our definition in terms of c-command, rather than asymmetric c-command, we would predict that in calculating the local context for  $A$ , we would have to ignore *believes*. This would yield the wrong results.

(23)

Now we are in a position to state the hierarchical transparency algorithm:<sup>14</sup>

**Definition 4.1.** Hierarchical Transparent Local Contexts:

The local context of expression  $E$  in LF  $L$  and global context  $C$  is the strongest  $\llbracket Y \rrbracket$  s.t., where  $\alpha$  is the lowest node which dominates a full clause containing  $E$ , for all good-completions  $D$  of  $L$  at  $\alpha$ , and for all  $Y$ -good-completions  $D^Y$  of  $L$  at  $\alpha$ ,  $\llbracket D \rrbracket \cap C = \llbracket D^Y \rrbracket \cap C$ .<sup>15</sup>

The idea, again, is similar to Schlenker's algorithm, except that the local context here is calculated by finding the strongest thing that we can add to the LF of the expression in question while preserving contextual equivalence, *no matter how that LF is completed*—rather than the strongest thing we can add to the linguistic string, no matter how it is completed. Let's note, first of all, the overlap with Schlenker's algorithm. Assuming that conjunction has the straightforward hierarchical syntax illustrated in (21), then it is easy to verify that the local context for  $A$  in  $A$  and  $B$  in global context  $C$  is just  $C$ ; and the local context for  $B$  is  $C \cap \llbracket A \rrbracket$ . Thus for instance consider again (21), repeated here.

(21)

In calculating the local context for *John came*, we first find the lowest node dominating a full clause containing *John came*. We assume that this counts as a full clause itself, and so the lowest such node will be  $\beta$ . In considering good-completions at  $\beta$ , we can ignore everything below  $\beta$  (*John* and *came*), as well as everything  $\beta$  asymmetrically c-commands (*Sue, came*). Then the question will be: what is the strongest thing we can conjoin just below  $\beta$  such that it will not change the meaning of the whole LF, no matter how the rest is filled in? Since all we know about the rest of the LF is that it will have an *and* in it, the answer is clearly: the

<sup>14</sup>We assume now that our denotation function is defined on LFs.

<sup>15</sup>Why the reference to 'full clause'? Consider the question of what the local context for *John came* is in (21). Since *John came* asymmetrically c-commands *Sue came*, the latter will, correctly, be predicted not to be entailed by the local context of the former. But now consider what the local context for the first *came* is in (21). Since *came* does *not* asymmetrically c-command *Sue came*, then, if we did not have reference to a 'full clause' in our definition, we would wrongly predict that the local context for *came* does entail that Sue came. What a 'full clause' amounts to is something that of course needs to be spelled out precisely, but something we will remain vague about; we return to this briefly below.

global context. By contrast, in calculating the local context for *Sue came*, we will consider good-completions at  $\alpha$ . Since  $\alpha$  does not asymmetrically c-command anything in this LF, we will only look at good-completions that vary in the material  $\alpha$  dominates, namely *Sue came*. What is the strongest thing that we can conjoin just under  $\alpha$  that will be guaranteed to preserve the meaning of the LF? Clearly it is the conjunction of the global context with *John came*.

Likewise, the local context for A in *A or B* in global context C is just C; and the local context for B is  $C \cap \llbracket \neg A \rrbracket$ . Likewise, finally, the local context for A in *Not A* in global context C is just C. These predictions are all identical to those of Schlenker's asymmetric algorithm (and, therefore, to the standard predictions of traditional dynamic theories).<sup>16</sup>

Things get more interesting, however, when we look at head-final or SOV languages like Korean. Assuming that the clausal part of the relative clause is asymmetrically c-commanded by its head noun, then, in our framework, the content of its head noun will always form part of the content of the local context for the relative clause, *whatever the relative linear order of the head and the relative clause*. That is, take a sentence like *John met an uncle who is a man*. We assume this sentence has an LF with a structure along the lines of  $[John [met [an [uncle [who_1 [t_1 is a man]]]]]]$ . In this structure,  $t_1 is a man$  does not c-command *an uncle*. This means that in calculating the local context for  $t_1 is a man$ , we will take into account *an uncle*, and thus we predict that the local context for  $t_1 is a man$  entails  $t_1 is an uncle$ , and therefore  $t_1 is a man$ . Crucially, in the hierarchical transparency account—unlike in Schlenker's parsing-based algorithm—this holds *whatever the linear order* of the relative clause and its head, provided that the hierarchical order is preserved. Similar considerations show that—since the complements of attitude predicates do not asymmetrically c-command the predicate—we predict that the local context under an attitude predicate is the set of attitude worlds, whether or not the attitude predicate precedes its complement, as in English, or follows it, as in Korean.

The hierarchical transparency approach to local contexts (or something roughly along these lines) seems to us to be the right way to preserve the explanatory and predictive virtues of Schlenker's algorithm, while respecting the fact that presupposition and triviality seem to be calculated in a way which depends on hierarchical structure, rather than linear order. But does it help with our problematic data involving antecedent-final conditionals? This depends crucially on the syntax of the conditional, both antecedent-initial and antecedent-final.

Start with antecedent-initial conditionals. We must suppose, first, that the antecedent asymmetrically c-commands the consequent; this would fall out, e.g., if the syntax of the conditional is roughly as in (24), where  $\Box$  is the conditional's (possibly covert) modal.

<sup>16</sup>It is worth noting here that we can also capture symmetric filtering for connectives in this algorithm if we assume non-standard syntactic structure in those cases. We could, of course, also assume that a secondary, symmetric algorithm comes into play in those cases, as Schlenker does; but the present approach gives us flexibility to explore the possibility that there is only one algorithm, and that variations in syntax account for right-to-left filtering.

Second, we must suppose, crucially, that for the purpose of our algorithm, the largest ‘full clause’ containing *A* is the whole antecedent *If A*, not *A* on its own. This assumption is crucial to ensure that the consequent is ignored in calculating the local context for the antecedent; otherwise, in calculating the local context for *A*, we would not be able to ignore the consequent, since it is not asymmetrically c-commanded by *A*, and we would predict that the local context for the antecedent entails the negation of the consequent.

Given these assumptions, the local context for the antecedent *If A* will not entail the negation of the consequent, since the antecedent asymmetrically c-commands *B*, and so we will ignore that part of the LF in searching for the strongest transparent restriction for the antecedent. Instead, the strongest transparent restriction will just be the global context. By contrast, the consequent *B* does not asymmetrically c-command anything, and so we will ignore nothing when calculating the strongest transparent restriction for *B*, predicting that the local context is the global context intersected with  $\llbracket A \rrbracket$ .

If we assume that antecedent-final conditionals are generated from the same LF as antecedent-initial conditionals, and simply linearized in a different way from antecedent-initial conditionals, this approach would make the correct predictions about the local contexts for the antecedents of both antecedent-initial and antecedent-final conditionals, thus solving our puzzle.

But this approach raises a number of serious questions. First, this approach assumes that the smallest ‘full clause’ that includes *A* in the sense relevant to our algorithm is *If A*, rather than just *A*; whereas the largest full clause containing *B* is *B* alone. It is not clear to us how to spell out these assumptions in a principled way. One way to do so would be to stipulate that the relevant notion is in part a semantic one, so that what counts as a full clause containing *E* in an LF *L* is the largest part of *L* whose denotation is equivalent to the smallest full clause containing *E*. Then, if we assume that *if* is semantically null (which would be natural in the kind of restrictor approach to the syntax of the conditional we are assuming here), it will fall out that the relevant clause to consider when evaluating the local context for *A* will be *If A*, rather than just *A* alone. By contrast, in evaluating the local context for *B*, we obviously will not take into account  $\Box$ , since  $\llbracket \Box B \rrbracket$  is certainly not the same as  $\llbracket B \rrbracket$ . There is much more to explore as to whether these assumptions are plausible in other environments, and why things would work this way.

Second, there are binding data which suggest that antecedent-final conditionals are not generated from structures like (24). For instance, the infelicity of the co-indexed variant in (25) suggests that the subject of the consequent of antecedent-final conditionals c-commands the subject of the antecedent, contrary to the picture we have assumed (see Bhatt and Pancheva 2006):

(25) He<sub>[1\*/2]</sub> isn’t at home, if John<sub>1</sub> is with Susie.

The plausibility of the hierarchical transparent approach will turn on whether appropriate syntactic assumptions can thus be fleshed out. This is a topic which we leave for future work. Let us note here, however, that, even if it does not solve the present problems, we might still opt

for the hierarchical transparent approach on the basis of evidence of the kind discussed above, from Ingason (2016) and Chung (2017), and then supplement that approach with the solution to our problem given in Mandelkern and Romoli 2017.

## 5. Dynamic semantics

In this section we explore a second strategy for incorporating hierarchical structure into the calculation of local contexts, investigating how we could couple traditional dynamic semantics with a structure-based order constraint.

Traditional dynamic semantics along the lines of Heim 1983 avoids our problems from antecedent-final conditionals. This is because in such a system, as Chemla and Schlenker (2012) put it, the ‘left-right asymmetries reach down to the lexical representations of logical operators.’ And once the lexical meaning of a conditional operator is stipulated, it doesn’t matter whether the antecedent appears sentence-finally or sentence-initially. In other words, given the way asymmetry is encoded in dynamic semantics, what matters is what is encountered first in semantic composition, rather than in linear order. And for both the antecedent-initial and antecedent-final cases, the denotation of *if* composes first with the antecedent and then with the consequent of the conditional. If *if* is treated as a (Curried) two-place sentential operator, as in Heim’s system, once we define a context-change potential for *if* which makes the right predictions for an antecedent-initial conditional, it will make the same correct predictions for the antecedent-final counterpart.

This approach, however, fails to address the explanatory challenge summarized at the outset. We can briefly illustrate the problem as follows: there is nothing in the system that prevents us from defining a meaning for *if* which is (in a sense we can make precise) truth-conditionally equivalent to the one Heim proposes, but which makes the wrong predictions about presupposition projection for both antecedent-initial and antecedent-final conditionals. Heim’s entry for the conditional is  $c[\text{If } A, \text{ then } B] = c \setminus c[A][\neg B]$ . A truth-conditionally equivalent entry would run  $c[\text{If } A, \text{ then } B] = c \setminus c[\neg B][A]$ . But this latter entry wrongly predicts that the negation of the consequent is taken into account in evaluating the presuppositions of the antecedent. The explanatory challenge for a theory like Heim’s is how to rule out the latter entry in a principled way.

Constrained dynamic approaches (Rothschild 2008, 2011; Schlenker 2009; Chierchia 2009) aim to solve the explanatory problem by giving a principled way to determine CCPs for connectives. Rothschild (2008, 2011) in particular argues that the explanatory problem can be met by constraining possible CCPs according to their truth-conditional adequacy. While this does not uniquely yield a CCP for a given connective, it yields a limited range of CCPs. Rothschild then argues that this range represents admissible interpretations of a given connective. In order to account for an asymmetric bias in evaluating presuppositions, insofar as there is one, Rothschild proposes adding a (possibly defeasible) order constraint along the following lines: in determining the CCP for a formula  $\psi * \phi$ , we do not allow any instance of the CCP for  $\psi$  to operate on a formula that contains  $\phi$ .

A key question here is what is meant by a formula with the form  $\psi * \phi$ : is the order of this schema meant to mirror linear order, or structural order? If the former, then Rothschild's system will fail to rule out the incorrect alternate CCP for the conditional just sketched. Indeed, Rothschild's system would make just the wrong prediction here: it would predict a strong, if perhaps defeasible, preference for that alternate CCP, where the negation of the consequent is entailed in the local context of the antecedent. A better option, then, is to interpret the order adverted to in Rothschild's order constraint in terms of hierarchical structure, rather than linear order. But it is tricky to spell out exactly how this is meant to go.

A natural first thought is that a sentence of natural language is mapped to  $\psi * \phi$ , in the sense relevant for Rothschild's order constraint, just in case  $\psi$  asymmetrically c-commands  $\phi$ . This would suffice to predict the ordinary asymmetric entries for conjunction and disjunction, since the first conjunct/disjunct asymmetrically c-commands the second, under standard syntactic assumptions; and it seems to capture Ingason's and Chung's data in a straightforward way. But does it help us? Only if both antecedent-initial and antecedent-final conditionals are such that the antecedent asymmetrically c-commands the consequent. This is the same assumption that we had to make in spelling out the hierarchical transparent approach in the last section. As we saw there, however, it is not obvious that this assumption is tenable in light of binding data from antecedent-final conditionals; much more work would have to be done to justify it.

A second approach would take the opposite tack: on this approach, a sentence of natural language is mapped to  $\psi * \phi$ , in the sense relevant for Rothschild's order constraint, just in case  $\phi$  asymmetrically c-commands  $\psi$ . If we go this way, then we need to say that the consequent of conditionals asymmetrically c-commands the antecedent in both antecedent-final and antecedent-initial conditionals. It is not clear to us whether this is plausible on general syntactic grounds. A simpler problem, however is that this approach yields the wrong results for conjunction and disjunction: since the first conjunct/disjunct asymmetrically c-commands the second, this approach will predict that the preferred interpretation of conjunction and disjunction will involve right-to-left filtering. While it seems to us open that the preferred interpretation of both conjunction and disjunction is symmetric, or that the preferred interpretation of both involves left-to-right filtering, it does not seem open to us that the preferred interpretation involves right-to-left filtering.<sup>17</sup> This approach also does not seem to account for Ingason's and Chung's data.

An alternative constraint, more semantic and less syntactic in spirit, builds on Chierchia (2009). The idea is to say that a sentence containing an operator  $*$  gets mapped to  $\psi * \phi$  just in case  $[[*]]$  first takes  $[[\psi]]$  as an argument, yielding a function which then takes  $[[\phi]]$  as an argument.<sup>18</sup> Now, if we assume that *if* denotes an operator which first combines with the meaning of the antecedent, yielding a new function which combines with the meaning of the consequent, then this way of mapping sentences into Rothschild's order constraint will ensure that the antecedent will always provide the local context for the consequent, but not vice versa, whether the antecedent is preposed or postposed, and whatever the underlying syntax turns out to be.

<sup>17</sup>Note that replacing 'asymmetrically c-commands' with 'c-commands' in either case does not help with the problems just sketched.

<sup>18</sup>This corresponds roughly to the relation Chierchia calls 'f-command'.

On first glance, the present approach faces the same objection as the last approach considered: again, if, as is standard, we assume that conjunction and disjunction denote functions which first combine with the right conjunct/disjunct, then this approach will wrongly predict exclusive right-to-left filtering for conjunction and disjunction.<sup>19</sup>

The present approach, however, unlike the last one considered, has a bit of room for maneuver in response to this issue. In particular, we can follow Chierchia (2009), who proposes a revisionary solution to this problem, based on two ingredients. First, we assume that conjunctions and disjunctions always contain either *both* or *either*, which can be overt or covert, and which, crucially, form a constituent with the first conjunct/disjunct, as in (26).

Second, the meaning of the two connectives is associated with *both* and *either*, respectively; *and* and *or* will be semantically vacuous. If we accept these two assumptions, the predictions of the hierarchical order account are now the expected ones: we will have left-to-right filtering for conjunction and disjunction, not right-to-left filtering. This is a substantial revisionary assumption about the syntax and semantics of connectives, however; the plausibility of this approach will depend on the plausibility of this assumption.

Another challenge for this solution is to explain cases of symmetric filtering with disjunction. A possible response would be to claim that a disjunction can involve an ambiguity as to whether the meaning of the connective is associated with *either* or it is associated with *or* when there is right-to-left filtering. The key question, again, is whether either structure is plausible on broader syntactic considerations.

A final challenge for this solution is whether it can be extended to account for the data we discussed in the last section involving triviality and presupposition projection in head-final and SOV languages. It is not at present clear to us how to do so.

## 6. Conclusion

We have used antecedent-final conditionals to formulate a problem for parsing-based theories of local contexts. Those theories—both in their incremental and the symmetric variants—predict that the negation of the consequent of antecedent-final conditionals will be entailed by the local context for the antecedent. Data from presupposition projection and triviality judgments, however, show that this is wrong.

In Mandelkern and Romoli 2017, we laid out one solution to this problem broadly within a parsing-based approach to local contexts. In this paper, we have explored two alternate solutions. The first builds on Schlenker's idea that a local context is the strongest trivial restriction in a given environment. Rather than taking the environment to be a linear string as Schlenker does, we explored an account which takes the environment to be an LF. The resulting theory

<sup>19</sup>See George 2008; Chierchia 2009 for discussion of this problem.

nicely accounts for a range of data which appear to show that the calculation of local contexts must be hierarchical. It helps with our problem only under certain assumptions about the syntax of the conditional, however—assumptions which raise a number of substantial questions which are beyond the scope of this paper.

The second solution builds on traditional dynamic semantic accounts along the lines of Heim 1983. As we discussed at the outset, this style of dynamic semantics has come under attack for being insufficiently explanatory. In recent years, however, more explanatory theories have been proposed which, like dynamic semantics, base the calculation of local contexts on compositional structure. We explored three ways in which hierarchical order could be used to constrain possible dynamic semantic entries according to the order of functional application. One way nicely accounts for Ingason's and Chung's data, but requires the same type of controversial assumption about the syntax of conditionals as the hierarchical transparency approach. The second and third approaches account for our data in a fairly straightforward way, but it is not clear they can account for Ingason's and Chung's data; and they face serious challenges in accounting for other connectives. We discussed a response on behalf of the third approach, based on Chierchia 2009, which avoids this objection by making certain revisionary assumptions about the syntax and semantics of other connectives—assumptions which, again, raise a number of substantial questions.

There have been various arguments in the recent literature that hierarchical order should play a direct role in the calculation of local contexts. It is not clear to us whether our data involving antecedent-final conditionals should be accounted for in this way, but, regardless of how those data are ultimately accounted for, we hope to have sketched several promising directions for incorporating hierarchical structure into the calculation of local contexts, along with some of the challenges those approaches face.

## A lexical marker of degrees of answerhood

Moria RONEN — *Bar Ilan University*

Yael GREENBERG — *Bar Ilan University*

Galit SASSOON — *Bar Ilan University*

**Abstract.** Questions and their answers have been discussed at length over the past few years. In this paper we present and analyze a Hebrew hedger, *be-gadol*, roughly translated as *basically*. We use the literature on questions, answers and the relation between them to suggest that *be-gadol* is an item which conveys a restriction on the context of utterance. This restriction concerns the relation between answers to the QUD on an answerhood scale, which is characterized as involving two notions, informativity (Roberts 1996) and resolution, defined using tools from decision theories (Ginzburg 1995; van Rooij 2003). This significantly supports the linguistic reality of these notions.

**Keywords:** formal semantics, decision theory, decision problems, utility, resolution, answerhood.

### 1. Introduction

This paper deals with the Hebrew particle *be-gadol*, which literally means ‘*in-big*’, and can be roughly translated as *in principle*, *by-and-large*, *in theory*, or *basically*. *Be-gadol* is a focus sensitive hedger/approximator which has a variety of uses and effects. The abundance of the effects leads to an empirical challenge, as it is very difficult to find a unified lexical entry which captures the variety of meanings of *be-gadol*. Moreover, we will argue that only some of the uses we find with *be-gadol* can be analyzed using existing tools. This leaves us in even deeper waters. Given the difficulties mentioned, the question at the center of this paper is how to account for all the data and all of these readings in a unified way, and which tools can be used for doing that.

The structure of the paper is as follows: This section will discuss some data to demonstrate the different uses of *be-gadol* and the next section will present our intuition. In section three we present the proposal in detail as well as apply it to several cases. We also review the theoretical tools needed for our purpose, in particular tools which deal with question resolution, informativity and utility (e.g. Roberts 1996, Ginzburg 1995, van Rooij 2003). In section four we examine an additional use of *be-gadol* which seems to pose a problem for our theory. We then propose a solution based on theories of projective meanings and relationships between questions under discussions and their answers (e.g. Simons et al 2010). Section five lays out some questions for further research, summarizes and concludes.

#### 1.1. Data: The empirical challenge

As discussed above, using *be-gadol* can yield a variety of effects. For example, some of the uses we find with *be-gadol* can be paraphrased using other particles, as in (1) which we refer to as the “approximative” use, and as in (2) which we refer to as the “temporal” use. Both

(1a) and (2a) paraphrase the specific use of *be-gadol* in (1) and (2), and (1b) and (2b) give alternative paraphrases using a correlating particle (e.g. *more or less* and *for the most part*).

- (1) ha-xeder be-gadol naki  
 the.room in.big clean  
 “The room is be-gadol clean.”  
 a. The room is not completely clean  
 b. The room is more or less clean
- (2) Context: John and Mary are talking about a party, John is inquiring about the mutual friend Rina’s actions at that party.
- John: What did Rina do at the party?  
 Mary: Rina be-gadol rakda  
 Rina in.big danced  
 “Rina be-gadol danced.”  
 a. Rina danced most of the time  
 b. Rina danced for the most part

Crucially, however, there are also uses which cannot be paraphrased using such expressions. We will argue that uses like the ones in (3) and (4) cannot be analyzed using the tools which have been proposed for *for the most part* or *more or less*. For example, (3) is similar to example (2) but is used differently. We refer to (3) as the “significance” use. Another example can be found in (4), which we refer to as the “not enough details” use. (3a) and (4a) paraphrase the meaning of (3) and (4), but (3b,c), and (4b,c) demonstrate that unlike (1b) and (2b), paraphrases with *more or less* and *for the most part* are not available for the examples below.<sup>1</sup>

- (3) Context: Rina sang, drank beer and spoke to the barman as she usually does in parties, but her dancing was her most significant, e.g. enthusiastic activity, attracting most of the attention. Dancing was not necessarily the longest activity, or atypical.
- John: What did Rina do at the party?  
 Mary: She be-gadol danced  
 a. The most significant thing Rina did in the party was to dance  
 b. ≠for the most part she danced  
 c. ≠she more or less danced
- (4) A: What do you do? What’s your occupation?  
 B: ani be-gadol orex sfarim  
 I in.big edit books  
 “I’m be-gadol a book editor.”

<sup>1</sup>Other interpretations of the same sentence are possible (e.g. paraphrases with *more or less*). However, they do not generate what we give in (3a) and (4a). The other available interpretations with the other particles correlate with the uses mentioned in (1) and (2). For example, one could say that *For the most part Rina danced* is a felicitous sentence, but instead of the meaning in (3a) we get the meaning that what Rina did during the party was mostly to dance.

- a. What I do is more specific (e.g. I edit books dealing with medieval history and religion)
- b.  $\neq$ for the most part I edit books
- c.  $\neq$ I more or less edit books

As the examples above show, *be-gadol* can lead to a wide range of hedging effects, and not all of them can be paraphrased using other particles. The main challenge is to unify all these examples despite their differences. Due to the diversity of uses, the hedging effect cannot be analyzed by resorting to quantificational tools, as done for example by Nakanishi and Romero (2004) for *for the most part*, or just by using coarser granularities/lower precision standards, as Sauerland and Stateva (2007) suggest for *more or less*. The characterization of the hedging effect induced by *be-gadol* should be thus more general and flexible. To proceed along that direction we will present our intuition regarding the common denominator between the different uses and propose a semantics for *be-gadol*. We then continue by presenting the tools we need to proceed with the analysis, and justify our proposed semantics for *be-gadol*. The last piece of the puzzle is what seems like a counterexample and its solution, followed by a summary and a few open questions.

## 2. Intuition and proposal

We propose that in all the uses presented in section 1.1 *be-gadol* is a marker of degrees of answerhood to the QUD, which indicates a hedging effect along two dimensions: the propositional dimension and the discourse dimension.

On the propositional dimension the use of *be-gadol* indicates that the prejacent *p* is not the most informative answer to the QUD (cf. Roberts 1996). There is a better answer to the QUD, *p<sub>best</sub>*. This *p<sub>best</sub>* entails *p* and rejects an implied enrichment of *p*, *q*, which is stronger than *p*. For example, in (3) *she be-gadol danced*, *p* (*she danced*), is not the most informative answer to the QUD (*what did she do in the party?*). There is a better answer, *p<sub>best</sub>*, *she danced most of the time and sang a little bit*, which entails *p* and rejects an implied enrichment of *p*, *q*, namely *she danced all of the time*, which entails *p*. We will claim that we cannot be satisfied with hedging solely along the propositional level, and that the hedging along the discourse level is central to the semantics of *be-gadol*.

On the discourse dimension, the use of *be-gadol* indicates that *p* is not the most helpful answer relative to the roles and goals of the participants in the discourse. The concept of roles and goals can be represented more concretely by resorting to the speaker's decision problem. For example, in (3) the question *What did Rina do in the party?* can be asked to learn about Rina's preferences, e.g. in a context where John wants to throw Rina a party and has to choose between different activities for the party. In this context John can inquire about Rina's preferences to resolve a decision problem regarding which party activities she might enjoy.

The better answer *p<sub>best</sub>* is required to be the most helpful answer to the QUD given this decision problem, but *p* is still close to being the most helpful answer given this decision problem. For example, in (3) (*she be-gadol danced*) we suggest that any possible *p<sub>best</sub>* (e.g. *she danced most of the time and sang a little bit*) is not only more informative than *p*, but also the most helpful answer relative to the roles and goals of the discourse participants in any possi-

ble context. In contrast, *she danced* is not the most helpful answer, but is nonetheless close to being most helpful. For example, *be-gadol* will be useful when for contextual purposes it is significant whether Rina danced all the time or did something else some of the time, because this fact might have consequences for the participants' decisions. The rejection of the strong enrichment that Rina danced all the time is helpful. Moreover, the fact that  $p$  is not the best answer but close to it emphasizes that the missing details of  $p_{best}$  may be relevant as well. We will illustrate all these notions with concrete examples below.

If this intuition is on the right track then the theoretical challenge at hand is how to capture 'degrees of answerhood' to the QUD, what exactly a *best* answer is, what makes  $p$  less good than  $p_{best}$ , and in what sense is  $p$  close to the best answer.

To answer these questions we will use the literature on resolving answers (e.g. Ginzburg 1995), and tools from decision theory (e.g. van Rooij 2003). In the following section we lay out our proposal and explain and illustrate the above intuition in further detail.

## 2.1. Proposal

As mentioned above, we suggest that the hedging operation with *be-gadol* results from the interaction between hedging along two levels – in the discourse level and the propositional level. In all its uses *be-gadol*  $p$  indicates that  $p$  is not the best answer to the QUD, and that a better answer ( $p_{best}$ ) to the QUD is true. This better answer  $p_{best}$  is related to  $p$  in two ways:

First,  $p_{best}$  is related to  $p$  since we take  $p_{best}$  to be more informative than  $p$ . In particular we require that  $p_{best}$  entails  $p$  and at the same time rejects a strong (but implied) enrichment of  $p$ . Defining  $p_{best}$  in this way is the first component in our proposed lexical semantics for *be-gadol* which leads to the hedging effect on the propositional level.

Second, we take  $p$  to be a proposition which is not the best answer to the QUD, but which is still 'close' to such a best answer,  $p_{best}$ . The notion of a 'best' answer, and of being 'close' to a best answer, will be defined relative to a decision problem. This second component leads to the hedging on the discourse level.

Given these two components our proposal is found in (5).

$$(5) \quad ||be-gadol||_{w,dp} = \lambda p \in QUD. \lambda w: \exists q [q \in QUD \wedge p \rightsquigarrow q \wedge q \subset p \wedge \exists BEST \neq \emptyset, \text{ where} \\ BEST = \{p_{best} \in QUD: p_{best} \subset [p \wedge \neg q] \wedge best_{dp}(p_{best}) \wedge Close_{dp}(p_{best}, p)\}]. \\ \exists p_{best} \in BEST [w \in p_{best}]$$

In words, *be-gadol* (relative to  $w$  and a decision problem  $dp$ ) combines with its prejacent, i.e. a proposition  $p$  which is a member of the QUD, and with a world  $w$ . It is defined if and only if there is a proposition  $q$  which is also a member of the QUD, which is stronger than (i.e. asymmetrically entails)  $p$  and is implied by it (i.e. it is a strong enrichment of  $p$ ). In addition, there is a nonempty set, BEST, of propositions  $p_{best}$  which are also members of the QUD, such that for any  $p_{best}$  in this set BEST:  $p_{best}$  entails  $p$  and the negation of  $q$  (i.e. entails  $p$  and

rejects its stronger enrichment),  $p_{best}$  is ‘best’ relative to the decision problem and  $p$  is ‘close’ to  $p_{best}$  relative to the decision problem.

Clearly, the notion of being a ‘best’ answer, and being ‘close’ to such a best answer, relative to the decision problem are the main novel parts of the definition. To explain these notions, and their necessary presence in the lexical entry of *be-gadol*, we will first consider in the following section the hedging effect of *be-gadol* along the propositional domain, i.e. the fact that some true answer,  $p_{best}$ , is required to entail  $p$  and reject a strong (implied) enrichment of it. We then show that this hedging effect is not enough to account for the full range of facts concerning *be-gadol*. To get a fuller picture we characterize precisely the ‘best’ and ‘close’ components in the lexical entry in (5), which capture the hedging along the discourse domain, and demonstrate how adding these components account for the remaining data.

## 2.2. Illustrations and support

To try and account for the data by assuming hedging along the propositional dimension alone, consider the following examples. In every example (a) gives the prejacent,  $p$ , (b) gives the strong enrichment of  $p$ ,  $q$ , and (c) gives an example of a possible  $p_{best}$ . Example (6) includes the gradable adjective *clean*. We follow von Stechow (1984) in assuming that gradable adjectives denote relations between degrees and objects, and in the positive form as in (6a) a null morpheme *pos* introduces a standard degree, s.t. (6) is true iff the room is at least as clean as the standard (formally,  $\exists d [d \geq \text{stand}_{\text{clean}} \wedge \text{clean}(\text{the room}, d)]$ ). Kennedy and McNally (2005) assume that the standard in adjectives like *clean* is maximal, although pragmatical shifts to lower standards are often used in actual context. Rotstein and Winter (2004), however, assume an interval of degrees in the maximal end of the scale, and hence semantically the standard is not always maximal. We follow Rotstein and Winter (2004) as well as McNally (2011), and Sassoon and Toledo (2011) in assuming that the standard for *cleanliness* can be identified with a point which is not exactly at the maximum of the scale.

- (6) The room is *be-gadol* clean
  - a.  $p$ : The room is clean
  - b.  $q$ : The room is maximally clean
  - c.  $p_{best}$ : The room is clean except for the windows
- (7) Rina *be-gadol* danced
  - a.  $p$ : Rina danced
  - b.  $q$ : Rina danced all of the time (e.g. of the party)<sup>2</sup>
  - c.  $p_{best}$ : Rina danced most of the time and sang a little bit.
- (8) Mary is *be-gadol* a book editor
  - a.  $p$ : Mary is a book editor
  - b.  $q$ : Mary edits books in general.
  - c.  $p_{best}$ : Mary is a book editor specializing only in medieval history and religion

<sup>2</sup>We think this implication is derived as a scalar implicature, namely that Rina’s dancing eventuality was the only activity in the party. We don’t go now into how precisely this is derived (e.g. how exhaustification scopes wrt the existential over events).

In all of these cases *be-gadol*  $p$  indeed indicates that a more informative answer,  $p_{best}$  (as in the (c) part of (6-8)) is true. This true answer indeed entails  $p$  (as in (a)) and rejects a stronger enrichment of it (as in (b)).

So far, everything seems to be working. However, as we said above, we require also that  $p_{best}$  be a ‘best’ answer to the QUD and that  $p$  be ‘close’ to it. To justify the two extra conditions on  $p_{best}$ , we turn to look at a case where hedging in the propositional level isn’t enough, and using it alone yields over-generalization.

- (9) Context: John is interested in arranging a birthday party for Rina and wants to have activities that she enjoys. He knows that Sarah and Rina went to a party last week. To be able to choose the activities that Rina will most enjoy in her birthday party, John wants to learn about her preferred party activities. For that purpose John is asking Sarah about Rina’s behavior during the party. Sarah is aware of John’s purpose. She saw that Rina danced most of the time of the party last week, sang for a little while, and spoke with the barman.

John: What did Rina do in last week’s party?

- a. Sarah: She *be-gadol* danced
- b. Sarah: #She *be-gadol* danced and sang

(9a) and (9b) have correlating  $p$ ’s,  $q$ ’s and  $p_{best}$ ’s, given in (10) and (11).

- (10) Sarah: She *be-gadol* danced
- a.  $p$ : she danced
  - b.  $q$ : she danced all the time
  - c.  $p_{best}$ : Rina danced and sang.

- (11) Sarah: #She *be-gadol* danced and sang
- a.  $p$ : Rina danced and sang
  - b.  $q$ : The only things she did in the party was to sing and dance.
  - c.  $p_{best}$ : Rina danced, sang, spoke with the barman.

In both cases there is a  $p_{best}$  which entails  $p$  and rejects a strong enrichment of it. Nonetheless, given the details of the context in (9), *be-gadol* is felicitous in (9a), and infelicitous in (9b).

To account for the infelicity of (9b), we propose the following intuition: *She be-gadol danced and sang* is odd because the information that Rina spoke with the barman does not seem to add anything relevant to what John is interested in. Thus, although a more informative answer is possible, e.g. the proposed  $p_{best}$  in (11c), it cannot count as a real appropriate ‘best’ answer. In fact, given John’s goals, it is not better than the prejacent *She be-gadol danced and sang* – it does not add any relevant information.

Moreover, changing the goals of the participants in the discourse can affect the felicity of *be-gadol* in these examples. The answer in (12) is judged better in the following situation:

- (12) Context: John suspects that Rina is a spy. He sends Sarah, a private detective, to follow Rina and report back to him. John and Sarah are talking as Sarah recounts Rina's actions during the party. Rina danced most of the time of the party, sang for a little while and spoke with the barman.

John: What did Rina do in last week's party?

Sarah: She *be-gadol* danced and sang

Intuitively, Sarah's answer is felicitous because the information that Rina spoke with the barman might be relevant under this context. That is, unlike what we saw in (9b), given these roles and goals of John and Sarah, *p* in (12) is really not the best answer anymore, so *be-gadol* achieves the hedging effect in the discourse domain. The conclusion from this is that characterizing the hedging effects of *be-gadol* using only informativity tools is not enough, and we need an additional type of hedging which is sensitive to the roles and goals of the participants in the discourse.

The observations we have made regarding *be-gadol* seem very similar to observations made in e.g. Ginzburg (1995) and van Rooij (2003) regarding answers to questions. Similarly to what we observed with *be-gadol*, these theories noted that for answers to be considered good answers, it is not enough that they are fully informative. Rather, they need to be also 'helpful' relative to the roles and goals of the participants in the discourse. Hence, we now turn to relevant details of these theories, so we can use the tools they developed to formally capture the complex hedging effect of *be-gadol*.

### 2.3. Hedging along the discourse domain

According to Ginzburg (1995), even if an answer is exhaustive (i.e. maximally informative), it is not always helpful (enough). In addition to that, a helpful answer can be non-exhaustive. Consider (13), inspired by example (15), on p.469 in Ginzburg (1995).

- (13) Context: A scientist is invited to give a lecture at a university he's unfamiliar with. The scientist asks who will attend the talk, with the goal of giving a good and clear talk.

Question: Who is going to attend the talk?

a. Answer 1: (Provides an exhaustive list of names).

b. Answer 2: A number of cognitive phoneticians and Willshaw-net experts.

While (13a) is exhaustive, it is not helpful given the scientist's goal and information state. In contrast, (13b) is not exhaustive, but is helpful given A's and information state.

Van Rooij (2003) formalizes sensitivity to goals and information states using notions from probabilistic decision theory. A decision problem of an agent can be modeled as a triple  $\langle P, U, A \rangle$ , where  $P$  is the agent's probability function which represents the agent's beliefs about the world,  $U$  is the utility function, which assigns each action a value, representing the agent's goals, and  $A$  is the set of alternative actions the agent considers. The expected utility (EU) of an action  $a$  in  $A$  is defined as in (14):

$$(14) \text{ EU}(a) = \sum_w P(w) \times U(a, w)$$

In words, the expected utility of an action  $a$  is the result of the summing operation over worlds of the probability of being in each specific world  $w$ , times the utility value of the action  $a$  in that world.

To make the best choice between these actions the agent can ask a question. The answer to this question can help resolve the decision problem, i.e. help the agent calculate which action is the most likely to be most helpful. Given this calculation, the agent knows which is the action with the highest expected utility. Given an answer  $C$ , the maximal expected utility of the decision problem equals the maximal value of summing the conditional probability of each world given  $C$ , times the utility of each action  $a$ :

$$(15) \text{ Max}(\{\sum_w P_C(w) \times U(a, w) : a \in A\})$$

Given this, the agent can know which is the action with the highest expected utility (EU) given the answer  $C$ .<sup>3</sup>

Finally, for van Rooij, an answer which resolves the decision problem, a ‘resolving answer’, is one which leaves the agent with exactly one action with the highest EU.

With these theoretical tools at hand, we can now analyze the second component from our proposed lexical entry, the one where *be-gadol* hedges along the discourse domain.

Consider again our proposed lexical entry, repeated here as (16).

$$(16) \text{ } ||\textit{be-gadol}||_{w, dp} = \lambda p \in \text{QUD}. \lambda w: \exists q [q \in \text{QUD} \wedge p \sim q \wedge q \subset p \wedge \exists \text{BEST} \neq \emptyset, \text{ where} \\ \text{BEST} = \{p_{\text{best}} \in \text{QUD} : p_{\text{best}} \subset [p \wedge \neg q] \wedge \text{best}_{dp}(p_{\text{best}}) \wedge \text{Close}_{dp}(p_{\text{best}}, p)\}]. \\ \exists p_{\text{best}} \in \text{BEST} [w \in p_{\text{best}}]$$

Above we suggested that the prejacent of *be-gadol*,  $p$ , is neither the most informative answer to the QUD, nor the most helpful, but still ‘close’ to being most helpful. This is captured in (16) by taking another answer, which we called  $p_{\text{best}}$ , to be the true answer to the QUD which entails  $p$  and rejects a stronger enrichment of  $p$ . In addition,  $p_{\text{best}}$  must be also best relative to the decision problem, and close to  $p$  relative to the decision problem.

We now define the notion of a best answer relative to the decision problem, and being ‘close’ to such a best answer more precisely, as in (17) and (18) respectively:

- (17)  $p_{\text{best}}$  is the best answer relative to the decision problem iff  
 a. It is resolving, i.e. leaves us with exactly one action, which has a maximal EU<sup>4</sup>

<sup>3</sup>Benz (2006) and Benz and van Rooij (2007) have argued that a decision problem must also take into account information about the speaker in order to define “goodness” of answers.

<sup>4</sup>Formally, following ideas in van Rooij (2003), we require that  $|p_{\text{best}}, A^*| = 1$ , where  $p_{\text{best}}, A^*$  is the set of propositions  $a^*$ , of the form “you should choose action  $a$  in  $A$ ”, which are consistent with  $p_{\text{best}}$  ( $p_{\text{best}} \cap a^* = \emptyset$ ). If the cardinality of this set is 1, then  $p_{\text{best}}$  is said to be ‘resolving’ – i.e. it leaves the agent with exactly one action: The one with the highest expected utility.

- b. And any other distinct answer is either non-resolving, or leads to an equal or lower maximal EU:

$\forall s \in \text{QUD} [s \neq p_{\text{best}} \rightarrow [[\neg \text{resolving}(s)] \vee \max \text{EU}(P_{\text{pbest}}, U, A) \geq \max \text{EU}(P_s, U, A)]]$ , i.e. no other answer is more helpful, and leads to a higher maximal EU.

- (18)  $p$  is ‘close’ to  $p_{\text{best}}$  iff

$p$  is also resolving i.e. it also leaves the agent with single action, one with the highest EU, and  $\text{Small}(\max \text{EU}(P_{\text{pbest}}, U, A) - \max \text{EU}(P_p, U, A))$

To explain (18) in words,  $p$  is close to  $p_{\text{best}}$  iff the maximal EU of the action with the maximal EU that we are left with after learning  $p$ , is lower than the one we are left with after learning  $p_{\text{best}}$  but only slightly so. This boils down to a situation where the agent is a bit more certain (less at risk) that the action chosen is the right one after learning  $p_{\text{best}}$  than after learning  $p$ .<sup>5</sup> In this case,  $p_{\text{best}}$  leaves us with one action, with the highest EU, and  $p$  leaves us with one action, but with a slightly lower EU.

### 3. Illustration

Consider the example from (3), repeated here in more detail as (19). John asks Sarah a question, and Sarah, who is aware of the decision problem, answers with *be-gadol*.

- (19) Context: John wants to throw a party for Rina, and plans an activity that she likes, out of the three potential activities in the following set of actions  $A$ :  $\{\text{prepare a dancing activity, prepare a karaoke competition, prepare a jumping activity}\}$ . John knows that Sarah and Rina participated in a party last week. To learn about what Rina likes to do in parties he asks Sarah, thinking that if Sarah tells him what Rina like to do he would know better which action to choose.

John: What did Rina do in last week’s party?

- a. Sarah: She be-gadol danced  
b. Sarah: #She be-gadol danced and sang

The felicity of (a) and the infelicity of (b) hold, for example, in the following two scenarios:

- (20) The ‘temporal’ scenario: Rina danced most of the time of the party, sang for a short while, and spoke with the barman.  
(21) The ‘significance’ scenario: Rina danced most enthusiastically in the party, sang, as she usually does, and spoke with the barman. Dancing didn’t occupy most of the time.

In both scenarios, we can find an answer,  $p_{\text{best}}$ , which meets the conditions in our definition, namely (22a) and (22b):

<sup>5</sup>There can be additional ways in which  $p$  can be ‘close’ to  $p_{\text{best}}$  (cf. van Rooij 2003). E.g., if  $p$  leaves us with more actions in the decision problem than  $p_{\text{best}}$  does, but not with many more. Alternatively, if given the decision problem our goal is just to gain more information, but  $p$  leaves us with less information than  $p_{\text{best}}$  does, but not with much less. We do not further discuss these options in the present paper.

- (22) a.  $p_{best}$  for the temporal scenario: Rina danced most of the time and sang for a while.  
 b.  $p_{best}$  for the ‘significance’ scenario: Rina danced extremely enthusiastically and sang.

In both cases  $p_{best}$  is a true answer which entails  $p$  (*she danced*) and at the same time rejects a strong implication of it (*she danced all of the time*). Moreover, it is indeed the best answer with respect to the decision problem because learning it we can rather safely conclude that the dancing activity is the activity she will enjoy most. More formally, learning one of these  $p_{best}$  answers, we are indeed left with one action with the highest expected utility (i.e. the one which is most likely to be most helpful).

Assuming that this is  $p_{best}$ , Sarah’s answer in (19a) (*She be-gadol danced*) is felicitous, since although the prejacent *She danced* is not the best answer, it is close to it. Despite the fact that like  $p_{best}$ ,  $p$  also leads to choosing dancing as the activity for the party, the expected utility of this answer is a bit lower. Upon learning *She danced*, all John would know is that there was a dancing eventuality by Rina in the party. However, John will not know how long it lasted, whether it was significant or not, whether there were other relevant events which lasted more or were more significant, etc. Thus, learning that Rina danced in last week’s party, John might choose the dancing competition for her party, but he will be less certain about whether this is the best choice to make. The EU of ‘prepare a dancing activity’ is still maximal compared to the other activities in the set, but lower given  $p$  than given  $p_{best}$ .

The infelicitous case in (19b) is discussed using the same context and decision problem as in (19). In this case, *She be-gadol danced and sang* seems odd since here  $p$ , namely *She danced and sang*, is not ‘resolving’: i.e. it leaves us with TWO possible actions (namely dancing and singing), and not one.

Moreover, if  $p$  does not end up less helpful than  $p_{best}$ , we get infelicity even when it IS resolving. To demonstrate this we will modify the context in (19) for the one in (23).

- (23) Context: John wants to choose a pair of activities for the party, out of the following pairs: *{singing & dancing, dancing & jumping, singing & jumping}*. In reality, Rina danced for a long time, sang for a short while and spoke with the barman.

John: What did Rina do in last week’s party?

Sarah: #*She be-gadol danced and sang*

Why is Sarah’s answer odd in this case? After all,  $p$  (*She danced and sang*) leaves us with one action with the highest EU (namely choosing the pair ‘dancing and singing’ for the party). One way to think about this is that in this case there is no appropriate  $p_{best}$ . The more informative *She danced for a long time, sang for a while and spoke with the barman* cannot function here as  $p_{best}$  since, given John’s goals it does not have a higher expected utility than *She danced and sang*. In other words, it is not more helpful, and hence, *be-gadol*’s required hedging in the discourse domain cannot be achieved.

To demonstrate the proposal further, we will consider two more cases, the ‘not enough details’ use in (24) and (25), and the ‘approximative’ use in (26) and (27).

- (24) Context: John is having a sports event next week and wants to know whether to invite Danny (who is in general a good candidate for consideration). To decide on this matter John is asking about Danny. For example:

John: Is Danny healthy?

Mary: He is *be-gadol* healthy

In this case, we take  $p$ ,  $q$  (the rejected strong enrichment of  $p$ ), and  $p_{best}$  to be as in (25):

- (25) a.  $p$ : Danny is healthy to a degree which is at least as high as the standard of health in the context.  
 b.  $q$ : Danny is healthy to a maximal degree  
 c.  $p_{best}$ : Danny is healthy except for a cold.

Learning  $p$  will encourage John to invite Danny. However, John will not be completely certain this is the right action to choose. Even given  $p$ , it is still possible that Danny is not maximally healthy. If this is the case, and given that John doesn't know what keeps Danny from being completely healthy, John may be worried that participating in the competition will not be good for him. However, given  $p_{best}$ , John will be in a better position to decide exactly what to do. No matter whether John decides to invite Danny or not, John will now be more certain about making the right call, and hence the expected utility (EU) of the action with the maximal EU given  $p_{best}$  will be higher than the maximal EU given  $p$ .

- (26) Context: Mary is looking to hire employees for her new publishing house, where most books deal with history, sociology, etc. Mary thinks we may want to interview Danny.

Mary: What does Danny do? What's his profession?

John: He is *be-gadol* a book editor (I'm not sure exactly which type of books he edits)

In this case, we take  $p$ ,  $q$  (the rejected strong enrichment of  $p$ ), and  $p_{best}$  to be as in (27):

- (27) a.  $p$ : Danny is a book editor  
 b.  $q$ : Danny can edit all types of books (i.e. he doesn't specialize in any specific field)  
 c.  $p_{best}$ : Danny edits history books

As before, after learning  $p$  Mary will probably tend to interview Danny. However, Mary will not be completely certain this is the right action to choose, since it is possible that Danny specializes in editing a type of books which is not relevant for the publishing house. Even so, it may be still helpful to interview Danny. Learning  $p_{best}$  Mary would be in a better position to decide exactly what to do, and to decide whether to interview Danny or not. Mary would then be more certain of the chosen action. Here too the EU of the action with the maximal EU given  $p_{best}$  is a higher given  $p_{best}$  than it is given  $p$ .

#### 4. An apparent counterexample and a suggestion for a solution

As mentioned above in section 1.1, *be-gadol* also yields a use which seems to pose a problem for our theory. An example is (28).

(28) Context: Danny tried to get into medical school. To do that one has to pass an exam. The passing grade for the exam is strictly 80 and, generally, if you pass you get accepted. Mary wants to know whether to congratulate Danny or not. She asks Sarah about his current situation.

- a. Mary: Well, what about Danny? Did he pass the exam?
- b. Sarah: *be-gadol hu avar, aval hayu yoter miday muamadim tovim*  
           in.big he passed, but were too many candidates good  
           “Be-gadol he passed, but there were too many good candidates.”

According to the analysis we proposed above, *be-gadol p* is felicitous iff *p* is not the best answer to the QUD, i.e. not most informative, and not most helpful. This is so because there is another answer, *p<sub>best</sub>* which IS the most informative and helpful answer.

The problem in (28b) is *be-gadol* is felicitous although its prejacent seems to be already the best answer: Most informative (i.e. does not imply some enrichment *q* which is negated by *p<sub>best</sub>*), and also most helpful, since Mary is left with one action (i.e. congratulate Danny), with the highest EU.

We suggest that this kind of example can be nonetheless covered by our proposal for *be-gadol*. To explain this we use an independently motivated mechanism proposed in Simons et al (2010), which has been proposed in the literature regarding the connection between projective meanings and questions under discussion.

Simons et al (2010) suggest that what is projected is ‘not at issue’, where such ‘not at issue’ material is often, but not always, a presupposition. Projection of presupposition can be blocked when the content is at-issue relative to the QUD, i.e. is relevant to determine which of the answers is true.

However, they bring some examples where it seems that at issue content is nonetheless projected. Consider (29) below, a slight variation of the original example in Simons et al., which is odd without its context.

(29) Context: Chloe is writing invitations for her birthday party to kids in her class. Her mother notices that all of the invitations are to girls.

- a. Mother: Are there any boys in your class?
- b. Chloe: I don’t like the boys in my class.

The direct answer to the mother’s question is that there are boys in Chloe’s class, and hence this answer constitutes at issue content. Importantly, this content is projected in Chloe’s answer. Simons et al. (2010) claim that this is not a counterexample for their generalization that content does not project when at-issue. The claim they make is that (29b) is not an answer to the mother’s explicit question, but rather to a broader QUD. Put in other words, the immediate QUD is stated explicitly in (29a), but there is also an implicit question, namely, *Why aren’t you inviting any of the boys in your class to your party?* Making the accommodation of this broader implicit question would explain what is going on in the sequence in (29). Giv-

en this broader question the sequence is felicitous since “there are boys in my class” is not at issue with respect to this implicit broader question, and hence is projected in (29b).

Considering the shift from the immediate QUD to a broader QUD, the example in (28) with *be-gadol*, can be reconsidered. Although the explicit question asked by Mary is *Did Danny pass?* this is just a subquestion of a broader, implicit question *Did Danny get into medical school?* Interpreting the answer in (28b) as an answer to the broader QUD, *p* is once again a not-best answer, as required by our theory. The best answer to the broad QUD would be an answer along the lines of *Danny passed the test but didn't get accepted*, as demonstrated in (30).

- (30) Rina: Danny *be-gadol* passed, but there were too many good candidates.  
 a. *p*: Danny passed, i.e., he most likely got accepted, but maybe not.  
 b. *q*: Danny got accepted.  
 c. *p<sub>best</sub>*: Danny passed but didn't get accepted.

In the context of the broader implicit QUD, if Mary wants to decide whether she should congratulate Danny or not on his acceptance to medical school, (30a) would not resolve this decision problem in the best way, since given *p<sub>best</sub>* Mary will be more certain in her decision (namely not to congratulate Danny). In addition, as required, the best resolving answer (30c) negates the strong implication *q* (30b) of *p* (30a). Despite not being the best answer, *p*, namely *he passed*, is still ‘close’ to being such a best answer, since its EU is just a bit lower than that of *p<sub>best</sub>*. This is because passing the exam almost always leads to getting accepted, so learning *p* Mary is close to being certain that she chooses the best answer (in this case, that she can congratulate Danny).

Also worth mentioning is the fact that this case is the only one where it is necessary to continue the *be-gadol* sentence with **but** (e.g. *but there were too many candidates*). *But* creates here a strong counterexpectational effect (see e.g. the QUD-based analysis of *but* in Toosarvandani 2014).

One possible explanation for this is that this is the only case where *p<sub>best</sub>* must leave us with the opposite action (e.g. not congratulate Danny) than the one we are left with after learning *p* (congratulate Danny). However, the precise nature of the relation between *but* and *be-gadol*, as well as other interesting interactions / parallels between the hedging operation of *be-gadol* and the semantics of *but* still await further inspection.

To conclude, we call this use the “change your question” use of *be-gadol*. For this use to be available *p* should be the complete answer to the immediate QUD (e.g. *Did he pass?*). To allow the hedging effect on the propositional level there must be a higher, super-QUD in the context (e.g. *Did he get accepted?*), or such a question must be available for accommodation. (see also Buring 2003, Simons et al 2010 on other constructions where such accommodation is necessary).

## 5. Summary and open questions

We looked at a range of hedging effects exhibited by *be-gadol*, which cannot be easily reduced to a single operation. To account for the full range of data in a unified way we suggested that *be-gadol* lexicalizes a hedging operation over answers to questions. It indicates that *p* is not the best answer to the QUD, and that there is a better answer, *p<sub>best</sub>*, which is true.

Crucially, the hedging operation is done on two levels. First, the propositional level where *p<sub>best</sub>* is more informative than *p*, since it entails *p* and rejects a strong enrichment of it. Second, the discourse level, where *p<sub>best</sub>* is more ‘helpful’ than *p* given the goals and information state of the participants (though *p* is ‘close’ to being most helpful). This aspect of *be-gadol* can be captured by resorting to notions from the literature on resolving answers, and using formal tools from decision theory. To the extent the analysis is on the right track, it supports the linguistic reality of these notions of tools in a new way.

There are several open questions that still need to be accounted for and directions to check. For example, we are still checking whether the analysis will work for all examples with *be-gadol*, across contexts and decision problems, whether there are other/better ways to define what ‘the best answer’ to the QUD is. In addition, perhaps there are also other possibilities to make *p* ‘close’ to *p<sub>best</sub>*, e.g. by ending up with more, but not many more actions after learning *p* than after learning *p<sub>best</sub>*.

Furthermore, we aim to explore whether there are other members of this ‘discourse hedgers’ family. Are there more hedgers that are sensitive to how helpful their prejacent is relative to the goals of the participants? Potential candidates for such hedgers are *theoretically* / *in theory* / *in principle* / *by and large* / *basically*...etc. If these are indeed members of the same family, it would be highly significant to define their core semantics and characterize the parametric differences between them.

Maybe the most central issue to understand is the reasons for which a cooperative speaker would use *be-gadol* at all. If the speaker knows the best answer to the question, why use *be-gadol p*, and indicate that *p* is NOT the best answer? Perhaps what *be-gadol* actually does is signal that while its prejacent *p* is the best answer to the immediate decision problem, there is a ‘higher’, more elaborated decision problem which still needs to be resolved. If this is so, we need to develop a model with hierarchies of decision problems, similarly to hierarchies of QUDs (cf. Roberts 1996, Büring 2003 on Contrastive Topics). We leave this issue for further research.

# Picture Descriptions and Centered Content<sup>1</sup>

Mats ROTH — *Cornell University*

Dorit ABUSCH — *Cornell University*

**Abstract.** There is an argument based on sentences that describe pictures in favor of a viewpoint-centered possible worlds semantics for pictures, over a propositional semantics (J. Ross 1997). The argument involves perspectival lexical items such as “front”. We show that when a projective possible worlds semantics for pictures is employed, there is a problem with the argument coming from propositional contents being strong. The argument is reconstructed in a model modal space involving linear worlds, and it is shown that it works there, by computing the possible worlds semantics. The construction involves propositions and centered propositions that are regular sets of strings. Finally, by manipulating the marking parameter in a projective semantics for pictures, the argument is reconstructed also for 3D models.

**Keywords:** Semantics of pictures, linguistic descriptions of pictures, centered possible worlds.

## 1. Introduction

Some recent work on the semantics and pragmatics of pictures and pictorial narratives has used a framework where these artifacts, just like sentences, have propositional semantic values that are constructed as sets of possible worlds or possible situations (Greenberg 2011, 2013; Abusch 2012, 2014, 2016). We use Scott brackets for both kinds of semantic values. Just as (1a) designates the semantic value of the sentence inside the brackets, (1b) designates the semantic value of the picture inside the brackets.

- (1) a.  $\llbracket \text{there are two cubes} \rrbracket$   
b.  $\llbracket \text{[Image of two cubes]} \rrbracket$

There are advantages in assuming information contents for pictures and linguistic phrases in the same semantic space. One comes in the analysis of multimodal messages consisting of a picture and sentence, where one wants to combine information from the two media into a whole. Another comes in the semantic analysis of sentences such as (2) that describe pictures. Ross (1997) gave a compositional semantic analysis of such sentences in terms of the propositional semantic value of the mentioned picture, and the propositional semantic value of the preadjacent clause beginning with *there*.

- (2) In the picture, there is a cube next to an octahedron.

---

<sup>1</sup>For comments and assistance, we thank audiences at SuB and McGill, Luis Alonso-Ovalle, Mark Steedman, Michael Wagner, and Ede Zimmermann.

Ross then pointed out a problem for this propositional theory having to do with sentences describing pictures where the preajacent clause includes perspectival constructions such as “in front of”, as in (3).

- (3) In the picture, there is a cube in front of an octahedron.

Ross addressed the problem by replacing propositional semantic values for pictures and for the preajacent sentence with *viewpoint-centered* semantic values. These are analagous to the agent-centered semantic values in Lewis’s *de se* analysis of attitude semantics (Lewis 1979). The point of this paper is to construct Ross’s argument using the semantic assumptions summarized in the next section, refute it, and then reconstruct it by modifying the semantic framework.

## 2. Ordinary and centered pictorial contents

Classic and modern treatises on perspective, and contemporary works on computer graphics, describe mathematical recipes for mapping a three-dimensional worlds to pictures (Szeliski, 2010). We proceed here by indentifying three-dimensional worlds with data structures that specify the location, scale, and orientation of geometric objects. (4) is a world with two cubes, and nothing else.

- (4) Possible world  $w_1$
- | <i>type</i> | <i>scale</i> | <i>translation</i> | <i>rotation</i> |
|-------------|--------------|--------------------|-----------------|
| cube        | 1.0          | [0,0,0]            | [0,0,0]         |
| cube        | 1.0          | [3,0,0]            | [0,0,0]         |

Given in addition a specification of a viewpoint (a certain kind of oriented location) and a “marking rule”, a picture is mathematically determined. The viewpoint has information that determines a family of oriented projection lines and a planar region (corresponding to the picture) in the three-dimensional space. A marking rule determines how points in the picture region are to be colored. Rule  $R_1$  combined with  $w_1$  and a certain viewpoint results in picture (6).

- (5)  $R_1$  : Mark a point in the picture plane black if the projection line from the viewpoint through that point intersects the edge of an object before it intersects any other part of an object, otherwise in gray if it intersects some object, and otherwise in white.

(7) describes the marking rule for a “line drawing”, resulting in pictures such as (8).

- (7)  $R_2$ : Mark a point of the picture plane in black if the directed projection line intersects the edge of an object, and otherwise in white.

Finally, projection lines can be determined in various ways with respect to the viewpoint. Using parallel projection lines instead of lines intersecting at the viewpoint results in an orthographic picture such as (9). Call the projection line parameter  $G$ .

Summing this framework up, there is a parameterized procedure that determines a picture  $p$  from a world  $w$  in a space of geometrically constructed worlds  $\mathcal{M}$ , a viewpoint  $v$ , a marking rule  $R$ , and a projection-line parameter  $G$ . This is summarized in (10).

$$(10) \quad p = \Pi(\mathcal{M}, w, v, R, G)$$

Starting from a picture  $p$  and a fixed  $\mathcal{M}$ ,  $R$  and  $G$ , a semantic value as a set of worlds is now obtained by inverting projection in the way defined in (11). The semantic value of  $p$  is the set of worlds  $w$  such that using  $R$  and  $G$ ,  $w$  projects to  $p$  from some viewpoint.

$$(11) \quad \llbracket p \rrbracket^{\mathcal{M}, R, G} = \{w \mid \exists v. p = \Pi(\mathcal{M}, w, v, R, G)\}$$

Alternatively, instead of existentially quantifying the viewpoint, the semantic value of a picture can be defined as a set of world-viewpoint pairs. This is a set of viewpoint-centered worlds, analogous to the believer-centered worlds discussed by Lewis (1979). The viewpoint-centered semantic value is defined in (12).

$$(12) \quad \llbracket p \rrbracket_{\Delta}^{\mathcal{M}, R, G} = \{\langle w, v \rangle \mid p = \Pi(\mathcal{M}, w, v, R, G)\}$$

### 3. Picture descriptions and Ross's argument

The analysis in Ross (1997) uses the formalization (13b) for sentence (13a). The operator  $[x]$  is a modal necessity operator based on the propositional content of  $x$ . The formula  $[x]\phi$  is true if and only if for every world  $w$  in the propositional content of  $x$ , formula  $\phi$  is true in  $w$ .

- (13) a. In one picture, there is a man on a couch.

- b.  $\exists x.\text{picture}(x) \wedge [x]\exists y\exists z[\text{man}(y) \wedge \text{couch}(z) \wedge \text{on}(y,z)]$

This semantics for picture descriptions is isomorphic to the subset semantics for belief descriptions. Sentence (13a) is true in a world  $w_0$  if and only if there is an  $x$  s.t.  $x$  is a picture in  $w_0$ , and for all worlds  $w$  in  $\llbracket x \rrbracket^{\mathcal{M}, R, G, w_0}$ , there is a  $y$  and a  $z$  such that  $y$  is a man in  $w$ ,  $z$  is a couch in  $w$ , and  $y$  is on  $z$  in  $w$ . A nice aspect of the analysis is that it uses the general propositional semantics for the prejacent sentence *there is a man on the couch* in (13a). There is no need to refer to a semantics for the prejacent sentence that is specific to the pictorial medium.

Ross's argument for centered contents has to do with the truth or falsity of sentence (14), construed as referring either to the picture on the left in (15), or the picture on the right. Intuitively the sentence is true with reference to the picture on the left (Picture 1), and false with reference to the picture on the right (Picture 2).

Suppose the pictures have identical propositional semantic values, along the lines of "there is a white ball and a black ball". We can't get different truth values for the sentences in (16), because the pictures enter into the subset semantics for the in-the-picture construction via their propositional semantic values.

- (14) In the picture, there is a white ball in front of a black ball.

(15)

- (16) a. In Picture 1, there is a white ball in front of a black ball.  
b. In Picture 2, there is a white ball in front of a black ball.

What goes wrong? Ross pointed out that the problem comes up when the prejacent sentence contains an element such as *in front of*, the semantics of which is sensitive to a perspective. Note that the sentences in (17), where there is no perspectival lexical item, are not problematic like the sentences in (16), because they do have the same truth value.

- (17) a. In Picture 1, there is a white ball next to a black ball.  
b. In Picture 2, there is a white ball next to a black ball.

This can be related to an independently motivated perspectival parameter in the semantics of *in front of*. Suppose Keisha uses sentence (18a) to tell Justin where his bike is. The information conveyed is similar to what is conveyed by (18b), but stronger in that Justin gets the information that the bike rack is between the oak and the route, not simply near the oak. This motivates the hypothesis that *in front of* includes a covert perspectival parameter—it is understood as *in front from a perspective on the route*.

- (18) a. On the route to school, there is bike rack in front of a big oak. The bike is locked there.  
 b. On the route to school, there is bike rack next to a big oak. The bike is locked there.

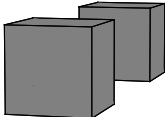

This kind analysis of *in front of* is well motivated, and there is substantial literature on it (Kemerer, 2006; Kelleher and van Genabith, 2006). Ross used it in a solution to the puzzle of the balls. The first step is to use a viewpoint-centered semantics for pictures, as introduced in Section 2. The second step is to hypothesize that the construction *in-x- $\phi$*  binds the viewpoint parameter of the prejacent sentence  $\phi$ . The result is that both the picture  $x$  and the prejacent  $\phi$  contribute viewpoint-centered propositions. The semantics for *in-x- $\phi$*  does the subset check for these viewpoint-centered propositions, rather than ordinary propositions as before.

- (19) Semantics for [*in x,  $\phi$* ]  
 For all  $\langle w, v \rangle$  in  $\llbracket x \rrbracket^{\mathcal{M}, R, G, w_0, g}$ ,  $\llbracket \phi \rrbracket^{w, g[v_0 \mapsto v]} = 1$ .

Notice now that the two pictures in (15) have different viewpoint-centered contents. In centered worlds  $\langle w, v \rangle$  in the content of Picture 1, there is a white sphere and that is closer to the viewpoint than a black sphere. The reverse is true of centered worlds in the content of Picture 2.

#### 4. A problem with strong pictorial contents

We want to ultimately agree with the argument summarized in Section 3, and with the conclusion. However, there is a problem. Ross assumes that pictures 1 and 2 have identical propositional contents. The same assumption is made in subsequent literature (Blumson, 2010). However, this runs afoul of the fact that pictorial contents as obtained in the projective theory are in some respects strong. For instance, the propositional content of the picture in (20a) is stronger than the propositional content of the sentence in (20b). This is shown by the fact that the possible world  $w_2$  given in (21) is in the content of the sentence, but not in the content of the picture. In  $w_2$ , there are two cubes, so (20b) is true. But there are no edges from different cubes that are parallel. In worlds consistent with picture (20a), there are two cubes with pairs of parallel and indeed co-linear edges, assuming perspectival projection. In general, any picture of two cubes gives information about the orientation of the cubes, and there is no picture that entails sentence (20b) and has no additional entailments.

- (20) a.   
 b. There are two cubes.

- (21) Possible world  $w_2$
- | type | scale | translation | rotation |
|------|-------|-------------|----------|
| cube | 1.0   | [0,0,0]     | [0,0,0]  |
| cube | 1.0   | [3,0,0]     | [1,1,1]  |

In the same way, the content of the pictures 1 and 2 in (15) is stronger than the proposition that there is a black sphere and a white sphere. One additional entailment in this case is that there are no *other* objects visible from particular viewpoints. Consider a world  $w_3$  with exactly three objects, which are a white sphere, a black sphere, and a black cube. The three are in line, with the white sphere in the middle. See (22).

(22) World  $w_3$ :

From the viewpoint  $v_1$ , the cube is not in view, and  $\Pi(\mathcal{M}, w_3, v_1, R, G)$  is  $p_1$ . However, from  $v_2$ , the black cube is in view in the background, and  $\Pi(\mathcal{M}, w_3, v_2, R, G)$  is not  $p_2$ . In fact, there is no viewpoint  $v$  such that  $\Pi(\mathcal{M}, w_3, v, R, G)$  is the picture  $p_2$ . Since the propositional denotation of  $p_2$  is  $\{w \mid \exists v \Pi(\mathcal{M}, w_3, v, R, G) = p_2\}$ ,  $w_3$  is not an element of  $\llbracket p_2 \rrbracket^{\mathcal{M}, R, G}$ . The propositional denotation of  $p_1$  is  $\{w \mid \exists v \Pi(\mathcal{M}, w_3, v, R, G) = p_1\}$ , and  $v_1$  is a witness for  $w_3$  being an element of  $\llbracket p_1 \rrbracket^{\mathcal{M}, R, G}$ . So contrary to what the argument from Section 3 has to assume,  $p_1$  and  $p_2$  do not have the same propositional contents, if propositional contents are defined by geometric projection as described in Section 2.

## 5. Pictures and projection in lineland

In this section we construct a family of models where Ross's argument does work, because pictures have weak contents that in a certain sense have no extra information. The worlds are "linelands"—worlds that have the form of a string. An additional feature is that the semantics is computable, because the propositions that are the denotations of sentences are regular sets of strings. These are the sets of strings that are representable by regular expressions and by finite state machines.

To illustrate, world  $s_1$  as defined in (23) is a world with (from the left) a ruby, an opal, a picture of a ruby in front of an opal, two opals, and finally a ruby. A "ruby" is the character  $r$ , and an "opal" is the character  $y$ . Pictures are delimited by brackets, with a square bracket marking the front of a picture, and round bracket marking the back. Within a picture, the character  $b$  depicts a ruby, and the character  $w$  depicts an opal. Thinking of  $b$  and  $w$  as black and white, these are black and white pictures. The assumptions are listed in (24).

(23) World  $s_1$   
 $r\_y\_ [bw) \_y\_y\_r\_$

- (24)
- |                |                  |
|----------------|------------------|
| <u>r</u>       | ruby             |
| <u>y</u>       | opal             |
| square bracket | front of picture |
| round bracket  | back of picture  |
| <u>b</u>       | ruby in picture  |
| <u>w</u>       | opal in picture  |

The underlined positions seen in (23) are reserved for discourse referents, which are used for compositional semantics. The ultimate discourse referent 1 is used for the most recently mentioned object, and the discourse referent 2 for the penultimately mentioned object. The indexed world in (25) has an ultimate discourse referent for a picture, because 1 immediately precedes the start of a picture. And it has a penultimate discourse referent for a ruby, because 2 immediately precedes r.

- (25) World  $s_2$   
 2r\_y1 [bbw) \_r\_y\_r\_y\_

Let *SitD* be the set of all indexed situations of this kind, and let *Sit* be the set of all situations without discourse referents. They are defined by terms in an extended language of regular expressions. *Sit* is a set of strings, used as the set of all worlds. Regular subsets of *Sit* are used as propositions, and regular subsets of *SitD* are used as information states in a dynamic semantics. Semantic composition is performed mainly using relation composition, using the relations listed in (26). *New* is the random choice operator of dynamic semantics. *Forget* deletes discourse referents to map to a proposition. The remaining operators are tests. *Ruby* checks that there is a ruby at the ultimate discourse referent, i.e. that r follows 1 in the string.

- (26)
- |               |                                                                  |
|---------------|------------------------------------------------------------------|
| <i>New</i>    | introduce random discourse referent 1,<br>while demoting 1 to 2. |
| <i>Forget</i> | delete discourse referents                                       |
| <i>Ruby</i>   | check that 1 is an ruby                                          |
| <i>Opal</i>   | check that 1 is an opal                                          |
| <i>Pict</i>   | check that 1 is a picture                                        |
| <i>Adj</i>    | check that 1 is adjacent to 2                                    |

In these terms, the proposition denoted by (27a) is defined by (27b). The circle indicates relation composition, or restriction of a relation to a domain or co-domain.  $R^{co}$  is the co-domain of relation *R*. In combination with *Forget*, it is used to map to a proposition. The dynamic semantics works by inserting 1 in a random location; checking that the object marked by 1 is an opal; inserting 1 in a random location while demoting 2 to 1; checking that the object marked by 1 is a ruby; checking that the objects marked by 1 and 2 are adjacent; and finally forgetting the discourse referents.

- (27)
- There is a ruby adjacent to an opal.
  - $[Sit \circ New \circ Opal \circ New \circ Ruby \circ Adj \circ Forget]^{co}$

These above sets and relations are defined in a language of extended regular expressions. Com-

plete definitions are found in the replication supplement (Rooth and Abusch, 2017). The definitions can be interpreted computationally, using Xfst or Foma (Beesley and Karttunen, 2003; Hulden, 2009), to obtain a computational representation of a propositions such as (27b).

The next issue is the encoding of centered propositions. A center or viewpoint is modeled with the character “>” or “<”, located in the block where discourse referents are also placed. A centered world has exactly one center. Examples are in (28)-(29).

- (28) Centered world  $c_1$ , with a center looking towards a ruby in front of an opal.

$r\_y\_ [bbw) \_r\_y > r\_y\_$

- (29) Centered world  $c_2$ , with a center looking towards an opal in front of a ruby.

$r\_y\_ [bbw) \_r\_y < r\_y\_$

(30) describes relations that randomly insert a center and delete a center. The basic relation *Front* requires that both 1 and 2 are in the direction indicated by the center, with 1 encountered first.<sup>2</sup>

- (30)     *NewC*     randomly insert a center  
              *ForgetC*   delete the center  
              *Front*     the center is >, > precedes 1,  
                               and 1 immediately precedes 2, or  
                               the center is <, 2 immediately precedes 1,  
                               and 1 precedes <.

The semantics of (31a) is defined in (31b), without deleting the drefs or the center. (31c) gives a sample of the centered indexed worlds in the centered proposition.

- (31)     a.     There is a ruby in front of an opal.  
              b.      $[Sit \circ NewC \circ New \circ Opal \circ New \circ Ruby \circ Front]^{CO}$   
              c.      $> [wb) 1r2y\_r\_r\_r\_y\_r\_r\_y\_r\_$   
                        $\_ (bbw) > r\_y\_r\_r\_1r2y\_$   
                        $2y1r\_ [bb) < y\_r\_r\_y\_$   
                        $> [bw) 1r2y\_$   
                        $\_r > (bwwwbbww) \_y\_y\_r\_y1r2y\_y\_$   
                        $2y1r < y\_r\_ [wb) \_y\_r\_y\_y\_y\_r\_r\_y\_y\_$   
                        $> (wbwbbwb) \_y\_y1r2y\_r\_$   
                        $2y1r < [bwbww) \_r\_r\_$   
                        $> [wb) 1r2y\_r\_$

A semantics for pictures is defined in the form of an accessibility relation. Starting from an indexed world  $s$  with a picture at dref 1, this is done by non-deterministically constructing a world that is consistent with the content of the picture. Transformations are made incrementally,

<sup>2</sup>This defines *Front* as *immediately in front*. It could be defined the other way.

using substitution and deletion relations. The steps are given in (32).<sup>3</sup>

- (32)
- a. Delete everything outside the picture at dref 1, retaining the dref marker.
  - b. Optionally reverse the picture at dref 1.
  - c. If the picture is left-oriented, non-deterministically insert any element of *Sit*>*Sit* to the left of the dref marker 1, and non-deterministically insert any element of *Sit* to the right of the picture marked by 1.
  - d. If the picture is right-oriented, non-deterministically insert any element of *Sit*<*Sit* to the right of the picture marked by 1, and non-deterministically insert any element of *Sit* to the left of the dref marker 1.
  - e. Substitute “y” for “w”, and “r” for “b”, in the picture following 1, while deleting the brackets for that picture.
  - f. Delete the dref marker 1.

Each transformation is definable as a regular relation, except for the reversal. These relations are composed to define the accessibility relation  $P_{\Delta}$ . Steps c-d preserve orientation, with the center in the output pointing towards the former location of the front of the picture. In order to include reversal, the length of pictures that are reversed has to be bounded.<sup>4</sup>  $P_{\Delta}$  is the composition of the six component relations. The centered semantic value of the picture at dref 1 in a world is obtained as an image, see (33).

- (33) The centered semantic value of the picture at discourse referent 1 in indexed world  $s$  is  $[s \circ P_{\Delta}]^{CO}$ .

While this construction does not explicitly employ projection, it is natural as a version of projective semantics. Since the worlds are one-dimensional, the projection procedure should look at a zero-dimensional object, that is a point. This indicates that a “projection line” corresponds to a distance in front of the viewpoint, determining a point in the world, the properties of which are checked to determine the picture.<sup>5</sup>

A propositional acquaintance relation  $P$  is obtained by composing  $P_{\Delta}$  with a relation that deletes the center, see (34), and a propositional semantic value is obtained as the image of  $P$ , see (35).

- (34)  $P \stackrel{\text{def}}{=} P_{\Delta} \circ \text{Forget}C$

- (35) The propositional semantic value of the picture at discourse referent 1 in indexed world  $s$  is  $[s \circ P]^{CO}$ .

We return now to Ross’s argument. The picture at dref 1 in world  $p_1$  given in (36a) is a picture

<sup>3</sup>See the definition of Pt (corresponding to  $P_{\Delta}$ ) in the supplement.

<sup>4</sup>Possibly this can be finessed, depending on how accessibility is to be used. The finite state calculus includes reversal as an operation, but reversal of a string is not a regular relation. In the code, only pictures of length three or less are reversed.

<sup>5</sup>We have not looked into developing this in the finite state construction.

of two rubies in front of an opal. The corresponding centered semantic value is (36b). This is a certain countably infinite set, which includes the worlds listed in (36c).

- (36) a. World  $p_1$   
        $- r - y \ 1 \ [b \ b \ w) - r - y - r - y -$   
       b.  $[p_1 \circ P_\Delta]^{CO}$   
       c.  $- (b \ w \ w \ w \ w) > r - r - y - [b \ b) -$   
            $> r - r - y - y - [b \ b) - [w \ b \ b) -$   
            $> (b \ w \ w \ w \ b \ b) - r - r - y - r -$   
            $- (b \ b \ b \ b \ w) - y - r - r - [w \ b) <$   
            $- (w \ b) - (w \ b) - [b \ b) - y - r - r <$   
            $- y - r - r < r - (w \ b) - (w \ w \ w) -$

The picture at dref 1 in the world  $p_2$  given in (37a) is a picture of an opal in front of two rubies. The corresponding centered semantic value is (37b). This is a certain countably infinite set, which includes the worlds listed in (37c).

- (37) a. World  $p_2$   
        $- r - y \ 1 \ [w \ b \ b) - r - y - r - y -$   
       b.  $[p_2 \circ P_\Delta]^{CO}$   
       c.  $- y > (w \ b) - y - r - r - (b \ w \ b) -$   
            $- (w \ b \ b) > y - r - r - y - (w \ w) -$   
            $> (w \ b \ w \ b \ w \ w) - r - y - r - r -$   
            $- r - r - y - [w \ b) - [b \ b) < (w \ b) -$   
            $- r - r - y < [w \ w \ w) - [w \ w \ b \ b) -$   
            $- r - r - r - y - [b \ w) < [b \ b \ w) -$

The centered semantic values are different if and only if at least one of the set differences  $[p_1 \circ P_\Delta]^{CO} - [p_2 \circ P_\Delta]^{CO}$  and  $[p_2 \circ P_\Delta]^{CO} - [p_1 \circ P_\Delta]^{CO}$  is non-empty. Given the explicit computable semantics, this can be checked computationally. Both differences are non-empty. (38) lists some worlds in the content of the first picture but not the second. (39) lists some worlds in the content of the second picture but not the first. So the centered contents of the two pictures are different, as required in the argument.

- (38)  $- y - r - r - r - [w \ w \ w \ w) < r -$   
        $> (w \ w) - r - r - y - [w \ b) - [w \ w) -$   
        $- r - y - [b \ w \ b \ w) > r - r - y -$   
        $- y - r - r - [b \ b \ w) - [b \ w) - r <$   
        $- [w \ w) - (w \ w) - y - r - r < [b \ b) -$   
        $- y - r - r - [w \ w \ b \ b \ b \ b \ b \ b) <$

- (39)
- r - r - y - [b b b) - (b b b b] <
  - [b b b) - r - r - r - y - [w w) <
  - (b b b w] - r - r - y - (b w b] <
  - r > y - r - r - (b b w] - (b w] -
  - r - r - y - [b b b b) - (w b b] <
  - > y - y - r - r - (w b] - [w w b) -

By the way, while the centered contents are different, they are not disjoint. (40) lists some worlds in the semantic conjunction of the two pictures.

- (40)
- [w w b) > y - r - r - y - (b w] -
  - > y - y - r - r - y - (w w w w] -
  - [b b) - y - r - r - y - (w b b] <
  - [w b w w b w) > y - r - r - y -
  - [w b b) - y - r - r - y - (w b] <
  - (b w b w] > r - r - y - r - r -

Second we evaluate the set differences  $[p_1 \circ P]^{co} - [p_2 \circ P]^{co}$  and  $[p_2 \circ P]^{co} - [p_1 \circ P]^{co}$  computationally. Both terms evaluate to the empty set, indicating that the propositional contents are the same. This is what failed in Section 4.

Finally, consider truth value of sentence (41a) in world  $p_1$ . We assume the pronoun picks up the center, marked by the dref marker 1. We are using a dynamic semantics, with the preajcent sentence formalized as in (41b). To check the truth value, we check whether any centered worlds are lost in moving from the centered proposition denoted by the picture to that proposition updated with the preajcent sentence. The original proposition is (42a), and the updated proposition is (42b). When these are compared computationally using a set difference, we find that no worlds are lost in the update; this indicates that (41a) is true in  $p_1$ . When the same experiment is done with  $p_2$ , worlds are lost, and sentence (41a) is false in  $p_2$ .

- (41)
- a. In it, there is a ruby in front of an opal.
  - b. There is a ruby in front of an opal.
  - c.  $[NewC \circ New \circ Opal \circ New \circ Ruby \circ Front \circ Forget]^{co}$
- (42)
- a.  $[p_1 \circ P_{\Delta}]^{co}$
  - b.  $[[p_1 \circ P_{\Delta}]^{co} \circ NewC \circ New \circ Opal \circ New \circ Ruby \circ Front \circ Forget]^{co}$

This reconstructs Ross's argument using the lineland modal space. Sentence (41a) is true with reference to the picture in world  $p_1$ , and false with reference to the picture in  $p_2$ , using a centered semantics computed as in (42). Using a non-centered semantics for the pictures can not give this result, because the propositional semantic values of the pictures are the same.

All of this shows that whether Ross's argument works or not depends on specifics of the modal space and of the projection procedure.

## 6. Back to 3D

There are ways of using pictures to give information about three-dimensional worlds where the pictures are not intended to carry as much information as they do in the projective semantics from Section 2. Keisha owns some regular polytopes. She told us about them by uttering the sentence (43a), and then showing the picture (43b). She intended to give information about the shape, color and relative orientation of her polytopes, but did not intend to imply anything about what else is or is not in the vicinity. She did not, for instance, intend to rule out the possibility that her polytopes are surrounded in every direction by spheres.

(43) a. I own two regular polytopes. This is how they are oriented.

b.

c. In the picture, my favorite polytope is in front.

This example can be turned into a Ross example by continuing as in (43c). The sequence carries the information that the favorite polytope is an octahedron. But if the picture is switched to (44), we get the information that the favorite polytope is a cube. (43b) and (44) are projected from the same world, but different viewpoints.

(44)

The above suggests fixing the argument by incorporating information about what objects are depicted. Keisha's intention comes down to not intending to depict anything other than her two polytopes. We suggest locating this in the marking rule. Often, pictures are used assuming marking rules with non-geometric side conditions. We can draw a map-like picture projected from above the northern reaches of our university campus, marking red for projection lines that intersect buildings belonging to the university, and gray for other buildings. Here red indicates ownership by the university, not anything geometric. In the same way, the marking rule can stipulate that only objects belonging to Keisha have an influence on marking.

Suppose the first sentence in (43) sets up a discourse referent  $X_2$  for two polytopes owned by Keisha. Before the picture is processed semantically, a marking rule is accommodated that marks only elements of  $X_2$ , see (45). If there are spheres surrounding the polytopes, these do not affect the picture. So with this marking rule, the picture does not carry the extra information that came up in Section 3.

- (45) Mark a point in the picture plane in black if the directed line from the viewpoint through that point intersects the edge of an element of  $X_2$  before it intersects any other element of  $X_2$ , otherwise in gray if the directed line from the viewpoint through that point intersects a black element of  $X_2$  before it intersects any other element of  $X_2$ , otherwise in white.

With a context and marking rule like this, we are back in business with a 3D version of Ross's argument. The pictures give the same information about the relative orientation of the objects belonging to Keisha, and the context and marking rule ensure that no other objects are depicted. The argument stated for spheres is given in (46)–(47). The centered contents are different, and the last sentence in (46) can come out true, while the last sentence in (47) comes out false. But the propositional contents are the same, indicating that no semantic rule that uses a propositional content for pictures can work.

- (46) Keisha owns two spheres<sub>3</sub>. This is how they are oriented.  
(Accommodate a marking rule that ignores objects that are not elements of  $X_2$ , marks black spheres in black, and white spheres in white.)

In the picture, there is a black sphere in front of a white sphere. Both belong to Keisha.

- (47) Keisha owns two spheres<sub>3</sub>. This is how they are oriented.  
(Accommodate a marking rule that ignores objects that are not elements of  $X_2$ , marks black spheres in black, and white spheres in white.)

In the picture, there is a black sphere in front of a white sphere. Both belong to Keisha.

This reconstructs Ross's argument from the spheres for centered pictorial contents. The moves we made with the marking rule are motivated, because speakers do use pictures intending that only certain specified or contextually determined objects are depicted. The contrast between this version of the argument and the original one indicates that whether or not different centered contents can collapse into a single propositional content depends on details of the marking rule.

# The Acquisition of Disjunctions: Evidence from German Children<sup>1</sup>

Uli SAUERLAND — *Leibniz-Zentrum Allgemeine Sprachwissenschaft (ZAS)*

Kazuko YATSUSHIRO — *Leibniz-Zentrum Allgemeine Sprachwissenschaft (ZAS)*

**Abstract.** Adults' interpretation of disjunction *or* depends on the sentential environment in which disjunction occurs. Putting aside numerous special cases (see e.g. Klinedinst and Rothschild 2012, Meyer 2012, 2016), adult behavior can be summarized as such: In downward entailing contexts, *or* is interpreted logically as the inclusive disjunction OR. But in upward entailing contexts, *or* is interpreted pragmatically as the exclusive disjunction XOR. Summarizing recent work on the acquisition of disjunction, children around age 5 seem to differ slightly: In downward entailing and free choice contexts, children seem to interpret disjunction like adults as inclusive OR (Chierchia et al. 2001, Crain 2008, Su and Crain 2013, Tieu et al. 2016). But in upward entailing, non free choice contexts, children have been found to interpret disjunction sometimes conjunctively as AND (Singh et al. 2016, Tieu et al. 2017).

Singh et al. (2016) advocate an account of the AND interpretation of *or* in terms of scalar implicature (or exhaustivization). In this paper, we present evidence for a novel alternative account based on lexical ambiguity. Specifically, we test the following prediction of the implicature account: Whenever implicatures are obligatory, children should obligatorily interpret *or* as AND. We show that the ambiguity theory makes the opposite predictions, and that the prediction of the ambiguity theory is borne out in data from German children.

**Keywords:** disjunction, implicature, acquisition, German, coordination, propositional logic

## 1. Introduction

Disjunction might be considered one of the *lab animals* of pragmatics. But despite the fact that pragmaticists have talked about disjunction at least since Grice's 1975 work, recent work has exposed several new aspects of the meaning and use of disjunction. In particular, Bowler (2015), Meyer (2012, 2016), Singh et al. (2016), and Tieu et al. (2017) argue that unembedded disjunction can be strengthened to a conjunctive interpretation in some cases for at least some groups of speakers. Our interest in this paper is primarily children's interpretation of disjunction. We set out to experimentally compare two possible accounts of the child data: The first account is the *implicature theory*, which is proposed for the child data by Singh et al. (2016) and derives from work by Fox (2007) and Kratzer and Shimoyama (2014) on free choice disjunction. The other account, the ambiguity theory, builds on the assumption that children consider a word such as *or* ambiguous between the *or* and the *and* interpretation, before they know the adult interpretation. In the remainder of this introduction, we consider both accounts in a little more detail. We then describe how an experimental design originally used by Tieu et al. (2017) tests a difference in prediction between the two accounts. While Tieu et al. (2017)

---

<sup>1</sup>We would like to thank Lyn Tieu for letting us reuse the experimental materials from Tieu et al. (2017), Rob Truswell for editorial comments, and audiences at the Disjunction Days Workshop at ZAS in 2016 and the Sinn und Bedeutung conference at Edinburgh in 2016 for helpful comments. This work was supported financially in part by the Bundesministerium für Bildung und Forschung (BMBF), grant 01UG1411 and by the Deutsche Forschungsgemeinschaft (DFG), grant SA 925/11-1.

report results from French and Japanese, we discuss results from German children in this paper.

The implicature theory assumes that adults and children associate different alternative sets with *or*: While  $\text{Alt}(A \text{ or } B) = \{A, B, A \vee B, A \wedge B\}$  for adults (Sauerland 2004 and others), for children  $\text{Alt}(A \text{ or } B) = \{A, B, A \vee B\}$ . This predicts that adults strengthen the interpretation of *A or B* to exclude  $A \wedge B$  when implicatures are computed. But children are predicted to strengthen *A or B* by excluding  $A \wedge \neg B$  and  $B \wedge \neg A$ , which predicts the conjunctive interpretation.

When implicatures are optional, children are predicted to assign either a logical *OR* interpretation to *or* when they don't compute an implicature, or a strengthened *AND* interpretation when they compute an implicature. The implicature theory predicts therefore that the conjunctive interpretation should be obligatory when implicature computation is obligatory.

The Ambiguity Theory provides an alternative account of the child data as we understand it. The account is in part motivated by the observation reported to us that French children should not be familiar with the disjunction marker *soit ... soit* that Tieu et al. (2017) included in their experiment. The implicature theory assumes though that children know that a morpheme is interpreted as logical disjunction and then strengthening to conjunction applies, which then explains the conjunctive interpretation observed by Tieu et al. (2017). If children aren't familiar with a connective, though, the starting point is already different.

We propose that *or* is ambiguous for children between two interpretations, a disjunctive and a conjunctive interpretation. The restriction to these two interpretations we see at this point as a preliminary assumption that is up to further discussion. In part, the assumption is motivated by the fact that many languages lexicalize these to binary boolean operators while operations such as NAND, NOR, and exclusive disjunction XOR are to the best of our knowledge not lexicalized in the languages. The ambiguity theory assumes furthermore that children apply the strongest meaning principle (SMP) in (1) to resolve the ambiguity.

- (1) *SMP*: If *S* is ambiguous between interpretations  $\alpha$  and  $\beta$  with  $\alpha \rightarrow \beta$  then the weaker interpretation  $\beta$  is inaccessible (Dalrymple et al. 1998 and others).

The ambiguity theory predicts all the data that have motivated the implicature theory. Consider first *or* in an antitone context.<sup>2</sup> (2) from Chierchia et al. (2001) is predicted to be ambiguous for children between  $\alpha$  and  $\beta$ . But because reading  $\beta$  logically entails  $\alpha$ ,  $\alpha$  is correctly blocked by the SMP.

- (2) Every dwarf who chose a banana **or** a strawberry received a jewel.  
 \* $\alpha$ : Every dwarf who chose a banana *and* a strawberry received a jewel.  
 $\beta$ : Every dwarf who chose a banana *or* a strawberry received a jewel.

But in an isotone context, the entailment relationship is the reverse. Therefore the OR-interpretation is blocked in (3).

<sup>2</sup>We use the order-theoretic terms *isotone* and *antitone* of e.g. Birkhoff (1940) instead of the terms *upward* and *downward monotone* of elementary calculus, which are more popular in the linguistic literature.

- (3) Every boy is holding an apple **or** a banana. (Singh et al. 2016)

$\alpha$ : Every boy is holding an apple **and** a banana.

$*\beta$ : Every boy is holding an apple **or** a banana.

But the ambiguity theory makes different predictions from the implicature theory for cases where implicatures are obligatory. As discussed by Spector (2014) and others, *exh* is ungrammatical when it cannot exclude any alternatives. The same constraint applies to *only*, and causes the ungrammaticality of *\*I ate only ALL*. Since AND is the maximally strong item in an UE context, obligatory exhaustivization blocks the AND-interpretation. Therefore the ambiguity theory predicts that only the OR-interpretation can be available when implicatures are obligatory.

## 2. Previous study: Tieu et al. (2016)

Spector (2014) and Nicolae and Sauerland (2016) argue that complex disjunctions, such as French *soit–soit* and English *either–or* involve obligatory exhaustivization. This predicts that children arrive at the strengthened AND more frequently with complex form of disjunction than with their simple counterpart, *ou* in French or *or* in English. An example from Japanese experiment is shown below.

- (4) a. Osaru-san-ga mado-**ka** doa-o aketa.  
 monkey-Nom window-KA door-Acc opened  
 ‘Monkey opened the window or the door.’  
 b. Osaru-san-ga mado-**ka** doa-**ka**-o aketa.  
 monkey-Nom window-KA door-KA-Acc opened  
 ‘Monkey opened the window or the door.’

Tieu et al. (2016) report an experiment (truth-value judgment task), testing this prediction. They conducted the experiment in French (complex *soit–soit* vs. simple *ou*) and in Japanese (complex *ka–ka* vs. simple *ka*). They replicated the earlier finding by Singh et al. (2016) in both French and Japanese and found that young children accept the use of disjunction in 2DT contexts. Their main findings were that (1) children, as previously observed by Singh et al. (2016), accept the use of disjunction in both context where one or where both of the disjuncts are true, whereas adults accepted only the exclusive interpretation (i.e. that rejected the sentence when both disjuncts were true, but accepted it when only one was true).

On the one hand, this is expected: according to the implicature analysis, children do not have  $\{A \wedge B\}$  as the alternative for the disjunction, and hence, when they exhaustivize the meaning of disjunction, they end up with only the conjunctive interpretation, AND. On the other hand, that there was no difference between simple and complex disjunction is puzzling, if we take the implicature analysis literally.

This puzzle lead us to test the disjunction in German, which has different morphological and syntactic characteristics from French *soit–soit/ou* and Japanese *ka–ka/ka*. In both French and Japanese, the complex disjunction involves a repetition of the same form. In German, however, the complexity is indicated by the morpheme *entweder*, which is distinct from a simple form

and only occurs as part of the complex disjunction.

### 3. Experiment: Truth-Value Judgment Task

In the present experiment, we tested children's comprehension of *oder* vs. *entweder-oder*. We adopted the design of Tieu et al. (2017) to German. The two experimental conditions were the 1DT (one disjunct true) and 2DT (two disjuncts true) scenarios. For sentence (5), the two scenarios are described in (5a) and (5b).

- (5) Monkey (either) opened the window or the door. (translated from German)
- a. **1DT:** Monkey opened only the door (or Monkey opened only the window)
  - b. **2DT:** Monkey opened both the window and the door

In addition, we varied across subjects whether the items included complex *either-or* or simple *or*. Participants were randomly assigned to one of the two conditions.

#### 3.1. Method

##### 3.1.1. Participants

64 monolingual German speaking children (4;2-8;6) and 21 adults participated in this study. We divided children into two age groups: 31 4-6 year olds (4;2-6;11,  $M=5;2$ ), and 38 7-8 year olds (7;0-8;6,  $M=7;8$ ). Child participants were recruited at one day care center and two public schools in Berlin, Germany. Adult speakers were recruited from the participant pool of Humboldt University, Berlin. Child participants received a sticker for their participation. Adult participants received 5 euro for their participation in the study.

##### 3.1.2. Material

We used simple (*oder* 'or') and complex (*entweder-oder*) disjunctions in German, and constructed two versions of experiments, using only one type of disjunction for each version. An example of the test material is shown below.

- (6) Das Huhn hat das Flugzeug oder den Bus geschubst.  
the chicken has the plane or the bus pushed  
'The chicken has pushed the plane or the bus.'
- (7) Das Huhn hat entweder das Flugzeug oder den Bus geschubst.  
the chicken has either the plane or the bus pushed.  
'The chicken has pushed either the plane or the bus.'

Participants were introduced to the context in the form of a story. On the first slide, the story

was told from the iPad. On the second slide, a puppet appeared on the monitor and predicted what might have happened next. The prediction contained a disjunction. On the third slide, the end of the story, which was either 1DT, 2DT, or 0DT, was shown. Participants were then asked whether the puppet made the right prediction: whether what the puppet said matched the ending of the story or not. They put a stamp on the answersheet (under a smily face when matched, under a sad face otherwise). When the story and the prediction did not match, the participants were asked to state what was wrong with the puppet's prediction. The whole experiment was audio-recorded, and later checked for the responses and explanation children made.

### 3.2. Result

Let us first consider children's responses for the 1DT contexts (in which only one of the disjuncts was true). Let us first consider the participants who were 4 to 6 years old, which is more comparable to the previous study by Tieu et al. (2017).

With simple disjunction, younger participants accepted the use of disjunction in 1DT context 73.3% of the time (44/60), and older participants accepted it in the same context 88.9% of the time (64/72). The difference between the two age groups was significant (Fisher's Exact test,  $p < 0.05$ ). With a complex disjunction, younger children accepted the use of disjunction in 1DT context 85.7% of the time (48/56), and older children did so 80.9% of the time (55/68). The difference in the ratio between acceptance and rejection between the two age groups was not significant (Fisher's exact test:  $p = 0.6313$ ). No other comparisons were significant.

Next consider children's responses for the 2DT context (in which both of the disjuncts were true). With simple disjunction, younger participants accepted its use in 2DT context 67.8% of the time (40/59), whereas the older participants did so 52.8% of the time (38/72). The difference in the ratio between acceptance and rejection between the two age groups was not significant ( $p = 0.1074$ ). With complex disjunction, younger participants accepted the use of disjunction 58.9% of the time (33/56), and older participants did so 39.7% of the time (27/68). The difference in ratio between the two groups was statistically significant ( $p < 0.05$ ). No other comparisons were significant. Most importantly, as is the case in French and Japanese, the difference between simple and complex disjunctions was not significant.

Let us now combine the results from both conditions and plot where each individual falls. In figure 1, we have plotted, for each individual, the score for 2DT contexts along the Y-axis, and the score for 1DT contexts along the X-axis. Let us first explain what the chart shows. When a speaker is in the XOR corner, that is when they accepted the use of disjunction in 1DT while rejecting its use in 2DT. When a speaker is in AND, on the other hand, it means that the speaker accepted the use of disjunction in 2DT context, while they rejected its use in 1DT context. A speaker in the OR corner accepted the use of disjunction in both 2DT and 1DT contexts. As expected, the adults are mainly in the XOR corner because of the implicature and only one is in the OR corner, and one rejected all conditions with *oder*. Children are distributed over three different corners except for the double rejection corner on the bottom left. However, especially among the 4–5 year old children only 2 are in the AND corner at this point. Instead it seems

Figure 1: Distribution of subjects by acceptance of 1DT (x-axis) and 2DT (y-axis) acceptance across the three age groups. Each grey dot represents a participant of the simple *oder* group, each red dot one of the *entweder-oder* group. Some random ‘jitter’ is added to the plot to reduce overlap of dots, the actual values are at round multiples of 20%.

that the 4–5 year old children most frequently access the inclusive interpretation for *oder* and also *entweder-oder*. No clear difference is apparent figure in 1 between the grey dots of the subjects that received the *oder* condition and the red dots of those receiving the *entweder-oder* condition.

### 3.2.1. Discussion

At this point, we would like to compare the results from Tieu et al. (2017) on French and Japanese. Recall that this study did not find differences between simple and complex disjunctions, on the one hand, and between French and Japanese children, on the other hand. Comparing the results from the three languages in figure 2, we note that German children are distributed more in XOR and OR areas, whereas Japanese and French children are distributed more in AND and OR areas.

We ran a mixed model logistic regression, with complexity and language as dependent variables. We found that language is a factor ( $p < 0.01$ ), although the complexity alone is not ( $p = 0.081$ ). In addition, we found an interaction between the language and complexity, however, showing that German children are significantly more sensitive to complexity than Japanese children are.

Recall that according to the implicature theory, we expect that children should (1) accept the use of disjunction in 2DT context, and (2) reject the use of disjunction in 1DT context. Furthermore, adopting Spector (2014), we assume that complex disjunction necessarily involves exhaustivization. These assumptions combined predict that more children should be in AND

Figure 2: Comparison of the results from German, Japanese and French 4–5 year old. As in figure 1, each grey dot represents a participant of the simple disjunction group, each red dot one of the complex disjunction group.

area when tested with a complex disjunction than when tested with a simple disjunction. Since we didn't find any significant difference between the two types of disjunction, our result doesn't allow us to exclude the implicature theory. The ambiguity theory makes the opposite prediction as the implicature theory: more children should assign a conjunctive interpretation in the simple disjunction condition than the complex disjunction condition more frequently. Again our presently non-significant finding doesn't allow us to exclude this prediction.

Another prediction of the ambiguity theory, though, seems problematic in light of our results. Namely on the ambiguity theory, complex disjunctions involve obligatory exhaustivization, and therefore only the exclusive disjunction interpretation should be possible in the complex disjunction condition. Though we find some German children who assign an XOR interpretation, there is nevertheless a sizable group of children in all three languages who assign an inclusive disjunction interpretation to complex disjunction.

# Aligning intentions: Acceptance and rejection in dialogue<sup>1</sup>

Julian J. SCHLÖDER — *ILLC, University of Amsterdam*

Antoine VENANT — *IRIT, Université Paul Sabatier*

Nicholas ASHER — *CNRS, IRIT*

**Abstract.** This paper presents an operational and grounded notion of *intention in dialogue* and links it to the *commitments* that speakers make in dialogue. We take these two concepts to then develop a conceptually sound way of doing formal pragmatics. Our model tackles a number of relevant phenomena: (i) we formally derive the illocutionary forces of the speech acts of *asserting* and *rejecting* a proposition; (ii) we give a suitable semantics to rejections of arbitrary speech acts, including rejections of rejections; (iii) we demonstrate how *cooperativity* is linked to how strongly the notion of *speaker commitment* is understood. That is, how tightly bound speakers are by their commitments directly influences how cooperative they are.

**Keywords:** dialogue, commitment, intention, acceptance, rejection

## 1. No mindreading

*Nobody knows what's in someone else's head.* This is a simple truism (Lepore and Stone, 2014). Yet, in conversation, we reason about our interlocutors' thoughts, desires and intentions—while the truth of these internal mental states remains obscure to us. This is a curious tension and it begs for resolution. At least two challenges are at hand here: in what sense can intentions be *public knowledge* as required for successful conversation, and where does that knowledge *come from*. The intuitive solution to both challenges lies in the follow-up truism that *we can only observe how other people behave*—and then draw conclusions about their mental states.

One promising approach, developed the furthest by Asher and Lascarides (2008, 2013), is to supply the interpreter of an utterance with some *default expectations* about what people engaged in dialogue intend. A simple example is that *askers of questions typically intend to get an answer* and the less simple dual *utterances following questions are typically intended as answers*. Our main interest in this paper lies with the pragmatic principles underlying the sharing of knowledge. Asher and Lascarides provide us with the following default principles governing this process.

**(Intent to Share Commitment)**  $C_A \varphi > C_A I_A C_B \varphi$ .

**(Cooperativity)**  $C_A I_A \varphi > I_B \varphi$ .

Here,  $>$  denotes a default conditional ( $p > q$  expressing roughly that 'if  $p$ , then typically  $q$ '),  $C_A \varphi$  means that the speaker  $A$  is publicly *committed* to the formula  $\varphi$  and  $I_A \varphi$  means that the speaker  $A$  *intends* to establish a state that brings about  $\varphi$ . The first axiom expresses that, typically, commitments are intended to be shared. The second axiom expresses that, typically,

<sup>1</sup>Julian J. Schlöder has received funding from the People Programme (Marie Curie Actions) of the European Union's Seventh Framework Programme FP7/2007-2013/ under REA grant agreement no. 607062. Nicholas Asher is supported by ERC grant no. 269427.

publicised intentions are shared. The sharing of commitment is supposed to be part of the purpose of an assertion (Stalnaker, 1978) and the uptake of intention to be a fundamental part of conversation (Clark, 1996). If we assume that a speaker A asserting the proposition  $p$  entails that A undertakes a commitment to  $p$  ( $C_{Ap}$ ), we can compute *agreement* as follows ( $\approx$  is a defeasible inference building on  $>$ ).

$C_{Ap}$  (A asserts that  $p$ ).

$\approx C_{AI_A}C_{Bp}$  by (Intent to Share Commitment).

$\approx I_B C_{Bp}$  by (Cooperativity).

$\rightsquigarrow B$  will agree.

This is an appropriate derivation, but a few things are left open. First, regarding the meaning and truth-conditions of the operators  $I_A/I_B$ : while Asher and Lascarides (2003, 2008) give a modal semantics to these operators, it is unclear what this semantics represents. As said above, intentions are inherently private to the interlocutors; so it is difficult to say when  $I_A \phi$  is true and, if it is, what grounds its truth. We want to find a *grounded* and *operational* notion of intention. By *grounded* we mean a notion that ties in with observable behaviour; by *operational* a notion that is suitable for inference and admits motivated truth-conditional scaffolding.

Second, we wonder about the status of *Intent to Share Commitment* and *Cooperativity* as axioms. The question is what licenses their stipulation and in what sense, if any, they express truths. One can surely take them to be non-trivial *empirical* facts, but we think it more principled to derive them from more basic principles. Third, the above representation leaves open what happens in noncooperative situations: the *Cooperativity* axiom is crucial to the derivation above, but it is unclear what replaces it in noncooperative settings. This ties in with the second issue; we seek a more basic principle that generalises *Cooperativity* and reduces to it in appropriate circumstances.

Thus, our goal is to buttress a theory of intentions in formal pragmatics on conceptually solid footing. We proceed towards that goal as follows. In the next section we give a discussion of our conception of dialogue intentions as *commitments to preferred futures* and address some conceptual and practical challenges to this conception. We will show how this notion allows us to do formal pragmatics by formally defining the *basic principles* that govern intentionality in dialogue. Afterwards, we can derive some previously stipulative facts from them, including the illocutionary forces of assertion and rejection; also, we establish a link from cooperativity to commitment. Before concluding, we outline a truth-conditional semantics backing our derivations.

## 2. Intentions and commitment

Research on intentions divides up into two camps: one that studies intentions as attitudes towards actions or plans (Bratman, 1987) and one according to which intentions are propositional attitudes (Cohen and Levesque, 1990). Given that dynamic semantics (Groenendijk and Stokhof, 1991), in which the contents of a sentence form an action to update an information

context, has blurred the line between actions and propositions, our model will have features of both approaches to intention. We will model intentions as being towards achieving a certain propositional *state*. Such states, naturally, are achieved through action, but we do not model an intention to the action.<sup>2</sup>

As mentioned, our concern lies with the meaning of intentional operators like  $I_A$  above. We first observe that having an intention has an inherently temporal component: an intention relates to some (potential) future act. Furthermore, intending an act or state  $\alpha$  includes a certain dedication to undertake that act or bring forth that state. This is a stronger attitude than merely *preferring*  $\alpha$  over not- $\alpha$  or *desiring* or *wanting*  $\alpha$ . For a simple example, consider someone who desires to go out for fine dining, but cannot afford to do so. It is perfectly reasonable to attribute the cognitive attitude “she wants to go out, but chooses not to” to someone, but “she intends to go out, but chooses not to” strikes us as more than just a little odd.

We can conceptualise this dedication to action as a notion we already understand: *commitment*. We can say that an intention to  $\alpha$  can be represented as a *commitment* (to oneself) to bring about  $\alpha$  and a publicised intention to  $\alpha$  as a *public commitment* (to one’s interlocutors) to bring about  $\alpha$ . It is useful to compare this to the felicity conditions for speech acts by Austin (1962). According to him, a successfully performed speech act must be made with the right intentions and, moreover, these intentions must be apparent to one’s addressees so they can take them up properly. In the terminology we have started to develop here, a speech act publicises a commitment to a (potential) future state or act; uptake consists in the addressees sharing the commitment. Only after all participants have thereby fulfilled the intentional felicity conditions does the illocutionary force of the act apply. We will return to a model for illocutionary force in the next section.

Thus, we can express an intentional operator derivatively from operators we already understand quite well: the operators for *commitment* ( $C_A$ ,  $C_B$ ) and *temporal modal operators* which we will put as  $\Diamond$  (‘eventually’) and  $\Box$  (‘from now on’, equivalent  $\neg\Diamond\neg$ ).<sup>3</sup> We can thus represent ‘A intends that  $\alpha$ ’ as  $C_A\Diamond\alpha$  (‘A commits that eventually  $\alpha$  obtains’). There is, however, a sleight of hand in this representation: we only understand commitment as *public* commitment, but have no grasp on (not publicised) commitments to oneself. This, however, is not a problem for our project. As far as intentions are required for the understanding of a speech act, they ought to be (implicitly or explicitly) publicised. In fact, the intentions going along with a speech act must be *apparent* to the addressee of that act.<sup>4</sup> Making explicit how implicit intentions are apparent from observable behaviour is the major drive behind the pragmatics we develop in the next section.

<sup>2</sup>We ignore here certain pathological cases where someone does the right thing for the wrong reasons; e.g. intending that  $\alpha$ , executing an ill-conceived plan to bring forth  $\alpha$ , and just by chance achieve  $\alpha$  in the process nonetheless.

<sup>3</sup>More complex temporal logics such as LTL (Pnueli, 1977) would arguably be a more appropriate choice here. For simplicity we remain with the normal modal logic language. We formalise temporal modal logic below as KT4; we do not need additional machinery, and KT4 seems to express universal truths about temporal reasoning.

<sup>4</sup>In noncooperative settings the apparent intentions might be purposefully misleading; nonetheless, one needs to display *some* intention (even if it is dishonest) when making a speech act.

For now, we must address a more pressing concern. Our semi-formal logical form  $C_A \diamond \alpha$  for the intention that  $\alpha$  is indistinguishable from the claim that  $\alpha$  *will happen* (if one understands claiming that  $p$  as the undertaking of a commitment to  $p$ ). Surely, claiming that something will happen is much stronger than intending it. The difference is, however, smaller than it appears. As argued above, an intention  $\alpha$  incurs a dedication to bringing forth  $\alpha$ . It is a minor step from there to conclude that the publicised intention to  $\alpha$  amounts to the claim that one will cause  $\alpha$  unless something unexpected happens. As a case in point, notice that it is absurd to intend something impossible.<sup>5</sup> In this sense, we can understand intentions as *defeasible* commitments: they reduce to the claim that the content of the intention will obtain *unless* circumstances unexpectedly prevent this.

With the preliminaries settled, we can now formulate a principle that we take to be *partly constitutive* of commitment in dialogue. Undertaking a commitment includes a certain dedication to upholding the commitment. Quite literally, a commitment that is undone without much ado is not a commitment. Thus we consider it a first principle of commitment that one does not intend to undo the commitment. We can therefore stipulate the following as fundamental axioms for our pragmatics.

**Definition 1** (Basic Principles). The following axioms are (partly) constitutive of commitment:

- (a)  $C_S \varphi > C_S \Box C_S \varphi$  (for each speaker  $S$ ).
- (b)  $C_S \neg C_S \neg \varphi > C_S \Box \neg C_S \neg \varphi$  (for each speaker  $S$ ).
- (c)  $C_S \diamond C_S \diamond \varphi > C_S \diamond \varphi$  (for each speaker  $S$ ).

The principle (a) states that if one makes a commitment, one intends to keep it (equivalently, does not intend to break it;  $C_S \neg \diamond \neg C_S \varphi$ ). Principle (b) states that if someone commits that they *might* commit to something (understanding  $\neg C_S \neg$  as the dual to  $C_S$ ), they also intend to keep that commitment. Note the difference to  $\neg C_S \neg \varphi$  which merely expresses that  $\varphi$  is compatible with  $S$ 's commitments; in this case,  $S$  can easily commit to either  $\varphi$  or  $\neg \varphi$  later without dropping any earlier commitment. In contrast,  $C_S \neg C_S \neg \varphi$  expresses that  $S$  has *committed* to potentially also committing to  $\varphi$ —hence committing to  $\neg \varphi$  requires dropping this earlier commitment. Finally, principle (c) expresses that an intention to intend something reduces to a single intention.

Note that we model intentions as intending *states*, not *acts*. If someone intends an act, completion of that act should resolve the intention. In our case, with speakers intending states, once the state is achieved the intention is preserved as the intention to *maintain* that state.

These axioms have privileged epistemic status over the principles *Intent to Share Commitment* and *Cooperativity* we discussed in the Introduction. The principles in Definition 1 are *constitutive* of commitment: that one intends to keep a commitment lies at the core of what it means to commit. We also maintain the Basic Principles in noncooperative settings; if commitment is the

<sup>5</sup>There might be situations where a speaker claims to intend something objectively impossible; in such cases, the speaker is mistaken. This seems to be similar phenomenon to someone claiming to *know* something false.

basic operation in dialogue and these principles are foundational to commitment they need to be maintained (at least as a pretense) even in noncooperative dialogue.<sup>6</sup> A prototypical noncooperative action is a lie; lies only work since the defeasible inference from public commitment to private belief is active even in noncooperative settings (i.e. *ceteris paribus* both parties are still assumed to speak truths). Similarly, the Basic Principles allow the noncooperative move of making false commitments—commitments one has no intention of keeping (e.g. an unfaithful promise).<sup>7</sup> The possibility to be insincere extends to publicised intentions as well: one can commit to intending something without actually intending it—hence (c) is a default as well.

To complete the picture it is left to give meaning to the temporal operators. As for the present model we only require future-oriented operators, we characterise them as the normal modal logic KT4.

**Definition 2** (Temporal Logic). For the sake of simplicity, we model temporal operators as KT4 modal logic:

- (K)  $\Box(\varphi \rightarrow \psi) \rightarrow (\Box\varphi \rightarrow \Box\psi)$ .
- (T)  $\varphi \rightarrow \Diamond\varphi$ . (If something is true now, it is also true eventually.)
- (4)  $\Diamond\Diamond\varphi \rightarrow \Diamond\varphi$ . (If it is eventually the case that eventually  $\varphi$ , then eventually  $\varphi$ .)

### 3. Formal pragmatics of acceptance and rejection

In the previous section we have developed the foundation to our formal pragmatics. We now develop a framework on top of this foundation that allows us to model the pragmatics of acceptance and rejection in dialogue.

#### 3.1. Asserting and rejecting propositions

The first task is to define what asserting and rejecting a proposition means with respect to public commitment. As already hinted at in Section 1, it is intuitive to think of an *assertion that p* as the undertaking of a commitment that *p* holds. This intuition sketches a general plan to capture the semantic effects of *A* asserting *p*: one needs to update a *conversational record* with the information that *A* committed to *p*.

While this intuitive idea constitutes a standard line of research (Brandom, 1983; Asher and Lascarides, 2008), putting it to work requires us to make some fundamental modeling choices: primarily, we need to define what the conversational record *is* and how it *changes* during conversation. That is, we need a formal representation of conversational records from which com-

<sup>6</sup>This corresponds roughly to what Asher and Lascarides (2013) call *basic cooperative*: the minimal cooperativity required to engage in conversation at all.

<sup>7</sup>One can argue that such insincere commitments are not commitments at all. We agree in principle, but the insincere speaker still *feigns* a commitment. And since we are concerned with observable behaviour only, we need to deal with such deceit and the consequences it has in a dialogue.

mitments can be easily projected. Then we need to capture the *immediate* effects of an assertion on this record; making the model too smart, so to speak, would go against our project of finding minimal, constitutive principles.

We can rely on existing work for this. Commitments are representable in static modal logic models (Asher and Lascarides, 2008), and Venant and Asher (2015) show how assertions enact *dynamic* updates of these models. Their model in particular accounts for updates associated with assertions that dispute previous commitments (undertaken by oneself or others). Furthermore, Venant and Asher (2016), building on Asher and Lascarides (2003), give a general method to link such models to a complex language for semantic representation and interpretation in a discourse context.

It is however not obvious how one ought to understand the *rejection of  $p$*  in such a framework. There is a clear intuition that rejection operates dually (in some way) to assertion; that is, rejection is the speech act that cancels or reverses an assertion. An old idea is to reduce rejection to assertion by claiming that a rejection of  $p$  is equivalent to the assertion of  $\neg p$  (Frege, 1952; Rumfitt, 2000). This idea does not seem to capture the breadth of linguistic data. For instance, Grice (1991) provides us with an example where a rejection of a proposition  $p$  is not equivalent to asserting that that  $p$  is false.<sup>8</sup>

- (1) If you say “X or Y will be elected,” I may reply “That’s not so; X or Y *or* Z will be elected.” Here, too, I am rejecting “X or Y will be elected” not as false but as *unassertable*. (Grice, 1991: p. 82, his emphasis)

Similarly, Stalnaker (1978) remarks in a footnote that to reject is not to assert a negative, but to refuse to accept (p. 87, footnote 9). Given Grice’s example and similar cases we agree with Stalnaker on this. Incurvati and Schlöder (2017) give multiple equivalent ways to formalise this conception; their commitment account models a speaker  $A$  rejecting  $p$  as undertaking a commitment *not* to commit to  $p$ ,  $C_A \neg C_A p$ . Our Basic Principles (Definition 1) predict that this is correct:  $C_A \neg C_A p$  entails—by the Basic Principles— $C_A \Box \neg C_A p$ . This can be read as  $A$  publicising the intention not to commit to  $p$  and thereby not to agree to  $p$ . This coincides with Stalnaker’s remark and with our intuition that a rejection is the dual speech act to assertion.

**Definition 3** (Assertion and Rejection). Let  $A$  be a speaker and  $p$  be a proposition.

In asserting that  $p$ ,  $A$  undertakes the commitment that  $C_A p$ .

In rejecting  $p$ ,  $A$  undertakes the commitment that  $C_A \neg C_A p$ .

### 3.2. Deriving illocutionary force

We now have described what commitments a speaker undertakes in performing the speech acts of assertion and rejection. The next question is what the *purpose* of these speech acts is. We

<sup>8</sup>Others have made similar arguments, e.g. Dickie (2010) and Walker (1996).

follow Austin (1962) in saying that one makes a speech act with a particular intention. We can formalise this as follows.

**Definition 4** (Speech-Act Related Goals). If a speaker  $A$  makes a speech act and we can derive from the resulting commitment structure that  $C_A \Diamond \gamma$  then  $\gamma$  is a *Speech-Act Related Goal (SARG)* of that act.

Trivially, according to the Basic Principles in Definition 1, it is a SARG of any speech act to maintain the commitments undertaken by making that act. However, committing to a proposition is rarely if ever a goal in and of itself, so there must be something more to their purpose. To answer this question, we first must ask what the overall purpose of conversation itself is; since speakers make speech acts to engage in conversation, their purpose can only be understood with respect to the purpose of the conversation.

The traditional conception has it that the goal of a conversation is to *exchange information* (Stalnaker, 1978; Skyrms, 2010). In other work (Asher et al., 2016; Asher and Paul, 2016), some of us have argued that conversations have many purposes that are not plausibly analysable as an exchange of information. For example, two politicians in a debate are often not exchanging information with each other but rather setting forth arguments and providing information to convince an audience, which might be not necessarily they themselves, but their peers, a committee, or an electorate. Thus, Asher et al. (2016), Asher and Paul (2016) abstract away from all these *particular* circumstances and conceive of conversations, at utmost generality, as being about achieving certain winning conditions with respect to an abstract *Jury*.

For the purposes of this paper, we will assume that these winning conditions are expressible in a standard propositional language and thus can be put as the goal to *convince the Jury*. On our commitment account, agreement between two interlocutors is to share a commitment. Hence we can fix another basic principle: both speakers engaged in a dialogue *intend to establish their commitments as shared with the Jury*. While in Definition 1 we recorded basic principles of *commitment*, we now fix this principle as partly constitutive of the activity of *conversing*.

**Definition 5** (Basic Principles). Let  $A$  and  $B$  be speakers engaged in conversation and let  $J$  be the Jury; let  $\Phi$  be the finite set of issues raised in the dialogue. The following axiom is (partly) constitutive of conversing:

- (d)  $C_A \Diamond \Box \bigwedge_{\varphi \in \Phi} (C_A \varphi \leftrightarrow C_J \varphi)$  and  $C_B \Diamond \Box \bigwedge_{\varphi \in \Phi} (C_A \varphi \leftrightarrow C_J \varphi)$ .  
Speakers intend to reach agreement with the Jury on the issues  $\Phi$ .

The Basic Principle (d) states that both speakers are committed to aligning with the Jury on all issues  $\varphi$  raised in the conversation. This does not mean to agree to  $\varphi$ , but rather to reach a state where the Jury *shares* a commitment with regards to  $\varphi$ ; that is, either both the speaker and the Jury commit to  $\varphi$  or both do not commit to  $\varphi$ . This principle is an idealisation. First, dialogues might be aborted at any point and so leave issues open. Second, speakers might have an argument just for the fun of it (as in debate club), or to convince the Jury of their conversational *ability* and not primarily of the *issues* they raise (as in debate competitions).

The first point does not impugn our general point that it is still their *goal* to resolve issues; the second point concerns situations that are, arguably, still conducted under a pretense of adherence to (d).

Now we are able to derive some particular SARGs of assertion and rejection. The following derivations show that the goal of an assertion is to prompt agreement, and the goal of a rejection is to prompt retraction of a previous commitment (if there was one). First suppose that speaker *A* asserts the proposition *p*.<sup>9</sup>

$C_A p$  (*A* asserts that *p*).

$\approx C_A \Box C_A p$  by Definition 1, (a).

$\approx C_A \Box \Box C_A p$  by Definition 2, (4).

$\approx C_A \Diamond \Box C_J p$  by Definition 5, (d).

$\approx C_A \Diamond C_J p$  by the dual of Definition 2, (T).

$\rightsquigarrow A$  wants the Jury to share the commitment to *p*.

Now suppose that speaker *B* rejects *p*.

$C_B \neg C_B p$  (*B* rejects *p*).

$\models C_B \neg C_B \neg \neg p$  by Double Negation Introduction.

$\approx C_B \Box \neg C_B \neg \neg p$  by Definition 1, (b).

$\approx C_B \Box \neg C_B p$  by Double Negation Elimination

$\approx C_B \Box \Box \neg C_B p$  by Definition 2, (4).

$\approx C_B \Diamond \Box \neg C_J p$  by Definition 5, (d).

$\approx C_B \Diamond \neg C_J p$  by the dual of Definition 2, (T).

$\rightsquigarrow B$  wants the Jury to be not committed to *p*.

These two SARGs seem to be of particular significance with respect to the Basic Principle (d), and therefore express the conventional purpose that assertion and rejection serve in a dialogue. Thus, we call them the *illocutionary forces* of the speech acts assertion and rejection.

A special case of the latter derivation is in the situation where *A* has already convinced the Jury of *p*. Then *B*'s intention is for the Jury to *retract* the commitment to *p*. This is in particular the case in everyday conversation where the Jury is the speakers themselves; that is, *B* wants to convince *A* and *A* wants to convince *B*. Then we derive  $C_A \Diamond C_B p$  as the illocutionary force of

<sup>9</sup>Again  $\approx$  is defeasible inference with defeasible modus ponens on  $>$ . That is,  $p > q, p \approx q$  unless that inference is blocked by information contradicting *q*.

assertion and  $C_B \Diamond \neg C_A p$  as the illocutionary force of rejection. Hence, if  $A$  asserts that  $p$ ,  $B$ 's rejection of  $p$  voices the intention that  $A$  retract her commitment to  $p$ . Moreover, this means we derive  $C_A p \models C_A \Diamond C_B p$  from basic principles, instead of stipulating the axiom *Intent to Share Commitment* we discussed in Section 1.

### 3.3. Rejecting rejections and other speech acts

The previous discussion dealt exclusively with rejecting a (previously asserted) proposition. But, in fact, any speech act can be rejected, cancelling its effects (Searle, 1969). A particular case is the rejection of a previous rejection.

- (2) a. A: It is the case that  $p$ .  
 b. B: No, it's not.  
 c. A: Yes, it is.

It is not obvious—in English—that A's utterance in (2c) is a rejection of B's rejection in (2b), rather than a re-assertion of A's own (2a). However, (2) can be translated to German as follows.

- (3) a. A: Es ist der Fall, dass  $p$ .  
 b. B: Nein, ist es nicht.  
 c. A: Doch, ist es.

In this case, A's utterance in (3c) contains the negative polarity item *doch* which requires a negated antecedent. Thus, the utterance that (3c) must rhetorically relate to is (3b) and it is implausible to model it as a re-assertion of  $p$ . English lacks a particle like *doch*, but in some cases a rejection syntactically mirrors the shape of a previous rejection. The following are attested examples from the AMI corpus (Carletta, 2007).

- (4) a. A: That's dependent on the television.  
 b. B: No, I don't think so.  
 c. A: I do know so.  
 (5) a. A: Mushroom is a vegetable.  
 b. B: I don't think it is.  
 c. A: It's vegetable.

In (4), the form of (4c) mirrors (4b), suggesting that (4c) functions as a rejection of the rejection (4b). In contrast, the form of (5c) suggests that it indeed works as a re-assertion of (5a). We note that it is not our goal to argue that rejection-of-rejection and re-assertion have different *effects*; surely, both (4c) and (5c) have the effect of  $A$  indicating that she stands by her original assertion. Rather, we want to verify that our approach squares with the data showing that one can reject a rejection. That is, we check that we can make sense of these cases without engaging in undue sleights of hand (such as simply defining rejections-of-rejections to be re-assertions).

Naïvely reproducing the semantics for rejection from Definition 3 will not do. In (6) we have added the resulting commitments, according to Definition 3, to the dialogue from (2). That

is, (6a) results in  $A$  undertaking a commitment to  $p$  and (6b) in  $B$  undertaking a commitment not to share  $A$ 's commitment. However, representing the rejection-of-a-rejection in (6c) as  $A$  committing not to share in  $B$ 's commitment is odd.

- (6) a.  $A$ : It is the case that  $p$ .  $C_A p$   
 b.  $B$ : No, it's not.  $C_B \neg C_B p$   
 c.  $A$ : Yes, it is.  $??C_A \neg C_A \neg C_B p$

Apparently, the way we characterised rejection in Definition 3 is specific to the rejection of a proposition. Rejecting an *act* (other than assertion) appears to be different. Let's try to make sense of this. Speech acts can be *cancelled* which means that their force does not obtain (Searle, 1969), i.e. that the associated intention is not fulfilled. We model rejection now as the speech act that realises the function of cancellation. That is, what a rejection cancels is the *illocutionary force* of its target act; or, more generally, a rejection can target a SARG. Put differently, in a Clarkian (Clark, 1996) understanding of conversation, every move in a dialogue proposes a joint action; execution of the action realises the move's illocutionary force. Thus we can say that to reject a speech act is to *refuse participation* in that act's joint action.

**Definition 6** (Rejecting Arbitrary Speech Acts). Suppose  $a$  is a speech act with SARG  $\alpha$ . To reject that SARG is to commit not to participate in  $\alpha$ ; that is, not to intend  $\alpha$ . Thus, if speaker  $B$  rejects  $\alpha$ ,  $B$  is undertaking a commitment to  $C_B \neg \Diamond \alpha$ . We assume that all else being equal the SARG of  $a$  that represents  $a$ 's illocutionary force is the relevant SARG here.

We can first verify that this generalises on the narrower definition from Definition 3. That is, we can reproduce that rejecting an assertion of  $p$  (as in 2b) results in the commitment  $C_B \neg C_B p$ , i.e. in rejecting the asserted proposition. Since here we talk about the speakers engaging in joint actions, we can model the Jury as the speakers themselves. Then the illocutionary force of an assertion that  $p$  is  $C_A \Diamond C_B p$ . By to Definition 6 the rejection of that act is  $C_B \neg \Diamond C_B p$ . Hence:

$$C_B \neg \Diamond C_B p \text{ (} B \text{ rejects } \alpha = \Diamond C_B p \text{)}.$$

$$\models C_B \Box \neg C_B p \text{ by a modal logic validity.}$$

$$\models C_B \neg C_B p \text{ by the dual of Definition 2, (T).}$$

Note in particular that these inferences are non-defeasible; that is, it is an unavoidable consequence of rejecting an assertion (in the sense of Definition 6) to reject the asserted proposition (in the sense of Definition 3).

Now we can check that Definition 6 also felicitously models rejections-of-rejections. In (6b), the illocutionary force we attribute is  $C_B \Diamond \neg C_A p$  (as derived earlier). Rejecting this force yields:

$$C_A \neg \Diamond \neg C_A p \text{ (} A \text{ rejects } \alpha = \Diamond \neg C_A p \text{)}.$$

$$\models C_A \Box C_A p \text{ by a modal logic validity.}$$

$$\models C_A C_A p \text{ by the dual of Definition 2, (T).}$$

$$\rightsquigarrow A \text{ is committed to her commitment that } p.$$

The intuitive reading of this derivation is that *A* is confirming or renewing her commitment to *p* as made in (6a). We think that this is correct for rejecting a rejection.

### 3.4. Cooperative commitments

Everything said so far goes for cooperative as well as noncooperative settings. Our final goal is to reproduce the *Cooperativity* axiom from Section 1. This axiom models that cooperative speakers adopt publicised intentions. Put differently, once an addressee has *understood* the SARG of an act, she is expected to *take up* that goal. We now demonstrate that this kind of cooperativity varies with the assumptions made on the strength of commitments. Consider the following three modal logic axioms.

$$(D) \neg C_A \perp \quad (4) C_A \phi \rightarrow C_A C_A \phi \quad (5) \neg C_A \rightarrow C_A \neg C_A \phi.$$

These axioms formalise some sort of sincerity on commitments: (D)+(5) expresses that one cannot claim to have made a commitment ( $C_A C_A p$ ) that one in fact has not made ( $\neg C_A p$ ); (D)+(4) that a speaker cannot make a commitment to a proposition ( $C_A p$ ) and simultaneously reject it ( $C_A \neg C_A p$ ). To see that these partially express cooperativity, note that (D)+(5) rule out the noncooperative act in (7a) and (D)+(4) the one in (7a').

- (7) a. A: I claimed earlier that *p*.  $C_A C_A p$   
           (when, in fact, A never asserted *p*, i.e.  $\neg C_A p$ )  
       a.' A: I never claimed that *p*.  $C_A \neg C_A p$   
           (when, in fact, A asserted *p* previously, i.e.  $C_A p$ )

Claims similar to (7) can be found, e.g., in political debates. This demonstrates that in noncooperative settings one cannot trust one's interlocutor to be sincere about their own commitments. Thus, we refer to KD45 operators  $C_A$  as *cooperative commitments*.<sup>10</sup> We now show that if we axiomatise our commitment structures to be KD45 models, we derive the cooperative principle that *understanding entails acceptance*; this inference is of course only made defeasibly, since rejections can occur for innocuous reasons in cooperative settings as well. This precisely formalises the claim of Schlöder and Fernández (2014) that a cooperative addressee is expected to take up a proposal unless there is a reason not to. Apparently, speakers are aware of this default expectation, as evinced by the following attested example from the British National Corpus (Burnard, 2000).

- (8) a. A: Do you agree with that?  
       b. B: I have no reason to disagree. Yes.  
           (BNC, file FMN, lines 492–493)

First we need to clarify what is meant by 'understanding' on the commitment-based account. Venant et al. (2014) already provide us with a model: understanding is also an attitude that ought to be displayed publicly if it is to be conversationally relevant (this appears to be the

<sup>10</sup>Incurvati and Schlöder (2017) also derive KD45 as the modal logic of cooperative commitment from independently motivated principles.

point of backchannel utterances; also recall our discussion of publicised intentions). Making something public, on the commitment-based account, is always the undertaking of a commitment. Now, according to Venant et al.,  $B$  understanding that  $A$  committed to  $\varphi$  is precisely  $B$  committing to the fact that  $A$  made that commitment,  $C_B C_A \varphi$ . We adopt this notion and can now demonstrate that under cooperative commitments, understanding an intent defeasibly entails sharing the intent.

**Theorem 7** (Cooperative Commitment). Assume that  $C_A$  and  $C_B$  satisfy the KD45 axioms and that  $A$  considers  $B$  her Jury and vice versa. Then  $C_B C_A \Diamond \varphi \approx C_B \Diamond \varphi$  (and the same for  $A$  and  $B$  switched).

*Proof.*  $C_B C_A \Diamond \varphi$  (assumption).

$\approx C_B \Box C_B C_A \Diamond \varphi$  by Definition 1, (a).

$\approx C_B \Box \Box C_B C_A \Diamond \varphi$  by Definition 2, (4).

$\approx C_B \Diamond \Box C_A C_A \Diamond \varphi$  by Definition 5, (d).

$\approx C_B \Diamond \Box C_A \Diamond \varphi$  by (D)+(5).

$\approx C_B \Diamond \Box C_B \Diamond \varphi$  by Definition 5, (d).

$\approx C_B \Diamond C_B \Diamond \varphi$  by Definition 2, (T).

$\approx C_B \Diamond \varphi$  by Definition 1, (c). □

Note that Theorem 7 is an accurate analogue of the *Cooperativity* axiom of Asher and Lascarides.

For the two speech acts we have defined here, we can do one better. Theorem 7 shows that understanding a *goal* entails uptake of that goal. The following derivations show that for assertion and rejection it suffices to understand the *act* itself.

|                                                               |                                                                      |
|---------------------------------------------------------------|----------------------------------------------------------------------|
| $C_B C_A p$ ( $B$ understands $A$ 's assertion of $p$ ).      | $C_B C_A \neg C_A p$ ( $B$ understands $A$ 's rejection of $p$ ).    |
| $\approx C_B \Box C_B C_A p$ by Definition 1, (a).            | $\approx C_B \Box C_B C_A \neg C_A p$ by Definition 1, (b).          |
| $\approx C_B \Box \Box C_B C_A p$ by Definition 2, (4).       | $\approx C_B \Box \Box C_B C_A \neg C_A p$ by Definition 2, (4).     |
| $\approx C_B \Diamond \Box C_A C_A p$ by Definition 5, (d).   | $\approx C_B \Diamond \Box C_A C_A \neg C_A p$ by Definition 5, (d). |
| $\approx C_B \Diamond \Box C_A p$ by (D5).                    | $\approx C_B \Diamond \Box C_A \neg C_A p$ by (D5).                  |
| $\approx C_B \Diamond \Box C_B p$ by Definition 5, (d).       | $\approx C_B \Diamond \Box \neg C_A p$ by (D4).                      |
| $\approx C_B \Diamond C_B p$ by Definition 2, (T).            | $\approx C_B \Diamond \Box \neg C_B p$ by Definition 5, (d).         |
| $\rightsquigarrow B$ intends to share the commitment to $p$ . | $\approx C_B \Diamond \neg C_B p$ by Definition 2, (T).              |
|                                                               | $\rightsquigarrow B$ intends not to commit to $p$ .                  |

The assumption that  $A$  and  $B$  consider each other their Jury stands to reason in everyday cooperative dialogue. Depending on how one models the Jury, the above derivations and Theorem 7 can also be recovered in a more general setting. For instance, if the Jury is *also* considered to be bound by the Basic Principles (a)–(d), Theorem 7 can be maintained, since then intentions percolate from  $A$  over  $J$  to  $B$ . However, in general, the Jury is a mere overhearer of the conversation and not a participant. So it is potentially bound by a different set of principles.

#### 4. Model theory

A model theory can be obtained by understanding the speech acts we consider as moves in an unbounded conversational game (Asher and Paul, 2013). We start with both participants initial commitments, as represented in a Kripke model satisfying the appropriate axioms. Computing a speech act leads to a model transition; we abstract away from explicitly computing these transitions (though it can be done; see Venant and Asher (2015)). Rather, we consider a conversation to be a sequence of public commitment models, where we tacitly assume that the transition from one model to the next was due to one participant undertaking a commitment by way of making speech act.

Thus, the complete tree of potential conversations is a tree in which each dot is a Kripke model for commitment. This allows us to understand the temporal operators  $\Diamond$  and  $\Box$  as quantifying over potential future commitment states. To define defeasible inference we modify Commonsense Entailment (Asher and Morreau, 1990) to include a temporal dimension.

**Definition 8** (Point). Let  $W$  be a set of worlds. A *point* on  $W$  is a model for three speaker public commitment modal logic ( $A$ ,  $B$  and the Jury  $J$ ), i.e. a structure  $t = \langle W, V^t, R_A^t, R_B^t, R_J^t \rangle$  where  $V$  is a valuation and  $R_A^t$ ,  $R_B^t$  and  $R_J^t$  are accessibility relations.

**Definition 9** (Intention Model). A *intention model* is a tuple  $M = \langle W, P, S, T, * \rangle$  where:

- $W$  is a set of worlds.
- $P$  is a set of points on  $W$ .
- $S \subseteq P^{<\omega}$  is a tree. That is,  $\emptyset \in S$  and  $S$  is a set of finite sequences on  $P$  such that if  $x \in S$  and  $y$  is an initial segment of  $x$ , then also  $y \in S$ . If  $x \in P^{<\omega}$ ,  $x = \langle t_1, t_2, \dots, t_n \rangle$ , we write  $x \oplus t = \langle t_1, t_2, \dots, t_n, t \rangle$  for the extension of  $x$  with  $t$ .
- $T$  is a function that maps an  $x \in S$  and a  $w \in W$  to a maximal branch in  $S$  extending  $x$  i.e.  $T(x, w) \subseteq S$  is a set of finite sequences such that:
  - $x \in T(x, w)$  and for all  $y \in T(x, w)$ ,  $x$  is an initial segment of  $y$ .
  - $\bigcup T(x, w)$  is infinite or there is no  $t \in P$  such that  $(\bigcup T(x, w) \oplus t) \in S$ .
  - $T(x \oplus t, w) = T(x, w) \setminus \{x\}$ .
- $*$  is a function  $* : W \times \mathcal{P}(S \times W) \rightarrow \mathcal{P}(S \times W)$  with:

- for all  $w \in W$  and  $X \subseteq S \times W$ ,  $*(w, X) \subseteq X$ .
- for all  $w \in W$  and  $X, Y \subseteq S \times W$ ,  $*(w, X \cup Y) \subseteq *(w, X) \cup *(w, Y)$ .

For  $x \in S$  write  $M^x = \langle W, V^x, R_A^x, R_B^x, R_J^x \rangle$  for the last point in  $x$ .

Intuitively,  $S$  represents possible conversations along transitions between the commitment structures  $P$ . A finite sequence represents a finite conversation and the last point in the sequence is the current commitment state in that conversation; intuitively  $T$  assigns a *future timeline* to every world in that state. Note that time at a world is linear, and the temporal modals are evaluated with respect to the same world at different points in time.

We use  $T$  to give truth-conditions to the temporal operators and  $*$  to give truth-conditions to defeasible conditionals. The function  $*$  assigns to a world and a set of sequence-world pairs (i.e. the extension of a proposition, computed globally on the entire tree) the set of sequence-world pairs where the proposition holds in a typical ('normal') manner.

**Definition 10** (Truth). Truth is defined in a model  $M = \langle W, P, S, T, * \rangle$  relative to an  $x \in S$ .

- $M, x, w \models p$  iff  $w \in V(p)$ ,
- $M, x, w \models \neg\phi$  iff  $M, x, w \not\models \phi$ ,
- $M, x, w \models \phi \wedge \psi$  iff  $M, x, w \models \phi$  and  $M, x, w \models \psi$ ,
- $M, x, w \models C_S\phi$  iff for all  $v \in R_S^x(w)$ ,  $M, x, v \models \phi$ ,
- $M, x, w \models \Diamond\phi$  iff there is a  $y \in T(x, w)$  such that  $M, y, w \models \phi$ .
- $M, x, w \models \phi > \psi$  iff  $\forall (y, v) \in *(w, \{(y, v) \in S \times W \mid M, y, v \models \phi\})$ ,  $M, y, v \models \psi$ .

Write  $\llbracket \phi \rrbracket = \{(y, v) \in S \times W \mid M, y, v \models \phi\}$  for the global extension of  $\phi$ .

Note that this definition of  $\Diamond$  satisfies KT4—and quite a lot more. The assumptions we have made in the preceding discussion were intentionally chosen to be minimal, *basic* assumptions. They are not *complete* for this model theory, as this would require some stronger assumptions. We leave an investigation into these for further work. Our goal here is to demonstrate that this semantic framework is expressive enough to define admissibility conditions corresponding to our basic principles.

**Definition 11** (Semantic Axioms for the Basic Principles). The Basic Principles correspond to the following structural axioms on intention models.

- (a)  $C_A\phi > C_A\Box C_A\phi$ .
- $\forall X \subseteq \mathcal{P}(S \times W), w \in W :$
- $*(w, \{(y, v) \in S \times W \mid \forall v' \in W : vR_A^y v' \rightarrow (y, v') \in X\})$
- $\subseteq \{(y, v) \in S \times W \mid \forall v' \in W \left( vR_A^y v' \rightarrow \forall y' \in T(y, v') (\forall v'' \in W (v'R_A^{y'} v'' \rightarrow (y', v'') \in X)) \right)\}.$

$$(b) \ C_A \neg C_A \neg \varphi > C_A \Box \neg C_A \neg \varphi.$$

$$\begin{aligned} & \forall X \subseteq \mathcal{P}(S \times W), w \in W : \\ & * (w, \{(y, v) \in S \times W \mid \forall v'' \in W (vR_A^y v'' \rightarrow \exists v' \in W : v''R_A^y v' \wedge (y, v') \in X)\}) \\ & \subseteq \{(y, v) \in S \times W \mid \forall v' \in W \left( vR_A^y v' \rightarrow \forall y' \in T(y, v') (\exists v'' \in W : v'R_A^{y'} v'' \wedge (y', v'') \in X) \right)\}. \end{aligned}$$

$$(c) \ C_A \Diamond C_A \Diamond \varphi > C_A \Diamond \varphi.$$

$$\begin{aligned} & \forall X \subseteq \mathcal{P}(S \times W), w \in W : \\ & * (w, \{(y, v) \in S \times W \mid \forall v' (vR_A^y v' \rightarrow \exists y' \in T(y, v') \forall v'' \in W : \\ & \quad (v'R_A^{y'} v'' \rightarrow \exists y'' \in T(y', v'') : (y'', v'') \in X))\}) \\ & \subseteq \{(y, v) \in S \times W \mid \forall v' \in W \left( vR_A^y v' \rightarrow \exists y' \in T(y, v') : (y', v') \in X \right)\}. \end{aligned}$$

$$(d) \ C_A \Diamond \Box (C_A \varphi \leftrightarrow C_J \varphi).$$

$$\forall x \in S, w \in W : \forall v (wR_A^x v \rightarrow \exists y \in T(x, v) \forall z \in T(y, v) : R_A^z = R_J^z).$$

Analogously for the axioms for speaker *B*.

The axioms for (a)–(c) look complicated, but are in fact just structural decodings of the truth-conditions of the Basic Principles. The soundness of (d) is trivial, and we present the soundness proof for axiom (a).

**Theorem 12 (Soundness).** On intention models *M* where the axioms for (a) from Definition 11 holds:  $\forall x \in S \forall w \in W : M, x, w \models C_A \varphi > C_A \Box C_A \varphi$ .

*Proof.* Fix *x* and *w*. It is to show that  $*(w, \llbracket C_A \varphi \rrbracket) \subseteq \llbracket C_A \Box C_A \varphi \rrbracket$ . Instantiate the axiom for (a) for  $X = \llbracket \varphi \rrbracket$  to obtain the sets:

$$\begin{aligned} & * (w, \{(y, v) \in S \times W \mid \forall v' \in W : vR_A^y v' \rightarrow (y, v') \in \llbracket \varphi \rrbracket\}) \\ & = * (w, \{(y, v) \in S \times W \mid \forall v' \in W : vR_A^y v' \rightarrow M, y, v' \models \varphi\}) \\ & = * (w, \{(y, v) \in S \times W \mid M, y, v \models C_A \varphi\}) \\ & = * (w, \llbracket C_A \varphi \rrbracket) \\ & \subseteq \{(y, v) \in S \times W \mid \forall v' \in W \left( vR_A^y v' \rightarrow \forall y' \in T(y, v') (\forall v'' \in W (v'R_A^{y'} v'' \rightarrow (y', v'') \in \llbracket \varphi \rrbracket)) \right)\} \\ & = \{(y, v) \in S \times W \mid \forall v' \in W \left( vR_A^y v' \rightarrow \forall y' \in T(y, v') (\forall v'' \in W (v'R_A^{y'} v'' \rightarrow M, y', v'' \models \varphi)) \right)\} \\ & = \{(y, v) \in S \times W \mid \forall v' \in W (vR_A^y v' \rightarrow \forall y' \in T(y, v') (M, y', v' \models C_A \varphi))\} \\ & = \{(y, v) \in S \times W \mid \forall v' \in W (vR_A^y v' \rightarrow \forall M, y, v' \models \Box C_A \varphi)\} \\ & = \{(y, v) \in S \times W \mid M, y, v \models C_A \Box C_A \varphi\} \\ & = \llbracket C_A \Box C_A \varphi \rrbracket \end{aligned}$$

This is precisely the truth-condition for  $C_A \varphi > C_A \Box C_A \varphi$ . □

## 5. Conclusion

The work we have presented here is intended to be foundational. We offer an understanding of *commitment* in conversation that is grounded in the basic principles we take to be partly constitutive of the concept. Moreover, this understanding allows us to straightforwardly understand the elusive notion of *intention* without requiring additional machinery. The result is a model that goes well beyond using commitment as a mere scorekeeping device on the conversational record. By taking *public commitments* as basic observable data, we validate sophisticated inferences from *what is observed* to *what is intended*.

By conceptualising speech acts as the undertaking of particular commitments, the model then explains what illocutionary forces are and what it means to take up a speech act. We can also define the dual of uptake—cancellation—through our general account of rejection: not just as the rejection of a proposition, but as the rejection (cancellation) of an arbitrary speech act. We have demonstrated how this works for the particular case of rejecting a rejection.

Our *Basic Principles* are designed to apply in full generality to cooperative and noncooperative situations. We are able to distinguish cooperativity by modulating additional constraints on what it means to *commit*: by strengthening how tightly speakers are bound by their commitments, we can exclude particular noncooperative moves, and ultimately arrive at the result that cooperative speakers *take up what they understand* (if they can).

In future work we intend to extend this discussion to further speech acts, in particular questions. As mentioned in the Introduction, there are *prima facie* natural intuitions of what speakers *intend* when asking or replying to questions. This project, however, faces some challenges. We first need to include suitable propositional semantics for questions into our (as of yet very simple) commitment structures. Then, it is well possible that there are additional principles that constitute commitment with respect to *questions*; i.e. our Basic Principles potentially underspecify what it means to be committed to a question.

# An anti-intellectualist treatment of German *wissen* ('know')<sup>1</sup>

Viola SCHMITT — *University of Vienna*

Frank SODE — *Goethe University Frankfurt*

**Abstract.** German *wissen* ('know') can embed both finite clauses ('*wissen*-FIN') as well as infinitives ('*wissen*-INF'). Based on novel empirical observations, we argue that *wissen*-INF cannot be reduced to the standard analysis of *wissen*-FIN, i.e. that *wissen* with infinitival complements does not involve a propositional attitude. As cross-linguistic evidence suggests that German *wissen* is not ambiguous, it follows that *wissen*-FIN cannot denote a propositional attitude, either. Accordingly, we require a new, uniform meaning for *wissen*. We derive this meaning by first considering *wissen*-INF, arguing that it combines semantic properties of ability modals with semantic properties of implicative verbs and *enough to*-constructions. We then show that these properties can also be used to characterize *wissen*-FIN, as long as certain non-standard assumptions are made about the denotation of the complement. This gives us a new, unified analysis of *wissen* and also helps to explain some properties of this verb (with both kinds of complements) that traditional analyses cannot account for.

**Keywords:** propositional attitudes, ability modals, actuality entailments

## 1. Introduction

Most treatments of English *know* and analogous expressions in other languages take its occurrence with finite declarative complements as their point of departure. Our focus here will be on German *wissen* ('know') – its finite declarative pattern is given in (1a). In these contexts, *wissen* ('*wissen*-DECL') seems to express a propositional attitude, i.e. a particular relation between the referent of the matrix subject and the content of the embedded clause. More specifically, following Hintikka's 1969 treatment of attitudes, the meaning of *wissen*-DECL involves a bipartition of the set of possible worlds – those worlds compatible with the subject referent's belief about the world of evaluation on the one hand vs. all the others – and the subsequent evaluation of the proposition w.r.t. the belief-worlds – the proposition must hold in all of them. (Henceforth we simply write '*x* believes *p* in *w*' for '*p* holds in all of *x*'s belief-worlds relative to *w*'). In addition to this, *wissen*-DECL is factive, i.e. it presupposes the truth of its complement (cf. Kiparsky and Kiparsky (1970)), so that we end up with the lexical entry in (1b).

- (1) a. Der Frank weiß, dass der Hedde die Pommes gegessen hat.  
The Frank knows that the Hedde the french-fries eaten has  
'Frank knows that Hedde ate the french fries.' *wissen*-DECL  
b.  $\llbracket \text{wissen-DECL} \rrbracket = \lambda w_s. \lambda p_{\langle s,t \rangle}. \lambda x_e. p(w) = 1. x \text{ believes } p \text{ in } w$

The core insight that *wissen*-DECL denotes a propositional attitude carries over to cases where *wissen* embeds a finite interrogative ('*wissen*-INT'), as in (2a) and (2b) (cf. Karttunen (1977))

<sup>1</sup>We would like to thank Silvio Cruschina, Peter Hallman, Nina Haslinger, Edgar Onea, Moreno Mitrović, Iulia Petrariu, Hagen Pitsch, Dóra Kata Takács, Thomas Weskott, Ede Zimmermann and Sarah Zobel. All errors are our own.

a.o.). Essentially, an individual can be said to *wissen*-INT a question iff it believes all the propositions that are true answers to that question in the world of evaluation. This is captured in the (simplified) lexical entry in (2c) (where  $Q(w)$  is the set of true answers in  $w$ ).

- (2) a. Der Frank weiß, wer die Pommes gegessen hat.  
The Frank knows who the french-fries eaten has  
'Frank knows who ate the french fries.' *wissen*-INT
- b. Der Frank weiß, ob der Hedde die Pommes gegessen hat.  
The Frank knows whether the Hedde the french-fries eaten has  
'Frank knows whether Hedde ate the french fries.' *wissen*-INT
- c.  $\llbracket \text{wissen-INT} \rrbracket = \lambda w_s. \lambda Q_{\langle s, \langle \langle s, t \rangle, t \rangle \rangle}. \lambda x_e. x \text{ believes } \bigcap Q(w) \text{ in } w$

Like many other attitude verbs, *wissen* does not only embed finite clauses as in (1) and (2) (here generalised as '*wissen*-FIN') but also infinitives, (3). The question is, how this occurrence of *wissen* ('*wissen*-INF') and its meaning relates to *wissen*-FIN and its meaning. (Note that the English paraphrase in (3) is a rough approximation and will be refined below.)

- (3) Der Frank weiß sich zu verteidigen.  
The Frank knows REFL to defend  
'Frank is able to defend himself.'/'Frank knows how to defend himself.' *wissen*-INF

There are two general strategies to tackle this question. On the one hand, *wissen* could be taken to be ambiguous, i.e. the meaning of *wissen*-INF would be independent of that of *wissen*-FIN. Below, we will show that this assumption is implausible, as several genetically unrelated languages behave like German. On the other hand, we could maintain that the denotation of *wissen* is uniform, i.e. that *wissen*-INF and *wissen*-FIN have the same denotation. Within the latter view, we can distinguish two positions. The first one could be considered a linguistic version of what is known in the philosophical literature as the 'intellectualist' position. Stanley and Williamson (2001) and Stanley (2011) take such a view w.r.t. English *know*, which embeds both finite clauses, (4a-c) as well as *wh*-infinitives, (4d): They argue that *know* embedding *wh*-infinitives is semantically reducible to *know* with finite complements, i.e. that *know* generally denotes a propositional attitude. Applied to German, this would mean that *wissen*-INF reduces semantically to *wissen*-FIN and that *wissen* generally denotes a relation between the subject-referent and a proposition, mediated by the subject-referent's epistemic state.

- (4) a. Frank knows that Hedde ate the french fries.  
b. Frank knows who ate the french fries.  
c. Frank knows whether Hedde ate the french fries.  
d. Frank knows how to defend himself.

This paper argues that the intellectualist position is untenable for German *wissen*, and proposes an alternative analysis that is essentially 'anti-intellectualist': It maintains a uniform meaning for *wissen*, but denies that this meaning (by itself) ever involves a propositional attitude.

Our reasoning is roughly as follows: We first show that *wissen*-INF as in (3) is not reducible

to a propositional attitude but rather involves semantic properties usually connected to ability modals (cf. Thomason (2005), Bhatt (2006)) and implicative verbs (cf. Karttunen (1971) a.o.): As already noted by Rumfitt (2003) for French, (3) is similar in meaning to (5) (it is not quite identical to it, as we will see below). In addition to this, *wissen*-INF also displays semantic characteristics observable in *enough-to* constructions (cf. Meier (2003), Hacquard (2005)).

- (5) Frank is able to defend himself.

Since the cross-linguistic data suggest that *wissen* is not ambiguous and since *wissen*-INF does not involve a propositional attitude, *wissen*-FIN cannot do so, either, hence the standard hypotheses about its meaning in (1b) and (2c), respectively, cannot be maintained. In order to arrive at a new, unified meaning of *wissen*, we 'reverse-engineer' the meaning of *wissen*, taking our findings from *wissen*-INF and transferring them to *wissen*-FIN. Broadly speaking, we will submit that *wissen* always combines with a property of individuals *P*. In the case of *wissen*-INF, this is straightforward, but in the case of *wissen*-FIN, this requires us to make non-standard assumptions about the denotations of finite embedded declaratives and interrogatives, respectively: Building on work by Kratzer (2006) and Moulton (2015), we suggest that they denote properties of individuals, namely, the property of having factual evidence for *p* (in the case of declaratives) (or for one of the alternatives of *p*, in the case of interrogatives).

It turns out that this gives us an empirically adequate treatment of *wissen*-FIN and furthermore derives data that traditional theories, i.e. the lexical entries in (1b) and (2c), cannot account for.

## 2. Why *wissen*-INF is not reducible to *wissen*-FIN

The intellectualist position taken by Stanley and Williamson (2001), Stanley and Williamson (2001) w.r.t. *know* involves two core assumptions, which we here apply to German: (i) the denotation of *wissen*-FIN involves a propositional attitude, and (ii) the denotation of *wissen*-INF is reducible to that of *wissen*-FIN.<sup>2</sup>

The empirical motivation for this hypothesis is that – at least at first sight – sentences with *wissen*-INF are adequately paraphrased by means of sentences with *wissen*-FIN – more specifically, with *wissen*-INT: (6a), from (3) above, and (6b) seem to be semantically equivalent.

- |     |    |                                                                                                                                                                              |                    |
|-----|----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| (6) | a. | Der Frank weiß [INF sich zu verteidigen].                                                                                                                                    | <i>wissen</i> -INF |
|     | b. | Der Frank weiß, [INT wie er/man sich verteidigen kann/soll].<br>The Frank knows how he/one REFL defend can/should<br>'Frank knows how he/one can/should defend him/oneself.' | <i>wissen</i> -INT |

Given this apparent identity, we can specify the intellectualist hypothesis: *wissen*-INF has the denotation assumed for *wissen*-INT above: It holds of a subject-referent and a question iff that subject-referent believes every true answer to the question, (7a). Since *wissen*-INF is semantically equivalent to *wissen*-INT, its infinitive complement must also have the same denotation as that of *wissen*-INT, i.e. it must denote a question – as sketched for (6) in (7b).

<sup>2</sup>It should be noted that Stanley (2011) explicitly refrains from making a similar point about German.

- (7) a.  $\llbracket \text{wissen-INF} \rrbracket = \llbracket \text{wissen-INT} \rrbracket = \lambda w_s. \lambda Q_{\langle s, \langle \langle s, t \rangle, t \rangle \rangle}. \lambda x_e. x \text{ believes } \bigcap Q(w) \text{ in } w$   
 b.  $\llbracket \text{INF} \rrbracket = \llbracket \text{INT} \rrbracket = \lambda w. \lambda p_{\langle s, t \rangle}. \exists m[m \text{ is a technique} \ \& \ p = \lambda w. \text{ one should use } m \text{ in } w \text{ for self-defence}] \ \& \ p(w) = 1]$

The following will show that this intellectualist position is untenable. It predicts that both *wissen-FIN* and *wissen-INF* require their subject-referent to hold a particular belief – and nothing else (i.e. holding that particular belief is both necessary and sufficient to make the sentence true). This turns out to be descriptively adequate for *wissen-FIN*, but crucially not for *wissen-INF*: First, for a sentence of the form in (8) to be true, *a* is required to have properties other than believing the true answers to the hypothetical denotation of *P* (*qua* (7b)). Second, for such a sentence to be true, it is not even required that *a* believes the true answers to the hypothetical denotation of *P*. In sum, holding a propositional attitude is neither sufficient nor necessary for *wissen-INF*, which falsifies the intellectualist claim.

- (8) *a wissen-INF P.*

## 2.1. Propositional attitude not sufficient for *wissen-INF*

Our first point is that *wissen-INF*, as opposed to *wissen-INT*, might require ‘more’ than the subject-referent holding a certain belief. That is, according to the intellectualist hypothesis in (7) above, both sentences should be true in a world *w* if Frank believes all propositions in (10) – but this is not sufficient for *wissen-INF*.

- (9) a. Der Frank weiß, wie er/man sich verteidigen kann/soll.  
 The Frank knows how er/one REFL defend can/should  
 ‘Frank knows how he/one can/should defend him/oneself.’ *wissen-FIN*  
 b. Der Frank weiß sich zu verteidigen. *wissen-INF*

- (10)  $\{p : \exists m[m \text{ is a technique} \ \& \ p = \lambda w. \text{ one should use } m \text{ in } w \text{ for self-defence}] \ \& \ p(w) = 1\}$

In particular, *wissen-INF* in (9b) requires a more ‘practical acquaintance’ with defence techniques than *wissen-INT* in (9a): A situation where Frank is aware of what the proper techniques of self-defence are, but has never tried to defend himself is adequately described by (9a) but not by (9b): Adding the continuation in (11) to (9a) gives us a well-formed discourse, but if we add it to (9b), the result is extremely odd.<sup>3</sup>

- (11) ??Er hat es zwar noch nie versucht, aber die Viola hat es ihm genau erklärt.  
 ‘He has never tried it, but Viola explained to him in detail how it works.’

Accordingly, theoretical knowledge – believing the propositions in the complement’s presumed denotation – is sufficient for the truth of a sentence with *wissen-FIN*, but not for a sentence with *wissen-INF*. This runs contrary to the predictions of the intellectualist position.

<sup>3</sup>Stanley and Williamson (2001) make similar observations concerning *know* + *wh*-infinitives.

2.2. Propositional attitude not necessary for *wissen*-INF

Our second point is that *wissen*-INF, as opposed to *wissen*-INT, does not even require the subject-referent to hold a certain belief. According to the intellectualist hypothesis, both (12a) and (12b) should be true in a world  $w$  iff our friend believes every proposition in (13). Yet sentences with *wissen*-INF can be adequate descriptions of situations where the subject-referent holds no such belief: In (12), the context specifies that our friend is agnostic about drinking techniques. Whereas (12a) is very odd, in this context, to say the least, (12b) is perfectly fine. Again, this runs contrary to the predictions of the intellectualist position.

- (12) Ich habe unseren neuen Freund aus Pennsylvania mit auf's Feuerwehrfest genommen. Es war unglaublich – er hatte noch nie von Alkohol gehört aber ich kann Dir sagen:  
'I took our new friend from Pennsylvania with us to the party of the local fire department. It was unbelievable – he had never even heard of alcohol, but I can tell you:
- a. ??Der Mann weiß, wie er/man trinken kann/soll.  
the man knows how he/one drink can/should  
'This man knows how he/one can/should drink.' *wissen*-FIN
- b. Der Mann weiß zu trinken.  
The man knows to drink *wissen*-INF

- (13)  $\{p: \exists m[m \text{ is a technique} \ \& \ p = \lambda w. \text{ one should use } m \text{ in } w \text{ for drinking}] \& p(w) = 1\}$

The following data provide even stronger evidence for the same point: *wissen*-FIN does not license inanimate subjects, as illustrated by (14a) and (15a). If *wissen*-FIN involves a propositional attitude, the reason is obvious: Inanimate individuals cannot entertain beliefs. However, *wissen*-INF may combine with inanimate subjects, as witnessed by (14b) and (15b).

- (14) a. #Ihre Stimme weiß, wie man das Publikum fesseln kann/soll.  
Her voice knows how one the audience enthrall can/should  
'Her voice knows how one can/should enthrall the audience.' *wissen*-FIN
- b. Ihre Stimme weiß das Publikum zu fesseln  
Her voice knows the audience to enthrall  
'Her voice is able to enthrall the audience.' *wissen*-INF
- (15) a. #Dieses Produkt weiß, wie man Leute überzeugen kann/soll.  
This product knows how one people convince can/should  
'# This product knows how can can/should convince people.' *wissen*-FIN
- b. Dieses Produkt weiß zu überzeugen.  
This product knows to convince  
'This product is able to convince people / is convincing' *wissen*-INF

Accordingly, whereas *wissen*-FIN requires its subject-referent to entertain beliefs, *wissen*-INF does not, which shows that the meaning of *wissen*-INF cannot involve a propositional attitude.<sup>4</sup>

<sup>4</sup>One could object that (14b) and (15b) involve coercion (of the subject or the verb). However, this begs the question why, if *wissen*-INF and *wissen*-INT are semantically identical, coercion is only easily available for

### 2.3. Interim summary

The previous paragraphs have shown that *wissen*-INF is not reducible to the meaning traditionally assigned to *wissen*-FIN: Attributing a propositional attitude to the subject-referent is neither sufficient nor necessary for a sentence with *wissen*-INF to be true. We are left with two questions: First, what is the meaning of *wissen*-INF? And second, does it bear any relation to the meaning of *wissen*-FIN? The next section addresses the first question.

### 3. *wissen*-INF: ability and quality

At first sight, ability modals, such as English *able* and German *können* ('can, be able') and *in der Lage sein* ('be able') provide an adequate paraphrase for *wissen*-INF (cf. Rumfitt (2003) for French). Our example from (3) above, repeated in (16a), and the modal sentences in (16b) more or less convey the same meaning. The same holds for (17a) with an inanimate subject, repeated from (14b) above: It is roughly identical in meaning to the sentences in (17b).

- (16) a. Der Frank weiß sich zu verteidigen.  
       b. Der Frank ist in der Lage zu / kann tanzen.  
           The Frank MOD                   to / MOD dance.  
           'Frank is able to dance.'
- (17) a. Ihre Stimme weiß das Publikum zu fesseln.  
       b. Ihre Stimme ist in der Lage / kann das Publikum (zu) fesseln.  
           Her voice   MOD                   / MOD the audience (to) enthrall.  
           'Her voice is able to enthrall the audience.'

So, does *wissen*-INF have the same denotation as an ability modal? This hypothesis would not only be attractive in terms of its simplicity, but also because it would provide an obvious explanation for the data discussed in section 2.2, including the facts about inanimate subjects: ability modals don't impose any requirements on the sentence's subject-referent in terms of intentionality (but cf. Kratzer (1981) for more discussion).

We will show that the situation is slightly more complex. *wissen*-INF does indeed share several semantic traits with ability modals (in particular, with the English *be able*, Bhatt (2006) and Hacquard (2006, 2010, ta)): So-called actuality entailments and what we here call '*P*-event-intiation', namely, that the subject-referent causes an event that is intended to be an event of the kind specified by the complement (the latter is henceforth referred to as '*P*'). However, it also exhibits two meaning components that ability modals arguably lack: A 'quality-threshold', namely, the requirement that the subject-referent be good at *P* and the condition that it must be compatible with the facts of the evaluation world that some individual is *P*.

*wissen*-INF. It also doesn't explain cross-linguistic differences in the infinitival patterns (see below).

### 3.1. Actuality entailments

As observed by Bhatt (2006) and Hacquard (2014) for English and French, ability modals with an episodic past / perfective aspect come with actuality entailments, i.e., from the truth of ' $x$  abil-modal  $P$ ' at some point in the past it can be concluded that ' $x$   $P$ ' is true at that point in the past. This also holds for the German modal *können* on an ability reading, as shown in (18).<sup>5</sup>

- (18) Im Endspiel konnte der Frank das Tor treffen.  
 In-the final can-PAST the Frank the goal hit.  
 'In the final, Frank was able to score a goal.'  $\rightsquigarrow$  *In the final, Frank scored a goal*

This pattern carries over to *wissen* ('know') + INF: a sentence like (19a) with an episodic past / perfective aspect cannot be continued by (19b) since this would contradict the actuality entailment of (19a).

- (19) a. Bei ihrem letzten Mittagessen wusste der Frank den Hedde abzulenken.  
 at their last lunch knew the Frank the Hedde to-divert.  
 'During their last lunch, Frank was able to divert Hedde.'  
 b. #Er hat es aber dann doch nicht gemacht, weil er ein schlechtes Gewissen hatte.  
 'But he didn't actually do it, because he felt bad.'

In contrast to the observations by Bhatt (2006), Hacquard (2014) for English and French, we even find 'unspecific' actuality-entailments for ability modals in German with a generic past or present / imperfective aspect.

- (20) Ja, früher, da konnte der Frank das Tor treffen.  
 Yes, in-those-days, EXPL can-PAST the Frank the goal hit.  
 'Well, in those days, Frank was able to score a goal.'  
 $\rightsquigarrow$  *At some point in the past, Frank scored a goal.*

We call these entailments 'unspecific' since there is no particular point in the past for which it has to be true that  $x$   $P$ 's as long as there *is* such a point for which it is true. Again, the same can be observed for *wissen* ('know') + INF with a generic past or present / imperfective aspect:

- (21) Ja, früher, da wusste der Frank zu tanzen – #er hat es zwar nie  
 Yes, in-the-old-days, EXPL knew the Frank to dance – he has it PRT never  
 gemacht, aber es wäre ihm ein Leichtes gewesen.  
 done but it would-have him an easy-thing been  
 'In the old days, Frank had the ability to dance – although he never did it, it would have been easy for him.'

These entailments have to be taken care of by the assertive component, since the entailments, as with ability modals, disappear under negation, see (22).

<sup>5</sup>In German, there is no overt marking of aspect. Nonetheless, we are assuming a semantic feature corresponding to perfective aspect for German, see Kratzer (1998) for a discussion.

- (22) Der Frank wusste den Hedde nicht abzulenken  
 the Frank knew the Hedde not to-divert.  $\nrightarrow$  Frank diverted Hedde's attention.

### 3.2. *P*-event initiation

Ability modals furthermore require that their subject-referent is conceptualized as the causer of the *P*-event (cf. related discussion in Bhatt (2006)). The decomposed lexical meaning of '*P*' in '*x* abil-modal *P*' must contain a CAUSE-relation – otherwise the assertion is odd, as in (23).

- (23) #Der Frank kann besorgt sein  
 The Frank can worried be  
 #'Frank is able to be worried.' BE

This property can also be observed for *wissen* ('know') + INF: While the examples in (24a) and (24b) take a predicate as their argument that introduces a CAUSE-relation, the example in (24c) with a predicate that doesn't involve a CAUSE-relation is as odd as (23).

- (24) a. Der Frank **weiß** ein Gedicht vorzutragen.  
 The Frank knows a poem to-recite  
 'Frank is able to recite a poem.' CAUSE(BEC(BE))  
 b. Ihre Stimme **weiß** zu fesseln.  
 Her voice knows to enthrall  
 'Her voice is able to enthrall the audience.' CAUSE(BEC(BE))  
 c. #Der Frank **weiß** besorgt zu sein.  
 The Frank knows worried to be BE

Crucially, the *P*-event has to be intended by someone to be a *P*-event. This is what goes wrong in (25), where the unintended outcome is highlighted by the adverb *zufällig* ('by chance').

- (25) #Der Frank ist gestolpert und wusste dadurch zufällig den Hedde abzulenken.  
 The Frank is tripped and knew thereby by-chance the Hedde to-divert  
 'Frank tripped and, by chance, WUSSTE thus to distract Hedde'

Again, we find a parallel for ability ascriptions with *fähig sein* ('be able') in (26).

- (26) #Der Frank ist gestolpert und war dadurch zufällig fähig den Hedde abzulenken.  
 The Frank is tripped and was thereby by-chance able the Hedde to-divert  
 '?Frank tripped and, by chance, was thus able to distract Hedde.'

The negated sentence in (27) has the same entailments – the subject-referent is the causer of an event and that has to be intended as a *P*-event – which indicates that the entailments are presuppositions of *wissen*+ INF. Accordingly, we conclude, as a first step, that *wissen*-INF presupposes the subject-referent to make an effort/try to *P*. This is in analogy for Bhatt's 2006

claims for *able*, which he directly relates to the behavior of implicative verbs such as *manage* discussed by Karttunen (1971); Karttunen and Peters (1979) (cf. also Thomason (2005)).

- (27) #Der Frank ist zufällig gestolpert. Es war nicht der Fall, dass er dadurch den  
 The Frank is by-chance tripped. It was not the case that he thereby the  
 Hedde abzulenken wusste.  
 Hedde to-divert knew  
 'Frank tripped by chance. It was not the case that he thereby WUSSTE to distract  
 Hedde'

However, the situation is complicated by the fact that examples like (17a) above showed that *wissen*-INF licenses inanimate subjects: An inanimate subject-referent cannot try/make an effort to *P*, yet we get the same intuition, namely, that there must be an intention for the subject-referent to *P* – even if it is not the subject-referent's own intention. This is shown by the fact that the discourse in (28) seems incoherent.

- (28) #Komparsin Gerda fiel während der Aufführung hin und stieß aus Versehen  
 Extra Gerda fell during the performance PRT and pushed inadvertently  
 einen Schmerzensschrei aus. Ihre Stimme wusste das Publikum (nicht) zu begeistern.  
 a scream-of-pain PRT her voice knew the audience (not) to enthrall  
 INTENDED: 'Extra Gerda fell down during the performance and inadvertently gave a  
 yelp of pain. Her voice was (not) able to enthrall the audience.'

So the correct generalisation is that *wissen*-INF requires the subject-referent to cause some event that *someone* intends to be a *P*-event.

### 3.3. The quality threshold

So far, we have determined that *wissen*-INF, just like ability modals, gives rise to actuality entailments and, analogous to ability modals and implicative verbs, requires a *P*-event initiation. However, there is one aspect of *wissen*-INF that sets it apart from (German) ability modals (but cf. Bhatt (2006) for a related discussion of *able*): It requires the subject-referent to be good at (doing) *P*, where *P* is the property expressed by the complement. In other words, there is an intuitive difference between (29b), with *wissen*-INF and (29a), with ability modals: (29b) conveys that Frank is especially good at swimming in some respect – depending on the context, this might relate to endurance, or style or artistic versatility – but the examples (29a) don't.

- (29) a. Der Frank kann schwimmen / is in der Lage zu schwimmen.  
 the Frank can swim / is in the position to swim.  
 'Frank is able to swim'  
 b. Der Frank weiß zu schwimmen.  
 the Frank knows to swim.

This intuition is corroborated by the contrast in (30): With ability *können* ('can'), a continuation

that explicitly denies the subject-referent being good at *P* is fine, (30a), but with *wissen*-INF, such a continuation is definitely odd, as witnessed by (30b).

- (30) a. Naja, der Frank kann schon schwimmen. Er ist zwar nicht wahnsinnig gut,  
Well the Frank can PRT swim. He is PRT not extremely good,  
aber er schafft es, 20 Bahnen durchzuhalten.  
but he manages it 20 laps to-hang-on  
'Well, Frank can swim. He might not be particularly good at he, but he manages  
to do 20 laps.'
- b. Naja, der Frank weiß schon zu schwimmen. #Er ist zwar nicht wahnsinnig  
Well the Frank knows PRT to swim. He is PRT not extremely  
gut, aber er schafft es, 20 Bahnen durchzuhalten.  
good, but he manages it 20 laps to-hang-on

In other words, *wissen*-INF behaves more or less analogously to constructions with ability modals + modification by *gut* ('good'). This parallel becomes evident once we look at predicates that one can be 'good at' only in a very peculiar way. Consider for instance (31a) with an ability modal: Without *gut*, the sentence can be used to express pure dispositional possibility. Adding *gut* immediately gives us a reading where we are talking about a particular skill. As breathing is usually considered something that comes naturally – i.e. does not require a particular design (granted you are a mammal) or technique, the result is odd – unless, of course, it is used in a context where special breathing techniques are required, such as a yoga class. The sentence in (31b) is analogous to (31a) with *gut*-modification: It is only appropriate in yoga-type contexts, i.e. contexts where breathing involves a particular skill.

- (31) a. Frank kann (#gut) atmen.  
Frank can (well) breathe  
'Frank is able to breathe well'
- b. #Frank **weiß** zu atmen.  
Frank knows to breathe

In sum, *wissen*-INF, compared to ability modals, exhibits an additional requirement: That the subject-referent be 'good' at the complement property *P*. We henceforth refer to this as the 'quality threshold' of *wissen*-INF. Just as *P*-event initiation, the quality threshold can be shown to be part of the presuppositional, rather than the assertive component of *wissen*-INF: When negating *wissen*-INF *P*, we don't only negate that the subject-referent is good at (doing) *P* (but is still able to do *P*), as witnessed by the fact that (32) is extremely odd:

- (32) #Naja, der Frank weiß nicht zu tanzen, aber er kann es schon etwas.  
Well the Frank knows not to dance, but he can it PRT a-little  
'Well, Frank doesn't *wissen* to dance but he can dance a little'

### 3.4. Circumstantial possibility

Another trait that sets *wissen*-INF apart from ability modals such as *können* ('can, be able') and *in der Lage sein* ('be able') is that sentences with *wissen*-INF require that having the property *P* must be compatible with the facts of the world. Put differently: *wissen*-INF requires the facts of the world to be compatible with some individual being *P*. (Cf. Kratzer's 1981 discussion of 'circumstantial' possibility' in this respect.) This particular property of *wissen*-INF is reflected in (33) and (34): In both examples, the possibility of someone being *P* is explicitly denied. Whereas it is fine to negate 'abil-modal *P*' in this context, as shown by (33a) and (34a), it is extremely odd to negate *wissen*-INF *P* in the same context.

- (33) a. Es ist generell so, dass Menschen nicht fliegen können.  
 It is generally thus that humans not fly can  
 'It is generally the case that humans are not able to fly.'
- b. #Es ist generell so, dass Menschen nicht zu fliegen **wissen**.  
 It is generally thus that humans not to fly know
- (34) a. Wenn die Riemann'sche Vermutung, nicht beweisbar ist, kann auch der Frank  
 If the Riemann conjecture not provable is can also the Frank  
 sie nicht beweisen.  
 it not prove  
 'If Riemann's conjecture is unprovable, Frank won't be able to prove it.'
- b. #Wenn die Riemann'sche Vermutung, nicht beweisbar ist, **weiß** auch der Frank  
 If the Riemann conjecture not provable is knows also the Frank  
 sie nicht zu beweisen.  
 it not to prove

In other words: If it is generally impossible for any individual to *P*, we cannot negate a *wissen*-INF *P*: This shows, that *wissen*-INF presupposes the circumstantial possibility that some individual is *P*.

### 3.5. Interim summary

In the preceding paragraphs, we tried to isolate the different meaning components of *wissen*-INF. We first showed that *wissen*-INF, just like ability modals, involves actuality entailments: Depending on its aspectual properties, a sentence *a wissen*-INF *P* has a specific actuality entailment ('*a* did *P* at point *t*') with perfective aspect and an unspecific actuality entailment ('at some point *t*, *a* did *P*') with imperfective. We argued that this meaning component must be asserted, as it does not survive under negation. As opposed to this, the three other components we identified must be presupposed, as they cannot be explicitly negated: The *P*-event initiation, i.e. that the subject-referent must cause an event someone intends to be a *P*-event, the quality-threshold, i.e. the intuition that some particular 'skill' is required for *a* to count as *P*, and circumstantial possibility, namely, that it must be compatible with the facts of the world that some individual is *P*. This is summarized in the following table:

|                                                                                      |                            |                    |
|--------------------------------------------------------------------------------------|----------------------------|--------------------|
| <i>a</i> is <i>P</i>                                                                 | actuality entailment       | <b>asserted</b>    |
| <i>a</i> causes an event that is intended by someone as a <i>P</i> -event            | <i>P</i> -event initiation | <b>presupposed</b> |
| the threshold for <i>a</i> being <i>P</i> is high                                    | quality threshold          | <b>presupposed</b> |
| it is compatible with the circumstances of <i>w</i> that some individual is <i>P</i> | circumstantial possibility | <b>presupposed</b> |
| <i>a wissen-INF P</i>                                                                |                            |                    |

The next section aims at deriving these empirical observations.

#### 4. The proposal

On the syntactic side, we assume that *wissen-INF* is a restructuring verb that shares properties with control and raising verbs. This is in agreement with common assumptions in the syntactic literature on German infinitival embedding verbs, see Reis (2001), Haider (2010), but is not motivated here for reasons of space. For a sentence like (35a), we assume a structure like in (35b).

- (35) a. ... dass der Frank zu trinken **weiß**  
 ... that the Frank to drink knows
- b. [TP Frank [T' [AspP [VP t [V' [vP PRO [v' zu-trinken AGENT ]] weiß-INF ]] IMPERF ] PRES ]]

Tracking the results of the previous section, we distinguish four parts of our proposal for the semantics of *wissen-INF*.

First, the assertive component: *wissen* predicates the denotation of the infinitival complement of its matrix subject-referent, (36). This – together with certain assumptions about the interpretation of AspP (see (39) – (44) below) accounts for the actuality entailments in case of a non-negated assertion.

$$(36) \quad \llbracket \mathbf{wissen} \rrbracket^c = \lambda w_s. \lambda P_{\langle s, \langle e, \langle v, t \rangle \rangle \rangle}. \lambda x_e. \lambda e_v. P(w)(x)(e) \quad \text{prefinal}$$

Second, *wissen* presupposes the initiation of an action with the individual denoted by the matrix subject as the agent. We assume there to be an initial part of the main event that is intended by someone – typically the agent – to be an event of the type denoted by the embedded predicate, (37). This accounts for the fact that unintended events don't qualify as abilities in the relevant sense for *wissen*.

$$(37) \quad \llbracket \mathbf{wissen} \rrbracket^c = \lambda w_s. \lambda P_{\langle s, \langle e, \langle v, t \rangle \rangle \rangle}. \lambda x_e. \lambda e_v: \text{there is an } e' <_{\text{init}} e \text{ such that } x \text{ causes } e' \text{ and someone intends } e' \text{ to become a } P\text{-event in } s. P(w)(x)(e) \quad \text{prefinal}$$

Third, *wissen* presupposes that the situation in which the event is initiated requires of the agent a minimal degree of performance-quality for the initiated event to become a *P*-event: it has to be considerably higher than the maximal degree of performance quality of any stereotypical *P*-

Figure 1: quality-threshold

event, as illustrated in figure 1. This part of the meaning combines aspects of the semantics of *enough to*-constructions, see Meier (2003), and the semantics of *very*, see von Stechow (2009). Reference to requirements by the situation highlights the factual modality of *wissen*-INF which is close in spirit to the factual modality of modals following Kratzer (2013). (38) gives the final version of the lexical entry for *wissen*-INF.

- (38)  $\llbracket \text{wissen} \rrbracket^c = \lambda w_s. \lambda P_{\langle s, \langle e, \langle v, t \rangle \rangle \rangle}. \lambda x_e. \lambda e_v$ : there is a situation  $s \leq w$
- a.  $x$  **initiates**  $P$ : there is an  $e' <_{\text{init}} e$  such that  $x$  causes  $e'$  and someone intends  $e'$  to become a  $P$ -event in  $s$
  - b.  $s$  **requires skill**: the minimal degree  $d_{\min}$  of performance-quality in the contextually relevant respect  $R_c$  required by  $s$  in  $w$  for  $e'$  to become a  $P$ -event is considerably higher than the maximal degree of performance-quality in the contextually relevant respect  $R_c$  of any stereotypical  $P$ -event in  $w$ .
- $P(w)(x)(e)$  final

Note that the last aspect of the semantics, the circumstantial possibility, is not explicitly represented in (38). The basic idea is that there only is a minimal degree of performance-quality required by the situation of an agent, if all the other circumstantial requirements are already satisfied, i.e., we assume as a part of the conversational background a hierarchy of circumstantial requirements that culminate in the situational requirements of the agent with respect to his performance. Following this logic, the presupposition of there being a quality-threshold for the agent presupposes that all other circumstantial requirements are already met.

Here are two examples illustrating the interaction of (38) with Perfective (39) and Imperfective Aspect (42).

- (39) a. Frank **wusste** zu trinken.  
Frank knew to drink
- b.  $[T' [_{\text{AspP}} [_{\text{VP}} \text{Frank} [_{\text{V}'} [_{\text{VP}} \text{PRO} [_{\text{V}'} \text{zu-trinken AGENT} ]]] \text{wu\ss}te ]]] \text{PERF} ] \text{PAST} ]$
- (40) a.  $\llbracket \text{zu-trinken} \rrbracket^c = \lambda w_s. \lambda e_v. \text{drink}(e)(w)$
- b.  $\llbracket \text{PERF} \rrbracket^c = \lambda w_s. \lambda P_{\langle v, t \rangle}. \lambda t_i: D_c \subseteq \text{dom}(P). \exists e \in D_c. (\text{time}(e) \subseteq t \wedge P(e))$ ,  
where  $D_c \neq \emptyset$
- c.  $\llbracket \text{PAST} \rrbracket^c = \lambda w : c \text{ provides time } t \leq t_c. t$
- d.  $\llbracket \text{AGENT} \rrbracket^c = \lambda w. \lambda P_{\langle v, t \rangle}. \lambda x_e. \lambda e_v. \text{agent}(x)(e)(w) \wedge P(e)$

- (41)  $\llbracket (39b) \rrbracket^c = \lambda w_s: c$  provides time  $t \leq t_c \wedge D_c \subseteq \{e: \text{there is a situation } s \leq w \text{ such that there is an } e' <_{\text{init}} e \text{ and Frank causes } e' \text{ and someone intends } e' \text{ to become a drinking-event in } s \wedge \text{the minimal degree } d_{\text{min}} \text{ of performance-quality in the contextually relevant respect } R_c \text{ required by } s \text{ in } w \text{ for } e' \text{ to become a drinking-event is considerably higher than the maximal degree of performance quality in the contextually relevant respect } R_c \text{ of any stereotypical drinking-event in } w\}. \exists e \in D_c. (\text{time}(e) \subseteq t \wedge \text{agent}(\text{Frank})(e)(w) \wedge \text{drink}(e)(w))$
- (42) a. Frank **wusste** zu trinken.  
Frank knew to drink  
b. [T' [AspP [VP Frank [V' [VP PRO [V' zu-trinken AGENT ]]] weiß ]]] IMPERF ] PAST ]
- (43)  $\llbracket \text{IMPERF} \rrbracket^c = \lambda w_s. \lambda P_{\langle v, t \rangle}. \lambda t_i: D_c \subseteq \text{dom}(P). \text{GEN } e \in D_c. (\text{time}(e) \approx t \rightarrow P(e)),$   
where  $D_c \neq \emptyset$
- (44)  $\llbracket (42b) \rrbracket^c = \lambda w_s: c$  provides time  $t \leq t_c \wedge D_c \subseteq \{e: \text{there is a situation } s \leq w \text{ such that there is an } e' <_{\text{init}} e \text{ such that Frank causes } e' \text{ and someone intends } e' \text{ to become a drinking-event in } s \wedge \text{the minimal degree } d_{\text{min}} \text{ of performance-quality in the contextually relevant respect } R_c \text{ required by } s \text{ in } w \text{ for } e' \text{ to become a drinking-event is considerably higher than the maximal degree of performance quality in the contextually relevant respect } R_c \text{ of any stereotypical drinking-event in } w\}. \text{GEN } e \in D_c. (\text{time}(e) \approx t \rightarrow (\text{agent}(\text{Frank})(e)(w) \wedge \text{drink}(e)(w)))$

## 5. A unified analysis of *wissen*-INF and *wissen*-FIN

Our discussion led to a new semantics for *wissen*-INF that is incompatible with the standard semantics of *wissen*-FIN. Does this mean that *wissen* is ambiguous? After all, *wissen*-FIN seems like a well-behaved attitude verb – its meaning thus bears no evident semantic connection to the meaning just proposed for *wissen*-INF.

The answer is: no, as the pattern discussed above is not an idiosyncratic property of German. Several other languages exhibit the same pattern, including dialects of Syrian Arabic (Peter Hallman, pc), south-western Slavic languages (Hagen Pitsch, pc, Moreno Mitrovič, pc), Romanian (Edgar Onea, pc) and Hungarian, which we use in (45) for illustration (the examples were provided by Dora Kata Takacz).

- (45) a. Frank **tudja** hogy Hedde megette a sült krumplit.  
Frank knows that Hedde up-ate the french fries  
'Frank knows that Hedde ate the french fries.' FIN  
b. Frank **tudja** hogy ki ette meg a sült krumplit.  
Frank knows that who ate up the french fries  
'Frank knows who ate the french fries.' FIN
- (46) a. Frank el **tudja** terelni Hedde figyelmét.  
Frank PRT knows to-distract Hedde attention.his.ACC  
'Frank is able to distract Hedde.' INF

- b. Az autó **tudte** lelkesíteni.  
 the car knew to-make-enthusiastic  
 'The car was able to /made people enthusiastic.'  
 INF

Accordingly, the crucial question is: Can we expand our analysis for *wissen*-INF to *wissen*-FIN? For this to work, we would have to assume that *dass*-complements to *wissen*-FIN share the semantic type that corresponds to the embedded infinitivals under *wissen*-INF, see the schematic tree in (48) for the example in (47).

- (47) Der Frank **weiß**, dass es regnet.  
 the Frank knows that it rains  
 'Frank knows that it is raining'

In the spirit of recent proposals for the semantics of complementizers (Kratzer (2006), Moulton (2015)), we propose the following meaning for *dass* in (49). (An analogous treatment can be given for interrogative complementizers, which would involve existential quantification over the alternatives of *p*.)

- (49)  $\llbracket \text{dass} \rrbracket^c = \lambda w_s. \lambda p_{\langle s, t \rangle}. \lambda x_e. \lambda e_v. \text{there is a situation } s \text{ such that } p(s) = 1 \wedge \text{experiencer}(x)(e)(w) \wedge \text{acquainted}(s)(e)(w)$

(51) gives the fully spelled out details for the example in (50).

- (50) a. Der Frank **wusste**, dass es regnet.  
 the Frank knew that it rains  
 'Frank knew that it was raining'  
 b. [T' [AspP [VP Frank [V' [CP dass es regnet ] weiß ] ] PERF ] PAST ]

- (51)  $\llbracket (50b) \rrbracket^c = \lambda w_s. c \text{ provides time } t \leq t_c \wedge D_c \subseteq \{e: \text{there is a situation } s \leq w \text{ such that there is an } e' <_{\text{init}} e \text{ such that Frank causes } e' \text{ and someone intends } e' \text{ to become an acquaintance-event in } s \wedge \text{the minimal degree } d_{\text{min}} \text{ of performance-quality in the contextually relevant respect } R_c \text{ required by } s \text{ in } w \text{ for } e' \text{ to become an acquaintance-event is considerably higher than the maximal degree of performance-quality in the contextually relevant respect } R_c \text{ of any stereotypical acquaintance-event in } w\}. \exists e \in D_c. (\text{time}(e) \subseteq t \wedge \text{there is a situation } s \text{ such that } p(s) = 1 \wedge \text{experiencer}(\text{Frank})(e)(w) \wedge \text{acquainted}(s)(e)(w))$

The resulting semantics is very close in spirit to the semantics for *wissen*-FIN in Kratzer (1989), Kratzer (2002) and inherits its advantages (for example in dealing with the Gettier-cases). The factivity of *wissen* follows from an interplay of the presupposition of *wissen* and the contribution of the complement: the existence of a fact is part of the circumstantial requirements that need to be satisfied so that there can be a minimal degree of performance-quality required of the agent by the situation. Or to put it in different words: the circumstantial possibility for the agent to be able to recognize the fact presupposes the settledness of the matter. Another neat property of the proposal is that it nicely meets the intuition that the use of *wissen* presupposes a high degree of certainty on part of the subject-referent. This is accounted for by the quality-threshold.

There is another at first sight puzzling piece of data that we want to mention in this connection. First, note that ability modals in German can be modified with *besser* ('better'), see (52).

- (52) Die Viola **kann** den Hedde **besser** ablenken als der Frank.  
 the Viola can the Hedde better distract than the Frank  
 'Viola is better at distracting Hedde than Frank'

Again, this is also true for *wissen*-FIN, see (53).

- (53) Die Viola **weiß** den Hedde **besser** abzulenken als der Frank.  
 the Viola knows the Hedde better to-distract than the Frank  
 'Viola has a better ability to distract Hedde than Frank.'

On our account, the explanation is straightforward since *besser* ('better') semantically combines with the *P*-event as the asserted part of the meaning. The more interesting aspect of the *besser* ('better') modification is the fact that a modification with *besser* ('better') is also possible with a finite complement, see (54).

- (54) Der Frank **weiß**, dass der Hedde gefährlich ist, aber die arme Viola **weiß** es noch  
 The Frank knows that the Hedde dangerous is but the poor Viola knows it PRT  
 viel **besser**.  
 much better  
 'Frank knows that Hedde is dangerous, but poor Viola knows it even better.'

On the proposed account, the *P*-event that gets modified with *besser* ('better') is the event introduced by the *dass*-complement which is an acquaintance-event: *besser wissen*, *dass* is understood as 'being better acquainted with' which matches our intuitions about the truth conditions of these examples. Notice that an intellectualist analysis with reference to a believe-relation would have problems in explaining examples of this type since *glauben* ('believe') in German cannot be modified with *besser* ('better'), see (55).

- (55) #Der Frank **glaubt**, dass der Hedde gefährlich ist, aber die arme Viola **glaubt** es  
 The Frank believes that the Hedde dangerous is but the poor Viola believes it

noch viel **besser.**

PRT much better

#'Frank believes that Hedde is dangerous, but poor Viola believes it even better.'

## 6. Summary and outlook

In this paper, we discussed two types of *wissen* ('know') in German: *wissen*-FIN and *wissen*-INF. We presented new data showing that *wissen*-INF cannot be reduced semantically to *wissen*-FIN. A closer look at the data revealed that *wissen*-INF combines semantic properties of ability modals with semantic properties of implicative verbs and *enough to*-constructions. Since the German pattern is found in a wide range of genetically unrelated languages, we argued against an ambiguity-analysis of *wissen* that assumes two different lexical entries for *wissen*-FIN and *wissen*-INF. Starting from *wissen*-INF, we showed how a semantics for *wissen*-FIN can be derived that maintains all the advantages of the standard analysis, if we make certain non-standard assumptions about the denotation of the complement clauses in *wissen*-FIN-constructions. The resulting proposal gives us a new, unified analysis of *wissen* and also helps to explain some properties of this verb (with both kinds of complements) that traditional analyses cannot account for.

It should be noted that our discussion had a very narrow focus, concentrating on German *wissen*. However, *wissen* is not the only verb that selects for both finite and infinitival complements and it is still an open question how our claims here relate to these other cases, which, at least at first sight, show a different behavior (cf. Karttunen (1971) for analogous cases in English). Take for instance *glauben* ('believe'): It can occur with both types of complements, (56), but as opposed to *wissen*, there is no obvious semantic difference between the two patterns.

- (56) Der Frank glaubt [FIN dass er sich verteidigt] / [INF sich zu verteidigen].  
 The Frank believes [FIN that he REFL defends] / [FIN REFL to defend]  
 'Frank believes that he is defending himself.'

Another open question is how our claims relate to languages where its lexical correlate does not display the behavior of German *wissen* – English being a particular prominent case (cf. Stanley and Williamson (2001), Stanley (2011)): Neither the pattern with *wh*-infinitives, (57a), nor the one with bare infinitives, (57b), is parallel to German *wissen*-INF. For instance, they don't license inanimate subjects, nor can they consistently be paraphrased by sentences with ability modals: (57b) and (57c) clearly differ in meaning.

- (57) a. Frank/# Frank's voice knows how to enthrall the audience.  
 b. Frank/# Frank's car knew to leave.  
 c. Frank was able to leave.

# Perspectival reflexives and event semantics<sup>1</sup>

Per Erik SOLBERG — *University of Oslo*

**Abstract.** This paper presents a unified semantic theory of long-distance reflexivity inside and outside of indirect discourse. Long-distance reflexives are argued to be discourse anaphors with presuppositional restrictions to (shifted) perspective holders. Perspective-shift is analyzed in the event semantics: In indirect discourse, the perspective is assigned to the agent/experiencer of the attitudinal event. By modelling the analysis in the event semantics instead of the modal semantics of indirect discourse, it is possible to generalize it to non-attitudinal cases of long distance binding, using other event types and thematic roles.

**Keywords:** long-distance reflexives, indirect discourse, perspective shift, anaphora.

## 1. Introduction

This paper discusses the semantics of long-distance reflexives (LDRs), reflexive pronouns with antecedents outside of their minimal clause. A typical environment where LDRs are found, is in indirect discourse. The Latin example in (1) illustrates this:

- (1) *Rogatus sum a ... matre<sub>i</sub> tua ... [ut venirem ad se<sub>i</sub>]*  
asked.PTCP is.1SG by mother your that come.PST.SBJV.1SG to REFL.ACC

‘I was asked by your mother<sub>i</sub> to come to her<sub>i</sub>’ (Cic. ad Brut. 24.1; Menge, 2000: p. 127)

LDRs in Latin are particularly frequent in indirect discourse, where they refer to the attitude holder (AH), the individual whose propositional attitude the indirect discourse expresses (Fruyt, 1987; Solberg, 2011; Jøhndal, 2012: chap. 4).<sup>2</sup> The AH is often, but not necessarily, a subject. Non-subject-orientation is exemplified in (1), where the LDR antecedent is in an agentive PP of a passivized speech predicate. LDRs with this behaviour are attested in several languages in addition to Latin, such as Japanese (Iida, 1996; Oshima, 2007; Nishigauchi, 2014), Mandarin (Huang and Tang, 1991; Huang and Liu, 2001), Icelandic (Maling, 1984; Sells, 1987; Sigurðsson, 1990) and Tamil (Sundaresan, 2012).

LDRs are also attested in certain non-attitudinal environments, as in the Latin sentence in (2), where an LDR occurs in a complement to *deserve* and refers to the subject of that predicate:<sup>3</sup>

<sup>1</sup>I would like to thank my supervisors Dag Haug and Corien Bary, the very constructive SuB reviewers, and my audience in Edinburgh, in particular Jefferson Barlew and Amy Rose Deal.

<sup>2</sup>I use *propositional attitude* in a wide sense, covering both mental states and utterances (see e.g. Pearson, 2015a).

<sup>3</sup>In (2), the deserving predicate itself is embedded under an attitude predicate, which is immaterial to the topic.

- (2) *unum hoc scio, [hanc<sub>i</sub> meritam esse [ut memor  
only.ACC this.ACC know.1SG she.ACC deserve.PTCP be.INF that mindful.NOM  
esses sui<sub>i</sub>]]  
be.SBJV.2SG REFL.GEN*

‘I know only this, that she<sub>i</sub> has deserved that you remember her<sub>i</sub>.’ (Ter. Andr. 281; Kühner and Stegman, 1955: p. 613)

This is not a Latin quirk. LDRs are also found in non-attitudinal environments in Tamil and Japanese, while they are restricted to indirect discourse in Mandarin and Icelandic. Cross-linguistic work suggest that long-distance reflexivity in non-attitudinal environments is related to perspective shift (Kuno and Kaburaki, 1977; Sells, 1987; Sundaresan, 2012, a.o.).

The non-attitudinal cases are challenging to the analysis of LDRs: Given the AH-orientation of LDRs in indirect discourse, an account involving centred worlds easily comes to mind. However, it is difficult to see how a centred worlds analysis could be extended in a motivated way to the non-attitudinal cases. An alternative is to propose a unified account of perspective shift both inside and outside of indirect discourse, and link LDR reference to this perspectival mechanism. The challenge then is to correctly predict AH-orientation in indirect discourse.

This paper will argue for such a unified approach to perspective shift, based on event semantics. In indirect discourse, the perspective is shifted to the agent of an utterance event or the experiencer of a mental state, which accounts for the AH-orientation. In non-attitudinal environments, other roles are involved. Furthermore, LDRs are argued to be discourse anaphors with presuppositional restrictions to perspective holders.

My analyses will be framed in Partial Compositional DRT (PCDRT; Haug, 2013). The primary motivation for analyzing long-distance reflexivity in a dynamic semantic framework is the occurrence of LDRs in so-called *unembedded indirect discourse* (Bary and Maier, 2014), stretches of indirect discourse which are not syntactically embedded and which often span multiple sentences. (3) is a Latin example of this. The phenomenon is also attested in Icelandic (Sigurðsson, 1990: sect. 3.3), and similar phenomena are found e.g. in Tamil and Japanese (Sundaresan, 2012: sect. 3.1.2; Sells, 1987: p. 455).

- (3) *pro<sub>i</sub> misit enim puerum<sub>j</sub>: se<sub>i</sub> ad me venire.*  
sent for boy.ACC REFL.ACC to me come.INF

‘[Hortensius<sub>i</sub>] sends a boy<sub>j</sub>: [to say that] he<sub>i</sub> will come to me.’ (Cic. Att. 10.16.5; Jøhndal 2012: p. 132)

An analysis of LDRs in unembedded indirect discourse is given in my doctoral dissertation<sup>4</sup>, but will be left out here. The dissertation will also include a more extensive version of the present account, including assumptions about compositionality.

<sup>4</sup>to be submitted at the University of Oslo in March 2017.

This paper is organized as follows: In section 2 I discuss some previous accounts of LDRs and point out a number of challenges. Section 3 shows how LDRs in indirect discourse can be accounted for by means of an event-based approach to perspective shift and an anaphoric semantics of LDRs. The account is extended to a non-attitudinal case of long-distance reflexivity in section 4. Finally, section 5 concludes the paper and suggests some topics for future research.

## 2. Previous accounts

Some version of a centred worlds or context quantification semantics is usually appealed to in contemporary analyses of AH-referring pronominals such as PRO, shifted indexicals and logophors (see e.g. Chierchia, 1989; Schlenker, 2003; Pearson, 2015b). This has also been tried out for LDRs: In their analysis of LDRs in Mandarin indirect discourse, Huang and Liu (2001) argue that the reflexive undergoes LF movement to the left periphery of the clause containing it. The moved pronoun is interpreted as an individual abstractor, turning the reported proposition into a property. This property is in turn interpreted as a *de se* attitude of the AH, following Lewis (1979) and Chierchia (1989). A slightly different, but related semantics is used in Oshima (2007). He draws on Schlenker (2003)'s context shift analysis of logophors to account for LDRs in indirect discourse in Japanese: They are indirect indexicals referring to the agent of a reported speech/thought context. Analyses of this kind readily account for the AH-orientation of LDRs, as the assumed semantics of indirect discourse makes available a variable with the right denotation: the centre or the reported contextual agent. However, it is unclear how analyses along such lines can be extended to non-attitudinal cases of long-distance binding, as they rely on specific semantic properties of indirect discourse to model long-distance binding.

Oshima proposes a separate analysis for the non-attitudinal cases in terms of perspective or empathy, following Kuno (1987). Perspectival expressions such as *to the left of, his/her dear* need to be evaluated relative to a perspective holder. By default, the perspective holder is the speaker, but in certain environments, the perspective can be shifted to a discourse-internal participant (see Bylinina et al., 2014 for an overview of the phenomenon and the relevant literature). LDRs in non-attitudinal environments have been shown to refer to shifted perspective holders (Kuno and Kaburaki, 1977; Kuno, 1987; Sells, 1987; Sundaresan, 2012; Bylinina et al., 2014; Char-navel, 2016).<sup>5</sup> There seems to be strong empirical reasons for analyzing the non-attitudinal cases in terms of perspective. However, it seems somewhat unsatisfactory to analyze attitudinal and non-attitudinal, perspectival LDRs along entirely different lines. Preferably, an account of long-distance reflexivity should explain why the reflexive has specifically these two uses in several languages.

A possible way to go is to assume that all LDRs are perspective sensitive, and propose an account of perspective shift which applies both in indirect discourse and in non-attitudinal environments. A prominent example of an approach along such lines is Sells (1987). Sells analyzes

<sup>5</sup>In languages where reflexive pronouns can take 1/2p antecedents, reference to the default perspective holder may be possible too. This seems to be the case in Mandarin, cf. Huang and Liu (2001: sect. 3.2.1), and at least in some dialects of Japanese, cf. Nishigauchi (2014: p. 159).

perspective in terms of three primitive discourse roles: the *Source*, i.e. a communicative agent, the *Self*, the individual whose mental content a piece of discourse represents, and the *Pivot*, the individual from whose spatio-temporal location the proposition is evaluated. By default, all three roles are assigned to the external speaker, but in given contexts, one or more of the roles can be shifted to a discourse-internal participant. Furthermore, he assumes that the shifting of the roles obeys an implicational hierarchy: If the Source is shifted, so are the Self and the Pivot, and shifting the Self implies a shift of the Pivot. However, the Pivot can be internal while the two other roles are external. In complements to utterance predicates, the Source, together with the two other roles, is shifted to the utterance agent. In complements to mental state predicates, the Self and the Pivot are shifted, while the Source remains external. In non-attitudinal cases of perspective shift, only the Pivot is shifted. LDRs are taken to be discourse anaphors restricted to shifted roles. To account for cross-linguistic distributional differences, Sells assumes that languages differ with respect to which role the LDR picks up.

By subdividing perspective into three discourse roles, Sells manages to capture attitudinal and non-attitudinal perspective shift in a uniform way. There are, however, problematic sides to the analysis. Firstly, it does not build on commonly assumed semantic machinery, but postulates dedicated discourse roles. Secondly, Sells uses uninterpreted DRT representations, and it is therefore not possible to calculate truth conditions or see how the discourse roles integrate with attitudinal semantics more generally.

Sundaresan (2012) offers a generalized perspective account of LDRs in Tamil, although in a quite different framework from Sells'.<sup>6</sup> In Tamil, LDRs are found in indirect discourse, where they refer to the AH, and in clauses characterized by spatio-temporal perspective shift. Sundaresan analyzes LDR binding as a two-step process: Firstly, there is a covert pronoun in the specifier of a perspectival functional projection of the clause containing the LDR. This perspective pronoun binds the LDR syntactically. Secondly, the perspective pronoun itself is resolved to a suitable antecedent. The covert perspective pronoun is not structurally bound, but finds its antecedent through some semantic/pragmatic mechanism. The antecedent of the covert perspective pronoun must be suitable, i.e. it must be an appropriate perspective holder and have phi-features matching those of the perspective pronoun. In other words, the LDR is always locally bound by the perspective pronoun, and the long-distance effect is due to the kind of antecedents the perspective pronoun can take. The perspective pronoun also has a semantic function in the clause that contains it. Clauses of indirect discourse are interpreted relative to the referent of the covert pronoun. It is, in other words, the perspective pronoun, not the attitude predicate, which is responsible for the AH-relative interpretation of the indirect discourse. In non-attitudinal perspective-shifting environments, the perspective pronoun shifts the spatial or temporal interpretation of the clause to its referent (see in particular Sundaresan, 2012: sect. 4.3).

Sundaresan's analysis does not spell out formally the semantic/pragmatic mechanism which resolves the perspective pronoun to an antecedent. Regardless of how this is done, the analysis makes a clearly unwanted semantic prediction in a specific environment: When an LDR is

<sup>6</sup>Analyses along similar lines have been proposed for Japanese by Nishigauchi (2014) and for French by Charnavel (2016).

embedded under multiple report predicates with different subjects, it is ambiguous between a resolution to a higher and a lower antecedent in Tamil as well as in other languages with LDRs (see e.g. Sundaresan, 2012: pp. 15-17; Solberg, 2011: pp. 27-28; Huang and Liu, 2001: pp. 146-147). The following fake English example illustrates this point, where the LDR can take both the sentence's AHs, John or Peter, as an antecedent.<sup>7</sup> Julie, the addressee of John's utterance, is not a suitable antecedent, as she is not an AH.

(4) John<sub>i</sub> says to Julie<sub>j</sub> that Peter<sub>k</sub> believes that Mary loves  $SE_{i/k/*j}$ .

On Sundaresan's approach, an LDR is always syntactically bound by its clause-local perspectival pronoun. Ambiguities like in (4) can therefore not be due to the binding of the LDR itself. According to Sundaresan, this pattern is a result of an ambiguity on the covert perspective pronoun (Sundaresan, 2012: sect. 5.5). Remember, however, that the perspective pronoun is also responsible for the interpretation of the clause containing it. On the reading of (4) where the LDR is bound by John, the higher AH, we are therefore forced to conclude that the report of Peter's belief is relativized to John, not Peter, which is clearly wrong.

To sum up: A generalized account of perspective seems like a promising way to unify the attitudinal and non-attitudinal cases of long-distance reflexive binding. It is important, however, that the account predicts AH-reference in indirect discourse and is able to handle the ambiguity of LDRs embedded under multiple attitude predicates.

### 3. A new account of perspectival reflexives in indirect discourse

The alternative I am proposing has two components: Firstly, I argue for a generalized account of perspective shift based on events and thematic roles, in part inspired by the account of context shift in Deal (2014). In indirect discourse, the perspective is shifted to the utterance agent or the experiencer of a mental state, which explains the AH orientation; in non-attitudinal environments, other roles are used. Secondly, LDRs are claimed to be discourse anaphors with presuppositional restrictions to perspective holders. When there are multiple perspective holders accessible to the anaphoric pronoun, as when it is embedded under multiple attitude predicates, ambiguity is immediately predicted. Section 3.1 presents an event semantics of indirect discourse and the implementation of perspective shift. Perspective anaphors are introduced in section 3.2. In section 4, I show how a non-attitudinal case of long-distance binding can be accounted for.

#### 3.1. Perspective shift in indirect discourse

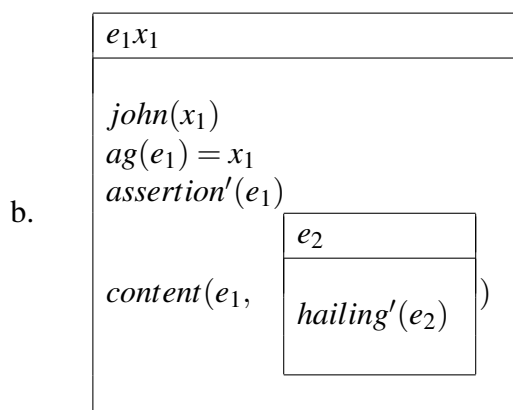

In standard semantic treatments of indirect discourse, an attitude verb is taken to quantify over the worlds compatible with the AH's speech, thought, desire etc. (Hintikka, 1969). In other words, the complement proposition is relativized to an individual. Events are usually omitted entirely.

<sup>7</sup> $SE$  represents an LDR here.

Valentine Hacquard has put forward an event-based semantics for indirect discourse (Hacquard, 2006, 2010; Anand and Hacquard, 2008). Utterance and mental state verbs involve a special kind of event, a *contentful event*, that is, an event associated with a propositional content. Instead of relativizing the complement proposition to the AH, it must hold in the worlds compatible with the content of the contentful event. (5) is a simple example of a speech report and the corresponding PCDRT representation, based on Hacquard's semantics:<sup>8</sup>

(5) a. John says that it is hailing.

The superordinate event  $e_1$  is an assertion event with John as the agent. The interpretation of the complement is relativized to this event. In my PCDRT semantics, the object embedded under the contentful event is a DRS, which is important for the anaphora account to be introduced below.

Attitudinal events have another property which is crucial for my purpose: They are associated with what we might call a *conscious participant*, an individual whose words or mind the complement clause expresses. This individual can be characterized in terms of thematic roles: It is the agent in the case of utterance events, or the experiencer in the case of mental states. Note that this individual corresponds to the AH in more traditional attitudinal semantics. It is therefore possible to use the thematic roles of the attitudinal event to uniquely identify the AH, and this will be a crucial component in the account of perspective shift.

The idea of using the Hacquardian event semantics of indirect discourse to analyze shifting phenomena comes from Deal (2014)'s account of context shift in Nez Perce. In that language, a number of indexicals can be shifted under attitude verbs. In particular, first person pronouns can be shifted to the AH. According to Deal, this is the consequence of operators in the left periphery of the attitudinal complement clause which overwrite coordinates of the context parameters with values derived from the thematic roles of the attitudinal event. In particular, the speaker coordinate can be overwritten by the agent/experiencer of the attitudinal event, which gives the shifted first person reading within the indirect discourse.

<sup>8</sup>The representation in (5b) looks a bit different from the representations in e.g. Hacquard (2010), but it does in fact involve the same modal semantics. In PCDRT, DRSs abbreviate complex lambda terms (Haug, 2013). In examples like (5b), the *content* condition abbreviates a quantification over worlds compatible with the content of the superordinate event. This will be spelled out in detail in my dissertation.

In my analysis, thematic roles are used in a similar way to model perspective shift to the AH in indirect discourse. Since I have an anaphoric account of long-distance binding, perspective shift should interact with anaphora resolution. One way of modelling that interaction is to introduce a dedicated discourse referent for the perspective holder within the embedded DRS. When perspective shift is added to the DRS in (5b), the result is as follows:

(6)

|                                                                                                                                                                                                                                                                                                                                                               |          |                                                                             |  |                                                                                                                                                                                                                                                                                                                                                    |          |                                                                  |

A discourse referent  $x_2$  is introduced in the embedded DRS. This discourse referent is associated with a special condition,  $PHolder_{reg}$ , marking it as a perspective holder. The subscript *reg* on this condition indicates that it is a *register condition*, a purely formal condition which labels the discourse referent without predicating anything of the individual assigned to that discourse referent.<sup>9</sup> This is important, because being a perspective holder is presumably not itself part of truth-conditional semantics. It only affects truth-conditional semantics when perspective-sensitive expressions are present. Furthermore,  $x_2$  is associated with a condition which states that the individual assigned to  $x_2$  is equal to the *cp* (conscious participant) of the embedding event, i.e. its agent or experiencer. This equality condition is marked as presuppositional by the partial operator  $\partial$  (Beaver, 1992). We know from the superordinate DRS that the experiencer of  $e_1$  is  $x_1$ . We can therefore replace the iota-expression with  $x_1$  in the equality condition, as I have done in the second DRS in (6).

Outside of shifting environments, the external speaker is the perspective holder. In a complete account, there should therefore be a perspective holder discourse referent in the matrix DRS. I leave that out here, however. LDRs referring to contextual participants is ruled out in Latin, since reflexive pronouns are obligatorily third person (but see footnote 5).

### 3.2. LDRs as perspective anaphors

In (6), the perspective shifting machinery serves no purpose, as there are no perspective-sensitive expressions in the indirect discourse. Let us now consider a sentence with an LDR,

<sup>9</sup> This is possible because PCDRT has a type distinction between discourse referents, which are *registers*, and the individuals (or events, time intervals etc.) assigned to those registers (cf. Haug, 2013). Register conditions apply to registers, while normal conditions apply to entities assigned to registers.

where the shifting does have an effect. In the Latin example in (7), an LDR is bound by the experiencer of a mental state predicate.<sup>10</sup>

- (7) *Iam inde ab initio Faustulo<sub>i</sub> spes fuerat [regiam stirpem*  
 already since from beginning Faustulus.DAT hope.NOM was royal.ACC lineage.ACC  
*apud se<sub>i</sub> educari].*  
 before REFL.ACC educate.INF.PASS

‘Already from the beginning, Faustulus<sub>i</sub> had the hope that someone of royal lineage was being educated with him<sub>i</sub>.’ (Liv. 1.5.5; Benedicto, 1991: ex. (21))

Note that in the Latin text, the mental state predicate is a nominative noun, and the experiencer is a dative, a pattern that isn’t rendered in the translation.

The LDR has the following denotation:

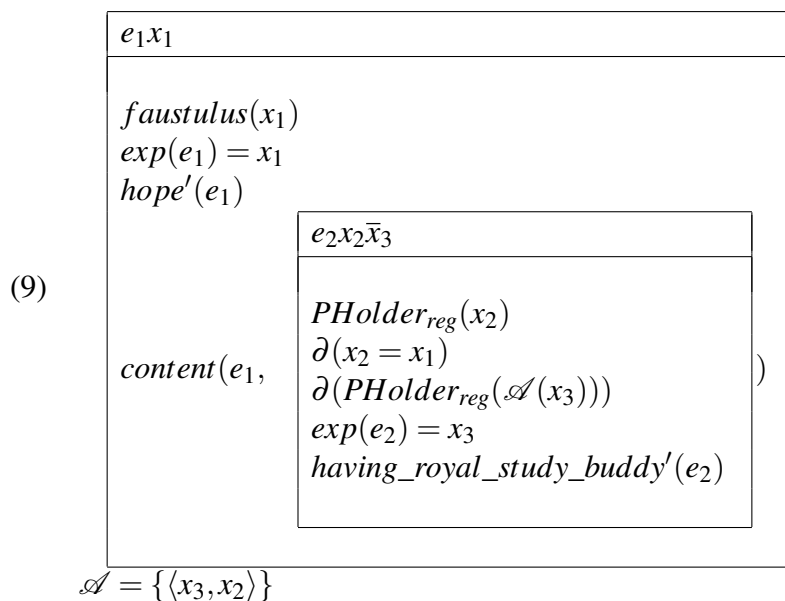

$$(8) \quad [[se]]^{M,g} = \lambda P. \begin{array}{|c|} \hline \bar{x}_1 \\ \hline \partial(PHolder_{reg}(\mathcal{A}(x_1))) \\ \hline \end{array} ; P(x_1)$$

It introduces a discourse referent  $x_1$ . The overline over the discourse referent marks it as discourse anaphoric. In PCDRT, anaphors are discourse referents with an underspecified resolution to an antecedent. The actual resolution is handled by a function  $\mathcal{A}$  which is driven by pragmatic inference, but constrained by the accessibility relations of DRSs (Haug, 2013: sect. 5.4). The discourse referent is furthermore associated with a presuppositional condition that the antecedent discourse referent,  $\mathcal{A}(x_1)$ , is a perspective holder, i.e. it is associated with  $PHolder_{reg}$ .<sup>11</sup>

With this denotation for the LDR, we can draw up a DRS structure of a somewhat simplified version of (7):

<sup>10</sup>In (7) the complement clause is an *accusative-with-infinitive* construction, not a finite clause. There are good empirical reasons for treating the binding into this clause type on par with binding into Latin finite clauses, e.g. because of the lack of subject orientation and the possibility of discourse antecedents in unembedded indirect discourse, as in example (3) (see e.g. Solberg, 2011).

<sup>11</sup> $PHolder_{reg}$  applies to  $\mathcal{A}(x_1)$ , not simply  $x_1$ , as  $PHolder_{reg}$  takes discourse referents, not individuals, as arguments. Discourse referents and individuals are of different types (cf. footnote 9), and while the discourse referent of the LDR and of the antecedent will be assigned to the same individual, they are still distinct discourse referents.

A perspective holder discourse referent  $x_2$  is introduced in the complement.  $x_3$  is the anaphoric discourse referent of the LDR. It must be resolved to a perspective holder antecedent. In this example, there is only one, namely  $x_2$ , and  $\mathcal{A}$  therefore maps  $x_3$  to  $x_2$ . The individual assigned to  $x_2$  is equal to  $x_1$ , Faustulus, as he is the experiencer of the hoping state  $e_1$ . The LDR ends up referring to Faustulus.

On this approach, the AH orientation of LDRs is the consequence of perspective shift to the agent/experiencer of the attitudinal event in indirect discourse. It is not modelled in a fine-grained modal semantics of indirect discourse, as it would be on a centred worlds approach. LDRs will typically refer back to subjects, as agents/experiencers are frequently linked to subjects. Whenever syntax links the agent/experiencer to non-subject arguments, as in (1) and (7), non-subject-orientation is correctly predicted.

The scope of the perspective shifting is a consequence of anaphoric accessibility: The perspective holder discourse referent is assigned in the embedded DRS representing the indirect discourse, and is therefore accessible within that DRS and in DRSs embedded under it (Kamp et al., 2011: pp. 134-137; Haug, 2013: sect. 5.2).

In (9) there was only one potential antecedent for the LDR. (10) is the DRS of (4), where an LDR is embedded under two attitude verbs with different subjects:

A crucial difference between this approach and that of Sundaresan (2012), discussed above, is that the LDR does not need to be locally bound in any way. Therefore, the ambiguity of deeply embedded LDRs can be accounted for as a consequence of recursive perspective shift, without making problematic predictions for the modal semantics. There is also no need to posit any kind of covert structural ambiguity, as the LDR does not retrieve its antecedent through structural binding.

There is nothing inherent to this system of perspective shift and long-distance reflexivity which restricts it to agents and experiencers. It is, for example, possible to model addressee-oriented

LDRs in indirect discourse, which is attested in complements to interrogative verbs in Japanese (Bylinina et al., 2014: sect. 2.4). But perhaps more importantly, nothing restricts perspective shift to attitudinal events, and we can therefore extend the account to non-attitudinal environments.

It seems to me to be more difficult to make strong empirical generalizations for long-distance reflexivity outside of indirect discourse than inside. A complete account should rely on a detailed investigation of the phenomenon in a language where such LDRs are widely attested. In this paper, I will simply draw up a draft of what such an account might look like, using a Latin example.

In Latin, LDRs are occasionally attested in subjunctive complement clauses to verbs meaning *deserve*, as exemplified in (11) (= (2)). The LDR picks up the subject of *deserve*:

- (11) *unum hoc scio, [hanc<sub>i</sub> meritam esse [ut memor  
only.ACC this.ACC know.1SG sheACC deserve.PTCP be.INF that mindful.NOM  
esses sui]]*  
be.SBJV.2SG REFL.GEN

‘I know only this, that she<sub>i</sub> has deserved that you remember her<sub>i</sub>.’ (Ter. Andr. 281; Kühner and Stegman, 1955: p. 613)

*Deserve* does not have an attitudinal semantics, as it does not imply that the subject is aware of the complement proposition. The difference between predicates like *deserve* and attitude predicate is minimal, however, as both have a modal semantics. I therefore assume that a deserving state is contentful. Furthermore, I analyze the subject as a benefactive. The perspective is shifted to the benefactive, as the following DRS illustrates:

- (12)
- |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                      |                                                                                                                                      |                                                           |

- $\mathcal{A} = \{ \langle x_4, x_2 \rangle \}$

The only difference between the embedded DRS in (12) and the embedded DRSs in the attitudinal cases is the thematic role of the individual assigned to the perspective holder discourse referent. In indirect discourse, it is the agent/experiencer of the attitudinal event; in (12) it is a benefactive argument. There is no need for a lexical ambiguous pronoun: We can use the same denotation for attitudinal and non-attitudinal LDRs.

## 5. Conclusion and remaining issues

In this paper, I have identified some problematic aspects of existing analyses of LDRs. Centred worlds analyses account well for the AH orientation of LDRs in indirect discourse. It is difficult to generalize such accounts to LDRs in non-attitudinal environments, however. Instead, I am favourable to accounts where long-distance reflexivity, both inside and outside of indirect discourse, is sensitive to perspective shift.

A challenge with such generalized perspective accounts, however, is to make sense of the AH orientation in indirect discourse. I have argued that this can be done if perspective shift is modelled using events and thematic roles. In indirect discourse, the perspective is shifted to the agent/experiencer of the attitudinal event, while other roles may be used in other environments.

Furthermore, I have argued that LDRs are discourse anaphors with presuppositional restrictions to perspective holders. By using anaphora, the ambiguity of LDRs embedded under multiple attitude predicates is immediately predicted.

An issue which has not been addressed here is the relationship between local and long-distance reflexives. There are good empirical reasons for distinct treatments of the two uses, both in Latin and other languages (cf. my doctoral dissertation; Huang and Liu, 2001; Reuland, 2001). However, there must be some reason why the same lexical item has these two different uses in language after language.

Another interesting issue is the cross-linguistic differences in the distribution of LDRs. As mentioned in the introduction, LDRs are restricted to indirect discourse in some languages, while they have a wider distribution in others. This might be related to differences in perspective shift, or alternatively, in the semantics of the reflexive itself.

# Proportional comparatives and relative scales<sup>1</sup>

Stephanie SOLT — *Leibniz-Zentrum Allgemeine Sprachwissenschaft (ZAS), Berlin*

**Abstract.** This paper examines the proportional interpretation of comparatives such as *More residents of Ithaca than New York City know their neighbors*, taking these as the starting point for an investigation of relative or proportional measurement more generally. Two mechanisms for deriving mappings from individuals to degrees of proportion are considered, the first based on posited proportional entries for *many/few*, the second involving proportional measure functions. It is shown that only the measure function approach adequately accounts for the distribution of proportional expressions and proportional interpretations. A further consequence is to eliminate the need to analyze words such as *many* as lexically ambiguous.

**Keywords:** degree, measurement, comparative, proportion, partitive.

## 1. Introduction

The sentences in (1)-(2) exemplify a curious type of comparative construction that to my knowledge was first discussed by Partee (1989):

- (1) More residents of Ithaca than New York City know their neighbors.
- (2) More Norwegians than Brazilians have university degrees.

At first glance, examples of this sort are entirely unobjectionable, but on further reflection, one realizes there is something rather odd about them. The number of residents of Ithaca, NY (population 30,000) who know their neighbors is without doubt smaller than the number of inhabitants of New York City (population 8 million) who do; and likewise, in absolute terms there are certainly a smaller number of Norwegians than Brazilians with university degrees. Nevertheless, both of these sentences have salient interpretations on which they are true.

Intuitively, on their true readings the above examples express comparisons of proportions: it is the proportion of Ithaca residents who know their neighbors that is greater than the corresponding proportion of New York City residents (and similarly, *mutatis mutandis*, for proportions of Norwegians versus Brazilians with degrees). The goal of this paper is to develop a compositional semantic analysis of examples such as (1)-(2) on their proportional readings, and in doing so to investigate the semantic structures underlying the interpretation of proportional expressions more generally.

In a degree-based semantic framework, comparatives are analyzed as expressing relations between degrees on a scale corresponding to some dimension of measurement (Cresswell 1977; von Stechow 1984; Heim 1985; Kennedy 1997; see Beck 2011 for a recent review). Taking this approach, we might loosely represent the meaning of (1) as follows:

---

<sup>1</sup>I am grateful to Susan Rothstein and Uli Sauerland for helpful discussion on the topic of this paper. Thanks also to the audiences at the ZAS, SuB21 and IATL 32, where versions of this work were presented. All errors are of course my own. This research was funded by the German Science Foundation under grant SO1157/1-2.

- (3)  $\max\{d : d\text{-many Ithaca residents know their neighbors}\} \succ$   
 $\max\{d : d\text{-many NYC residents know their neighbors}\}$

If we take the degrees  $d$  here to range over values on the scale of cardinality – that is, natural numbers – we get only the false absolute reading. To get the true proportional reading, it is necessary for  $d$  to range over degrees of proportion. That is, we require a scale that tracks proportions of a totality. In the context of current work in degree semantics, this is an unusual idea. As has been observed by Cresswell (1977), Wellwood (2015) and many authors in between, comparative *more* can operate over a variety of dimensions, including not just cardinality (e.g. (4a)) but also mass quantity dimensions such as volume (e.g. (4b)) as well as adjectival dimensions such as intelligence (e.g. (4c)).

- (4) a. Sue owns more books than John. (cardinality)  
 b. Sue drank more wine than John. (volume)  
 c. Sue is more intelligent than John. (intelligence)

The existence of proportional scales, however, is not generally recognized. I will argue here that precisely such scales are a necessary part of the degree ontology, and that they play a role beyond comparative constructions of the sort exemplified above.

The structure of the paper is as follows: Section 2 introduces two possible approaches to the semantics of proportional comparatives, the first based on a well known ambiguity in the interpretation of the vague quantity expressions *many* and *few*, the second making use of the notion of domain-restricted measure functions, one instantiation of which is a proportional measure function. Section 3 turns to other sorts of proportional expressions, comparing how the two proposed solutions to proportional comparatives fare in accounting for their distribution. Section 4 returns to consider the readings available to *many* and *few*, and demonstrates that only the measurement-based approach allows a principled explanation for the constraints on the availability of proportional readings of their positive and comparative forms. Finally, Section 5 wraps up with some conclusions and questions still left open.

## 2. Two accounts of proportional comparatives

### 2.1. Ambiguous *many* and *few*

Since Bresnan (1973) it has been common to analyze *more* and *fewer* as the comparative forms of *many/much* and *few*, respectively. As discussed by Milsark (1977) and especially Partee (1989), *many* and *few* themselves appear to be ambiguous between two distinct readings which have come to be called ‘cardinal’ and ‘proportional’. For instance, (5) might be interpreted to mean simply that a large (small) number of aspens burned (the cardinal reading) or instead that a large (small) proportion of some contextually relevant set of aspens burned (the proportional reading).

- (5) Many (few) aspens burned.

The cardinal/proportional ambiguity is easiest to detect in the case of *few*. On its proportional interpretation, *few* can be paraphrased as ‘a small proportion of’. But on the cardinal reading, *few Ns* can actually be all of the relevant *Ns*, as demonstrated by the following example (from Partee 1989):

- (6) Few egg-laying mammals were found in our survey, perhaps because there are few.

Partee argues that the existence of these two readings is more than a matter of radical context dependence but instead involves a true lexical ambiguity, which corresponds to a more basic distinction in semantic type; specifically, she proposes to analyze *many/few* as ambiguous between an adjectival entry with cardinal semantics and a quantificational entry with proportional semantics.

Partee’s notion of a lexical ambiguity has been adopted by many later authors (e.g. Herburger 1997; Cohen 2001; though see Greer 2014 for an opposing view). Recently, Romero (2015) has developed an updated version of the ambiguity account in a degree-based framework, according to which *many/few* are ambiguous between cardinal and proportional entries, each of which has the type of a gradable quantifying determiner, type  $\langle d, \langle et, \langle et, t \rangle \rangle$ :<sup>2</sup>

- (7) a.  $\llbracket many_{CARD} \rrbracket = \lambda d \lambda P_{\langle et \rangle} \lambda Q_{\langle et \rangle} . |P \cap Q| \succeq d$   
 b.  $\llbracket many_{PROP} \rrbracket = \lambda d \lambda P_{\langle et \rangle} \lambda Q_{\langle et \rangle} . \frac{|P \cap Q|}{|P|} \succeq d$
- (8) a.  $\llbracket few_{CARD} \rrbracket = \lambda d \lambda P_{\langle et \rangle} \lambda Q_{\langle et \rangle} . |P \cap Q| \prec d$   
 b.  $\llbracket few_{PROP} \rrbracket = \lambda d \lambda P_{\langle et \rangle} \lambda Q_{\langle et \rangle} . \frac{|P \cap Q|}{|P|} \prec d$

In both cases, the initial type  $d$  argument can be saturated or bound by a degree modifier, just as in the case of gradable adjectives such as *tall*. When *many/few* appear in their unmodified form (e.g. as in (5)), it is proposed that this role is played by a null degree operator *POS*, again in parallel to a standard analysis of the unmodified forms of gradable adjectives. For example, if *POS* is taken to introduce a standard of comparison in the form of a ‘neutral range’  $Std_c$  relative to some context  $c$  (von Stechow, 2009), a simple example such as (10a) on its proportional reading receives the interpretation in (10b), depicted in (10c):

- (9)  $\llbracket POS \rrbracket^c = \lambda I_{\langle dt \rangle} . Std_c \subset I$
- (10) a. Many students wrote papers.  
        $POS_1 \llbracket [t_1\text{-many}_{PROP} \text{ students}] \text{ wrote papers} \rrbracket$
- b.  $Std_c \subset \{d : \frac{|students \cap wrote \text{ papers}|}{|students|} \succeq d\}$

<sup>2</sup>Romero further notes that *few* might be decomposed into a degree-negation operator plus *many*. Note also that while she does not discuss quantificational *much* and *little*, these might be handled by replacing the cardinality operator with a measure function suitable for portions of matter.

Returning to the topic of the present paper, the proportional entry for *many* in (7b) in combination with standard assumptions about the syntax and semantics of comparatives give us what we need to derive the proportional reading of our original examples. Specifically, we can take the comparative morpheme *-er* to express a relation between two sets of degrees:

$$(11) \quad \llbracket -er \rrbracket = \lambda I_{\langle dt \rangle} \lambda J_{\langle dt \rangle} . \max(J) \succ \max(I)$$

Syntactically, an example such as (12) is taken to be a (covert) clausal comparative, with the *than*-clause containing an elided copy of *many* whose degree argument is bound by a null operator *OP*. The comparative morpheme *-er* plus the *than* clause as a whole originate within the noun phrase, but must undergo quantifier raising (QR) for type-driven purposes, yielding the LF in (13).

(12) More Ithaca residents than New York City residents know their neighbors.

(13)  $[-er \text{ than } [OP_2 [t_2 \text{ many NYC residents know their neighbors}]]]_1 [t_1 \text{ many Ithaca residents know their neighbors}]$

The first argument of *-er* is saturated by the *than* clause, while the second is provided by the matrix clause via lambda abstraction over the trace of the raised comparative morpheme, yielding the following interpretation:

$$\begin{aligned} (14) \quad & \max\{d : \llbracket d\text{-many}_{PROP} \rrbracket(\llbracket Ithaca \text{ residents} \rrbracket)(\llbracket know \text{ neighbors} \rrbracket)\} \succ \\ & \max\{d : \llbracket d\text{-many}_{PROP} \rrbracket(\llbracket New \text{ York City residents} \rrbracket)(\llbracket know \text{ neighbors} \rrbracket)\} \\ & = \max\{d : \frac{|Ithaca \text{ residents} \cap know \text{ neighbors}|}{|Ithaca \text{ residents}|} \succeq d\} \succ \\ & \max\{d : \frac{|NYC \text{ residents} \cap know \text{ neighbors}|}{|NYC \text{ residents}|} \succeq d\} \end{aligned}$$

As desired, this expresses a comparison of the proportions of residents of the two cities who know their neighbors. That is, we are able to derive the proportional reading of our original example (1).

## 2.2. Domain-restricted measure functions

The account developed in the previous section relies crucially on the analysis of *many/few* themselves as parameterized quantificational determiners, the same semantic type (once their initial type *d* argument is saturated) as quantifiers such as *every*. While this is a common view, which can be traced back to classic works such as Barwise and Cooper (1981), there is evidence

that it cannot be correct. The issue is that words of the *many* class have uses on which they do not quantify over individuals, a prime example being the differential use (e.g. *Many fewer / few more than 100 students attended the lecture*). Instead, authors including Rett (2006, 2008) and Solt (2009, 2015) propose that *many/few* have degree-based interpretations.

To formalize this, we make the following assumptions about the semantics of degree and measurement. A **scale** is a triple of the following form:

- (15)  $S = \langle D, \succ, DIM \rangle$ , where
- $D$  is a set of degrees;
  - $\succ$  is an ordering relation on that set;
  - $DIM$  is a dimension of measurement.

This formalization has the effect of establishing a one-to-many relation between dimensions of measurement and the scales that track them (as a simple example, think of height measured in inches vs. centimeters). Entities are mapped to degrees by **measure functions**, where  $\mu_{DIM}$  is a function that maps members of the domain of individuals  $D_e$  to degrees on some scale corresponding to dimension  $DIM$ .

Following Solt (2015), vague quantity words such as *many* can then be interpreted as gradable quantifiers over degrees (where *many/few* are distinguished from *much/little* in that the former select for degrees of cardinality, while the latter are blocked in the cardinality case):

- (16) a.  $\llbracket \text{many/much} \rrbracket = \lambda d \lambda I_{\langle dt \rangle}. d \in I$  (Solt, 2015)  
 b.  $\llbracket \text{few/little} \rrbracket = \lambda d \lambda I_{\langle dt \rangle}. \neg d \in I$

On their (apparently) quantificational uses, the degrees over which these expressions operate are introduced by a phonologically null functional head *Meas*, which encodes an underspecified measure function  $\mu_{DIM}^c$ :

- (17)  $\llbracket Meas \rrbracket^c = \lambda P_{\langle et \rangle} \lambda x. [P(x) \wedge \mu_{DIM}^c(x) = d]$

The specific dimension introduced by *Meas* is contextually determined, as is the individual scale that tracks that dimension; but we require that the dimension so introduced be **monotonic** on the part-whole relationship between individuals (Schwarzschild, 2006), as defined below:<sup>3</sup>

- (18) **Monotonicity constraint:**  $\forall x, y \in D_e, x \sqsubset y \Rightarrow \mu_{DIM}^c(x) \prec \mu_{DIM}^c(y)$

Once their first degree argument is saturated by a degree expression or its trace, *many/few* have the type of degree operators, which like other such operators (e.g. *POS* in (9) or *-er* in (11)) must undergo QR to be interpreted. A simple quantificational example thus has the LF in (19a); assuming that quantification over individuals arises via existential closure, the corresponding interpretation is that in (19b).<sup>4</sup>

<sup>3</sup>For discussion on the source of this constraint, see Rett (2014).

<sup>4</sup>See Solt (2015) for details of the compositional derivation.

- (19) a. Many students wrote papers.  
        $\text{POS}_2 [t_2 \text{ many}]_1 [[t_1 \text{ Meas students}] \text{ wrote papers}]$   
       b.  $\text{Std}_c \subset \{d : \exists x [\text{students}(x) \wedge \mu_{DIM}^c(x) = d \wedge \text{wrote-papers}(x)]\}$

If  $\mu_{DIM}^c$  is set to be a cardinality function, it is the cardinal reading that most naturally emerges: the number of students who wrote papers exceeds some value or range that serves as the threshold for what counts as ‘many’ in the context. On this approach to words of the *many* class, it is then tempting to treat the proportional reading of sentences such as this contextually, by specifying the standard range introduced by *POS* in such a way that values that exceed it correspond to a large proportion of the relevant totality (here, the students). But this is not sufficient to derive the proportional reading of comparative constructions, for which we need a scale that directly tracks proportions.

To address this, I propose to introduce a new type of measure function, namely one that is restricted to measuring subparts of some entity:<sup>5</sup>

- (20) A **domain-restricted measure function**  $\mu_{DIM;x}^c \rightarrow S_{DIM}^c$  is a function that maps parts of some entity  $x \in D_e$  to degrees on some scale  $S$  tracking dimension  $DIM$ .

Since the domain of a function of the form in (20) is restricted, its range is likewise restricted to degrees that are measures of some part of the domain, which might constitute a proper subpart of the full scale  $S$ .

I further propose that one particular variety of domain-restricted function that the grammar makes available is one that maps parts of an entity to values that encode the proportion they represent of the totality (with respect to the dimension in question):

- (21) A **proportional measure function** is a function of the following form:

$$\text{For } y \sqsubseteq x : \mu_{DIM;x}^c(y) = \mu_{DIM-prop;x}^c(y) = \frac{\mu_{DIM}^c(y)}{\mu_{DIM}^c(x)}$$

The three types of measure functions discussed here – ordinary unrestricted, domain-restricted and proportional – are depicted graphically in Figure 1.

Importantly, if a measure function  $\mu_{DIM}^c$  tracking dimension  $DIM$  satisfies the monotonicity constraint (18), so too do corresponding domain-restricted measure functions  $\mu_{DIM;x}^c$ , including the proportional measure function  $\mu_{DIM-prop;x}^c$ . This means that the latter two sorts are possibilities for the measure function introduced by the functional head *Meas*. Thus I take it that *Meas* can have the following form, where the relevant totality is that formed by summing over entities in the denotation of the common noun phrase:

- (22)  $\llbracket \text{Meas} \rrbracket^c = \lambda P_{\langle et \rangle} \lambda x. [P(x) \wedge \mu_{DIM;\oplus P}^c(x) = d]$

<sup>5</sup>Kennedy (2007) utilizes domain-restricted measure functions of a different sort to account for facts in the adjectival domain. I leave it as an open question whether there might be a connection between the two cases.

Figure 1: Varieties of measure functions

**a. Unrestricted measure function****b. Domain-restricted measure function****c. Proportional measure function**

Taking advantage of the possibilities offered by (22), we are able to derive the proportional readings of *many/few* and their comparative forms. Starting with the unmodified case, the proportional reading of examples such as *Many (few) aspens died* can be derived by assuming a domain-restricted measure function, and making one more very plausible assumption, namely that whenever the measure function introduced is of this variety (either an ‘ordinary’ domain-restricted function or a proportional one), the standard range introduced by *POS* is fully contained within the segment of the scale that is the range of this function, as illustrated below (where  $x$  is the relevant totality):

(23)

This has the effect of ensuring that *many Ns* is a suitably large proportion of all the *Ns*, and crucially that *few Ns* cannot be all of the *Ns*. While this may seem to be a stipulation, note that essentially the same stipulation is required under the ambiguity analysis (see (10c) above), where it must be assumed that the standard range is fully contained in the interval  $[0,1]$ .

The proportional interpretation of comparatives can now be derived by taking the contextually determined measure function to be a proportional one  $\mu_{DIM-prop;\oplus P}^c$ . Maintaining the earlier assumptions regarding the syntax and semantics of comparative constructions, a relevant example has the LF in (24), and the interpretation in (25), where the underlying dimension that forms the basis for the calculation of proportions is cardinality, indicated by #.

(24) [-er than [OP<sub>4</sub> [~~t<sub>4</sub> many~~<sub>3</sub> [~~t<sub>3</sub> Meas~~ NYC residents ~~know their neighbors~~]]]]<sub>2</sub> [~~t<sub>2</sub> many~~<sub>1</sub> [~~t<sub>1</sub> Meas~~ Ithaca residents know their neighbors]]

(25)  $\max\{d : \exists x[Ithaca-res(x) \wedge \mu_{\#-prop;\oplus Ithaca-res}^c(x) = d \wedge know-neighbors(x)]\} \succ$   
 $\max\{d : \exists x[NYC-res(x) \wedge \mu_{\#-prop;\oplus NYC-res}^c(x) = d \wedge know-neighbors(x)]\}$

$$= \max\{d : \exists x[Ithaca-res(x) \wedge \frac{\mu_{\#}^c(x)}{\mu_{\#}^c(\oplus Ithaca-res)} = d \wedge know-neighbors(x)]\} \succ$$

$$\max\{d : \exists x[NYC-res(x) \wedge \frac{\mu_{\#}^c(x)}{\mu_{\#}^c(\oplus NYC-res)} = d \wedge know-neighbors(x)]\}$$

Crucially, the function introduced by *Meas* in the matrix clause maps pluralities of Ithaca residents to the proportion they represent of the totality of Ithaca residents, while its copy in the *than* clause correspondingly maps pluralities of NYC residents to the proportion they make up of all NYC residents. Thus as above we get the desired comparison of proportions.

### 2.3. Summary

In this section we have seen two possible approaches to the analysis of proportional comparatives. Both relate the reading of interest to the proportional interpretations of *many* and *few*, and both feature some mechanism for mapping individuals to scalar values that represent proportions. Where they differ is in how the required proportional scale is derived. The first analysis localizes the calculation of proportions in the semantics of *many* and *few* themselves on their proportional interpretations, one of two distinct lexical entries for these items. The second assumes a simpler and unambiguous semantics for *many/few*, with measurement instead encoded by an underspecified functional element *Meas*, which as one possibility can introduce a mapping from elements in the denotation of a nominal expression to a degree representing their proportion of the totality of such entities. Both of these analyses are able to capture the facts seen so far. In the remainder of the paper we will examine how they fare in accounting for a wider range of data. Previewing the findings, we will see that only the measurement-based analysis provides a satisfactory explanation for certain facts relating the the distribution of proportional expressions and proportional interpretations.

## 3. The semantics of percent

Words such as *many* are of course not the only sorts of expressions with a proportional meaning, the other obvious case being those of the form *n percent*, as in the following:

- (26) a. Twenty percent of the students wrote papers.  
 b. Sixty percent of the wine we sell is German.

There is surprisingly little work on the semantics of such relative or proportional measures, notable exceptions being Ionin et al. (2006) and more recently Ahn and Sauerland (2015, 2017). The latter authors propose the following as the lexical entry for *percent*:

$$(27) \quad \llbracket percent \rrbracket = \lambda x_e \lambda n_d \lambda P_{et}. \left[ \frac{\mu(x \sqcap \oplus P)}{\mu(x)} = \frac{n}{100} \right]$$

On this analysis, examples such as (26) do not involve the direct measurement of proportions. Rather, the measure function  $\mu$  maps entities to values on ordinary quantity scales. In (26a), for example,  $\mu$  is interpreted as a cardinality function; in (26b) it is a function mapping portions of wine to some appropriate measure of liquids, perhaps volume in liters. The computation of proportions itself is lexicalized by *percent*. Assuming *of* to be semantically vacuous, (26a) receives the following analysis:

$$(28) \quad \frac{\mu_{\#}(the-students \sqcap \oplus (individuals \text{ who wrote papers}))}{\mu_{\#}(the-students)} = \frac{20}{100}$$

Although this approach is appropriate for examples such as (26), there is reason to believe that in other cases expressions of the form *n percent* have interpretations on which they directly denote degrees. The strongest evidence for this is that they occur in the same syntactic positions as do numerals when these are analyzed as degree denoting. Three such contexts are illustrated below:

- (29) a. Twenty times ten equals two hundred.  
 b. More/fewer than twenty of the students wrote papers.  
 c. We sold twenty fewer houses this year than last year.
- (30) a. Twenty percent of ten percent equals two percent.  
 b. More/fewer than twenty percent of the students wrote papers.  
 c. We sold twenty percent fewer houses this year than last year.

The (a) examples above are mathematical statements, which appear to express relations between degrees. The (b) examples involve comparative quantifiers. It is common (e.g. Nouwen, 2010) to analyze the comparative morpheme in this case as a degree quantifier that takes an initial number or degree argument, as in (31). We must then conclude that *twenty percent* in (30b), just like *twenty* in (29b), can denote a degree that can saturate this argument.

$$(31) \quad \llbracket -er \rrbracket = \lambda d \lambda I. max(I) \succ d.$$

Finally, the (c) examples illustrate the differential use of measure expressions. In (29c), there is quite obviously no plurality of houses which is asserted to have cardinality twenty. Rather, the numeral describes the distance between two values on the number line; that is, the sentence is true if it holds that the difference between *|houses we sold last year|* and *|houses we sold this year|* equals 20. It seems that a parallel analysis must be extended to (30c).

Importantly, in none of the examples in (30) can *twenty percent* be given an analysis based on the proposed lexical entry for *percent* in (27). Instead, we require it in each case to be interpreted as denoting a degree, i.e.  $\llbracket twenty \text{ percent}_d \rrbracket = 20\%$ . This provides further evidence that we require a scale of proportion on which such degrees are situated.

Let us consider how this set of facts might be accounted for under the two approaches to proportional comparatives introduced in the previous section, each of which provides in one way or another a mapping to scalar values that represent proportions of a totality.

In the ambiguity account of Section 2.1, the calculation of proportions is part of the semantic function of the proportional versions of *many* and *few*. While we do not assume measure functions that map individuals to proportions, the first arguments of *many/few* on their proportional readings (7b), (8b) can be viewed as ranging over degrees of proportion. This leads us to predict that we will detect degrees of proportion – and expressions that refer to them – only in the presence of *many/few* (or *much/little*). This makes proportional expressions in mathematical statements such as (30a) somewhat unexpected, though we might propose to construe them as answers to covert *how many<sub>PROP</sub>?* questions. Expressions of proportion in comparative quantifier examples such as (30b) can be handled by taking these to be based on comparative forms of proportional *many* and *few*, i.e. essentially the same analysis given above to proportional comparatives. But differential examples such as (30c) are problematic. The only kind of proportion that can be derived from the proportional entries of *many/few* is the proportion that a plurality represents of some totality that it is a part of. But *twenty percent* in (30c) does not have this sort of interpretation. In fact, as noted above, in this example there is no plurality whose measure is reported. Rather, the percentage expression describes the difference between two values in proportional terms. This value cannot be calculated on the basis of the proportional entry for *few* proposed in Section 2.1. It is necessary to posit some other mechanism; for example, we might start with an interpretation of the comparative morpheme that allows differential degrees (see e.g. Beck 2011), and modify it to allow these to express proportions.

Note also that an account based on proportional interpretations for *many/few* and degree-denoting interpretations for expressions of the form *n percent* does not in itself provide an analysis of simple partitive examples such as (26), because there is apparently no element present that introduces degrees of proportions. There are several ways this issue might be addressed. As one possibility, we might propose that *n percent* has a second interpretation based on Ahn & Sauerland's entry for *percent* in (27). Alternately, we might assume that such partitive examples include a covert counterpart of *many<sub>PROP</sub>*, or that a comparable function is encoded in the semantics of partitive *of*. All of these potential solutions add duplication to the system as a whole; below, we will see some further issues that they present.

Now let us turn to how the same data can be handled by the measurement-based account developed in Section 2.2. Recall that on this analysis, quantity measurement is encoded by a null functional element *Meas*, which introduces a contextually determined measure function. One potential option for this function is a domain-restricted function, and more specifically a proportional one. Thus in contrast to the previous approach, this analysis assumes a measure function whose range is a scale of proportion (see Fig. 1). It is thus not surprising that there are linguistic expressions that refer to points on this scale: just as *twenty* can refer to a point on the number line and *twenty inches* to a point on a scale of height, so too can *twenty percent* refer to a point on a scale of proportion.

Degrees of this sort can form the basis for mathematical statements such as (30a), and can saturate the degree argument of the comparative quantifier version of *-er* in (31). An example such as (30b) can then be analyzed as involving degrees derived via a proportional instantiation of the measure function introduced by *Meas*, with *more/fewer* analyzed as the comparative forms of the degree quantifier entries in (16) above; again, this is parallel to the treatment of our original proportional comparative examples.

Putting aside for the moment the tricky example in (30c), let us consider proportional partitives such as (26). The simplest way to analyze such examples in the measurement-based framework is to treat partitive *of* as the overt instantiation of *Meas*. Such an approach goes back to Schwarzschild (2006), who was among the first to posit the existence of a null measuring element parallel to *of* underlying the interpretation of words of the *many* class. Specifically, we can analyze *of* in such cases as encoding a domain-restricted measure function:

$$(32) \quad \llbracket of \rrbracket = \lambda x \lambda d \lambda y. [\mu_{DIM,x}^c(y) = d]$$

On this view, partitive *of* has a dual function, establishing the ‘part of’ relation (as in Ionin et al. 2006) and also associating entities with degrees.

Importantly, this approach to *of* allows an analysis of both numerical partitives such as (33a) and proportional partitives such as (33b). The first of these involves a domain-restricted measure function that maps subgroups of the relevant totality of students to a subsegment of the number line corresponding to the cardinalities of such subgroups. For example, if there are fifty relevant students, the corresponding scale segment is  $[0, 50]$ . In the latter proportional case, the measure function is the proportional variety of a domain-restricted function, whose range is the proportions from 0% to 100%.

- (33) a. Twenty of the students wrote papers.  
 $\mu_{\#;the-students} : x \sqsubseteq the-students \rightarrow [0, \# \text{ of the students}]$
- b. Twenty percent of the students wrote papers.  
 $\mu_{\#-prop;the-students} : x \sqsubseteq the-students \rightarrow [0\%, 100\%]$

In both cases the domain – and therefore also the range – of the measure function is restricted. The difference is that in one case the values on the scale are construed as numbers (cardinalities), while in the other they are construed as proportions.

A nice consequence of unifying partitive *of* with *Meas* is that we correctly account for the fact that the same monotonicity constraint is present in both cases. As an example, *more copper than silver* – which we take to involve a comparative form of *much* – can describe a portion of copper that has a greater measure than the corresponding portion of silver in terms of volume or weight (both monotonic on the part-whole relation among entities), but not in terms of temperature or purity (both non-monotonic). By the same token, *twenty percent of the copper* can be a portion of copper whose measure in terms of volume or weight is 20% of that of the relevant totality of

copper, but not one whose purity or temperature is 20% of that of the totality.<sup>6</sup> This parallel is not captured by an account on which the semantics of relative measures such as *twenty percent* are based on Ahn & Sauerland's entry for *percent* in (27), while *more* comparatives are based on generalized quantifier entries for *many/much* such as Romero's in (7).

Finally, let us return to the differential use exemplified in (30c), repeated below. While these might be handled in the same way suggested above for the ambiguity account, the measurement-based analysis offers another possibility. Recall that the semantics of *Meas* is underspecified: both the dimension of measurement and the particular scale tracking that dimension are contextually determined. Even when the dimension is set to be cardinality or number, there are multiple possible scales and corresponding measure functions. One such function is that which maps the totality of houses sold last year to the point 1 (or equivalently 100%), and other pluralities to values expressed in relation to this. In (30c), *twenty percent* describes the length of an interval on this scale:

- (34) We sold twenty percent fewer houses this year than last year. (= (30c))

Note that the measure function here is not a proportional one (or for that matter a domain-restricted one of any sort); but it satisfies monotonicity, making it a licit choice.

To summarize, in this section the inquiry has been extended to include expressions of the form *n percent*. Contrary to the predictions of some current theories, it has been seen that certain uses of such expressions must be analyzed as degree denoting, thus providing further evidence for the existence of proportional scales. The measurement-based theory can handle these uses via the same mechanisms applied to proportional comparatives, while assuming a single degree-denoting entry for *n percent*. The ambiguity approach instead requires some sort of duplication to be added to the system, i.e. distinct interpretations for *n percent*, or multiple loci for the computation of proportions. Perhaps the most parsimonious enhancement to this account would be to assume a null proportional *many* in proportional partitives. Below it will be shown that this does not get the facts right.

#### 4. Cardinal readings, proportional readings and their distribution

In this section we will examine more directly the proposal that *many* and similar words are actually lexically ambiguous between cardinal and proportional interpretations, and compare this view to one in which their different readings arise instead from underspecification in measurement, in conjunction with a distinction between ordinary and domain-restricted measure functions. The question to be addressed is which of these approaches best captures the distribution of the two readings in question.

<sup>6</sup>For related discussion on dimensions available in partitive constructions, see Krifka 1989.

The first observation to be made is that the availability of distinct cardinal and proportional readings for words of the *many* class is not an idiosyncratic fact about English: a similar ‘ambiguity’ has been documented for the corresponding forms in languages including German (Kobele and Zimmermann, 2012), Dutch (Ruys, 2017), Slovenian (Stateva and Stepanov, 2017), Basque (Etcheberria, 2008), Japanese (Tanaka, 2006) and Hausa (Zimmermann, 2008) (though Russian distinguishes the two meanings lexically; see Krasikova 2011). On an account that treats this as a lexical ambiguity, one would need to claim that the same essentially accidental pairing of meanings with a single surface form has arisen in a range of typologically unrelated languages, an unlikely situation. On the measurement-based approach a more general account suggests itself: the availability of the two interpretations derives from the interaction of the lexical semantics of vague quantity words with the semantics of quantity measurement, which we might propose to universally come in domain-restricted and non-restricted varieties. To further develop this idea, it would be beneficial to investigate in more depth the facts relating to proportional measurement cross-linguistically.

Returning to English, a second important observation is that cardinal and proportional readings are not universally available; rather, their distribution is constrained by both syntactic and semantic factors. One of these relates to predicate type. In particular, Milsark (1977), Partee (1989) and others have observed that in combination with individual-level predicates (Carlson, 1977) *many* and *few* allow only the proportional reading, and not the cardinal one. As discussed above, the availability of the cardinal interpretation is most easily diagnosed in the case of *few*. Recall that (6), repeated here as (35), is felicitous, evidence that the sentence has a cardinal reading on which *few Ns* can be all of the *Ns*. But when the stage-level predicate *identified in our survey* is replaced by the individual-level *suckle their young* in (36), the same continuation is infelicitous, indicating that only the proportional reading is available.

- (35) Few egg-laying mammals were found in our survey, perhaps because there are few.  
 (36) Few egg-laying mammals suckle their young, #perhaps because there are few.

I cannot claim to offer a fully developed account of the source of this restriction, but one can imagine how this pattern might be approached from the perspective of the two analyses discussed in Section 2. On the ambiguity view, we might say that (for whatever reason) only the proportional entries for *many/few* can select an individual-level predicate as their second argument. On the measurement-based approach, the proposal would instead be that in the presence of such a predicate, the measure function introduced by *Meas* is necessarily of the domain-restricted variety; this might be related to a proposal by Ladusaw (1994) that such predicates participate in two-stage categorical judgments (Kuroda, 1972), in the first stage of which the judge’s attention is drawn to an individual to which the predicate will be associated (see Solt 2009 for discussion).

Crucially, these two approaches make different predictions regarding the readings available to proportional comparatives. Consider again our original examples, repeated below:

- (1) More residents of Ithaca than New York City know their neighbors.  
 (2) More Norwegians than Brazilians have university degrees.

Both of these feature individual-level predicates, and as such it is not surprising that they have proportional readings. But both also clearly have (false) cardinal readings, where it is absolute numbers of Ithaca vs. NYC residents and of Norwegians vs. Brazilians that are compared. On the ambiguity analysis, augmented as suggested to account for the facts relating to predicate type, this reading cannot be derived: if *more* in quantity comparatives is analyzed as the comparative form of *many*, and only the proportional version of *many* can surface with individual level predicates, then we predict only the proportional reading for these examples.

In the measurement-based account, a different picture emerges. Suppose, as suggested above, that in the presence of an individual-level predicate the measure function is necessarily a domain-restricted one  $\mu_{DIM;\oplus P}$ . As was demonstrated in Section 2.2, when this is interpreted in particular as a proportional measure function (Fig. 1c), we derive the proportional reading of the comparative. On the other hand, if it is interpreted as an ‘ordinary’ domain-restricted function (Fig. 1b), which maps pluralities to some bounded segment of the number line, the cardinal reading of the comparative results. But in either case, the standard range introduced by the positive morpheme *POS* is necessarily situated on the bounded segment of the scale (see the diagram in (23) above). As a result, bare *many* in a corresponding positive example such as (36) must be interpreted proportionally. That is, in the case of a domain-restricted quantity measure, we derive only the proportional reading of the unmodified positive form, but both cardinal and proportional readings of the comparative.

A second context in which only the proportional reading of *many/few* surfaces is the partitive (Milsark, 1977; Partee, 1989), and here again we observe a divergence between the positive and comparative. By way of example, (37) is false in a situation in which there are only a small number of first-year students and they all wrote papers, evidence that *few* must be interpreted proportionally. By contrast, (38) seems to allow a proportional reading, on which it is proportions of first- and second-year students that are compared; but it also fairly clearly has a cardinal reading, which expresses that the absolute number of first-year students who wrote papers is larger (smaller) than the corresponding number of second year students who did.

- (37) Few of the first year students wrote papers.  
 (38) More/fewer of the first year students than the second year students wrote papers.

On the measurement-based analysis, this can be accounted for in the same way as with individual level predicates. Partitive *of* is analyzed as having a domain-restricted measure function as part of its semantic content (see (32) above), which necessarily yields a proportional reading for bare *many/few* due to a constraint on the scalar position of the threshold, but yields both readings of the comparative, depending on whether or not the measure function is specifically a proportional one. And with the ambiguity analysis, we run into the same issue that we did above: if only the proportional versions of *many/few* can occur with the partitive, we predict only the proportional reading of the corresponding partitive comparatives, a prediction that is not supported by examples such as (38).

Note that the issue for the ambiguity analysis also extends to numerical partitive constructions such as *twenty percent of the students*. Recall that one way to approach these from the perspec-

tive of the ambiguity analysis would be to assume they include a null version of proportional *many* that introduces degrees of proportion to which an expression such as *twenty percent* can refer. But if we make the reasonable assumption that this null *many* obeys the same constraints as the overt one, specifically that in the partitive construction it must be interpreted proportionally, we seem to predict that only proportional measures will be possible, which is contradicted by examples such as *twenty of the students*. As discussed in Section 3, the measurement-based account can generate both absolute and proportional measures in partitives.

To summarize, we have seen two contexts in which there is a divergence in the interpretations available to positive and comparative forms: the former are necessarily interpreted proportionally, while the latter can but need not have this interpretation. This pattern is problematic for an ambiguity analysis of the form presented in Section 2.1, but not for the measurement-based approach of Section 2.2, because the latter offers a mechanism that the ambiguity approach does not, namely the possibility of quantity measurement that is relative (to a suitable totality) but not explicitly proportional.

Here a reader might object that the ambiguity analysis could be modified to address this objection, by incorporating the same semantic mechanism proposed to underlie the measurement-based account, and then replacing Romero's entries for cardinal and proportional *many* with something along the lines of the following:

- (39) a.  $\llbracket \text{many}_{\text{CARD}} \rrbracket = \lambda d \lambda P_{\langle \text{et} \rangle} \lambda Q_{\langle \text{et} \rangle} \cdot \mu_{\#}(P \cap Q) \succeq d$   
 b.  $\llbracket \text{many}_{\text{PROP}} \rrbracket = \lambda d \lambda P_{\langle \text{et} \rangle} \lambda Q_{\langle \text{et} \rangle} \cdot \mu_{\#; \oplus P}(P \cap Q) \succeq d$

This is certainly true, but with this change, the difference between the two analyses reduces essentially to one of semantic type. On one approach (the 'ambiguity' analysis), *many* and like words are ambiguous between two quantifying determiners that differ in whether the measurement they encode is unrestricted or domain restricted (or we might even take them to have a single underspecified meaning that encompasses both possibilities). On the alternate approach (the 'measurement' analysis), an equivalent underspecification or ambiguity is localized in the semantics of a null measuring element (sometimes spelled out as *of*), while *many* words have a single simple interpretation as gradable predicates of sets of degrees. The data that would adjudicate between these two options falls outside the scope of the present paper; but as alluded to earlier, there are reasons to favor the degree-based analysis over the generalized quantifier approach, in that it allows a more general account of these items across the range of contexts in which they occur (see Solt 2015 for discussion). In any case it must be concluded that with regards to capturing the availability of distinct cardinal and proportional readings for *many* etc., the generalized quantifier approach does not have an advantage over the degree-based one.

## 5. Conclusion and Open Issues

The starting point for this paper was the proportional reading of quantity comparatives, which poses a challenge for a degree-based semantic framework. I have argued for an analysis based on the notion of domain-restricted and more specifically proportional measure functions, which map individuals to degrees that encode the proportion they represent of some totality they are

part of. It has been demonstrated that this mechanism can be extended also to other sorts of proportional expressions, and that it offers advantages over an alternate approach based on explicitly proportional entries for gradable quantity words such as *many* and *few*. The conclusion is that proportional scales, and the corresponding measure functions, are a necessary part of the degree ontology. A secondary finding is that it is no longer necessary to analyze words of the *many* class as lexically ambiguous, a satisfying result given that the purported ambiguity is present in a range of typologically diverse languages.

At this stage there are, to be sure, some fairly significant questions left open. In that the account presented here depends crucially on underspecification in the linguistic encoding of quantity measurement, it faces the issue of overgeneration. As one aspect of this, we do not have an explanation for the observation (see e.g. Bale and Barner, 2009) that the default dimension for count noun comparatives is cardinality (number): *more students than teachers*, for example, must be a greater number of students, not, say, a group of greater weight. Interestingly, though, since a comparative such as this allows a proportional reading, we must consider proportion-of-number to be a variety of cardinality measurement. Perhaps more significantly, the restriction that quantity measurement be monotonic still allows an infinite number of specific measure functions for the representation of cardinality, or any other dimension. This proved useful in developing an analysis of proportional measures in differential position (see Section 3), but also has some less desirable consequences: for example, nothing would prevent selecting a measure function that maps pluralities to a value equal to twice their ‘ordinary’ cardinality, such that a group consisting of three students could be described as *six students*. I do not have a concrete proposal for how this can be avoided, though I suspect it might ultimately require a distinction to be made between counting and other forms of measurement, as proposed among others by Rothstein (2017).

Note finally that the present analysis does not yet capture all uses and interpretations of proportional expressions. In particular, I have not attempted to address non-conservative ‘reverse’ readings, which are available for both quantity words and percentage expressions (see Westerstahl 1985; Herburger 1997; Cohen 2001; Romero 2015 for the former and Ahn and Sauerland 2015, 2017 for the latter). For example, *Many Scandinavians have won the Nobel Prize in literature* has a reading on which it is true if Scandinavians make up a large proportion of winners, and *The firm hired 75% women* means that 75% of those hired were women (not that 75% of some group of women were hired). Recent works have analyzed these with reference to alternatives generated via focus, though in different ways: Romero proposes that such alternatives form a comparison class on the basis of which the standard for proportional *many* is derived, while Ahn & Sauerland analyze them as providing a set whose measure serves as the denominator for the calculation of (reverse) proportions. I leave it to be determined whether one of these approaches could be integrated with the account of proportional measurement developed in this paper. I have sought here to unify the analysis of the proportional reading of *many/few* and proportional measures of the form *n percent*, and it would be desirable to investigate if a unified treatment of their reverse readings is likewise possible.

# Complement coercion in Polish and the role of selectional restrictions revealed in a self-paced reading study<sup>1</sup>

Alexandra Anna SPALEK — *Universitetet i Oslo*

Barbara Maria TOMASZEWICZ — *Universität zu Köln, Uniwersytet Wrocławski*

**Abstract** So-called ‘complement coercion’ (*‘begin a book’*), understood as a combinatorial conflict, is mainly analysed as a repair operation in composition. Experimental data has shown that there is an extra cognitive effort in the processing of event-selecting verbs with entity-denoting arguments. These results support the formal analysis of ‘complement coercion’ as an enriched form of semantic composition (Pustejovsky, 1995; Egg, 2003; de Swart, 2011; Asher, 2015). Recently, an alternative view has been proposed by Piñango and Deo (2015) arguing that there is no mismatch between the verb and its complement, but an ambiguity resulting from the different dimensions along which an aspectual verb in composition with its argument can be interpreted (e.g. temporal, spatial, etc.). This approach has been supported by experiments showing that aspectual verbs like *begin* incur greater processing cost in coercing contexts than psychological verbs like *enjoy* (Lai et al., 2014). We designed a self-paced reading experiment to compare the different predictions that the two approaches make for the processing of matching and mismatching verb-noun combinations. Our results are compatible with enriched composition, but not with dimensional ambiguity. We find facilitation in conditions where the selectional restrictions of the verbs are satisfied (*‘begin a fight’*, *‘see a book’*), and longer processing times in the conditions *‘begin a book’*, *‘see a fight’*, which does not support the dimensional ambiguity approach. Our experiment thus provides evidence that selectional restrictions are a fundamental property of a predicate and that they need to be understood as a graded continuum of combinatorial preferences, as also argued in Spalek (2014).

**Keywords:** Complement coercion, aspectual verbs, real-time processing, self-paced reading.

## 1. Introduction

The minimal pair in (1) presents a challenge for the compositional derivation of meaning: in (1a) the verb *start* combines with an event-denoting complement, in (1b) with an entity-denoting complement. In the first case, the event is explicitly referred to, in the second, we can only infer that an event involving the soup was started. Cases like (1b) exhibit so-called ‘complement coercion’ – an operation by which the verb ‘coerces’ its semantically mismatching object to the appropriate semantic type.

- (1)    a.    The boy started the fight.  
      b.    The boy started the soup.

---

<sup>1</sup>We would like to thank Joanna Błaszczak, Elsi Kaiser, Roumi Pancheva, Kjell Johan Sæbø, Petra Schumacher and the audience at the ESSLLI 2016 workshop (Referential Semantics One Step Further) for inspiring comments and discussion. We are also grateful to Joanna Błaszczak and Marcin Orszulak for assistance with conducting the experiment. The work on the experiment was supported by the FOCUS grant from the Foundation for Polish Science.

This contrast imposes the following consideration to be accounted for theoretically: given that the verb *start* presupposes an argument of eventuality type, predication in example (1b) should go wrong, because it seems that there is a conflict between the demands of the predicate on the type of its argument and the argument the predicate actually gets. Yet the sentence (1b) is interpretable and can refer to an event of soup eating or soup cooking, etc. Any compositional theory of meaning needs to account for the means by which a predicate like *start* can compose both with an eventuality-denoting noun, e.g. *fight* in (1a), and with an individual-denoting noun, e.g. *soup* in (1b). ‘Complement coercion’ thus raises a very general question of conceptual knowledge and how it is supposed to interact with referential semantics.

Crucially for our study, the verb *start* in the minimal pair in (1) contrasts with verbs such as *see*, *criticize* or *prepare*, which *prima facie* combine easily with both kinds of noun phrases, event nouns and individual-denoting nouns. Many studies classify verbs like *start* as ‘aspectual verbs’ and show that they typically allow for ‘complement coercion’. The verbs in (2), in contrast, are classified as non-aspectual verbs, but not much has been said about their selectional restrictions so far.

- (2) a. The man saw/ criticized/ prepared the fight.  
 b. The man saw/ criticized/ prepared the soup.

The present study explores the combinatorial compatibility of the two kinds of verbs, aspectual verbs (1) versus non-aspectual verbs (2), with eventuality-denoting and individual-denoting arguments. Comparing the ease of processing of the different verb-noun combinations, we obtained contrasts indicating the complexity of semantic processing during real-time comprehension, which we argue have concrete implications for the models of meaning based on the idea that predicates select their arguments. We designed two self-paced reading studies that contrast aspectual verbs with non-aspectual verbs (henceforth, ‘AV(s)’ and ‘N-AV(s)’), using Polish. Polish seemed particularly interesting for our purpose, because it has two kinds of entity-denoting nouns that differ in their morphology, one of them being morphologically non-transparent and another containing a verbal root. The latter allowed us to manipulate the ‘coercion effect’ in one of the experiments.

Before advancing, we introduce a terminological clarification. Since the term ‘complement coercion’ is widely accepted in the literature on AVs to refer to the combinations where an AV takes an individual-denoting DP, we will refer to these combinations as ‘coercing contexts’ and to the group of verbs as simply ‘coercing verbs’, without correlating these terms with any particular theoretical account.

## 2. On complement coercion

Coercing verbs, like *enjoy*, *begin*, *start*, *finish*, *stop*, etc., have been extensively discussed since Pustejovsky (1991), and their capacity to take an individual-denoting noun as a complement, so-called ‘complement coercion’ (1b), has been the object of a rich theoretical discussion (Pustejovsky, 1995; Copestake and Briscoe, 1995; Fodor and Lepore, 1998; Egg, 2003; de Swart, 2011; Asher, 2011). The common denominator of these well-known accounts has been

to take complement coercion as a semantic type mismatch between the selectional requirements of the predicate and its argument. Diverse solutions have been proposed as to how the missing specification of the event is recovered (e.g. in (1b) it could be either an eating or a cooking event depending on the context). Pustejovsky (1995) posits a complex lexical entry for the argument which is able to give access to the event reading. Fodor and Lepore (1998), on the other hand, propose that the event-reading results from post-lexical inferences, while many others advocate for some kind of enriched form of composition (Egg, 2003; de Swart, 2011; Asher, 2011). In some cases, the enriched process of composition comes together with the assumption that the lexicon is underspecified, as in Egg (2003); in other cases, certain lexical units, such as AVs, license dependent types that trigger a repair process during composition (Asher, 2011).

Abstracting away from the formal details, these approaches share the assumption that AVs determine the semantic type of their arguments and that to satisfy those semantic requirements some operation needs to be performed to ‘coerce’ the entity-denoting complement into the appropriate semantic type. We will refer to this as the Enriched Semantic Composition hypothesis following the terminology proposed in lexical-semantic research (Pustejovsky, 1991, 1995; Jackendoff, 1997). This hypothesis finds support in various kinds of experimental results (McElree et al., 2001; Traxler et al., 2002, 2005; McElree et al., 2006; Pytkänen and McElree, 2007; Frisson and McElree, 2008; Kuperberg et al., 2010), which have shown that combining a coercing verb with an entity-denoting complement (1b) during real-time comprehension engenders more processing cost than combining it with an event-denoting complement (1a).

More recently, taking a special focus on entity-denoting complements of AVs, Piñango and Deo (2015) called the type-mismatch analysis into question by observing that there is a whole range of combinations of AVs and individual-denoting nouns that represent configurational relations. In combinations such as in (3), Piñango and Deo (2015) observe that there is no need for coercion and propose that these cases are prevalent, rather than exceptions. This observation leads them to develop a generalized lexical semantics for AVs that dispenses with coercion.

- (3) This is the famous perch that officially begins the Appalachian Trail.  
((7d) in Piñango and Deo (2015))

Based on the idea of generalized paths (Gawron, 2009), Piñango and Deo (2015) propose a unifying lexical semantics for AVs, where AVs specify relations between the sub-parts of the axis determined by their complements’ denotation. On this account AVs presuppose their arguments to be structured individuals with respect to a contextually determined function in some domain. AVs thus make reference to parthood relations formalized as contextually defined functions, e.g. a spatial trace function in the case of example (3). With this analysis Piñango and Deo (2015) argue that what has been called ‘complement coercion’ can be explained as a case of ambiguity between the different dimensions that a particular AV can access. An interesting example to illustrate this account in more detail is (4).

- (4) The little girl began the queue. ((29a) in Piñango and Deo (2015))

According to Piñango and Deo (2015), the interpretation of a sentence containing an AV, such as *begin* in (4), is dependent on determining the specific dimension along which the denotation of the complement is structured. (4) is thus ambiguous and can be paraphrased either as ‘The little girl began forming the queue’ (temporal dimension) or as describing the position of the little girl relative to the structure of the queue (spatial dimension). Examples of this kind lead Piñango and Deo (2015: 14) to conclude that ‘any analysis of aspectual verbs that assumes that they select for event-denoting complements is not tenable’.

This approach crucially assumes that AVs do not impose restrictions on the type of their arguments, but rather establish ‘parthood relations between objects along a range of familiar (and, sometimes not so familiar) dimensions’ (Piñango and Deo, 2015: 10). The processing cost in experimental studies can, therefore, be attributed to the need of identifying the appropriate dimension for the interpretation of an AV and its complement. This proposal finds support in studies showing that only a subset of coercing verbs engender additional processing cost, namely strictly AVs, such as *begin*, *start*, etc., but not psychological coercing verbs, such as *enjoy*, *prefer* (Katsika et al. (2012), Lai et al. (2014)). We will refer to this approach as the Dimension Ambiguity Hypothesis.

The Enriched Composition approach predicts that during real-time sentence processing AVs create strong expectations for the semantic type of their arguments. The Dimensional Ambiguity hypothesis, on the other hand, makes no assumptions about selectional restrictions and predicts that the ease of the identification of a temporal dimension for the interpretation of the entity-denoting complement will affect the ease of the processing of coercion contexts. In the absence of ambiguity between dimensions (with N-AVs and their complements), no processing costs should be observed. We measured the processing cost in terms of reading times, and our experiment was designed on the basis of prior reading studies on complement coercion. In the next section we present prior experimental results that guided the design of our study in order to test the two different approaches to AVs and their selectional properties.

### 3. Differences in reading times

The processing cost of complement coercion, (1b) in contrast to (1a), was first shown in the self-paced reading and eye-tracking during reading experiments of McElree et al. (2001) and Traxler et al. (2002). In a self-paced reading experiment participants read the sentences presented on the computer screen chunk-by-chunk, advancing at their own pace (Just et al., 1982). The times of each button press to move to the next chunk are recorded, and longer reaction times (RTs) are interpreted as reflecting a higher level of processing difficulty. Using self-paced reading, McElree et al. (2001) tested the basic question whether AVs, like *start* in (5a), are more difficult to process than N-AVs, like *write*, *read* in (5b)-(5c). They compared the reading times at the noun complement and at the following adverbial in three conditions: coercion context (5a), preferred combination (5b) (the verb explicitly expressed the event) and non-preferred combination (5c) (the verb explicitly expressed a less frequent but plausible event).<sup>2</sup>

<sup>2</sup>Ratings for the preferred and non-preferred verb-noun combinations were obtained in a separate norming study.

- (5) a. The author was starting the book in his house. – Coercion  
 b. The author was writing the book in his house. – Preferred  
 c. The author was reading the book in his house. – Non-preferred

They found that while the non-preferred verb-noun combinations elicited longer RTs than the preferred ones, there was an extra cost associated with the coercion contexts. (The reading times were measured both at the target (noun) and post-target (adverbial) regions, because the processing of the target region affects the processing of the following regions. The RTs at the target noun were significantly longer in the coerced and the non-preferred conditions than in the preferred condition. The RTs at the adverbial were significantly longer in the coerced condition than in both the preferred and the non-preferred conditions.)

Traxler et al. (2002) further tested the nature of the processing delay using self-paced reading and eye-tracking during reading methodologies. While in a self-paced reading experiment segments must be presented sequentially, in an eye-tracking experiment natural reading is possible and different measures of the processing cost are available (e.g. total reading times for a region, just like in self-paced reading, but also the time spent reading a word for the first time, re-reading it again, etc.). They investigated whether the effects found by McElree et al. (2001) could be caused by the fact that while *start* has a preference for a verbal complement, it receives a nominal complement in (5a). Their test items involved quadruples of sentences such as (6) and (7). The pair in (6) contains an AV combined with a matching event-denoting noun (6a) and with an entity-denoting noun that requires coercion (6b). In pair (7) a N-AV is combined with an entity-denoting noun (7a) and with an event-denoting noun (7b).

- (6) a. The boy started the fight after school today. – No Coercion (AV, EventN)  
 b. The boy started the puzzle after school today. – Coercion (AV, EntityN)
- (7) a. The boy saw the puzzle after school today. – No Coercion (N-AV, EntityN)  
 b. The boy saw the fight after school today. – No Coercion (N-AV, EventN)

The results of both experiments, the eye-tracking study and the self-paced reading experiment, indicated that the complement coercion condition, (6b), incurred extra processing cost. The self-paced reading data showed no significant differences at the target noun region like in the McElree et al. (2001) study. At the adverbial region, there was a main effect of NP-Type (EntityNs received longer RTs than EventNs) and a significant interaction: sentences with AVs and EntityNs, (6b), generated longer RTs than sentences with N-AVs and EntityNs, (7a). This means that the RTs at the adverbial were the slowest in the AV+EntityN condition, (6b). Of interest to our study, as will be explained in section 4, is also the result that sentences with AVs and EventNs, (6a), had numerically (not significantly) shorter RTs than sentences with N-AVs and EventNs, (7b).

The eye-tracking data revealed reading differences already at the noun region, with the coercion condition (6b) being the hardest. Crucially, the measures that are typically considered to reflect

integrative processing in eye-movement data ('second pass time'<sup>3</sup> and 'total time') revealed that at the noun region EntityNs were harder to process with AVs – there was a main effect of NP-Type and a significant interaction. Second pass time and total time are later measures which can explain the lack of effects on the noun in their self-paced reading study. Moreover, at the noun, in the second pass time data, the RTs in the AV+EventN condition, (6a), were numerically lower than in the N-AV+EventN condition, (7b) – though this difference was not significant, just like in the self-paced reading experiment, we take this finding into account for the design of our study, as explained below (section 4).

The Traxler et al. (2002) study provided evidence that AVs with EntityNs are costly to process. It did not yield statistically significant results indicating that AVs create an expectation for EventNs during processing, but in both of their experiments there was clearly such a trend (EventNs received faster RTs after AVs than N-AVs). The goal of our study was to confirm that coercion contexts require extra processing cost in Polish, and to find out what causes this extra cost: (i) the verb and its selectional restrictions (Enriched Semantic Composition) or (ii) the noun interpreted as a structured individual (Dimension Ambiguity). We based our experimental design on Traxler et al. (2002), but structured the whole experiment in such a way that we could take advantage of two different classes of nouns in Polish that allowed us to manipulate both coercion contexts and the properties of the complement nouns, as presented in the next section.

#### 4. The present study

We designed a self-paced reading experiment to compare the different predictions that the Enriched Composition approach and the Dimension Ambiguity approach make for the processing of matching and mismatching verb-noun combinations. The two approaches make different predictions for (i) the processing AV+EventN combinations in contrast to N-AV+EventN, and for (ii) the processing of those EntityNs that are morphologically non-transparent and those that contain a verbal root.

The first contrast follows from the fact that, as discussed in section 2, the Enriched Composition approach, but not the Dimension Ambiguity approach, assumes that AVs select for event-denoting complements. This predicts that during incremental processing, when the parser encounters an AV, an expectation for an event-denoting complement is created. In contrast, N-AVs, which can select for both entity- and event-denoting arguments, should not create such an expectation during parsing. Accordingly, AVs but not N-AVs should display a bias for EventNs in processing. The Dimension Ambiguity, on the other hand, predicts the absence of such a bias, because AV+EventN combinations are simply unambiguous, just like N-AV+Entity/EventN combinations. As noted above in section 3, in the two experiments in Traxler et al. (2002) there was a trend towards AVs facilitating EventNs (not statistically significant), therefore we hypothesized that we could increase the sensitivity of the parser to the contrast between AVs and N-AVs by increasing our participants' exposure to coercing contexts.

---

<sup>3</sup>Second pass time includes all of the time spent in the region following first-pass fixations and the time at second access after exiting the region to the left or right

The second set of predictions where the two theories diverge follows from the assumption of the Dimension Ambiguity approach that EntityNs as complements to AVs are interpreted as structured individuals. During processing, the parser must choose the contextually relevant dimension along which the individual is structured, so when several dimensions are available the parser must resolve the ambiguity. We know from reading experiments on lexical ambiguity that ‘balanced’ and ‘biased’ ambiguous words are processed differently (Rayner and Duffy, 1986). Biased ambiguities are those where the two meanings are asymmetric in their likelihood, such that one meaning is dominant and the other subordinate (e.g. *ball* ‘a spherical object’, ‘a social gathering for dancing’), though the context can reverse which of the meanings is the dominant one. In balanced ambiguities both meanings are equally available. Rayner and Duffy (1986) found that within a sentence balanced ambiguous targets were read slower than biased ambiguous targets, but in the post-target region there was an additional cost with biased ambiguous words. Thus, the two types of ambiguities received clearly different processing profiles. Accordingly, we hypothesized that we should find such different processing profiles with EntityNs biasing a temporal dimension and with EntityNs that are balanced. Polish provided us with two types of EntityNs that differed in the likelihood of a temporal interpretation: morphologically simple nouns denoting physical objects and morphologically complex nouns containing a verbal root.

The two sets of predictions were tested as two sub-experiments of one study. This combined presentation allowed us to expose our participants to a wide variety of coercion contexts, which, as noted above, was hypothesized to increase the parser’s sensitivity to the different selectional requirements of AVs and N-AVs. In effect, 25% of all the sentences in the whole experiment involved coercion contexts. We discuss the predictions, materials and results for each of the sub-experiments in turn.

#### 4.1. Sub-Experiment 1

The goal of the experiment was two-fold. First, we wanted to replicate the results of Traxler et al. (2002) by finding evidence for the processing cost of AV+EntityN combinations in Polish. Second, we wanted to test whether AV+EventN combinations facilitated processing relative to N-AV+EventN combinations, as predicted by the Enriched Composition approach. If AVs create an expectation for an eventuality-denoting complement, AV+EventNs should be easier to process than N-AVs which do not create expectations for one specific type of complement. Accordingly, we predict a three-way distinction in the processing cost:

- (8) AV+EntityN > N-AV+EntityN/EventN > AV+EventN  
       ‘begin book’ > ‘see book/fight’ > ‘begin fight’  
       type mismatch > no specific requirement > requirement satisfied

The Dimensional Ambiguity approach, on the other hand, predicts a two-way contrast – between the AVs+EntityN combination, which requires the resolution of dimension ambiguity, and the other three combinations, where there is no ambiguity to resolve:

- (9) AV+EntityN > N-AV+EntityN/EventN, AV+EventN  
 ‘begin book’ > ‘see book/fight’, ‘begin fight’  
 dimension ambiguity > no ambiguity

Since an AV merely requires that its argument is a structured individual with respect to a contextually determined dimension, in the combination AV+EventN, the noun is unambiguously interpreted along the temporal dimension. Therefore, the Dimensional Ambiguity analysis does not predict differences in the processing of AVs with EventNs and N-AVs with either kind of complement.

#### 4.1.1. Materials and procedure

We used the Polish adaptations of the 24 items from Traxler et al. (2002) in the same four conditions as in (6) and (7): AV+EntityN, AV+EventN, N-AV+EntityN, N-AV+EventN. We used the AVs listed in (10)<sup>4</sup> and the N-AVs listed in (11).

- (10) **Aspectual verbs** selecting event denoting complements:  
*zacząć* (begin)×4; *rozpocząć* (begin)×4; *skończyć* (finish)×4; *ukończyć* (finish)×2;  
*zakończyć* (finish)×2; *przerwać* (pause)×2; *wytrzymać* (endure)×2; *oczekiwać* (await)  
 ×2
- (11) **Non-aspectual verbs** taking both entity- and event-denoting complements:  
*zobaczyć* (see)×4; *skrytykować* (criticize)×2; *przygotować* (prepare)×2; *pochwalić*  
 (praise)×4; *zignorować* (ignore)×2; *obejrzeć* (watch)×2; *opisać* (describe)×4; *wspom-*  
*nieć* (mention)×2

In addition to the 24 experimental items, the participants ( $n=36$ , all native speakers of Polish, students from the University of Wrocław) saw the 24 items from Sub-Experiment 2 and 24 unrelated fillers containing the comparative construction (e.g. ‘*The daughter downloaded more games on the home computer than the son.*’)

The self-paced reading experiment was conducted using the Linger program (Rohde (2001), <http://tedlab.mit.edu/~dr/Linger/>) in a moving-window paradigm. The whole sentence was initially presented with all the words masked by dashes. Participants pressed the space bar to reveal a phrase (consisting either of a single word, a compound word or a preposition and a word), and when the new phrase appeared, the previous phrase was masked again (non-cumulative presentation). Half of the sentences in the experiment were followed by a ‘yes/no’ question testing comprehension. The Linger program distributed the items (from both sub-experiments) and the fillers into four lists and randomized the order of presentation of sentences within each list for each participant. Each list contained 72 test and filler sentences. The experiment took about 30 min to complete.

<sup>4</sup>Following Traxler et al. (2002) we included the verb *forget*, but after the experiment was conducted, we realized that it can create a coercion context. When you forget an article, you either forget what it was about or you forget the action of taking/bringing it. As a result, we did not include the two items with *forget* in our statistical analysis.

#### 4.1.2. Data analysis

Data from participants with at least 70% accuracy on the comprehension questions, ( $n=35$ ), was analyzed. None of the participants' mean reading time was more than 2.5 standard deviations from the participant mean. For reading time data analysis, we used the two-step model of Jaeger et al. (2008), Hofmeister (2011); Hofmeister et al. (2013), where first residual reading times are obtained and then those are used for the statistical analyses.<sup>5</sup> We removed the outlier RTs below 200ms and above 4000ms, which represented 0.33% of the experimental and filler data, and used the Box-Cox procedure (Box and Cox, 1964) to determine that the reading times should be log-transformed to meet the assumption of the linear model that residuals be normally distributed (see Baayen and Milin (2010) and Vasishth et al. (2013) a.o. for arguments that the normality assumption is important for reaction time data, whose distribution is positively skewed). For each subject we computed residual reading times to account for the differences in: (a) kind of stimulus (Sub-Experiment 1 and 2, fillers), (b) word length (because there is no linear relationship between the number of characters in a word and the required reading time), (c) word position in a sentence (because it also has no linear effect on reading times) and (d) the log-transformed trial number (because readers speed up as the experiment progresses). The residual reading times correct for these individual differences between participants' reading speeds (e.g. Ferreira and Clifton (1986), Trueswell and Tanenhaus (1994)). Statistical analyses were carried out over the residual reading times without further trimming using linear mixed-effects models in R (version 3.3.2; R Core Team (2016)) with the lme4 package (version 1.1-12; Bates et al. (2015)). We report the results of linear mixed effects models with a fully specified random effects structures (including random intercepts and for all fixed effects by participants and by items, Barr et al. (2013)); in case of convergence failures the random effects structure was simplified following Baayen et al. (2008). The  $p$ -values were obtained using the Satterthwaite approximation implemented in the lmerTest package (Kuznetsova et al., 2016).

#### 4.1.3. Results

We found no differences in reading times at the subject and verb regions (see the plot in Figure 1). At the object noun region, there was a significant interaction between Verb-Type and NP-Type ( $\beta = -.11$ ,  $SE = .047$ ,  $t = -2.357$ ,  $p = .02$ ). AVs were faster with EventNs ( $-.009$  vs.  $.03$ ) while N-AVs were faster with EntityNs ( $-.025$  vs.  $.046$ ).

At the region of the adverbial, we found both a highly significant interaction ( $\beta = -.13$ ,  $SE = .04$ ,  $t = -3.283$ ,  $p = .001$ ) and main effects of Verb-Type ( $\beta = .01$ ,  $SE = .028$ ,  $t = 3.547$ ,  $p = .0004$ ) and NP-Type ( $\beta = .075$ ,  $SE = .028$ ,  $t = 2.668$ ,  $p = .008$ ). As can be seen in the plot, at the adverbial, N-AVs were slower than AVs and EntityNs were slower than EventNs. A four-way comparison revealed that the AV+EventN condition (the red line in the plot) was significantly faster than both the AV+EntityN condition (green) ( $\beta = .074$ ,  $SE = .028$ ,  $t = 2.6$ ,  $p = .014$ ), and the N-AV+EventN condition (blue) ( $\beta = .1$ ,  $SE = .03$ ,  $t = 3.348$ ,  $p = .002$ ). Additionally, the N-AV+EventN condition (blue) was marginally slower than the N-AV+EntityN

<sup>5</sup>For the implementation in R see Jaeger's blog entry <https://hlplab.wordpress.com/2008/01/23/modeling-self-paced-reading-data-effects-of-word-length-word-position-spill-over-etc/>

condition (purple) ( $\beta = -.0564$ ,  $SE = .031$ ,  $t = -1.802$ ,  $p = .07$ ), but not significantly slower than the AV+EntityN condition (green) ( $\beta = -0.025$ ,  $SE = .033$ ,  $t = -0.762$ ,  $p = .45$ ).

Figure 1: Sub-Experiment 1. Average Log-Transformed Residual Reading Times.

At neither the noun nor the adverbial region was the AV+EventN condition (red line) significantly different from the N-AV+EntityN condition (purple) ( $\beta = .044$ ,  $SE = .028$ ,  $t = 1.572$ ,  $p = .12$ ,  $\beta = .04$ ,  $SE = .031$ ,  $t = 1.385$ ,  $p = .18$ ). For the four-way comparison we used simple contrast coding with AV+EventN as the baseline because the theory predicts that AVs select for EventNs, hence the satisfaction of selectional requirements in this condition can account for the faster reading times seen in the results. The fact that EventNs were significantly faster with AVs than with N-AVs suggests that a processing cost was associated with the N-AV+EventN combination. This indicates that N-AVs in our experiment biased EntityN complements just like AVs biased EventN complements.

#### 4.1.4. Discussion

At the region of the adverbial, we found the two-way contrast in (12). This result is compatible with the predicted three-way contrast in (8), but not the two-way contrast in (9) predicted by Dimensional Ambiguity hypothesis, because the two conditions that receive longer reading times, AV+EntityN and N-AV+EventN, do not form a class on the Dimensional Ambiguity theory.

- (12) AV+EntityN, N-AV+EventN > AV+EventN, N-AV+EntityN  
 ‘begin a book’, ‘see a fight’ > ‘begin a fight’, ‘see a book’

The faster reading times with both, AV+EventN and N-AV+EntityN, suggest that in both cases processing might be facilitated by the fact that the parser encounters what it expects, that is, the complement whose type matches the selectional restrictions of the predicate. What we can conclude from the bias for EntityNs after N-AVs is that N-AVs select for EntityNs as their ‘preferred’ arguments in contrast to EventNs.

Notably, the predicted 3-way contrast in (8) also involves a slow-down for the AV+EntityN condition, which we did not find, as opposed to Traxler et al. (2002). The AV+EntityN condition (green) and the N-AV+EventN condition (blue) did not differ: they were both significantly slower than the AV+EventN condition (red). This null result means that in our experiment coercion was no more costly than the combination of N-AVs with EventNs. We have just said that N-AVs combine with EventNs as their ‘less preferred’ complements, so does our null result suggest the same for AVs with EntityNs? Given the wide range of prior experiments showing extra cost for coercion contexts beyond the cost of the dispreferred combinations (e.g., McElree et al. (2001) discussed in section 3), we speculate that the absence of the extra cost in the AV+EntityN condition in our experiment results from the fact that we increased our participants’ exposure to coercion contexts by combining the two sub-experiments. The processing of coercion became easier, at the same time, however, new differences became exposed, namely that both AVs and N-AVs create a bias for a particular semantic type of their nominal complement.

#### 4.2. Sub-Experiment 2

The goal of this sub-experiment was to test the assumption of the Dimension Ambiguity approach that the EntityNs as complements to AVs are ambiguous between different dimensions along which the event could be structured. This predicts that the ease of identification of a particular dimension will affect the ease of processing of AV+EntityN combinations and that in the absence of ambiguity between dimensions, i.e., with N-AVs, no processing costs should be observed. As explained at the beginning of section 4, we compared two kinds of EntityNs available in Polish that differed in the likelihood of a temporal interpretation and thus should result in two different processing profiles. The first kind were morphologically simple nouns (SimpleNs) which denoted physical objects (e.g. *kolekcja* ‘collection’), and thus should give rise to dimension ambiguity as complements to AVs vs. N-AVs. The ambiguity should elicit longer RTs already at the noun region.

The second kind were morphologically complex nouns (ComplexNs) (e.g. *zbiór* ‘set’, ‘collection’) containing verbal roots (verb: *zbierać* ‘to collect’) which also denoted entities, but in some cases could have a subordinate event-reading (we should note here that these nouns were not nominalizations, cf. *zbieranie*). We hypothesized that ComplexNs might contrast with SimpleNs in that they would more readily allow the selection of the temporal dimension in the context of AVs. What is special about AVs on the Dimensional Ambiguity approach is that they require the identification of a particular dimension, which needs to happen with both ComplexNs and SimpleNs. With ComplexNs, however, this could be easier because the temporal dimension could be easier to access due to the verbal root (and the secondary eventive reading for some of the items). Accordingly, we should find the following three-way contrast:

$$(13) \quad \text{AV+SimpleN} > \text{AV+ComplexN} > \text{N-AV+ComplexN}, \text{N-AV+SimpleN}$$

The alternative approach, Enriched Composition, makes two kinds of predictions: nouns with verbal roots may be more ready to participate in the entity-to-event semantic shift, (14); or

alternatively, the semantics of the verbal root may not be able to override the semantics resulting from the nominal morphology, (15) (this is a more compositional version of the approach).

- (14) AV+SimpleN > AV+ComplexN, N-AV+ComplexN, N-AV+SimpleN  
type-mismatch > type-match (assuming access to the event semantics of the verbal root of ComplexNs)
- (15) AV+SimpleN, AV+ComplexN > N-AV+ComplexN, N-AV+SimpleN  
type-mismatch > type-match (assuming **no** access to event semantics of the verbal root of ComplexNs)

#### 4.2.1. Materials and procedure

We constructed 24 items in four conditions: AV+SimpleN, AV+ComplexN, N-AV+SimpleN, N-AV+ComplexN. We selected 24 SimpleN–ComplexN pairs that minimally differed in meaning. For instance *zbiór* ‘set’, ‘collection’ is usually used in reference to the mathematical object while *kolekcja* is not; both, however, can be used to refer to a gathering of valuable items, e.g., in a museum. We were able to construct 24 such pairs, and tried to match their members in terms of frequency, although this was not always possible. For example, a corpus can provide the frequency of use in the formal register, but some members in the pairs were very colloquial and frequent in everyday contexts (e.g., *jedzonko* ‘goodies’, ‘food’ has only 571 hits in the monitor corpus of Polish (<http://monco.frazeo.pl/>), whereas *potrawa* ‘dish’, ‘plate’, ‘meal’ has 4033 hits because it is frequently used in written recipes). In the appendix, we provide the list of the ComplexN–SimpleN pairs indicating if there is a difference in their usage frequency.

Furthermore, five of the ComplexNs have a dominant entity-reading, as well as a secondary event-reading. The latter is hardly available for those words presented in isolation, but can be made explicit by adding some minimal context (e.g., *zbiór truskawek* ‘strawberry picking’ or ‘*Zbiór trwał 2 godziny*’ ‘The gathering lasted 2 hours’). Those five nouns were: *zbiór* ‘set’, *wydruk* ‘printout’, *przesyłka* ‘package’, *okop* ‘trench’, *opowieść* ‘story’. There were six ComplexNs which cannot have event readings, *budynek* ‘building’, *zapalka* ‘matchstick’, *rysunek* ‘drawing’, *rzeźba* ‘sculpture’, *napój* ‘drink’, *mrożonki* ‘frozen food’, as evidenced by the fact they cannot appear in the frame ‘*X lasted 2 hours*’. The rest of the ComplexNs denote the results of activities, e.g. *napar*, ‘infusion’, and if they appear in our test frame, they start denoting events but those readings are odd unless more supporting context is present.

Crucially, ComplexNs contained roots that are related to the verbs implicit in the event recovered in the coercing contexts and not any other verbs (compare how in English ‘*John began the queue*’ refers to a queueing event, whereas ‘*John began the pullover*’ means that John started making a garment named *pullover* and not that he started pulling the garment over himself).

We used the same set of verbs as in Sub-Experiment 1.<sup>6</sup> The procedure and the treatment of the data for statistical analysis was as described in section 4.1.1.

#### 4.2.2. Results

The plot of the reading data in Figure 2 shows that already on the verb there were differences in reading times, with the N-AV+SimpleN condition being the slowest (the purple line in the plot). We found a main effect of NP-Type in this region ( $\beta = .073$ ,  $SE = .03$ ,  $t = 2.442$ ,  $p = .015$ ) and a marginal interaction ( $\beta = -.08$ ,  $SE = .043$ ,  $t = -1.748$ ,  $p = .08$ ). The main effect (the N-AV+SimpleN and N-AV+ComplexN conditions are significantly slower than the AV+SimpleN and AV+ComplexN conditions) is clearly driven by the slow reading times for the the N-AV+SimpleN condition. A four-way comparison reveals that N-AV+SimpleN (purple) condition is significantly slower than the N-AV+ComplexN (blue) condition ( $\beta = -.073$ ,  $SE = .03$ ,  $t = -2.393$ ,  $p = .019$ ) but is not significantly slower than the other two conditions. This result is mysterious because the subject and the verb in the N-AV+SimpleN and N-AV+ComplexN conditions were identical, so the reading times should be no different (as is the case in Sub-Experiment 1 – the sets of verbs in both experiments was identical).<sup>7</sup>

Figure 2: Sub-Experiment 2. Average Log-Transformed Residual Reading Times.

At the noun region there was a significant interaction between Verb-Type and NP-Type ( $\beta = -.113$ ,  $SE = .051$ ,  $t = -2.212$ ,  $p = .031$ ) and a main effect of Verb-Type ( $\beta = .073$ ,  $SE = .035$ ,  $t = 2.072$ ,  $p = .04$ ), but no effect of NP-Type ( $\beta = .053$ ,  $SE = .039$ ,  $t = 1.354$ ,  $p = .18$ ). A four-way comparison revealed that the AV+ComplexN condition (the red line in the plot) was significantly slower than the N-AV+ComplexN condition (blue) ( $\beta = -.074$ ,  $SE = .039$ ,  $t = -2.129$ ,  $p = .036$ ) and marginally slower than the AV+SimpleN condition (green) ( $\beta = -.06$ ,

<sup>6</sup>Therefore, we needed to remove two items with the verb *forget* as explained in footnote 4. We also removed one item with a typo in the verb.

<sup>7</sup>We excluded the possibility that an outlier was driving this effect or that the slow-down accumulated over the course of the experiment for some reason: in Appendix A we present a boxplot and the distribution of RTs over the course of the trials showing that the RTs in the N-AV+SimpleN condition are slower at the beginning of the experiment.

$SE = .034$ ,  $t = -1.683$ ,  $p = .09$ ). This means that ComplexNs are harder with AVs than with N-AVs and that after reading an AV, a ComplexN is harder to process than a SimpleN.

At the regions of the subject and the adverbial, there were no significant differences in reading times.

#### 4.2.3. Discussion

The experiment showed that ComplexNs are harder with AVs than with N-AVs, while SimpleNs are equally hard with both kinds of verbs (though the result that N-AV+SimpleN condition is so slow may be an artifact given the oddly high RTs at the verb). Additionally, ComplexNs are harder to process than SimpleNs following AVs. The differences in reading times can be summarized as follows:

- (16) AV+ComplexN, (N-AV+SimpleN) >  
(N-AV+SimpleN), AV+SimpleN, N-AV+ComplexN

The greatest processing cost occurred in the AV+ComplexN condition (red), and this condition was significantly slower than the N-AV+ComplexN condition (blue), and marginally slower than the AV+SimpleN (green). We predicted that AVs+ComplexNs would elicit the processing profile of ‘biased’ ambiguities (as identified in Rayner and Duffy (1986); see introduction to section 4), such that the RTs at the noun region would be faster than with SimpleNs and slower RTs would emerge at the post-target region. This prediction was not borne out, hence, we conclude that the ambiguity was not processed, possibly because the morphological complexity prevents access to the verbal root during semantic composition. Since there was no significant difference between the N-AV+ComplexN (blue) and the AV+SimpleN (green) conditions with respect to the AV+ComplexN condition (red), we can infer that morphological complexity without coercion (blue) is as hard to process as regular nouns with coercion (green).

The RTs in the N-AV+SimpleN condition (purple) are difficult to interpret, due to the mysteriously high RTs at the verb region which carry over to the noun region. It needs to be pointed out, however, that the difference between N-AV+SimpleN condition (purple) and N-AV+ComplexN condition (blue) is not significant, suggesting that in the absence of an AV there is no special cost for morphological complexity (while the cost in the AV+ComplexN condition (red) is evidenced by significantly longer RTs than in the N-AV+ComplexN condition (blue)). Accordingly, we place the N-AV+SimpleN condition in parentheses in (16).

Since the items from Sub-Experiment 2 were intermixed with the items from Sub-Experiment 1 we can conclude that the participants were sensitive to the semantic differences between the entity-denoting and event-denoting complements and the need for coercion in the context of AVs. Therefore, the fact that Sub-Experiment 2 showed the largest processing cost in the coercion condition with morphologically complex nouns seems to indicate that real-time comprehension semantic composition has no access to the morphological structure below the word level. This result is compatible with the predictions of the Enriched Composition approach in (15) where direct compositionality does not allow access to the semantics of the root inside a

complex noun (recall that ComplexNs were not nominalizations). The predictions in (15) distinguish between the conditions with type-match and those with type-mismatch, but we found that morphological complexity adds to the cost of type-mismatch.

The result is also compatible with the predictions of the Dimensional Ambiguity approach, because the fact that the AV+SimpleN condition was not the hardest to process as predicted in (13), could be due to the easier resolution of dimension ambiguity in this condition than in the AV+ComplexN condition. As opposed to what we hypothesized, morphological complexity does not facilitate the selection of a dimension appropriate to the semantics of the verb.

## 5. General discussion

Our experiment showed that AVs with EventNs (*'begin a fight'*) and N-AVs with EntityNs (*'see a book'*) were easier to process than AVs with EntityNs (*'begin a book'*) and N-AVs with EventNs (*'see a fight'*). This result indicates that processing is easier when the parsing expectations created by the predicate are met. AVs create an expectation for EventNs, which is unsurprising if they specifically select for them. N-AVs, on the other hand, are semantically compatible with both EntityNs and EventNs as their argument, yet EntityNs appear to be preferred over EventNs (at least in Polish). The assumption of the Dimensional Ambiguity hypothesis, that what is at stake for AVs in coercion contexts is the difficulty of identifying the specific dimension along which the complement is construed as a structured individual, cannot account for the fact that the AVs+EventNs and N-AVs+EntityNs are easier to process. However, a theory based on selectional restrictions allows us to explain why these combinations facilitate processing. We should note here that our experimental setup with the increased exposure to coercion contexts (25% of the sentences in the whole experiment) resulted in the absence of a special processing cost for the AV+EntityN condition. Yet, the obtained results clearly show that predicates impose semantic restrictions on their arguments, which supports the Enriched Semantic Composition hypothesis. A theory based on selectional restrictions can also accommodate the result that N-AVs such as *see* combine with both EntityNs and EventNs but are easier to process with the former. This result is in line with the findings in Spalek (2014), who has shown that verbs select for a variety of semantic types of complements, where some of those types are the primary ones while others can be considered secondary but still not anomalous.

Selectional restrictions have been the subject of a longstanding discussion at least since Katz and Fodor (1963) and later Chomsky (1965), who incorporated them as part of grammar in an attempt to express limitations on the applicability of predicates to arguments. Two major questions have been at stage ever since: 1) whether selectional restrictions should be treated as a lexical semantic property or as a matter of world knowledge, and 2) how rich and rigid the inventory of selectional restrictions should be. Our results contribute to this discussion by showing that the idea of incorporating conceptual knowledge into compositional semantics through the notion of selectional restrictions of predicates is fundamentally right, but should be refined by taking into account combinatorial preference patterns. On the basis of our findings we can conclude that AVs differ from N-AVs in that they impose a strong selectional constraint for event nouns, whereas N-AVs have merely a preference for entity-denoting nouns but also

combine with event nouns. Our results suggest that a graded notion of selectional satisfaction conditions as mentioned in the work of Wilks (1978) is more appropriate. We propose that the satisfaction conditions of a predicate should be understood as a graded continuum of highly typical arguments and less probable arguments and should thus be called more appropriately ‘selectional preferences’. Accordingly, the degree to which various selectional (mis)matches will be judged as semantically anomalous will vary since they do not result from a violation of hard constraints (Resnik, 1996).

# Conjoining imperatives and declaratives<sup>1</sup>

William B. STARR — *Cornell University*

**Abstract.** This paper investigates conjoined imperatives and declaratives (IaDs). It argues that some IaDs are best explained in terms of true conjunction and anaphora between conjuncts, despite challenges posed by von Fintel and Iatridou (2017). The key to addressing these challenges is a dynamic, non-modal analysis of imperatives building on Starr (to appear). The other IaDs are explained by appeal to a semantically related use of *and*, e.g. ‘left-subordinating *and* (*LSand*)’ (Culicover and Jackendoff 1997). These other IaDs neutralize the directive meaning of the imperative, and this paper offers a new account of this building on ‘parameter-change conjunction’ (Klinedinst and Rothschild 2012). New data is presented that helps distinguish between the varieties of IaD, and it is shown that the proposed analysis captures it.

**Keywords:** Conjunction, imperatives, dynamic semantics, anaphora, discourse relations

## 1. Dividing IaDs and the von Fintel and Iatridou (2017) challenge

Imperative meaning bears on deep theoretical questions about the nature of meaning, especially given standard commitments inherited from the logical tradition that informs contemporary formal semantics. As Frege (1923) comments, and Dummett (1973: Ch.10) later detailed, truly conjoined imperatives and declaratives do not fit with the standard assumptions of formal semantics where all meaning, especially the meaning of connectives, is purely truth-conditional — at least not without assimilating imperatives and declaratives. Dummett (1973: Ch.10) argues that English does not permit such a construction, and that all attempts result in ‘non-compositional conditional meanings’. Philosophers now have the benefit of an extensive, sophisticated empirical literature on these constructions.<sup>2</sup> I will draw on the insights of this literature and new data to argue against Frege (1923) and Dummett (1973: Ch.10): natural languages contain truly conjoined imperatives and declaratives, and conditional meanings arise in a principled, compositional manner that is not specific to imperatives. The catch is that one must adopt a dynamic semantics that departs from the assumption that connectives have only truth-conditional meaning.

As a preliminary, it is important to observe that while the compositional issues surrounding classic IaDs like (1) are unresolved, it is a mistake to draw any general conclusion about these issues just from IaDs. As argued by Starr (to appear), conjunctions with the opposite order like (2) establish that imperatives and declaratives compositionally combine via true conjunction.

(1) Make tortillas and I’ll serve them.

(2) I love you and don’t (you) forget it.

---

<sup>1</sup>I thank the following for their generous help with this project: Maria Biezma, Ezra Keshet, Kai von Fintel, Sarah Murray and the organizers and audience members at *Sinn und Bedeutung* 21.

<sup>2</sup>E.g. Bolinger (1979); van der Auwera (1986); Clark (1993); Lascarides and Asher (2003); Txurruka (2003); Franke (2005); Russell (2007); Asher (2007); Franke (2008); Scontras and Gibson (2011); Kaufmann (2012); Keshet (2013); von Fintel and Iatridou (2017), among others.

Examples like (2) are strong evidence against Dummett's (1973: Ch.10) hypothesis — more recently entertained by Franke (2005) and von Fintel and Iatridou (2017) — that *all* conjunctions of imperatives and declaratives involve a special conditional meaning of *and*.<sup>3</sup>

The literature now recognizes three kinds of IaDs, exemplified by (3a)-(5a).<sup>4</sup>

- (3) a. Make tortillas and I'll make chile. (endorsed-IaD)  
 b.  $\left\{ \begin{array}{l} \#So \\ \#But \end{array} \right\}$  don't make tortillas
- (4) a. Screw up the tortillas and I'll rub a chile in your eye. (not endorsed-IaD)  
 b.  $\left\{ \begin{array}{l} So \\ \#But \end{array} \right\}$  don't screw up the tortillas.
- (5) a. Make tortillas and you'll need flour. (not endorsed-IaD)  
 b.  $\left\{ \begin{array}{l} \#So \\ But \end{array} \right\}$  don't make tortillas, it'll make a mess.

(3b)-(5b) are my own contribution to the literature. Previously, examples like (3a) have been described as endorsing the directive conveyed by the imperative conjunct, and so called e-IaDs. Examples like (4a) and (5a) were described as not endorsing the imperative conjunct, and so called n-IaDs. Further, it was noted that examples like (4a) convey a negative evaluation of following the imperative while examples like (5a) present the imperative neutrally. These semi-theoretical descriptions have not been accompanied by a clear empirical diagnostic. While Culicover and Jackendoff (1997) and Kaufmann (2012) observe that *please* can felicitously (and non-sarcastically) occur in examples like (3a) but not in examples like (4a) and (5a), this does little to explain the contrast between (4a) and (5a). I propose that the follow-ups in (3b), (4b) and (5b) can provide just such an empirical diagnostic.

The fact that there is a felicitous way of following up the imperative conjunct with its contrary in (4b) and (5b) shows that the imperative conjunct cannot have directive force. Similarly, the infelicity in (3b) shows that the imperative conjunct does have directive force. Further, the difference between the felicity of *but* and *so* in (4b) and (5b) shows that the non-endorsement of the imperative conjunct is different. The undesirable state of affairs brought about by following the imperative in (4a) invites the inference that the contrary directive should be followed — hence *so* in (4b). The unavailability of *but* follows naturally from this: since the contrary directive (*Don't screw up the tortillas*) follows from what (4a) says in context, its issuance does not contrast with expectations in the way that *but* requires. For (5a), the imperative appears to neutrally introduce the prospect of an action, making it infelicitous to claim with *so* that the contrary imperative follows. It is, however, felicitous to contrast the contrary imperative using *but* since the directive meaning of (5a)'s imperative does not escape the conjunction.

<sup>3</sup>This hypothesis also makes it more awkward to explain the syntactic findings of Scontras and Gibson (2011) which indicate that there are systematic syntactic differences between Type I and Type II IaDs.

<sup>4</sup>See especially Clark (1993), Russell (2007) and von Fintel and Iatridou (2017).

Given these empirical diagnostics and the explanations they suggest, the overall shape of Kaufmann's (2012: Ch.6) divided analysis seems appealing:

### Divided Analysis

1. Type I IaDs like (3a) involve true conjunctions that allow the directive meaning to emerge, and the second conjunct's modal is contextually restricted to worlds where the imperative has been followed.
2. Type II IaDs like (4a) and (5a) involve a semantically distinct connective *LSand* (Culicover and Jackendoff 1997) which effectively traps the imperative meaning in the antecedent of a conditional.

The appeal of a Divided Analysis is strengthened by a recent study which finds systematic syntactic differences between Type I and Type II IaDs (Scontras and Gibson 2011). The conditional, non-directive meaning of Type II IaDs can be explained in terms of *LSand* (Culicover and Jackendoff 1997; Klinedinst and Rothschild 2012), the scope-based analysis of modals and conjunction called *conditional conjunction* (Keshet 2013) or an approach based on a conditional discourse relation being associated with *and* in particular syntactic environments and discourse contexts (Lascarides and Asher 2003). For Type I IaDs, the question is how exactly the modal *will* in the second conjunct is restricted to worlds where the imperative has been followed. Kaufmann (2012: Ch.6) and Lascarides and Asher (2003) treat it as a kind of modal subordination, as in *You should make tortillas and I'll make chile*. Here, the speaker only commits to making chile *if* the addressee makes tortillas. The second modal is interpreted in a way that is subordinated to the first: it is restricted to worlds where the prejacent of the first modal is true. But this appealing approach faces an important problem raised by von Fintel and Iatridou (2017: §3.1): Type I IaDs are felicitous where explicit modal subordination is not. This, of course, throws into doubt the attempt to derive the conditional meaning of Type I IaDs through modal subordination.

Modal subordination is the general phenomenon by which one modal is taken to be restricted to worlds where the prejacent of an earlier modal holds (Roberts 1989). For example, the modal *would* in (6a) is taken to be restricted to worlds where a wolf has wandered in, rendering (6a) and (6b) equivalent.

- (6)    a.    A wolf might wander in. It would eat you.  
          b.    If a wolf wanders in, it would eat you.

Von Fintel and Iatridou (2017: §3.1) observe that while (7a) is felicitous, an exactly parallel explicit case of modal subordination is not felicitous in (7b).

- (7)    a.    Invest in this company and you will become rich.  
          b.    #You must invest in this company and you will become rich.

As they note, the infelicity of (7b) could be explained by the general fact that conjunction prohibits the right conjunct from explaining the left (Txurruka 2003):

- (8) a. Gabe is not allowed in the tent. He will get it dirty.  
 b. #Gabe is not allowed in the tent and he will get it dirty.

Von Fintel and Iatridou (2017: §3.1) rightly observe that this only explains why (7b) is infelicitous, not why (7a) is felicitous. Further, von Fintel and Iatridou (2017) challenge a modal subordination analysis to explain the contrast in (9a) and (9c).

- (9) a. Don't park there! You'll be towed.  
 b. = Don't park there! If you park there, you'll be towed.  
 c. ≠ Don't park there and you'll be towed.

The puzzle is that if modal subordination allows (9a) to be interpreted as (9b), and Type I IaDs like (9c) involve modal subordination, then why doesn't that modal subordination allow the same 'polarity switched' interpretation? Fortunately for the Divided Analysis, I believe these puzzles can be answered. However, it requires abandoning the idea that imperatives are modals, appealing to a more general mechanism of modal anaphora rather than the specific mechanism of modal subordination and investigating the discourse relations that support modal anaphora.

## 2. Meeting the challenge

Von Fintel and Iatridou (2017: §3.1) give the impression that modal subordination across *and* is always degraded with an explicit deontic modal in the first conjunct.<sup>5</sup> But there is no degradation in conjunctions that don't involve a discourse relation of explanation:

- (10) a. Contact your superior and she will explain your next mission.  
 b. You must contact your superior and she will explain your next mission.

Investigating these good examples, and comparing them to the bad ones yields deeper insight. However, the most important ingredient for understanding these conjunctions is the temporal differences between simple imperatives and modals.

Modals, unlike imperatives, involve *two* eventualities: both of the modality holding — the requirement of contacting your superior — and of the described eventuality — contacting your superior.<sup>6</sup> Crucially, it is the modal eventuality which serves as the argument of higher operators. This is evident with adverbials, which are notoriously sensitive in the same way. The contrast observed by Gärtner (2017) regarding adverbial modifications of imperatives and deontic modals is telling:

- (11) a. #Usually, contact your superior.  
 b. Usually, you must contact your superior.

<sup>5</sup>See von Fintel and Iatridou (2017: fn15) where they grant the existence of naturally occurring examples, but maintain that they are degraded.

<sup>6</sup>To be more precise, modal sentences involve three eventualities and imperatives two, since both also involve the utterance event itself. It is arguably this eventuality that is involved in the interpretation of indexicals like *now* and 'metatalk' discourse relations.

Adverbs like *regularly* that scope low do not exhibit this contrast:

- (12) a. Contact your superior regularly.  
b. You must contact your superior regularly.

Together, this suggests that imperatives differ fundamentally from necessity modals in that they do not make the necessity itself available as an eventuality to other operators. This insight is directly relevant to IaDs, since discourse relations are fundamentally temporal, and are sensitive to the eventualities topicalized by the conjuncts. In particular, it follows that conjunctions with a modal conjunct will be infelicitous where the corresponding IaDs are felicitous because the discourse relations are relating *different eventualities*. The challenge, then, is to explain why this leads to different behavior in (7) and (10).

Let me first explain why (7a) is felicitous and (7b) is not.<sup>7</sup>

- (7) a. Invest in this company and you will become rich.  
b. #You must invest in this company and you will become rich.

Von Stechow and Iatridou (2017) are on the right track when they say that (7b) is not felicitous because it attempts to combine an explanation relation with conjunction. But, crucially, that failed explanation interpretation relates *the state of being required to invest* and you becoming rich. No such interpretation is possible for (7a) since the imperative, as detailed above, does not make that state salient. This general limitation is made clear by (13).

- (13) ??Invest in this company because you will become rich.

It is perhaps useful to note that (13) is not anomalous because of a general problem with imperatives and *because*:

- (14) Donate blood because our reserves are low.

Further, it is often felicitous to explicitly assert an explanation relation for a modal, where it is infelicitous with an imperative.

- (15) a. ??Report for duty because your contract requires you to.  
b. You must report for duty because your contract requires you to.

All of this evidence suggests that (7a) does not involve an explanation relation, even though (7b) does. (7a) instead involves the relation RESULT.<sup>8</sup> (16a) makes this point clear, while (16b)

<sup>7</sup>Throughout, I will assume familiarity with the basic discourse relations discussed by Kehler (2004), Asher and Lascarides (2003) and Hobbs (1985). While I will follow the general definitions from Kehler and Hobbs, I will assume with Asher and Lascarides (2003) that fully adequate definitions must appeal to eventualities rather than just propositions. Please see these references for further details.

<sup>8</sup>RESULT is typically defined as follows (Kehler 2004: 247): where  $S_1$  and  $S_2$  are the related sentences, infer  $P$  from the assertion of  $S_1$  and  $Q$  from the assertion of  $S_2$ , where normally  $P \rightarrow Q$ . To generalize to where  $S_1$  is an imperative, appealing to eventualities helps:  $e_1$  is the topical eventuality of  $S_1$  and  $e_2$  of  $S_2$ , where normally

shows that such an interpretation with the explicit modal would be anomalous.

- (16) a. Invest in this company and, as a result, you will become rich.  
 b. ??You must invest in this company and, as a result, you will become rich.

The anomaly in (16b) lays bare the situation. Of course (16b) is not felicitous on the same reading as (16a), since that would amount to saying that your riches will result from the state of being (prudentially) required to invest in the company. In short, the contrast von Fintel and Iatridou (2017: §3.1) offer between (7a) and (7b) is manufactured by two different discourse relations, and the complication that imperatives and modals make different eventualities available to those discourse relations. No general point about modal anaphora between conjuncts follows from this though. von Fintel and Iatridou (2017: §3.1) are absolutely right that this anaphoric dependence cannot be assimilated to modal subordination in the strict sense. But this does not preclude a more general *modal anaphora* approach whereby the *will* of the second clause anaphorically retrieves a restriction on its domain from the first clause.

So much for the contrast in (7). What about the lack of any such contrast in (10)? Unlike (7), (10) involves the same discourse relation in the imperative and modal variants, and, somehow, this interpretation works for both variants. (10) clearly involves the relation of OCCASION (Kehler 2004: §3.1.3, Hobbs 1985: 10). Since this relation is a bit more complex, let me explain more precisely what it is. Kehler (2004: 242) offers (17a) as a paradigm example of OCCASION, while (17b) illustrates the limits of OCCASION.<sup>9</sup>

- (17) a. George delivered his tax plan to Congress. The Senate scheduled a debate for next week.  
 b. ?George delivered his tax plan to Congress. The Senate scheduled hearings into former President Clinton's pardon of Marc Rich.

The crucial feature in (17a) is that elements of a complex situation through an intermediate state of affairs that serves to connect two parts of that complex situation: the state where the tax plan has been delivered to the Senate connects that delivery, and the scheduling of the debate. Unlike RESULT this relation can be much more complex and nuanced than cause/effect or defeasible entailment. For example, the tax plan could only be a very small and minor component of the debate, but procedurally required for scheduling the debate. This highlights how domain knowledge, such as protocol, can inform the inference of OCCASION. (17b) makes clear that this is a substantive constraint. When there is no perceived script (prototypical chain of events) connecting the two events, this discourse is not coherent.

*Causes*( $e_1, e_2$ ) — *Causes* is a non-monotonic conditional-like operator (Asher and Lascarides 2003).

<sup>9</sup>OCCASION between  $S_1$  and  $S_2$  is typically defined as: (i) a change of state can be inferred from the assertion of  $S_1$ , whose final state can be inferred from  $S_2$ ; or (ii) a change of state can be inferred from the assertion of  $S_2$ , whose initial state can be inferred from  $S_1$  (Hobbs 1985: 10). Here, the terms of 'final' and initial should be understood in terms of prototypical sequences of events, given relevant domain knowledge. I will generalize this by understanding OCCASION as follows: (i)  $e_1$  is the topical eventuality of  $S_1$ ,  $e_2$  is the topical eventuality of  $S_2$  and  $e_1$  results in a change of state whose final state results from  $e_2$ ; or (ii)  $e_1$  is the topical eventuality of  $S_1$ ,  $e_2$  is the topical eventuality of  $S_2$  and  $e_2$  results in a change of state whose initial state results from  $e_1$ .

Returning now to imperatives, Hobbs (1985: 10) actually offers the imperatives in (18) as a paradigm illustration of OCCASION at work:

- (18)    a.    Walk out the door of this building.  
           b.    Turn left.  
           c.    Go to the corner.

A complex situation, namely the sequence of actions needed to get the addressee to a specific location, is explained through a series of intermediate states of affairs that connect the events described by each sentence. The imperative (18a) introduces a change of location whose result holds during the event described in the next imperative (18b), and similarly for (18b) and (18c). This helps clarify that OCCASION is often at work with imperatives, and the fact that *and* could be placed between these sentences makes clear that conjunction is compatible with *and*. It also further clarifies that OCCASION is very different from RESULT in that it needn't involve a cause/effect relationship. With all this in mind, let us consider why OCCASION supports both variants in (10).

- (10)    a.    Contact your superior and she will explain your next mission.  
           b.    You must contact your superior and she will explain your next mission.

The operation of OCCASION in (10a) is clear enough. The causal result of contacting your superior produces a state that leads to the goal of the discourse: an informed agent. But, how does OCCASION work in (10b), given that the first conjunct topicalizes the state of being required to contact your superior, rather than the event of you contacting them? The prototypical result of that requirement is fulfillment, which connects the conjuncts as before. The reliance on prototypical sequences of events allows OCCASION this inferential flexibility.

As Kehler (2004) and Hobbs (1985) highlight, OCCASION is highly sensitive to surprising nuances of human cognition and discourse goals. From the infelicity of (7b), we can infer that there is no relevant prototypical sequence of events connecting a prudential requirement to invest and becoming rich that satisfies the agents' domain goals. On reflection, that is an independently plausible description of the natural context for (7). The discourse goal, presumably, is for the speaker to convince an undecided hearer to invest. This means that there is no shared 'final state' which OCCASION can target with a prototypical chain of events. On reflection, it is clear that (10) involves a case where speaker and hearer have a shared 'final state', allowing the speaker to invoke a prototypical chain of events culminating in that final state. While these nuanced differences are easy to miss when studying isolated examples, they are precisely the details that form the natural habitat of human discourse.

One more piece of data from von Stechow and Iatridou (2017: §3.1) needs to be addressed: the polarity switch contrast in (9a) and (9c).

- (9)    a.    Don't park there! You'll be towed.  
           b.    = Don't park there! If you park there, you'll be towed.  
           c.    ≠ Don't park there and you'll be towed.

It has been established thus far that modal anaphora between conjuncts is very much a live explanation of Type I IaDs. From this perspective, (9a) involves complement anaphora. But then (9c) is exactly what one expects, given that complement anaphora is known to be incompatible with conjunction (Nouwen 2003).

- (19) a. Few congressmen admire Kennedy. They think he's incompetent.  
 b. #Few congressmen admire Kennedy and they think he's incompetent.

This means that a fully general theory of modal anaphora can appeal to the same mechanisms at work in (19) to explain (9), all while sticking with an explanation of Type I IaDs on which the second conjunct anaphorically retrieves a proposition made salient by the first conjunct. I now turn to that analysis.

### 3. Preference semantics with modal anaphora

This section will adapt the dynamic preference semantics from Starr (to appear) to offer analyses of Type I and Type II IaDs. After introducing this basic analysis of imperatives and connectives in §3.1, I will turn to Type I IaDs in §3.2 and Type II IaDs in §3.3. There are three key innovations in these sections. The first is to model the process by which modal anaphora generates a conditional meaning in Type I IaDs. The second is to model the meaning of *LSand* in a way that neutralizes the directive meaning of the first conjunct. The third is capturing the fact that negative Type II IaDs seem to entail the prohibition of the first conjunct. In particular, it will be shown that this can be captured as a simple contextual entailment on a dynamic preference semantics. Together, these innovations explain the basic data of (3)-(5) from §1. Throughout this section, my presentation of the semantics will aim only to convey the basic ideas and innovations. Full formal definitions are reserved for Appendix 4.

#### 3.1. Preference semantics for imperatives

The data discussed so far places non-trivial restrictions on the kind of imperative semantics that can be used to explain IaDs. The data discussed in §2 are problematic for modal analyses like Kaufmann (2012) and Aloni (2007). This problem is avoided by static non-propositional analyses like Portner (2004) and Roberts (2015) which assign imperatives and declaratives to distinct semantic types and to distinct pragmatic context update rules. As Starr (to appear) argues in detail, those two commitments make it impossible to adequately capture conjunctions like (2) and other related examples. Starr (to appear) addresses this limitation by adopting a dynamic preference semantics for imperatives. A dynamic semantics also makes capturing the anaphoric dynamics within a conjunction far easier. The basic idea of this dynamic semantics for imperatives is simple: !A introduces a preference for A-worlds over ¬A-worlds.<sup>10</sup> This basic idea can be represented graphically as in Figure 1. Here, worlds are dots with a capital letter indicating truth and lowercase falsity and preferences are indicated with complimentary pairs

<sup>10</sup>While Portner (2004) has the primary pragmatic effect of imperatives to be the update of a To-do List, a secondary effect is that the To-do List is used to generate an ordering of worlds from the context set. By contrast, the account here has the primary semantic meaning of imperatives be an update on an ordering. Having an ordering over sets of worlds affords a useful resource for conditional imperatives (Starr to appear).

Figure 1: Imperative and Declarative Updates

of colors. The warm color of the pair is used for the preferred alternative. This makes clear that the meaning of imperatives is dynamic: its meaning is specified in terms of how it changes a preference relation  $r$ . It also clarifies how imperatives and declaratives differ. A declarative  $\triangleright B$  would eliminate  $\neg B$ -worlds entirely.

Formally, a preference relation is a set of pairs of propositions:  $r = \{\langle p_1, p_2 \rangle, \dots, \langle p_n, p_m \rangle\}$ . The context set is reconstructed by unioning all of the ranked alternatives:  $c_r = \bigcup (\text{dom } r \cup \text{ran } r)$ .  $r_0$  simply ranks all the worlds over the empty set:  $r_0 = \{\langle \{w_{AB}, w_{Ab}, w_{aB}, w_{ab}\}, \emptyset \rangle\}$ . So  $!A$  changes  $r$  to  $\{\langle p_1, p_2 \rangle, \dots, \langle p_n, p_m \rangle, \langle c_r \cap \llbracket A \rrbracket, c_r - \llbracket A \rrbracket \rangle\}$ , while the declarative  $\triangleright A$  will eliminate  $\neg A$ -worlds from each proposition ranked in  $r$ . On this approach,  $[\phi]$  is the meaning of  $\phi$ , applying to  $r$  to yield  $r'$ :  $r[\phi] = r'$ .<sup>11</sup> To analyze disjunction, Starr (to appear) lifts the type of states to *sets of preference relations*, and calls them *preference states*. Since disjunction is not at issue here, I will present the system in the simpler form here.

In this framework, conjunction can be analyzed in the standard dynamic way, sequential update:  $r[\phi \wedge \psi] = (r[\phi])[\psi]$ . Unlike a static analysis like Portner (2004), this allows imperatives and declaratives to fluidly combine. It offers an immediate account of examples like (2) which would have the general form of  $\triangleright B \wedge !A$ . The result is depicted in Figure 2. This result plausibly

Figure 2: Update with a DaI (Declarative-and-Imperative)

gives the meaning of mixed conjunctions like (2), but not for Type I IaDs. Applying this analysis to (3a) does not capture the fact that it only commits the speaker to making chile in worlds where the addressee makes tortillas.

- (3) a. Make tortillas and I'll make chile.

<sup>11</sup>While I borrow the notation from Veltman (1996), this is not an update semantics in the technical sense defined by Veltman (1996): it is not generally true that  $r \subseteq r[!A]$ .

To capture this feature of (3a), one has to model the anaphoric relationship between the conjuncts. Further, since discourse relations mediate this anaphora and feature into the interpretation of conjunction itself, a more complex interpretation of *and* is needed. This will be addressed in §3.2. For now, I will turn to introducing some further details about this general approach to imperatives that will be used below.

In order to explain (3)-(5) from §1, it is necessary to define notions of support and consistency for imperatives. Developing these concepts in an adequate way is rather difficult for a non-propositional analysis. Static analyses like Portner (2004) do not provide adequate definitions of these concepts, but a dynamic preference semantics provides useful resources here (Starr to appear). Like other dynamic accounts (e.g. van Rooij 2000; van Benthem and Liu 2007; Portner 2012), I will model the logic of imperatives in terms of how they update an ordering of alternatives. Dynamic accounts of *informational support* ( $\models$ ) hold that  $c$  informationally supports  $\phi$  just in case updating  $c$  with  $\phi$  doesn't change  $c$  (e.g. Veltman 1996). This idea can be applied here by focusing on *preferential support*:

**Preferential Support**  $r \models \phi \iff r[\phi] = r$ .

This notion of support will be relied upon to explain the felicity (or lack thereof) for the *so* follow ups in (3b)-(5b). The basic idea is that  $\text{So}(!A)$  is felicitous just in case  $!A$  is preferentially supported by the preference relation that results from updating with prior discourse.

Preferential consistency is understood with an eye to the practical function of preferences: they are to motivate choices. Accordingly, inconsistent preferences are those that would not facilitate choosing an alternative. This is particularly clear when considering contrary imperatives, and the preferences they lead to, as depicted in Figure 3. The resulting preference relation

Figure 3: Contrary Imperatives Lead to Cyclic Preferences

$r_0[!B][!¬B]$  is irrational because it has a cyclic subset  $\{\langle b, \bar{b} \rangle, \langle \bar{b}, b \rangle\}$ . These preferences are irrational in a practical way: it would be defective for motivating choices because every alternative is worse than another. Starr (to appear) details the conditions preferences must have to be rational in this sense. For our purposes here, acyclicity is all that will matter. Preferential inconsistency simply requires that the sentences never lead to a rational preference relation:

### Preferential Inconsistency

$\phi$  and  $\psi$  are preferentially inconsistent just in case there is no  $r$  such that  $r[\phi][\psi]$  is rational. (See Starr to appear for the relevant definition of *rational*.)

This will be used to explain the infelicity of *but* follow-ups in (3b)–(5b). The basic idea is that  $\text{But}(\phi)$  is not felicitous when  $\phi$  is preferentially or informationally inconsistent with the prior sentences in the discourse.

### 3.2. Type I IaDs

There are a number of feasible ways to capture the anaphoric conditional meaning of *will* in the second conjunct. The analysis proposed here makes three key assumptions.

#### Essential Features of Analysis

1. !A introduces an eventuality or proposition — the event or proposition that A — that subsequent operators can anaphorically retrieve (Hobbs 1985; Lascarides and Asher 2003 and Murray and Starr to appear).
2. *Will* can anaphorically retrieve the eventuality or proposition introduced by !A to treat as its domain of universal quantification (Frank and Kamp 1997; Stone 1999; Stojnić 2016).
3. The anaphoric interpretation of *will* is mediated by inferred discourse relations (Hobbs 1985; Lascarides and Asher 2003; Stojnić 2016).

Since *will* has a partly temporal semantics, and discourse relations primarily relate eventualities, no analysis of IaDs will be complete without attending to temporal issues. However, doing so also introduces a number of complexities that are peripheral to the main project here. Accordingly, I will offer a purely modal analysis of *will* cast in a stack-based update semantics similar to Kaufmann (2000). This implementation choice introduces three inessential assumptions that are worth highlighting at the outset.

#### Inessential Implementation Features

1. Modals like *will* are tests (Veltman 1996).
2. *Will* expresses simple epistemic necessity with respect to  $c_r$  (Kaufmann 2000).
3. By default, *will* is anaphoric to the previously introduced modal topic.

It would be perfectly feasible to recast the basic analysis presented here within Kratzer's (1981) approach to modality, integrating temporality in any of a number of ways (Portner 2009: Ch.5). Or, one could treat *will* as having a purely temporal semantics and make use of the eventuality introduced by imperatives. Any analysis within these broad families could be made to fit with the general proposal that follows. On the third inessential feature, it is important to clarify that this is not presumed to be an empirically justified default, but rather an attempt to abstract from the complex details of anaphora resolution and discourse structure.<sup>12</sup> While this limits the empirical testability of the theory as stated, this is just as it should be. I am not attempting to predict particular anaphoric patterns here, but just show how to characterize the anaphoric interpretations when they do arise.

As highlighted above, I will treat  $\text{Will}(A)$  as a test that all of the worlds drawn from some

<sup>12</sup>For one plausible account of these complexities see Stojnić (2016).

contextually salient information source are worlds where A is true. If this test is passed, then the input  $r$  is returned; otherwise the empty relation results. On this approach,  $!A \wedge \text{Will}(B)$  should first introduce a preference for A-worlds and then test that all of these A-worlds are B-worlds. As Figure 4 shows, a preference relation like  $r_0$  fails this test but one like  $r_1$  passes it. As the diagram for  $r_1[!A \wedge \text{Will}(B)]$  makes clear, B only has to hold among the live A-worlds.

Figure 4: Type I IaDs

While this specifies the target interpretation, I have not said how it is compositionally produced. This is achieved by defining updates over *states*.

A state  $s = \langle r_s, d_s \rangle$  pairs a preference relation  $r_s$  with a tuple of modal discourse topics  $d_s = \langle p_i, \dots, p_j, c_{r_s} \rangle$ , which are just sets of worlds. The context set  $c_{r_s}$  is always a possible modal discourse topic, so  $d_s$  will always contain  $c_{r_s}$  — I reserve the last slot of  $d_s$  for  $c_{r_s}$ . Now, in addition to introducing a preference for A-worlds,  $!A$  will also append those A-worlds to the front of  $d_s$ .  $\text{Will}(B)$  can then anaphorically retrieve its domain from  $d_s[!A]$ : it tests that B holds throughout the first modal topic in  $d_s[!A]$ . This is laid out in Figure 5, which illustrates how  $\text{Will}(B)$  gains access to the A-worlds. This basic approach to the semantics also provides a

Figure 5: Anaphoric Interpretation of  $!A \wedge \text{Will}(B)$ 

way of capturing the anaphoric interpretation of imperatives themselves, as in (18). Of course, to make this a comprehensive analysis for any of the data presented here, one needs an actual theory of anaphora resolution rather than assuming that *will* is always anaphoric when it follows an imperative across *and* or a discourse segment. For conjunctions, this would involve specifying  $s[!A][DR_\wedge][\text{Will}(B)]$ , where  $DR_\wedge$  is a non-monotonically inferred discourse relation lexically compatible with *and* which specifies whether or not  $\text{Will}(B)$  gets interpreted in a state where the A-worlds are the first discourse topic. Non-anaphoric discourse relations could de-topicalize those A-worlds. The same style of analysis would work across discourse segments, where the lexical constraints on discourse relations are lifted.

Here's why (3b) is infelicitous. So! $\neg A$  is infelicitous after  $!A \wedge \text{Will}(B)$  because  $!\neg A$  is not preferentially supported by  $!A \wedge \text{Will}(B)$  in this context.  $!\neg A$  will add a preference for  $\neg A$ -worlds that  $!A \wedge \text{Will}(B)$  does not require to be present. But  $!\neg A$  is infelicitous after  $!A \wedge \text{Will}(B)$

because it requires at a minimum that  $!A \wedge \text{Will}(B)$  and  $! \neg A$  are preferentially consistent. But that leads to preferences like Figure 3 — the paradigm case of a preferential inconsistency.

### 3.3. Type II IaDs

The central challenge for Type II IaDs is to explain both how the conditional interpretation arises, and how the directive meaning of the imperative conjunct is neutralized. As Culicover and Jackendoff (1997) observe, these features also arise with some declarative conjuncts:

- (20) a. You drink another can of beer and I'm leaving.  
 b. Big Louie sees you with the loot and he puts out a contract on you.

Neither variant involves asserting the first conjunct, just as neither (4a) nor (5a) involve directives. Culicover and Jackendoff (1997) propose that there is a semantic ambiguity between the familiar meaning of *and* and the *left-subordinating and* ( $_{LS}and$ ) in (20). This general approach to Type II IaDs has been pursued by Russell (2007), Kaufmann (2012), Klinedinst and Rothschild (2012), among others. It also coheres nicely with an experimental study of IaDs (Scontras and Gibson 2011). This study compared quantitative acceptability ratings of emphatic *do* and explicit subjects in Type I and Type II IaDs across a large sample of naive speakers. They found that these elements very significantly decreased the acceptability of Type II IaDs, but not Type I IaDs. I will pursue a variant of this ambiguity analysis below, showing how it is possible to relate the two meanings of *and* and allow imperatives to have their normal directive semantics without having their normal directive effect on context. But a brief word about alternative analyses is in order.

Keshet (2013) and Keshet and Medeiros (2017) argue that the Type I/Type II distinction is a fundamentally syntactic, scopal one. Imperatives are taken to be modal operators, and it is maintained that Type II IaDs involve that modal scoping over the entire conjunction with the first conjunct serving as the restrictor and the second as the nuclear scope. On this approach, Type II IaDs are not really conjoined imperatives and declaratives, but rather a complex type of modal sentence. (Though Type I IaDs are true conjunctions of imperatives and declaratives.) This approach has the merit of not postulating an ambiguity in *and*, and does not require any account of how the first imperative's directive force is neutralized. The latter achievement is particularly attractive since some existing accounts of the neutralization like Han (1998) and Russell (2007) are problematic. I will not follow this syntactic approach since I think it is problematic to treat imperatives as modal operators for the reasons discussed in §2 and Starr (to appear). However, I take seriously the merits of this approach and speak to them below.

Similar to the 'parameter shifting *and*' defined in Klinedinst and Rothschild (2012), I propose that the first conjunct of  $_{LS}and$  only has its effect on  $d_s$ .

**Semantics of  $_{LS}and$**   $s[\phi_{LS} \wedge \psi] = (\langle s, d_{s[\phi]} \rangle)[\psi]$

This does not attribute completely unrelated meanings to  $_{LS}\wedge$  and  $\wedge$ : while  $\wedge$  sequentially up-

dates both components of states,  $LS^\wedge$  only updates one of them. Klinedinst and Rothschild (2012) argue that this a general feature of connectives that a multidimensional dynamic framework is well-suited to capture. This variant of conjunction neutralizes the first conjunct's effect on  $r_s$  and allows the conditional interpretation to be derived anaphorically just as with Type I IaDs, i.e. by inferring appropriate discourse relations between the conjuncts. Just as with *and*, there must be substantial constraints on which discourse relations are compatible with  $LS^\wedge$  — indeed it is clear that it must require subordinating discourse relations like Explanation, Instance, Background, Elaboration, Generalization, etc. Presumably something like this restriction would be needed to explain why not all combinations of tense/aspect work in purely declarative  $LS^\wedge$  constructions, and why emphatic *do* degrades Type II IaDs. Unfortunately, this component of the analysis is beyond the scope of this paper.

On this approach, (5a) amounts to  $!M_{LS^\wedge}Will(F)$ . Crucially,  $!M$  only contributes its modal discourse topic to the state in which the second conjunct is evaluated. As with Type I IaDs, the conditional reading is generated when *will* is anaphoric to this topic. (As discussed above, the conditional readings of (20a) and (20b) would have to be derived from inferred subordinating discourse relations.) This not only explains the conditional interpretation, and the lack of directive meaning. It explains why *So*  $!-\neg M$  is an infelicitous follow-up while *But*  $!-\neg M$  is felicitous. Updating  $!M_{LS^\wedge}Will(F)$  has no effect directly on the preferences, so it cannot guarantee that the preferences added by  $!-\neg M$  will already be present in the state. Thus *So*  $!-\neg M$  is infelicitous. However, for the same reason,  $!M_{LS^\wedge}Will(F)$  and  $!-\neg M$  are preferentially consistent. Further, there is no tension between this context an the contrastive content of *but*, so *But*  $!-\neg M$  is felicitous. I now turn to Type II IaDs like (4a).

Figure 6: Negative Preferences and Type II IaDs

Explaining the pattern in (4b) requires examining more closely the context in which (4a) occurs. Both speaker and hearer can take it for granted that worlds where the speaker doesn't rub chile in the hearer's eye ( $\neg R$ ) are preferable to ones where they do ( $R$ ). This background context is depicted as  $r_2$  in Figure 6. The Type II IaD (4b) *Screw up the tortillas and I'll rub chile in your eye* is represented as  $!S_{LS^\wedge}Will(R)$  and, in general, rules out the world  $w_{sr}$ , depicted in Figure 6. So in its natural context,  $!S_{LS^\wedge}Will(R)$  will lead to the third preference relation depicted in Figure 6. This explains why *So*  $!-\neg S$  is a felicitous follow-up while *But*  $!-\neg S$  is not.  $\langle r_2, \langle c_{r_2} \rangle \rangle[!S_{LS^\wedge}Will(R)]$  is a state that preferentially supports  $!-\neg S$ : the imperative would impose a preference already in place. For this reason, the contrastive or contrary-to-expectations content of *but* rules out *But*  $!-\neg S$  as a follow up, though it is preferentially consistent.

## 4. Conclusion

This paper has proposed an analysis of IaDs that captures their conditional meaning as modal anaphora and explains the contrasts between types of IaDs exhibited in (3)-(5). I argued that this modal anaphora approach can be made to meet the challenges posed by von Fintel and Iatridou (2017) if it draws a sharp distinction between modals and imperatives. The dynamic, non-modal analysis has much in common with Lascarides and Asher (2003), in particular its reliance on inferred discourse relations. But, instead of founding the Type I/Type II distinction purely in the inferred discourse relation, I followed Klinedinst and Rothschild (2012) in taking this distinction to involve two semantically overlapping connectives. This made it possible to neutralize the directive meaning of the first conjunct without the problematic assumptions made by Han (1998) and Russell (2007).<sup>13</sup> By relating imperatives to preferences instead of actions as Lascarides and Asher (2003) do, it was possible to explain the interaction of contextual preferences with the interpretation of negative IaDs. Future work is needed to spell out the resolution of discourse relations in this analysis and to extend it to conditional readings of disjunctions (e.g. Franke 2005 and Biezma and Rawlins 2016).

## Appendix A. Dynamic Logic of Mood with Modal Anaphora

### Definition 1 (DLMA Syntax)

- (1)  $\alpha \in \mathcal{Rad}$  if  $\alpha \in \mathcal{At} = \{A, B, C, D, \dots\}$
- (2)  $\neg\rho \in \mathcal{Rad}$  if  $\rho \in \mathcal{Rad}$
- (3)  $(\rho_1 \wedge \rho_2) \in \mathcal{Rad}$  if  $\rho_1, \rho_2 \in \mathcal{Rad}$
- (4)  $\text{Will}(\rho) \in \mathcal{Sent}$  if  $\rho \in \mathcal{Rad}$
- (5)  $\triangleright\rho \in \mathcal{Sent}$  if  $\rho \in \mathcal{Rad}$
- (6)  $!\rho \in \mathcal{Sent}$  if  $\rho \in \mathcal{Rad}$
- (7)  $(\phi \wedge \psi) \in \mathcal{Sent}$  if  $\phi, \psi \in \mathcal{Sent}$
- (8)  $\neg\phi \in \mathcal{Sent}$  if  $\phi = \text{Will}(\rho) \ \& \ \rho \in \mathcal{Rad}$

### Definition 2 (Preference Relations)

1. A **preference relation**  $r$  is a relation on propositions
  - $W$  is the set of possible worlds; each assigns every atomic radical to one truth-value
    - $W:\mathcal{At} \mapsto \{0, 1\}$
  - $r: \wp(W) \times \wp(W)$
2.  $r$ 's **context set**  $c_r$  is the union of propositions ranked by  $r$ .
  - $c_r = \text{field } r$ , where  $\text{field } r = \text{dom } r \cup \text{ran } r$

**Definition 3 (States)** A state  $s = \langle r_s, d_s \rangle$  is a pair consisting of a preference relation  $r_s$  and an  $n$ -tuple of propositions  $d_s = \langle p_i, \dots, p_j, c_{r_s} \rangle \in \wp(W)^n$ , where  $n \geq 1$ .

- $d_s$  is the list of modal discourse topics.
- $d_s$  always contains  $c_{r_s}$  as its last element;  $c_{r_s}$  is always a discourse topic.
- When  $n = 1$ ,  $d_s = \langle c_{r_s} \rangle$ .

<sup>13</sup>Han (1998) employs a controversial feature deletion, while Russell (2007) incorrectly assumes that Type II IaDs involve an infinitive rather than an imperative (von Fintel and Iatridou 2017: §3.4).

**Definition 4 (Initial State)**  $\mathbf{I} := \langle \{ \langle W, \emptyset \rangle \}, \langle W \rangle \rangle$

**Definition 5 (Atomic Radical Semantics)** For  $c \subseteq W$ ,  $\alpha \in At$ :  $c[\alpha] = \{w \in c \mid w(\alpha) = 1\}$

**Definition 6 (Imperative Semantics)**

$$s[!\rho] = \langle r_s \cup \{ \langle c_{r_s}[\rho], c_{r_s} - c_{r_s}[\rho] \rangle \}, c_{r_s}[\rho] \circ d_s \rangle$$

- $q \circ d_s := \langle q, p_n, \dots, p_1 \rangle \in \wp(W)^{n+1}$  where  $q \subseteq W$ ,  $d_s = \langle p_n, \dots, p_1 \rangle \in \wp(W)^n$  and  $n \geq 1$ .

**Definition 7 (Declarative Semantics)**

$$s[\triangleright \rho] = \langle r_s + \rho, c_{r_s}[\rho] \bullet d_s \rangle, \text{ where } r_s + \rho = \{ \langle a[\rho], a'[\rho] \rangle \mid \langle a, a' \rangle \in r_s \text{ \& } a[\rho] \neq \emptyset \}.$$

- $q \bullet d_s := \langle q, p_n, \dots, q \cap p_1 \rangle \in \wp(W)^{n+1}$  where  $q \subseteq W$ ,  $d_s = \langle p_n, \dots, p_1 \rangle \in \wp(W)^n$  and  $n \geq 1$ .

**Definition 8 (Will Semantics)**

$$s[\text{Will}(\rho)] = \langle \{ \langle a, a' \rangle \in r_s \mid 1(d_s)[\rho] = c_{r_s} \}, d_s \rangle, \text{ where } 1(d_s) \text{ is the first element of } d_s.$$

**Remark 1** Definition 8 does not have *will* introduce any modal topics, but that is only for simplicity. At the very least, it should probably introduce  $1(d_s)[\rho]$  as a modal topic — but exploring the relevant data here is not possible.

**Definition 9 (Connective Semantics)**  $\rho, \rho_1, \rho_2 \in \mathcal{Rad}$ ;  $\phi, \psi, \neg\phi \in \mathcal{Sent}$

1.  $c[\rho_1 \wedge \rho_2] = (c[\rho_1])[ \rho_2 ]$
2.  $c[\neg\rho] = c - c[\rho]$
3.  $s[\phi \wedge \psi] = (s[\phi])[ \psi ]$
4.  $s[\neg\phi] = s \ominus s[\phi]$

- $s \ominus s' := \langle \{ \langle a_1, a_2 \rangle \mid a_1 = a_3 - c_{s'} \text{ \& } a_2 = a_4 - c_{s'} \text{ \& } \langle a_3, a_4 \rangle \in r_s \}, d_s \rangle$   
 –  $s \ominus s'$  removes any modal topics in  $s'$  and not in  $s$ , and removes worlds from every alternative in  $r_s$  that are in  $c_{r_{s'}}$ .

**Definition 10 ( $L_S$ and Semantics)**

$$s[\phi_{LS} \wedge \psi] = (\langle s, d_s[\phi] \rangle)[ \psi ]$$

# Let's talk about the future: An investigation of temporal reference in Kaqchikel<sup>1</sup>

Tammi STOUT — *University of Texas at Austin*

**Abstract.** This paper provides an analysis of temporal reference in the understudied language, Kaqchikel (Mayan). Building on results from recent studies of temporal reference in languages that lack overt grammatical tense by Matthewson (2006) for St'át'imcets and Tonhauser (2011) for Guaraní as well as the distantly related language Yucatec Maya by Bohnemeyer (1998), I consider both a tensed and tenseless analysis for Kaqchikel. Testing first for whether or not the obligatory aspect/mood markers on finite verbs contribute temporal reference and then testing for the possibility of covert tense, I show that Kaqchikel lacks the non-future temporal restriction present in St'át'imcets and Guaraní. Instead, I argue that Kaqchikel behaves more like Hausa as discussed in Mucha (2013), and ultimately I conclude that Kaqchikel is a tenseless language where temporal reference is determined by context and temporal adverbials.

**Keywords:** Tense and aspect, tenseless languages, Mayan linguistics.

## 1. Introduction

The observation that languages vary with respect to how temporal relationships are encoded is not a novel one. Out of this observation has sprung a lively debate about the status of tense in languages that appear to be tenseless, where tense is minimally not an overt morphological marking. One of the central questions in the discussion is whether or not there are truly tenseless languages, where tense is not a grammatical category. For languages to be truly tenseless, the reference time of an utterance is established using other means, such as discourse context and temporal adverbials rather than a grammaticized tense morpheme. However, languages like St'át'imcets (Lillooet Salish), which are at least tenseless on the surface, are observed to have a restriction on future reference times. Matthewson (2006) provides an account of St'át'imcets as a language that is only superficially tenseless with a phonologically empty non-future tense morpheme, TENSE, restricting reference times to non-future time intervals with respect to utterance time. Another language with a similar pattern with a non-future restriction for finite clauses is Paraguayan Guaraní (Tupí Guaraní). Tonhauser (2011) tests both a tensed and tenseless analysis of Guaraní, and ultimately concludes that a tenseless approach for Guaraní is the simpler and thus preferable analysis based on evidence from subordinate clauses and other more complex sentence types.

While both Guaraní and St'át'imcets finite verbs discussed in the two aforementioned studies are unmarked for aspect or mood, the focus of this paper is Kaqchikel (Mayan), a language in which finite verbs are obligatorily marked for aspect or mood. Because all finite clauses are marked for with one of four (tense)-aspect-mood ((T)AM) markers, it shifts the direction of the present study to first considering whether or not any of the (T)AM markers are encoding tem-

---

<sup>1</sup>I would like to thank the Kaqchikel speakers in Sololá, Guatemala that I have had the opportunity to work with, namely Rigoberto Choy and Lucia Choy. Without their endless patience and willingness to help, none of this work would be possible.

poral reference, and if not, then asking the question as to what, if any, restrictions on temporal reference there are. Ultimately, I conclude that Kaqchikel is best analyzed as a truly tenseless language, which exhibits no restrictions on future reference times, namely for verbs marked with the imperfective aspect.

Following the ideas first formalized in Reichenbach (1947) and further developed by Klein (1994) among others, I assume that temporal relationships in natural language involve three times: the time at which utterance is made (utterance time), the time interval the eventuality is constrained (reference time), and the time that the eventuality takes place (event time). Further, I assume that tense is the relationship between the reference time (RT) and utterance time (UT) and that aspect relates reference time (RT) to event time (ET). Languages that are said to be tensed languages, such as English, encode the relationship between UT and RT grammatically with tense morphology, which is illustrated in (1). In (1a), the verb *play* is marked with the morpheme *-ed*, which encodes the past tense in that the RT is prior to UT ( $RT < UT$ ). In (1b), the auxiliary verb *be* is inflected for the present tense, and the RT is the same as UT (i.e.  $RT=UT$ ).

- (1) a. I played basketball.  
b. I am playing basketball.

Grammatical tense in English serves to establish the RT with respect to UT, but the RT time interval can be further constrained either in context or using temporal adverbials (e.g. *tomorrow*, *yesterday*, *at 8 o'clock tonight*) to a more specific time interval within the past/present/future RT. In (2a) the RT is constrained to a past RT and further to a time interval coinciding with the day prior to UT, which is established by use of *yesterday* in Speaker A's question. In (2b), the time interval introduced by *last week* constrains the basketball playing event to the time interval that coincides with the week prior to UT.

- (2) a. A. What did you do yesterday?  
B. I played basketball.  
b. I played basketball last week.

While tense deals with the relationship between RT and UT, aspect deals with the relationship between RT and ET. For example, the perfective aspect situates ET inside the time interval established by RT ( $ET \subseteq RT$ ). However, the perfect aspect situates ET before RT ( $ET < RT$ ). In 3a, RT is established as a past time that occurred the day before UT as denoted by the adverbial *yesterday*, and further the event of basketball watching was completed within that RT. For (3b), the perfect construction using the auxiliary *have* marked for past tense tells us that the RT is before UT (past tense) and further the RT is the time interval at which the speaker arrives at the party. The perfect aspect marked on the main verb with the past participle *-en* tells us that ET is before RT. That is, the 'eating' event takes place prior to the 'arriving' event.

- (3) a. Yesterday, I watched the basketball game.  
b. When I arrived at the party, I had already eaten.

In English, the temporal adverbials and contextual information serve to provide additional information about the reference time, but for languages that lack overt tense morphology, the reference time is only established in the discourse context or using temporal adverbials. In (4a) for Kaqchikel, an utterance marked with the imperfective aspect is underspecified for temporal reference, so any of the three given translations are possible. However, for (4b), the reference time is established by the presence of the temporal adverbial *iwir pa tiqaq'ij* 'yesterday in the afternoon'.

- (4) a. y-i-wär  
IMPF-B 1S-sleep  
'I was sleeping/am sleeping/will be sleeping.'
- b. y-i-wär iwir pa tiqaq'ij  
IMPF-B 1S-sleep yesterday PRE afternoon  
'I was sleeping yesterday in the afternoon.'

Unlike the Kaqchikel data in (4a), St'át'imcets finite clauses, which are only marked for person/number agreement, are restricted to non-future reference times. In (5), (5a) shows that both a past and present reference time is available, which is suggestive of a tenseless clause. However, (5b) is unacceptable when combined with a future denoting adverbial suggesting that perhaps a covert non-future tense is responsible for the reference time restriction. Matthewson (2006) refers to such utterances as superficially tenseless sentences, or STSs. In (5), the STS is only felicitous when the interpretation is a non-future reference time, as indicated in the contrast between (5a) and (5b), which appears with future denoting temporal adverbials. The example in (5c) illustrates that the utterance can combine with non-future denoting adverbials.

- (5) a. sáy'ez'-lhkan  
play-1SG.SUBJ  
'I played/I am playing' (Matthewson, 2006: p. 676)
- b. \*sáy'ez'-lhkan natcs/zánucwem  
play-1SG.SUBJ one.day.away/next year  
Intended: 'I will play tomorrow/next year. (Matthewson, 2006: p. 677)
- c. sáy'ez'-lhkan i-tsilkstásq'et-as  
play-1SG.SUBJ when.PAST-Friday-3CONJ  
'I played on Friday.' (Matthewson, 2006: p. 677)

Matthewson (2006) proposes that the non-future temporal restriction is due to a phonologically empty tense morpheme TENSE. Further, she claims that any future-oriented utterances must receive overt marking, and the future interpretation is akin to the WOLL analysis for English *will* and *would* as proposed in Abusch (1985), where each form is composed of WOLL, a future-shifting operator, plus tense. Under this analysis, the prediction is that a language only allows future readings when overt morphology is present. In (6), Matthewson analyzes *kelh* as the overt spellout of WOLL in St'át'imcets, which is underlyingly the non-future TENSE plus the future-shifting operator.

- (6) sáy'ez'-lhkan kelh  
 play-1SG.SUBJ *kelh*  
 'I will play.'

(Matthewson, 2006: p. 677)

In a separate study on Guaraní, Tonhauser (2011) observes that the data is similar to St'át'imcets in that matrix clauses only marked for person/number agreement (i.e. superficially tenseless) have the same non-future restriction, which warrants consideration of a covert tense analysis as well. However, on the assumption that the non-future covert tense morpheme must be present in all matrix clauses, the tensed analysis for Guaraní leads to problems accounting for the behavior of some subordinate tenseless clauses and for non-initial matrix clause conjuncts, which do actually license future reference times. To make a tensed analysis work, certain stipulations would be necessary to account for these cases. Thus, a tenseless analysis of Guaraní is a simpler approach and accounts for the various problematic cases for the tensed approach making it the preferred analysis for Tonhauser.

Data from other languages including Kalaallisut (Bittner, 2005), Chinese (Smith and Erbaugh, 2005; Lin, 2006), and Hausa (Mucha, 2013), among others, have also contributed to the discussion on the status of tense in languages that lack overt tense morphology. The primary focus of this paper is to add to the discussion with an analysis of the Kaqchikel temporal system and address the open question as to whether or not tense is encoded in the language. Although Kaqchikel differs from both St'át'imcets and Guaraní in that finite verbs are never unmarked for aspect or mood, the data leads to the conclusion that Kaqchikel is best analyzed as a tenseless language. Further, the non-future temporal restriction in clauses only marked for aspect or mood does not apply to Kaqchikel as with both St'át'imcets and Guaraní, which strengthens the argument for a tenseless analysis. In order to motivate this conclusion, I provide a description of Kaqchikel aspect and mood in §2. §3 discusses both a tensed and a tenseless approach for Kaqchikel finite matrix clauses, and §4 considers reference times of subordinate clauses. I conclude in §5.

## 2. Introduction to (T)AM in Kaqchikel

Turning now to Kaqchikel, the first important difference, as already mentioned, is that unlike both St'át'imcets and Guaraní, all finite verbs are obligatorily marked with one of four (tense)-aspect-mood ((T)AM) markers, which are given in Table 1.

| Morpheme         | Function                  |
|------------------|---------------------------|
| <i>n-/y-/nk-</i> | Imperfective aspect       |
| <i>x-</i>        | Perfective                |
| <i>xt-/xk-</i>   | Potential mood            |
| <i>t-/k-</i>     | Imperative/hortative mood |

Table 1: (T)AM morphemes and functions

In addition to being inflected for (T)AM, verbs are marked for person/number agreement. The basic verbal template for Kaqchikel is given in (7), where Set A refers to the ergative agree-

ment markers and Set B refers to the absolutive agreement markers. Kaqchikel displays an ergative/absolutive alignment where intransitive subject arguments are marked the same as transitive objects (Set B) and the subjects of transitive arguments are marked with a different set of agreement markers (Set A). Examples for fully inflected verbs for the imperfective and perfective aspect are given respectively in (8a–8c). Both (8a) and (8b) are intransitive, so only Set B markers are used for agreement, but (8c) shows use of a transitive verb marked with both the Set A and Set B markers.

(7) (T)AM-SETB-SETA-verb-(optional suffixes)

- (8) a. y-in-atin  
 IMPF-B1S-bathe  
 'I was/am/will be bathing.'
- b. x-in-atin  
 PRFV-B1S-bathe  
 'I bathed.'<sup>2</sup>
- c. y-at-in-tz'ët  
 IMPF-B2S-A1S-see  
 'I see you.'

In addition to the frequently used imperfective and perfective aspects, the potential and hortative/imperative moods are also available to fill the (T)AM slot, which are exemplified in (9a–9c) respectively. Note that (9b) is a regular second person singular imperative, but (9b) is in the third person singular and shows the hortative use of the marker.

- (9) a. xk-i-wär  
 POT-B1S-sleep  
 'I will sleep.'
- b. k-a-pa-e'  
 IMP-B2S-stand-ITV  
 Stand!
- c. t-u-mestaj  
 IMP-B3S-forget  
 'May he forget.'

For the present study, I focus only on the perfective, imperfective and potential markers. In the next section, both a tensed and tenseless analysis of the morphemes and of the finite clauses in which they appear are considered.

<sup>2</sup>The non-past interpretation of the perfective utterance is judged to be infelicitous to native speakers. However, a non-past reading is possible when enough context is added, which is discussed further in §3.2.

### 3. Status of 'tense' in Kaqchikel

In this section, I consider both a tensed and tenseless analysis for finite verbs in Kaqchikel. Previous descriptions of (T)AM in Kaqchikel vary on this point. Rodríguez Guaján and García Matzar (1997) analyze the language as tenseless, but only the imperfective is shown as being compatible with various RTs. Brown et al. (2006), although pedagogical, refers to the imperfective also as a present tense, the perfective as a past tense, and the potential as a future tense. Because of the lack of consensus and lack of evidence to support a tenseless analysis, each morpheme is potentially responsible for introducing grammatical tense. Further, the possibility that covert tense is responsible for introducing the RT remains in the instance that the aspect/mood markers are shown to not encode tense. To discern between a tensed or tenseless analysis of Kaqchikel there are three hypotheses to test here:

1. The aspect/mood morphemes are also encoding tense, so there is no covert tense present because tense is overtly indicated by the aspect and mood markers in addition to aspect/mood information.
2. The aspect/mood morphemes are not encoding tense and only aspect/mood information. Tense is thus a covert morpheme restricting reference times. Additionally, to get future interpretations, special morphology must be used.
3. There is no covert or overt tense restricting reference times in Kaqchikel. Reference time is supplied only by temporal adverbials and in the discourse context.

For each hypothesis above, I provide tests for each morpheme to determine the status of tense.

#### 3.1. Hypothesis 1: *Kaqchikel TAM morphemes encode aspect/mood+tense*

To test for the first hypothesis, I evaluate whether or not any of the three aspect/mood markers are restricted to only one reference time interval, which includes consideration of a past/present distinction or the non-future only distinction. If any of the morphemes encodes grammatical tense, the expectation is that they will be incompatible with temporal adverbials denoting various RTs with respect to utterance time. A further test that I employ in this section considers temporal adverbials that are ambiguous with respect to RT, which is exemplified in (10) with *at 6 o'clock in the morning*, where the tense in English restricts the interpretation of the adverbial as a past/present/future RT. In (10a), the past tense restricts the time interval to a past RT, so the temporal adverbial denotes a past time that coincides with 6 o'clock in the morning. However, (10b) refers to a future 6 o'clock in the morning with respect to UT.

- (10) a. I woke up at 6 o'clock in the morning.  
       b. I will wake up at 6 o'clock in the morning.

If an underspecified temporal adverbial remains underspecified (setting aside interpretation preferences for the moment) with any of the aspect/mood morphemes in Kaqchikel, it suggests

that tense is not being encoded by a given aspect/mood marker as is the case for English in (10).

Starting with the imperfective, we already saw that past/present/future RTs are available, as exhibited by (8a), which already points in the direction of a tenseless analysis of at least the imperfective aspect. To further support this claim, (11) shows that matrix clause verbs marked with the imperfective aspect are compatible with past (11a), present (11b) and future (11c) denoting temporal adverbials. Just a brief note that although the imperfective alone can be used for the progressive meaning, use of the periphrastic progressive with the auxiliary *tajin* is preferred by the speakers I work with to distinguish between the progressive and other imperfective meanings, which is shown by the non-progressive habitual interpretation shown in (12). However, the temporal reference restrictions are unaffected by use of the periphrastic form over the imperfective (i.e. RT is still underspecified and future RTs are possible). In some dialects, the progressive auxiliary is also marked with the imperfective aspect, but in the Sololá dialect only the unmarked *tajin* is used.

- (11) a. Iwír        *tajin* y-e-xajon  
          yesterday PROG IMPF-B3P-dance  
          ‘Yesterday, they were dancing.’ (RT<UT)
- b. Wakamĩ   *tajin* y-e-xajon  
          now/today PROG IMPF-B3P-dance  
          ‘They are dancing now.’ (RT=UT)
- c. Chwaq     *tajin* y-e-xajon  
          tomorrow PROG IMPF-B3P-dance  
          ‘Tomorrow, they are dancing.’ (RT>UT)
- (12) q’ij q’ij y-in-atin  
       day day IMPF-B1S-bathe  
       ‘I bathe daily.’

Looking at the second test using underspecified temporal adverbials, I return to the example given in (11b) with the temporal adverb *wakamĩ*, which can either be used to mean ‘now’ or ‘today’. The same utterance can be translated as *Today, I was dancing/Now, I am dancing/Today, I will be dancing*. In order to establish whether the utterance is to be interpreted as past, present, or future, additional context is necessary. In a context where the RT is established as a future RT, (13) is no longer ambiguous between ‘today/now’ interpretations and further the non-future interpretations are no longer available.

- (13) [Context: What will you be doing later when I get home from work?]  
       *tajin* y-i-xajon        wakamĩ  
       PROG IMPF-B1S-dance now/today  
       ‘I will be dancing today/#I am dancing now.’

Given that the imperfective aspect is compatible with any RT and is insufficient for determining

the RT of underspecified temporal adverbials, the evidence strongly supports an analysis of the imperfective marker not marking tense.

The perfective aspect is less freely shifted into different reference times. In out of the blue contexts, speakers find non-past interpretations to be infelicitous.

- (14) x-i-jote'                      ch-u-wi              jun juyu  
 PRFV-B1S-ascend PRE-A3S-RN one mountain  
 'I climbed a mountain/#I will have climbed a mountain.'

Further, it is not possible to use non-past denoting temporal adverbials with the perfective aspect, which is shown in (15b). For (15a), the adverb *iwir* is felicitous, but speakers judge use of the adverb *chwaq* 'tomorrow' to be bad in (15b) and tend to offer the explanation that use of *x-* must be in the past.

- (15) a. Iwir,              x-i-jote'                      ch-u-wi              jun juyu  
           yesterday PRFV-B1S-ascend PRE-A3S-RN one mountain  
           'Yesterday, I climbed a mountain.'
- b. '#Chwaq x-i-jote'                      ch-u-wi              jun juyu  
           tomorrow PRFV-B1S-ascend PRE-A3S-RN one mountain  
           Intended: 'Tomorrow, I will have climbed a mountain.'

Underspecified temporal adverbials are also interpreted as past denoting when used with the perfective aspect. Taking the adverbial *wakamĩ* again, the future interpretation as an event occurring sometime later that day is not possible.

- (16) [Context: When is your mother coming to visit?]  
           x-ø-pĩ                      wakamĩ.  
           PRFV-B3S-arrive now/today  
           'She arrived today/#She will have arrived (by) today.'

Both (15a) and (15b) point in the direction of analyzing the perfective aspect as also being restricted to past reference times and thus encoding a past tense. However, as Tonhauser (2011) points out, more complex utterances need to be considered before reaching a conclusion or at least richer contexts which allow for the past RT interpretations to be overridden. In fact, combining both a richer context and a future denoting temporal adverbial allows for non-past reference time for the perfective aspect. In (17), the context establishes that the party under discussion is at a future time. The temporal adverbial is underspecified as to whether 8 o'clock is before or after utterance time, but in the given context it can only be interpreted as a future 8 o'clock, which constrains the RT of the entire utterance to a future time interval.

- (17) [Context: You and a friend are planning a party for 9 o'clock that night. Your mother is baking the cake for the party, and your friend is worried that she won't be there with the cake in time. You tell her: ]

Pa taq a las 8 chaq'a wakamī, x-ø-pī yan  
 PRE when PRE(Sp) DET(Sp) eight night now/today PRFV-B3S-arrive PAR  
 nu-te'  
 A1S-mother

'By 8 o'clock tonight, my mother will have already arrived.'

In spite of the fact that non-past interpretations do not easily arise with the perfective aspect, examples like (17) exclude the possibility of an analysis of the perfective aspect as an absolute past tense in Kaqchikel.

Similarly, the reference time for the potential mood is not easily shifted to times other than the future. In absence of additional context or a temporal adverbial, utterances with the potential mood are always interpreted with future reference times, so for (18) only the future interpretation is available.

- (18) xk-i-b'iyin pa ri tienda  
 POT-B1S-walk PRE DET store(Sp)  
 'I'll walk to the store/#I was going to walk to the store.'

Temporal adverbials are also restricted with the potential mood, where only future denoting adverbials are felicitous, such as *chwaq* 'tomorrow' but not *iwir* 'yesterday'

- (19) xk-i-b'iyin pa ri tienda chwaq/iwir  
 POT-B1S-walk PRE DET store(Sp) tomorrow  
 'I'll walk to the store tomorrow/#yesterday.'

When combined with the temporal adverbial *wakamī* 'today/now', again only a future interpretation is found to be available to speakers. In (20), the context establishes that the speaker is referring to a time prior to UT, which should allow the interpretation of the 'earlier today' reading and not just the 'later today' reading. However, the context is not sufficient for shifting the reference time of the utterance nor the interpretation of *wakamī* to a past interpretation. The response in (20) can only be interpreted as the 'I will go to the store today.'

- (20) [Context: You are asked if you've already been to the store to get groceries for the week. You respond:]  
 xk-i-b'iyin pa ri tienda wakamī  
 POT-B1S-walk PRE DET store(Sp) now/today  
 Intended: 'I was going to go to the store (earlier) today.'

Just as with the perfective aspect, the data up to this point suggest that the potential mood is restricted to future reference times. However, the following examples show that the potential mood can be used when a past reference time is established in complex utterances. The first ex-

ample is taken from *Ri Kitziñon kan ri Qati't Qamama*, a children's book containing traditional folk narratives. The first line in (21a) establishes that this is a story that takes place during a past time interval. In (21b), the verb marked with the potential mood is in the subordinate relative clause under the belief-predicate *nojij* 'to think/believe'. The time at which they believed they would be eaten by the jaguar is established as a time that follows the time the animal roars but precedes the time at which they see the cat fighting the jaguar in (21c). In this example, the potential is not interpreted as an absolute future reference time.

- (21) a. K'o cha' jun q'ij x-ka-k'axaj jun chikop n-ø-sik'in chunaqaj ri  
 EXST QUOT one day PRFV-B3P-hear one animal IMPF-B3S-call near DET  
 ko-choch.  
 A3P-house  
 'One day they heard the roar of an animal near their houses.'
- b. Janila' x-ø-ki-xib'ij ki' r-uma x-ki-nojij che ri chiköp  
 very PRFV-B3S-A3P-scare 3P B3S-RN PRFV-B3P-think REL DET animal  
 xk-e-ru-tij  
 POT-B3P-A3S-eat  
 'They were frightened because they thought the animal was going to eat them.'
- c. Xa ja k'a ri ti ki-me's x-u-pab'a' ri ch-u-wäch jun  
 PAR FOC PAR DET DIM 3P-cat PRFV-B3S-stand.up DET PRE-B3S-face one  
 b'alam.  
 jaguar  
 'But it was their cat that stood up in the face of the jaguar.'

The second example of a potential mood in a non-future reference time contains the phrase *ri' ojer* 'the past' in the same clause as the verb marked with the potential, which is clearly establishing a non-future reference time for the clause and further for the entire utterance.

- (22) kan xk-a-ch'oj-in ri' ojer, ma jun tä ri' kuy-un-ik  
 INTS POT-B2S-demand-AP DET past NEG one IRR DET forgive-AP-INF  
 'In the past, even if you demanded it, there was no forgiveness.' (González, 2016: 35)

Both (21) and in (22) provide strong evidence that the potential mood is also not contributing temporal reference and should be analyzed as only a mood marker.

Summarizing the findings for hypothesis 1, there is sufficient evidence to conclude that none of the three markers is contributing temporal reference, so at this point Kaqchikel looks to be a tenseless language unless testing hypothesis 2, a cover tense analysis, reveals restrictions on reference times for clauses marked for aspect/mood.

### 3.2. Hypothesis 2: *Kaqchikel* has covert tense

Hypothesis 1 and hypothesis 2 are closely related and the data from the previous section already suggests that a covert tense analysis is unlikely for *Kaqchikel*. A covert tense analysis relies on temporal restrictions for clauses not overtly marked for tense, so underlyingly all finite clauses are assumed to be marked with a phonologically empty tense morpheme, TENSE. For both Guaraní and St'át'imcets, the temporal restriction is to non-future times, but additional covert temporal restrictions are possible (e.g. a covert past tense). Under the assumption that covert tense is restricting reference times, finite matrix clauses are predicted to be only interpreted with restricted temporal reference. However, we already saw that this is not the case for *Kaqchikel*. Namely for finite matrix clauses marked with imperfective aspect and the potential mood, temporal reference is not restricted to any specific RTs. Focusing on the restrictions observed in other languages on future reference times, the examples in (23) and (24) demonstrate that both past and future temporal reference are available if a salient RT is established. If a future RT is established in context or by a temporal adverbial, future interpretations are available for *Kaqchikel*. For (23), the context preceding the target utterance marked with the imperfective aspect introduces a salient reference time that restricts the RT of the response to past RTs. However, in (24), the context introduces an RT, which is in the absolute future of UT.

- (23) [Context: You called your friend earlier that morning, but she didn't answer. You see her later and ask what she was doing that morning: ]

(tajin) y-in-samäj

(PROG) IMPF-B I S-work

'I was working.'

- (24) [Context: Your friend wants to get dinner later that evening. You are unable to attend, so she asks what you will be doing instead. You respond:]

(tajin) y-in-samäj

(PROG) IMPF-B I S-work

'I will be working.'

Given that matrix clauses in *Kaqchikel* are not restricted to non-future RTs, there is no evidence that a phonologically empty non-future tense morpheme is restricting the temporal reference of an utterance. Rather, *Kaqchikel* temporal reference is established in the discourse context or with temporal adverbials. However, this does leave open the question as to how temporal reference is established in out-of-the-blue contexts, but I reserve further discussion for §4.

In addition to the implications for past and present RTs, the covert tense analysis has implications for how to analyze future discourse in languages that are (at least) superficially tenseless like St'át'imcets. Matthewson (2006) argues that there is no absolute future tense category and future discourse is realized by the combination of tense (covert or overt) and a prospective aspect. The prospective aspect acts as a future-orienting operator that shifts the ET to a future time of the RT rather than the UT. This accounts absolute future interpretations in which the RT is at UT, so the ET is shifted to a time that temporally follows RT ( $RT < ET$ ,  $RT = UT$ ). It also accounts for future of the past interpretations, where the reference time is established a past RT

and ET temporally follows RT ( $RT < ET$ ,  $RT < UT$ ) giving rise to ETs that can still be in the past with respect to UT or after as exemplified for English in (25).

- (25) a. A child was born who will become ruler of the world.  
 b. A child was born who would become ruler of the world. (Kamp, 1971)

An additional feature of the covert tense analysis is the proposal that special morphology or marking is required in order to get future interpretations, such as *kelh* in St'át'imcets. Recall that clauses for St'át'imcets cannot be interpreted as having absolute future reference times. Rather, the marker *kelh* situates the event time of the utterance to a time that temporally follows the reference time ( $RT < ET$ ). If an utterance is interpreted with a future reference time for an event, this is due to the combination of TENSE restricting the reference times to non-future times plus *kelh*, which is shown in the contrast between (26) and (27) both repeated here for convenience. For (26), the reference time is restricted to either a past or a present time interval, but when *kelh* is used in (27), the playing event is shifted to a time after RT. In this case, the RT is the same as UT, so the absolute future interpretation is expected.

- (26) sáy'ez'-lhkan  
 play-1SG.SUBJ  
 'I played/I am playing.' (Matthewson, 2006: p. 676)

- (27) sáy'ez'-lhkan kelh  
 play-1SG.SUBJ *kelh*  
 'I will play.' (Matthewson, 2006: p. 677)

Data from St'át'imcets (in Matthewson, 2006), Guaraní (in Tonhauser, 2011), and Hausa (in Mucha, 2013) all provide cross-linguistic evidence that (at least some) instances of future reference times do require special morphology (prospective aspect). However, according to Mucha (2013) Hausa allows for future interpretations for clauses marked with the continuous aspect, which is shown in (28).

- (28) Su-àn wàsà  
 3PL-CONT play  
 'They are playing/(were playing)/(will play)' (Mucha, 2013: p. 372)

Again, the Hausa data looks quite similar to the Kaqchikel data from (24), where no additional morphology is required for the utterance to be interpreted with an absolute future RT. Because neither components of the covert tense analysis apply to the Kaqchikel data, the remaining hypothesis, that Kaqchikel is a truly tenseless language, is likely to be the preferred analysis.

### 3.3. Hypothesis 3: *Kaqchikel is tenseless*

To summarize the results of testing for hypothesis 1 and hypothesis 2, we already saw that hypothesis 1 (*Kaqchikel TAM morphemes contribute aspect/mood+tense*) is ruled out because

each of the aspect/mood morphemes lacks any restrictions for temporal reference ignoring restrictions due to pragmatic principles, which will be discussed in the next section. Hypothesis 2 was then ruled out because finite matrix clauses in Kaqchikel are not restricted to non-future reference times nor are any other reference time restrictions (i.e. a non-past restriction) present in the data. Further, future temporal reference is available for utterances that are otherwise unmarked for a prospective aspect (in the sense Matthewson's future-shifting operator). Discourse context and temporal adverbials are sufficient for giving rise to future RTs. This leaves open the question as to whether or not hypothesis 3 that Kaqchikel is tenseless is, indeed, the most suitable analysis of Kaqchikel. Evidence that no overt or covert morphological marking in the language restricting the reference time in a given utterance (or finite clause) has already been discussed. Instead of rehashing these points, I turn to additional evidence that comes from future discourse in the language.

To realize future discourse in Kaqchikel, more than one option is potentially available. Tonhauser (2011) refers to the two possible options for how languages realize future discourse as the *reference time option* and the *eventuality time option*. The ideas are developed from a similar analysis of how eventualities are situated with respect to utterance time in more than one way (Reichenbach, 1947). Tonhauser (2011) appeals to the two possible options in order to discuss how an eventuality can be situated in the absolute future of UT. If future discourse is realized by the reference time option, there must be a salient reference time in the absolute future, and the ET is then situated as occurring in the absolute future of the UT. On the other hand, the eventuality time option assumes that all utterances have a past or present RT, and future discourse is realized by situating the ET at a time that temporally follows the RT. Tonhauser (2011) analyzes Guaraní as a language that relies on the eventuality time option, whereas English *will* constructions are an example of the reference time option.<sup>3</sup> I analyze Kaqchikel as a language that uses both the eventuality time option and the reference time option (with restrictions).

Because I analyzed Kaqchikel as a tenseless language, it may seem as though the reference time option for future discourse is ruled out by the absence of grammatical tense. However, in principle it should still be available so long as there is a means for indicating absolute future temporal reference in the language. In (29), the temporal adverbial *chwaq* 'tomorrow' introduces an absolute future reference time because the speaker is talking about the day in the absolute future of utterance time. Note that the verb is marked with the imperfective aspect, which we already know is the only aspect marker easily shifted into different reference times using only a temporal adverbial or in context.

- (29) Chwaq y-i-jote' ch-u-wi jun juyu  
 tomorrow IMPF-B1S-ascend PRE-A3S-RN one mountain  
 'Tomorrow, I'll climb a mountain.' (UT < RT ⊆ ET)

The eventuality time option is also available for the imperfective aspect. In (30), the temporal adverbial *iwir* 'yesterday' restricts the RT of the utterance to the past. However, the temporal

<sup>3</sup>This is on the assumption that English *will* introduces an absolute future reference time in contrast to the WOLL analysis given in Abusch (1985). This also contrasts to the 'eventuality time' option in English with the *is/are going to* construction, which has a present tense RT and the ET temporally follows the RT.

adverbial *chaq'a wakamĩ* 'tonight' situates the ET after RT, which is also located in the absolute future of UT.

- (30) Iwĩr, Maria x-i-ru-b'ij chĩ n-ø-pe chaq'a wakamĩ  
 yesterday Maria PRFV-B1S-A3S-tell REL IMPF-B3S-come night today/now  
 Yesterday, Maria told me that she is coming tonight.'

The perfective aspect, though difficult to shift to non-past RTs, can also realize future discourse with the reference time option. The earlier example of the perfective aspect shifted to a future RT (17) (partially repeated here for convenience) relies on the temporal adverbial *pa taq a las 8 chaq'a wakamĩ* 'By 8 o'clock tonight' constrains the RT of the utterance to a future time. The RT is in the absolute future of the UT, and the event of the mother's arrival, or the ET, is a completed event at or before RT.

- (31) Pa taq a las 8 chaq'a wakamĩ, x-ø-pĩ yan  
 PRE when PRE(Sp) DET(Sp) eight night now/today PRFV-B3S-arrive PAR  
 nu-te'  
 A1S-mother  
 'By 8 o'clock tonight, my mother will have already arrived.' (UT<RT⊆ET)

Future discourse can also be realized using the eventuality time option for the perfective as well, but it also achieved with similar difficulty as the reference time option. However, the example in (32) is constrained to a past RT by the temporal adverbial *iwĩr* 'yesterday'. The first event in the utterance is the saying event, which also occurs at a past time, but the temporal interpretation of the second clause containing the event of finishing the work is temporally located in the absolute future.

- (32) Iwĩr, Maria x-i-ru-b'ij chĩ x-ø-ru-k'is ru-samaj chaq'a  
 yesterday Maria PRFV-B1S-A3S-tell REL PRFV-B3S-A3S-finish A3S-work night  
 wakamĩ  
 today/now  
 'Yesterday, Maria told me that she will have finished her work by tonight.'

Finally, the potential mood is the only marker that I argue is restricted to the eventuality time option for future discourse. If the potential were actually a future marker, then all utterances could be interpreted as taking place in the absolute future. A further consideration is the difference between speaker choice for when to use the imperfective or the potential to describe incomplete events, such as the contrast in (33). In (33a), the imperfective aspect is used to describe the event of walking to the store at a future time. For (33b), the potential mood is used. Speaker intuitions about the difference in these examples is that the imperfective is used when there is more certainty that the event will occur, while the potential mood introduces more uncertainty of the realization of the event.

- (33) a. y-i-b'iyin pa ri tienda chwaq  
 IMPF-B1S-walk PRE DET store(Sp) tomorrow  
 'I will walk to the store tomorrow.'
- b. xk-i-b'iyin pa ri tienda chwaq  
 POT-B1S-walk PRE DET store(Sp) tomorrow  
 'I'll (potentially) walk to the store tomorrow.'

I argue that the RT of (33a) is a future RT ( $UT < RT$ ), but the RT in (33b) is the time of utterance ( $UT = RT$ ). The event description of walking to the store takes place at a time interval in the absolute future of UT, but the potential for the event to take place is only at the time the sentence is uttered. A further example of the potential mood in future discourse is given in (34). The example comes from one of the folk stories in *Ri Kitzijon kan ri Qati't Qamama*'. Prior to this in the story, a group of animals is approaching a woodpecker to ask for a favor. They need a hole drilled in a stone in order to reach food. The response of the woodpecker is in (34). Although the narrative itself takes place in the past, the clauses of concern are those embedded under *-b'ij* 'to say/tell'. He offers them a deal that in exchange for the favor they ask, he wants a dress (costume) that they have. The RT for the speech act introducing the wish or request by the woodpecker is the time he utters it, but the events described are in the absolute future of UT.

- (34) X-u-b'ij chi-ke chï xt-u-k'öt ri abäj we xti-ki-sipaj yan

 tzyäq chi-re.  
 dress RN-3S  
 'He [the woodpecker]told them he will drill the hole in the stone if they give him the dress.'

#### 4. Interpretational preferences

For the remainder of the paper, I address the question introduced earlier in the paper about why different aspect/mood markers have interpretational preferences in out-of-the-blue-contexts or in underspecified contexts. For instance, all three markers discussed here have interpretational preferences, of which some are stronger than others (i.e. less easy to override with context). The imperfective tends to be interpreted with present temporal reference, the perfective with the past RT, and the potential with the future. In order to account for these preferences that arise in Kaqchikel, I turn to a pragmatic approach as discussed in Smith et al. (2003), Smith and Erbaugh (2005) and Smith et al. (2007) but also related to approaches developed in Bohnemeyer (1998) for Yucatec Maya and Mucha (2013) for Hausa.

The first principle deals with the deictic nature of speech, which is simply that events are described in a deictic relationship to speech time. When interpretational preferences arise, they are always situated with respect to UT. Additionally, the structure of the event described (telic/atelic, stative, etc.) affects the 'default' interpretation. The following are the observed deictic patterns for preferred interpretations as given in Smith and Erbaugh (2005).

1. Ongoing events are in the present
2. States (unbounded) are in the present
3. Bounded events are in the past
4. Explicit temporal reference may override [any of the above] (Smith and Erbaugh, 2005: p. 715)

The deictic principles offer a preliminary view of how eventualities are situated with respect to utterance time, but it stops short of explaining why, for example, bounded events are interpreted in the past and why some interpretational preferences are more difficult to override.

First, bounded events are events that are completed (though whether the boundedness includes both the initial point and terminal point is language dependent), and generally, completed events occur prior to utterance time. When shifting a bounded event to a future temporal interval, the event is still considered a completed within the time interval. Because bounded events must be completed within the time interval denoted by the RT, bounded events are not compatible with a present reference time. For Kaqchikel, this explains the restriction for the perfective aspect to past and sometimes future time intervals. Smith and Erbaugh (2005) refer to this as the *bounded event constraint*. The bounded event constraint is simply that bounded events are not located in the present.

The final pragmatic principle of relevance is the *simplicity principle of interpretation*. This principle simply states ‘choose the interpretation that requires the least additional information’ (Smith and Erbaugh, 2005: p. 717). Under this principle, we can account for why perfective, or bounded, events in Kaqchikel are more easily interpreted at past RTs and require a much richer context in order to shift the RT to the future as does a shift from a future interpretation to a past interpretation for the potential mood.

By considering pragmatic principles when trying to understand temporal reference in a language like Kaqchikel, it allows for a much simpler analysis as a tenseless language. It predicts that, although interpretational preferences arise due to the structure of the event described in an utterance, these preferences are due to pragmatics and not by underlying semantic machinery, such as covert tense. While a tensed analysis works for languages like St’át’imcets, it fails to account for the patterns in Kaqchikel. To analyze Kaqchikel as a tenseless language, in which temporal reference is established in context, with temporal adverbials, or via interpretational preferences driven by pragmatic principles, is thus the preferred analysis.

## 5. Conclusion

In summary, this paper provides an analysis of Kaqchikel temporal reference by showing that neither overt or covert tense is present in the language. Ultimately, temporal reference in utterances is interpreted using alternative means. The results of the present study contribute data from a new language to add to a growing typology of how temporal reference is established

cross-linguistically. Additionally, this work sets the stage for future research evaluating other aspects of Kaqchikel that contribute to temporality, such as temporal particles and information structure.

# Restrictions on subkind coercion in object mass nouns<sup>1</sup>

Peter SUTTON — *Heinrich Heine University, Düsseldorf*

Hana FILIP — *Heinrich Heine University, Düsseldorf*

**Abstract.** Rothstein (2015) raises the following puzzle. Why should it be the case that mass nouns like *rice* receive a coerced taxonomic plural reading when directly modified by a numerical expression, but object mass nouns like *furniture*, *jewellery* and *crockery* do not? For example, *three rices* can mean THREE KINDS OF RICE, but *three furnitures* cannot mean THREE KINDS OF FURNITURE. We attempt to solve this puzzle by providing an analysis of kind readings for concrete count and mass nouns generally, which is based on the analysis of their non-kind predicate readings in Sutton and Filip (2016a). The key property driving our analysis is the extensional overlap of subkinds at each level of categorisation. Object mass nouns have extensionally overlapping subkinds relative to a level of categorisation, while other mass nouns do not. We also differentiate between count and mass nouns in terms of counting contexts. Artefact denoting count nouns such as *vehicle* have a felicitous taxonomic plural, because, on our account, count nouns are linked to specific counting contexts, which force the resolution of potential overlap between objects in their denotation. Artefact denoting mass nouns such as *furniture* do not have a felicitous taxonomic plural, because mass nouns are saturated with the null counting context which leaves any overlap in the noun's subkind structure unresolved.

**Keywords:** kinds, subkinds, taxonomic plurals, count/mass distinction, context sensitivity.

## 1. Introduction

Concrete mass nouns can be generally coerced into count noun interpretations, PORTION or SUBKIND, modulo context (as is well known since at least Pelletier (1975)). Different classes of nouns differ with respect to the ease with which they can be coerced into a count interpretation. For example, *water* in (1a)-(1b) is easier to coerce into a count noun interpretation than *rice* in (2a)-(2b), while count interpretations of *mud* are possible only in highly specialised contexts such as in (3a)-(3b).

- (1) a. Three waters, please!  
e.g. three [GLASSES/BOTTLES OF] water. (portion)
- b. I ordered three waters for the party: still, sparkling, and fruit-flavoured for the kids.  
i.e. three [KINDS OF] water (subkind)

 These three rices have basmati's viscosity and cooking style, but smaller individual grains.<sup>3</sup>  
 i.e. three [KINDS OF] rice (subkind)
- (3) *Context: yield points of different mud samples before contamination*  
 The three muds experienced particles dispersion at the same temperature with different yield points.<sup>4</sup>
- a. The three [SAMPLES OF] mud... (portion)
- b. The three [KINDS OF] mud... (subkind)

Object mass nouns (which have also been called, *inter alia*, 'fake' or 'neat' mass nouns) include, in English, *furniture, footwear, cutlery, crockery, equipment*. These nouns are, like prototypical count nouns such as *chair* and *cat*, considered to be 'naturally atomic' in that "what counts as one entity is not determined by context but by the naturally atomic structure of the stuff. What counts as one *P* is part of our knowledge of what a *P* is" (Rothstein, 2010). What is remarkable and complicates the analysis of this subset of mass nouns derives from the observation that objects that count as one *P* in the denotation of a given object mass *P* stand in a network of kind-subkind relations. For example, *furniture* is a SUPERORDINATE CATEGORY term in that its constituent members comprise terms for BASIC LEVEL categories: *table, chair, bed*, etc. Basic level categories, in turn, subsume members labeled by SUBORDINATE LEVEL categories: for *chair*, we have *kitchen chair, dentist chair*, for instance. There is also a level of subkinds of superordinate categories: for FURNITURE, we have *bedroom furniture*, which is a kind of *furniture*.

### 1.1. The puzzle: Rothstein (2015)

Object mass nouns strongly resist coercion in numerical count constructions, in which either specific ordinary individuals of the same (sub)kind) or different (sub)kinds are counted. For example, in (4a), we see a resistance to the grammatical counting of individual items of furniture (that realise basic-level kinds). In (4b), we see resistance to counting basic level kinds, and in (4c), we see resistance to counting superordinate-level kinds.

- (4) a. #I ordered three furnitures from Ikea: one table and two chairs.  
 b. #I ordered two furnitures from Ikea: chairs and tables.  
 c. #I ordered two furnitures from Ikea: bedroom and living room furniture.

<sup>2</sup><http://www.derbytelegraph.co.uk/speciality-dishes-star-turn-littleover-s-red/story-20536589-detail/story.html> ACCESSED: 10/10/2016.

<sup>3</sup>*The Ultimate Rice Cooker Cookbook*, Harvard Common Press, 2003. p. 23

<sup>4</sup>From: Adekomaya, Olufemi A. 2013. Experimental analysis of the effect of magnesium saltwater influx on the behaviour of drilling fluids. *Journal of Petroleum Exploration and Production Technology* 3. 61–67.

This is puzzling because there are clearly identifiable and conceptually accessible ‘atomic’ entities in the denotation of object mass nouns (e.g., single items of furniture such as single tables or chairs), and yet they cannot be accessed via coercion. Subordinate categories labeled by object mass nouns have identifiable sub-/superkinds, and yet members at these levels cannot be accessed for grammatical counting in coerced environments, even when the relevant sub-/superkinds are easily retrievable from the context.

The above data are well-known, but rarely directly addressed, with a few notable exceptions. Among the recent ones is Sutton and Filip (2016a) dealing with the restrictions on grammatical counting of object mass nouns that concerns the cardinality of ordinary objects that realise basic-level kinds (4a). Rothstein (2015), as a side observation, raises the question about the lack of pluralisation with a subkind interpretation (illustrated by our example (4b) above): If mass nouns like *water* (1b) can pluralise with a coerced taxonomic subkind interpretation, why do object mass nouns not have such taxonomic plurals? However, the answer to this question lies beyond the scope of her main agenda. A recent attempt at answering this question can be found in Grimm and Levin (2016), who focus on the failure of artefact denoting nouns to form well-formed taxonomies (see Section 5). Building on some ideas of Sutton and Filip (2016a), in this paper, we pose our main question as follows: Why do object mass nouns resist mass-to-count coercion for counting taxonomic subkinds?

## 1.2. Superordinacy

The (apparent) SUPERORDINATE nature of object mass nouns like *furniture* cannot be what underlies the data. There are SUPERORDINATE COUNT nouns like *vehicle*, *weapon*, which are grammatically countable, and which have natural plurals with a subkind interpretation, as in (5a). Some of these have mass counterparts that cannot be coerced into countable subkind readings (5b).

- (5) a. The brief for the government-backed project is to produce four vehicles ranging in size from the Ford Fiesta to the Vauxhall Cavalier.<sup>5</sup>  
 b. #The brief for the government-backed project is to produce four transports...

It is worth noting that the restriction on a coerced subkind interpretation of object mass nouns is less strict in other languages. For instance, in German, there are subkind readings for indefinite NPs formed with object mass nouns. Take *Gebäck* (‘pastry’ or ‘baked good’), for instance, as in (6a). However, felicity is significantly worsened for direct numerical attachment, as in (6b). Such cross-linguistic differences have not yet been noticed, to our knowledge, but they lie outside of the scope of this paper and we plan to investigate them in our further research.

### 1.3. Outline

Object mass noun concepts like FURNITURE are associated with sub-/superkind structures that are inconsistent with a well-formed taxonomy, as has been observed (see e.g., Wierzbicka, 1985; Wisniewski et al., 1996). Related to this, we propose that they have sub-/superkind structures that overlap in their extensions, and such overlap cannot be contextually coerced into disjointness. To count kinds, overlap must be resolved; if overlap cannot be resolved, counting of 'kind units' goes wrong.

We implement this idea by relying on ideas independently introduced in three accounts of the mass/count distinction, which will be briefly summarized in Section 2: Rothstein (2010), Landman (2011), and Sutton and Filip (2016a). In Section 3, we give a semantics for kind readings of count and mass nouns by generalising restrictions on counting of particular individuals, proposed in Sutton and Filip (2016a), to restrictions on counting of kinds. In Section 4, we provide a semantics for explicit kind-extracting expressions such as *kind of* and *type of* and we show how our account from Section 3 can be used to derive the restrictions on subkind coercion. In Section 5, we briefly discuss Grimm and Levin (2016), the one other account of these data we are aware of, in the light of our analysis.

## 2. Background

### 2.1. Rothstein (2010): Count nouns are indexed to counting contexts

There is an agreement that prototypical mass nouns (*water*, *air*) are not naturally atomic (i.e., do not have stably discrete, non-overlapping objects in their denotation across all contexts), and are divisible (proper parts of *Ps* are also *Ps*). Building on Zucchi and White (1996, 2001) (and B. Partee, p.c.), Rothstein (2010) focuses on puzzling nouns, the denotations of which are divisible and not naturally atomic, but which are nonetheless lexicalized as count nouns. For example, take *fence*. What counts as a single fence is determined in context, so by Rothstein's definition, *fence* is not naturally atomic. Furthermore, nouns such as *fence* denote entities that are divisible in that a long fence could itself be divided up into smaller fence units, which also felicitously fall under the denotation of *fence*.

<sup>6</sup>Obtained from the DWDS corpus <https://www.dwds.de>

Rothstein's innovation is to introduce the notion of a counting context. Whereas mass nouns are of type  $\langle e, t \rangle$ , and denote sets of entities, count nouns are of type  $\langle e \times k, t \rangle$  and denote *semantic atoms*, that is, atomic entities indexed to counting contexts. Grammatical counting is a context dependent operation. We count, in a particular context  $k$ , instances of the noun denotation which in that context are considered atomic instances of that noun denotation.

Count predicates are derived from number neutral 'root' predicates via a  $COUNT_k$  operation. For example, suppose the root predicate  $FENCE$  denotes  $\{f_1, f_2, f_3, f_4, f_1 \sqcup f_2, \dots, f_1 \sqcup f_2 \sqcup f_3 \sqcup f_4\}$  (the set of atoms closed under mereological sum,  $\sqcup$ ) and that there are two contexts  $k_1$  and  $k_2$ :

$$\begin{aligned}
 FENCE_{\text{count}} &= COUNT_k(FENCE) = \{\langle d, k \rangle : d \in FENCE \cap k\} \\
 k_1 &= \{f_1, f_2, f_3, f_4, g_1, g_2, \dots\} \\
 k_2 &= \{f_1 \sqcup f_2 \sqcup f_3 \sqcup f_4, g_1, g_2, \dots\} \\
 COUNT_{k_1}(FENCE) &= \{\langle f_1, k_1 \rangle, \langle f_2, k_1 \rangle, \langle f_3, k_1 \rangle, \langle f_4, k_1 \rangle\} && \Rightarrow \text{Four fences} \\
 COUNT_{k_2}(FENCE) &= \langle f_1 \sqcup f_2 \sqcup f_3 \sqcup f_4, k_2 \rangle && \Rightarrow \text{One fence}
 \end{aligned}$$

In default cases, applying  $COUNT_k$  to a predicate at a context results in a disjoint set. In our analysis of kind readings for concrete nouns, we will, inspired by Rothstein (2010), also appeal to contexts as devices for yielding disjoint sets, and hence countable sets.

## 2.2. Landman (2011, 2016) on neat mass nouns

The central concept in Landman (2011, 2016) are sets that generate  $N$  denotations under mereological sum,  $\sqcup$ . These are referred to as 'generator sets' in Landman (2011) and base-sets in Landman (2016) (henceforth we mostly use terminology from Landman (2016)). Landman analyses noun denotations in terms of pairs of sets  $\langle \text{body}, \text{base} \rangle$  (an "i-set"). Bodies are the sets that determine truth conditions for predicates. Bases generate bodies under sum. The count/mass status of a noun is determined by overlap or disjointness in the base: For i-set  $X$ , " $X$  is count iff  $\text{base}(X)$  is disjoint, otherwise  $X$  is mass." (Landman, 2016: p. 8).

Of particular interest in the context of this paper, are what Landman calls *neat mass* nouns. Neat mass nouns are, approximately, those nouns otherwise referred to as object mass nouns (*furniture, kitchenware*). Neat mass nouns are mass as per the above definition, but are also neat (as opposed to mess nouns like *water, meat, salt*): " $X$  is neat iff  $\min(\text{base}(X))$  is disjoint and  $\min(\text{base}(X))$  generates  $\text{base}(X)$  under  $\sqcup$ , otherwise  $X$  is mess." (Landman, 2016: p. 9).

Entities in the base sets for neat mass nouns represent that which intuitively counts as 'one'. For example, the base-set for *kitchenware* would include, *inter alia*, single pestles, mortars, pans, and lids, but also pestle and mortar sums, and pan and lid sums. With such a denotation, *kitchenware* would be neat since e.g.  $\min(\text{base}(\text{KITCHENWARE})) = \{\text{pestle}, \text{mortar}, \text{pan}, \text{lid}\}$ , a disjoint set. However, *kitchenware* would be mass since e.g.  $\text{base}(\text{KITCHENWARE}) = \{\text{pestle}, \text{mortar}, \text{pan}, \text{lid}, \text{pestle} \sqcup \text{mortar}, \text{pan} \sqcup \text{lid}\}$ , an overlapping set.

The reason Landman emphasizes overlap in base sets is that overlap makes counting go wrong. In Landman's (2011) terminology, variants,  $V$  of a set  $X$  are maximally disjoint subsets  $X$  and

$*V \subseteq X$  such that  $\sqcup X \in *V$ . For the above example for *kitchenware*, possible variants would be:

$$\begin{array}{l|l} V_1 = \{mortar, pestle, pan, lid\} & (4 \text{ items}) \\ V_2 = \{pestle \sqcup mortar, pan, lid\} & (3 \text{ items}) \\ V_3 = \{mortar, pestle, pan \sqcup lid\} & (3 \text{ items}) \\ V_4 = \{pestle \sqcup mortar, pan \sqcup lid\} & (2 \text{ items}) \end{array}$$

The existence of different variants leads to multiple different answers to the question *how many?*, hence counting goes wrong (even if we can count the items in each variant, of course). The connection between Rothstein’s (2010) default counting contexts and variants should be relatively transparent (however see Sutton and Filip (2016b) for an in-depth discussion). In our account, we will make use of a similar notion, albeit in the context of kind and subkinds.

### 2.3. Sutton and Filip (2016a): Mass Ns are saturated with the null counting context

Our analysis of object mass nouns as predicates of entities (Sutton and Filip, 2016a) is, in part, a synthesis of Landman’s variants and Rothstein’s counting contexts. Counting contexts are indices on interpretations of predicates. We assume a domain of counting contexts  $\mathcal{C} = \{c_0, c_1, \dots, c_n\}$  such that  $c_1, \dots, c_n$  are default counting contexts in the sense of Rothstein (2010), roughly Landman’s variants, and  $c_0$  is the null counting context. We define the NULL COUNTING CONTEXT  $c_0$  to model contexts in which overlapping entities in a noun’s denotation “can all count as one simultaneously in the same context” (Landman, 2011: pp. 34-5), such that overlap makes counting go wrong. The interpretation of a predicate at the null counting context  $c_0$  is the union of the interpretations of the predicate at all counting contexts (i.e. variants). Examples for specific, disjoint counting contexts and the null, overlapping, counting context are given in Figure 1.

Figure 1: Null counting context  $c_0$  and disjoint counting contexts  $c_1$ - $c_4$

We propose that all concrete nouns contain a context variable in their lexical entries, which means that they are of type  $\langle c, \langle e, t \rangle \rangle$ . However, the lexical entries of mass nouns are saturated with the null counting context, which  $\beta$ -reduces them to type  $\langle e, t \rangle$ . For example, the lexical entry for the mass noun *kitchenware* is given in (7). Although uttered in  $c_i$ , the entry is saturated with the null counting context  $c_0$ .

$$[[\text{kitchenware}]]^{c_i} = \lambda x \langle \text{K\_WARE}(x), \text{IND}(\text{K\_WARE})(c_0)(x) \rangle \quad (7)$$

The null counting context allows for overlap in noun denotations, as  $c_0$  in Figure 1 shows. This makes them grammatically uncountable.

The lexical entries of count nouns are NOT saturated with the null counting context. Instead, the counting context argument is filled by the specific context of use. This has the effect that, when

used in a given utterance, their context argument saturated with a particular counting context. So, count nouns also  $\beta$ -reduce to type  $\langle e, t \rangle$  in a particular context. For example, the lexical entry for the German count noun *Küchengerät* ('kitchenware', lit. kitchen.device) is given in (7). The expression is uttered and evaluated at  $c_i$ .

$$[[\text{Küchengerät}]]^{c_i} = \lambda x \langle \text{K\_WARE}(x), \text{IND}(\text{K\_WARE})(c_i)(x) \rangle \quad (8)$$

Specific counting contexts only determine discrete, non-overlapping objects, as we see in  $c_1, c_2, c_3, c_4$ , in Figure 1. If there is any overlap present in the noun's denotation, specific counting contexts will resolve it.

A major strength of this account is that it allows us to easily account for crosslinguistic variation in count/mass lexicalization patterns (as shown in (7) and (8)). The only difference between a mass noun like the English *kitchenware* and a count noun like the German *Küchengerät* ('kitchenware', lit. kitchen.device), is that the IND-set of individuated entities is evaluated at the null counting context  $c_0$  in the first instance and at the counting context of utterance  $c_i$  in the second. This results in an overlapping IND-set for *kitchenware* and a disjoint IND-set for *Küchengerät*. This explains why *kitchenware* is mass, but *Küchengerät* is count.

Another advance made in Sutton and Filip (2016a) lies in the explanation of why mass-to-count coercion is blocked for object mass nouns, even if they have 'natural atoms' (ordinary individuals like chairs, tables, in the denotation of *furniture*) in their denotation. That is, we explain why the mass-to-count coercion operation cannot access 'natural atoms' that are available in their denotation.

Our analysis hinges on contrasting the implicit classifier concepts needed in cases of mass-to-count coercion (*three* [PORTIONS OF] *water*) with the role of explicit unit-extracting expressions in e.g. *piece/item of furniture*. We analyse unit-extracting classifier expressions such as *piece of*, *item of* as functions that forcibly insert the counting context of utterance into the interpretation of the whole unit-extracting phrase. In other words, such expressions shift the interpretations of nouns from being indexed at the null context ( $c_0$ ) with overlapping IND-sets to being indexed to disjoint counting contexts ( $c_1, c_2, c_3, c_4$ ). The effect on *kitchenware*, for example, is that *item of kitchenware* is interpreted with the same entry as the right hand side of (8), a pair with a disjoint, and so countable, IND-set. Based on these two assumptions, the reason why *#three kitchenwares* cannot be coerced to mean 'three ITEMS OF kitchenware' is that IMPLICITLY provided unit-extracting classifier concepts cannot perform the 'heavy handed' semantic operation of rewriting the null-context as the context of utterance. We must, we argue, evaluate at the null counting context provided by the lexical entry of the object noun, so overlap is not resolved. This blocks grammatical counting for object mass nouns in terms of a cardinality of a particular set of object instances. Counting goes wrong, even if the units for counting are conceptually accessible.

### 3. A semantics for kind readings of count and mass nouns

In this section, we argue that there are parallels between counting particular individuals and counting kinds (or subkinds). From this parallelism, we are justified in applying much of the basic architecture for analysing predicate readings of count and mass nouns, developed in Sutton and Filip (2016a) to the analysis of kind readings of count and mass nouns.

One parallel between counting particular individuals and counting kinds is that, in both cases, overlap makes counting go wrong. As we saw in Section 2, Landman's (2011; 2016) idea was that counting means non-overlap (or overlap made irrelevant). This main property behind mass/count lexicalization was adopted and built on in Sutton and Filip (2016a). We generalise this from particular individuals to kinds. First, we will argue that object mass nouns have an extensionally overlapping subkind structure, while other mass nouns do not. Then we point out that this tracks the felicity of countable subkinds in coercion environments. Finally, we provide some evidence that extensional overlap on the level of kinds prohibits felicitous counting.

By way of a working example, compare the English mass nouns *furniture* and *rice*. We do not claim that there is, definitively, a single way to analyse the kind-subkind structure of these nouns, however, two possible (partial) representations are given in Figures 2 and 3. Subkinds of **furniture** include categories such as **bedroom furniture**, **living room furniture**, and **dining room furniture**. In turn, subkinds of these categories include basic level category kinds such as **beds**, **chairs**, and **cabinets**. As Figure 2 shows, when we look to the extensional level, such as the extension of the basic level kind **chairs**, there are entities that are chairs that count as **bedroom**, **living room**, and **dining room** furniture. But this means that the subkinds **bedroom**, **living room**, and **dining room** furniture overlap extensionally. This makes sense, given that, for example, chairs labelled as 'bedroom chairs' (say in department store catalogue) can look and function just like chairs labelled 'kitchen chairs' or 'dining room chairs'.

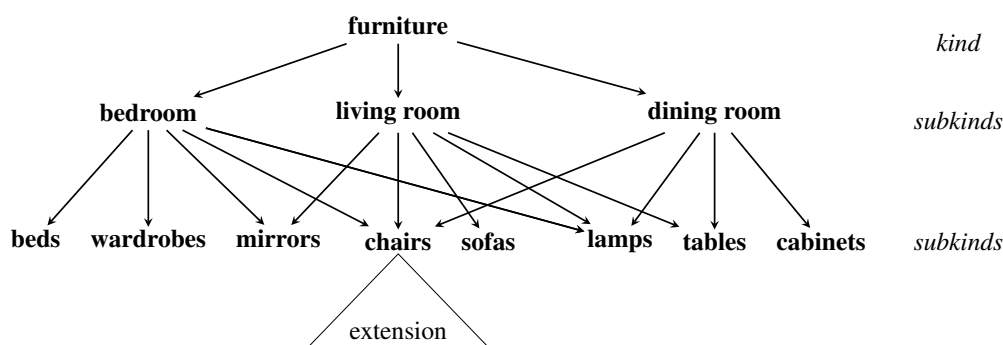

Figure 2: Kind-subkind structure of *furniture*

In contrast, subkinds of **rice** plausibly include categories such as **long grain** and **short grain**. In turn, subkinds of these categories include species kinds such as **jasmine** and **arborio**. Notice, however, that relative to one horizontal level in Figure 3, the subkinds do not overlap.<sup>7</sup> It will be important, as part of our fuller account to say more about the significance of such horizontal levels. We give a more precise characterisation of this in Section 3.1.

<sup>7</sup>It is possible that, as with most natural language expressions, the borderline between categories may be vague. We do not rule out, therefore, that there may be, for example, some rice that is a borderline case between long grain and short grain rice. However, this is distinct from the overlapping case for furniture in which, for example, some chair could be a clear case of both a dining room chair and a bedroom chair. When we use the term 'overlapping' with respect to kinds, we therefore mean 'clearly overlapping' as is the case with the denotation of *furniture*, as opposed to possibly vaguely overlapping, as could be argued for most natural language expressions.

Figure 3: Kind-subkind structure of *rice*

We hypothesise that there are two sources for the kind of overlap we see for *furniture*-like nouns but not for *rice*-like nouns. First, nouns like *rice* form a well-formed biological taxonomy, and, as such form disjoint subkinds. Nouns such as *furniture* do not denote well formed taxonomies.<sup>8</sup> Second, nouns such as *furniture* denote highly heterogeneous collections of artefacts. Members of collective artefact categories like **furniture**, **footwear**, **jewellery** are related through a network of ‘family resemblance’ style overlapping and criss-crossing relations. Furthermore, their ‘vertical’ kind-subkind relations are inconsistent with a well-formed taxonomy (inheritance of properties, transitivity, (see e.g., Wierzbicka, 1985; Wisniewski et al., 1996)).

These two properties (ill-formed taxonomies and heterogeneity), together, seem to make the probability of extensional overlap between kinds very high. Furthermore, we have seen from the distinction between *vehicle* and *transport* in (5a) and (5b), that the inaccessibility of countable subkind readings is restricted to a subclass of mass nouns. These factors, taken together, yield the following prediction. If a noun is mass and denotes a collection of homogenous artefacts, then there will be no felicitous mass-to-subkind reading when the noun is directly modified by a numerical expression or is pluralised.

In summary, we have diagnosed some properties that we think give rise to the kind of extensional overlap between kinds that we have described above. We gave some reason to associate overlap with a failure of counting entities in our discussion of (Landman, 2011, 2016): overlap makes counting go wrong because it gives rise to multiple answers to the question ‘how many?’. We end this section with some evidence that non-overlap matters for counting kinds.

In English, one can explicitly access subkinds for mass nouns by using kind classifier expressions such as *kind (of)*, *type (of)*, and *sort (of)*. This is useful, because we can see that in cases where there is nonetheless overlap between explicitly referred to subkinds, counting of subkinds is only possible if any overlap is resolved. For example, (9) would be felicitous in cases where two sets of chairs were bought (one for the kitchen, one for the dining room), even if either set of chairs could have been used in the other location.

(9) I ordered two kinds of furniture: kitchen furniture and dining room furniture.

<sup>8</sup>We will address an alternative account proposed by Grimm and Levin (2016) which focuses on the failure of taxonomic properties for artefact denoting nouns in Section 5.1.

That is to say, if we ignore or remove overlap and treat the sets as disjoint, then counting is possible. However, if we make the removal of overlap impossible, we get infelicity in numerical constructions. For example, the truth-conditions of (9) exclude a case where one ordered one set of chairs that could function both as kitchen chairs and dining room chairs.

### 3.1. Formal account

The main idea to be formally elaborated upon here is that counting subkinds is sensitive to KIND COUNTING CONTEXTS that remove overlap between subkinds in their constituent members. We introduce kind counting contexts as an index in the formalism. However, their precise mechanisms are likely to be dependent on pragmatic speaker-hearer decisions based on intensional criteria. From the set of kind counting contexts, we define a NULL KIND COUNTING CONTEXT. The null counting context does not resolve overlap. Akin to the treatment of mass nouns in Sutton and Filip (2016a), the lexical entries of mass nouns are saturated with the null kind counting context. Count nouns will take the kind counting context of utterance.

We restrict our semantics to kind (or subkind) readings, modelled as Boolean semilattices closed under sum. Models  $M$  are a tuple  $M = \langle \mathcal{D}, \mathcal{C}, \mathcal{L} \rangle$ :

- $\mathcal{D} = \{\mathbb{D}_e, \mathbb{D}_k, \mathbb{D}_t\}$
- $\mathbb{D}_e$  = the domain of entities, a semilattice structure of atomic entities closed under  $\sqcup_e$ .
- $\mathbb{D}_k$  = the domain of (sub)kinds,  $k_i$ , a semilattice structure of atomic subkinds closed under  $\sqcup_k$ .
- $\mathbb{D}_t = \{0, 1\}$
- $\mathcal{C}$  = set of counting contexts  $c_i$
- $\mathcal{L}$  = set of levels of categorisation  $l_i$

Other formal terminology is as standard except we mark relations between entities with a subscript  $e$  and relations between kinds with a subscript  $k$ .

|                 |                                 |                 |                                     |
|-----------------|---------------------------------|-----------------|-------------------------------------|
| $\sqcup_e$      | mereological sum for entities   | $\sqsubseteq_k$ | part of (kinds and subkinds)        |
| $\sqcup_k$      | mereological sum for (sub)kinds | $\sqsubset_k$   | proper part of (kinds and subkinds) |
| $\sqsubseteq_e$ | part of (entities)              | $a : k$         | $a$ is of (sub)kind $k$             |
| $\sqsubset_e$   | proper part of (entities)       | $k \circ k'$    | $k$ overlaps with $k'$              |

We do not commit to a particular analysis of kinds, we assume a basic intuitive taxonomic ‘kind of’ relation. Notably, the mereology of kinds mirrors the mereology of entities. For example, the definition of the part of relation for kinds is *mutatis mutandis* identical to the definition of ‘part of’ in standard mereology (10). However, subkinds also imply relations between entities of that kind (like subtypes in type theory) as defined in (11). Because we wish to capture overlap between parts of entities as well as whole entities, we adopt Landman’s (2016) use of Boolean part sets defined in (12). Extensional overlap between kinds is defined in (13).<sup>9</sup>

<sup>9</sup>We presume this is relative to a world but we suppress such details here.

$$\forall k, k' [k \sqsubseteq_k k' \leftrightarrow k \sqcup_k k' = k'] \quad (10)$$

$$\forall k, k' [k \sqsubseteq_k k' \leftrightarrow \forall x_{\langle e \rangle} [x : k \rightarrow x : k']] \quad (11)$$

$$(x) = \{y \mid y \sqsubseteq_e x\} \quad (12)$$

$$\forall k, k' [k \circ k' \leftrightarrow \exists x, y, z_{\langle e \rangle} [y : k \wedge z : k' \wedge x \in (y) \wedge x \in (z)]] \quad (13)$$

In words, two kinds extensionally overlap if an entity or a proper part of some entity that is in one is an entity or a proper part of an entity in the other.

**Levels of categorisation:** When it comes to counting subkinds, the requisite resolution of overlap with respect to a counting context amounts to the restriction of not simultaneously counting entities at DIFFERENT LEVELS of categorisation. For example, it is highly marked to say *I bought two kinds of furniture: tables and living room*. We semi-formally define levels of categorisation in the following way.

$k, k'$  are admissible on the same level of categorisation, iff

- (i)  $\neg(k \sqsubset k')$  and  $\neg(k' \sqsubset k)$
- (ii)  $k$  and  $k'$  form part of a natural comparison class of subkinds.

We assume a pre-theoretic notion of *natural comparison class* and give only the examples in Table 1 to demonstrate it. Examples of levels of categorisation for the kinds **rice** and **furniture** are also given in Table 1.

Table 1: Examples of levels of categorisation

| Kind             | level                   | subkinds forming a natural comparison class |
|------------------|-------------------------|---------------------------------------------|
| <b>rice</b>      | <i>colour</i>           | <b>brown, white</b>                         |
|                  | <i>grain length</i>     | <b>long grain, short grain</b>              |
|                  | <i>origin</i>           | <b>USA, India</b>                           |
| <b>furniture</b> | <i>furnishing space</i> | <b>bedroom, office</b>                      |
|                  | <i>item type</i>        | <b>chairs, sofas</b>                        |

**Counting contexts:** Kind counting contexts,  $c_i$ , are mappings from sets of subkinds (at some level) to maximally disjoint sets of subkinds (at that level). For example, there are different EXTENSIONAL RESOLUTIONS of the sub-kinds **dining room** and **bedroom** furniture. We will call these e.g. **dining room**<sub>1</sub>, ..., **dining room** <sub>$n$</sub> , **bedroom**<sub>1</sub>, ..., **bedroom** <sub>$n$</sub> . Extensional resolutions differ, for example, with respect to whether some particular chair counts as dining room furniture or bedroom furniture. In this sense, they are different from *variants* since they have no condition of maximal disjointness or generation of the extension of the full extension under sum. Some of the resolutions from one subkind may overlap with some resolutions from the other, but some of the resolutions from one subkind may be disjoint with some resolutions from the other. Kind counting contexts resolve the overlap inherent in the subkind structure of the kind by selecting non-overlapping extensional resolutions for each subkind in a set of subkinds. Effectively, counting contexts force a choice for specific items in the domain: “Is this dining room furniture or bedroom furniture in this context?”

At the *null counting context* ( $c_0$ ), subkinds may be overlapping in their constituent members and extensional overlap makes counting of subkinds go wrong. The *null counting context* ( $c_0$ ) is defined in (14), relative to a counting level, in terms of the union of counting contexts  $c_{i \geq 1} \in \mathcal{C}$  (all maximally disjoint subsets of  $X$ ).

$$X_{c_0, l_i} = \bigcup X_{c_i, l_i} \text{ computed from all } c_{i \geq 1} \in \mathcal{C} \quad (14)$$

**IND<sub>k</sub> function:** Kind predicates are interpreted relative to levels ( $l_i \in \mathcal{L}$ ) of categorisation and counting contexts ( $c_i \in \mathcal{C}$ ). The intuitive notion of ‘counting as one’ is here recast as a function IND<sub>k</sub>. We assume that IND<sub>k</sub> is intensional and also dependent on, *inter alia*, the purposes and goals of the communicative agents. For simplicity, we set these complications aside. IND<sub>k</sub> accesses the subkind structure of a kind predicate (a set of subkinds  $\langle k, t \rangle$ ) and introduces a counting context argument  $c$ , and a counting level argument  $l$ . At a context and a level the subkinds in the set count as ‘one’. IND<sub>k</sub> is of type  $\langle k, \langle l, \langle c, \langle k, t \rangle \rangle \rangle \rangle$ . Given a kind, a level and a context, it outputs a set of (sub-)kinds that can be counted if they do not overlap extensionally.

$$\text{IND}_k = \lambda k_1 \lambda l \lambda c \lambda k_2 [k_2(l)(c) \wedge k_2 \sqsubseteq k_1] \quad (15)$$

**Examples of IND<sub>k</sub>, counting contexts and levels:** In order to solidify how these different parts of our formal apparatus operate, we provide a toy example of how the subkinds structure of *furniture* can be broken down into different levels of categorisation and made disjoint at different counting contexts. Table 2 shows some of the subkinds for *furniture* at two different levels indexed for different extensional resolutions. Table 3 demonstrates how, relative to level  $l_1$ , the extensions of the different extensional resolutions can overlap. In this example, there are two elements,  $c$  and  $d$ , which are in the extension of more than one subkind.

Table 2: Examples of subkinds for *furniture* at two different levels of categorisation, indexed for different extensional resolutions.

| Level | Subkinds                                                                                                                    |
|-------|-----------------------------------------------------------------------------------------------------------------------------|
| $l_1$ | <b>dining_room</b> <sub>1, ..., dining_room<sub>n</sub></sub> , <b>bedroom</b> <sub>1, ..., bedroom<sub>n</sub></sub> , ... |
| $l_2$ | <b>chairs</b> <sub>1, ..., chairs<sub>n</sub></sub> , <b>tables</b> <sub>1, ..., tables<sub>n</sub></sub> , ...             |

Table 3: Some extensional resolutions for subkinds of *furniture*.

| dining_room              |                          |                          | bedroom              |                      |                      |
|--------------------------|--------------------------|--------------------------|----------------------|----------------------|----------------------|
| dining_room <sub>1</sub> | dining_room <sub>2</sub> | dining_room <sub>3</sub> | bedroom <sub>1</sub> | bedroom <sub>2</sub> | bedroom <sub>3</sub> |
|                          |                          |                          |                      |                      |                      |
| extension                | extension                | extension                | extension            | extension            | extension            |
| ↓                        | ↓                        | ↓                        | ↓                    | ↓                    | ↓                    |
| $\{a, b\}$               | $\{a, b, c\}$            | $\{a, b, c, d\}$         | $\{e, f\}$           | $\{d, e, f\}$        | $\{c, d, e, f\}$     |

There are different ways to resolve this overlap by applying kind counting contexts in order to ensure that the extensional resolutions of subkinds are non-overlapping. Three of the possible counting contexts are given in Table 4. At each counting context, one extensional resolution is chosen from each subkind (at a particular level) such that the subkinds are disjoint.

Table 4: Some possible counting contexts for *furniture* at  $l_1$ .

| Context | Subkind Resolution                                |
|---------|---------------------------------------------------|
| $c_1$   | $\{\mathbf{dining\_room}_1, \mathbf{bedroom}_3\}$ |
| $c_2$   | $\{\mathbf{dining\_room}_2, \mathbf{bedroom}_2\}$ |
| $c_3$   | $\{\mathbf{dining\_room}_3, \mathbf{bedroom}_1\}$ |

Finally, we give an example of how the  $\text{IND}_k$  function provides the argument structure for levels and counting contexts. The formulas below will form parts of lexical entries of kind readings of nouns. We give details of this in Section 3.2.

$$\begin{aligned}
 \text{IND}_k(\mathbf{furniture}) &= \lambda l \lambda c \lambda k [k(l)(c) \wedge k \sqsubseteq \mathbf{furniture}] = \{\mathbf{dining\_r}_1, \dots, \mathbf{dining\_r}_n, \\
 &\quad \mathbf{bedroom}_1, \dots, \mathbf{bedroom}_n, \\
 &\quad \mathbf{chairs}_1, \dots, \mathbf{chairs}_n, \\
 &\quad \mathbf{tables}_1, \dots, \mathbf{tables}_n, \} \\
 \text{IND}_k(\mathbf{furniture})(l_1) &= \lambda c \lambda k [k(l_1)(c) \wedge k \sqsubseteq \mathbf{furniture}] = \{\mathbf{dining\_r}_1, \dots, \mathbf{dining\_r}_n, \\
 &\quad \mathbf{bedroom}_1, \dots, \mathbf{bedroom}_n\} \\
 \text{IND}_k(\mathbf{furniture})(l_1)(c_1) &= \lambda k [k(l_1)(c_1) \wedge k \sqsubseteq \mathbf{furniture}] = \{\mathbf{dining\_r}_1, \mathbf{bedroom}_3\} \\
 &\quad \text{(two non-overlapping subkinds} \\
 &\quad \text{relative to level } l_1 \text{ \& context } c_1)
 \end{aligned}$$

### 3.2. Lexical entries for kind denoting expressions

We wish to remain neutral with respect to the relationship between kind readings and predicate readings for nouns in English. However, a reasonable working hypothesis is that there is a kind shifting operation from predicates to kinds (generally available for mass nouns, for count nouns, licensed by the bare plural noun morphology or definite article plus singular noun constructions).

Kind readings of nouns are interpreted as pairs  $\langle \mathbf{kind}, \mathbf{counting\_base} \rangle$ . The **kind** is the kind for a noun (the result of a kind shifting operation). The **counting\_base** is the result of the application of the  $\text{IND}_k$  function to a kind ( $\text{IND}_k(\mathbf{n})$ ). Recall that the  $\text{IND}$  function for kinds applies to a kind  $\mathbf{n}$  and yields a function from counting levels  $l$  to a function from counting contexts  $c$ , to a set of subkinds  $k$  each of which count as ‘one’ with respect to the kind  $\mathbf{n}$ . Counting of kinds is licensed only when the counting base does not overlap extensionally. Count nouns are interpreted at the level and counting context of utterance. Mass nouns are interpreted at the level of utterance, but come saturated with the null counting context ( $c_0$ ). This means that any overlap in the  $\text{IND}$ -set at a level remains and so can block the counting of subkinds.

*Rice*: the entry for the mass noun *rice* is given in (16). The first in the pair is the kind **rice**. The second in the pair is the set of subkinds of rice at the level  $l_j$  and the null counting context  $c_0$ .

$$\llbracket \text{rice} \rrbracket^{c_i, l_j} = \langle \mathbf{rice}, \text{IND}_k(\mathbf{rice})(l_j)(c_0) \rangle \quad (16)$$

As Figure 4 helps to show, even at the null counting context, relative to a level, the subkinds of *rice* are extensionally disjoint. This means that they are available for counting. We will give an account of mass-to-subkind coercion in Section 4, however, in principle, this means that directly attaching a numerical expression to *rice* can yield a felicitous subkind reading as in (2b).

Figure 4: Subkinds at each level have *Disjoint Extensions*

Notice, also, that the subkind structure for *rice* preserves *property inheritance*: the subkind has the same properties as the superkind plus one or more additional properties. For example, Basmati rice is a type of long-grain rice and has the properties of long-grain rice; long-grain rice is a type of rice and has the properties of rice.

*Furniture*: The lexical entry for the mass noun *furniture* is given in (17) and (18). The only difference between them is how the argument for level of categorisation has been filled.

$$\llbracket \text{furniture} \rrbracket^{c_i, l_1} = \langle \mathbf{furniture}, \text{IND}_k(\mathbf{furniture})(l_1)(c_0) \rangle \quad (17)$$

$$\llbracket \text{furniture} \rrbracket^{c_i, l_2} = \langle \mathbf{furniture}, \text{IND}_k(\mathbf{furniture})(l_2)(c_0) \rangle \quad (18)$$

Figure 5: Subkinds at  $l_1$  have *Overlapping Extensions*

Like *rice*, *furniture* is a mass noun and so the entry is saturated with the null counting context. Unlike *rice*, however, the subkinds for *furniture* are not extensionally disjoint at the null counting

context at either level as Figures 5 and 6 help to show. At level  $l_1$ , for example, some chairs ( $\{c_1, c_2, c_3, c_4\}$ ) count as bedroom, kitchen and dining room furniture. There are, therefore, different answers to the question *how many kinds?* which makes counting of subkinds go wrong. At level  $l_2$ , for example, the basic level category **vanities** extensionally overlaps with the basic level categories **chairs**, **tables** and **mirrors**. There are, therefore, different answers to the question *how many kinds?* which makes counting of subkinds go wrong.

Figure 6: Subkinds at  $l_2$  have *Overlapping Extensions*

*Vehicles*: The entry for the plural count noun *vehicles* is given in (19). The kind-subkind structure of this collective artefact denoting noun also has overlapping subkinds (just like *furniture*). However, as a count noun, *vehicles* is NOT saturated with the null counting context. Therefore, it is interpreted relative to the counting context of evaluation.

$$\llbracket \text{vehicles} \rrbracket^{c_i, l_2} = \langle \mathbf{vehicle}, \text{IND}_k(\mathbf{vehicle})(l_2)(c_i) \rangle \quad (19)$$

Figure 7: Subkinds at  $l_2$  have *Overlapping Extensions*

That is to say that although the structure of *vehicles* looks just like the structure of *furniture* in terms of overlapping subkinds, because the counting context of evaluation is not the null counting context, extensional overlap between subkinds at each level of categorisation is resolved. Specific counting contexts force the resolution of overlap and so, there is, in any one context, only one answer to the question ‘*how many kinds?*’. This makes the counting of subkinds possible.

#### 4. Kind extracting expressions and restrictions on subkind coercion

First, in Section 4.1, we give an outline for the semantics of kind extracting classifier expressions such as *kind of*, *type of* and *sort of*. The outcome of this will be a compositional analysis of

complex noun expressions such as *kind of furniture*. Our main focus will be on how such expressions compose with lexically simple mass nouns to yield something countable. Second, in Section 4.2 we will provide an analysis of mass-to-subkind cases of coercion. We will show how, combined with or account from Section 3.1, we can explain why coercion is possible for nouns such as *rice* (see example (2b)), but not for collective artefact nouns such *furniture* (see examples (4b) and (4c)).

#### 4.1. Kind extracting expressions

Our account of the kind-subkind structure denoted by concrete nouns allows us to give a very straightforward analysis of kind extracting expressions such as *type of*, and *kind of*. On the assumption that English count nouns are standardly predicate denoting and English mass nouns are standardly kind denoting (Chierchia, 1998), first kind extracting expressions license a type shift to a kind reading for singular count nouns such as *vehicle* in *kind of vehicle* (details of this shifting operation suppressed below). However, more importantly, second, kind extracting expressions force a resolution of any extensional overlap between subkinds at some level of categorisation. Formally, we can represent this as a function that introduces a further context argument into the counting base (we use the standard functions  $\pi_i, \pi_2$  such that for an expression  $\langle X, Y \rangle_{\langle a \times b \rangle}$ ,  $\pi_1(\langle X, Y \rangle) = X$  and  $\pi_2(\langle X, Y \rangle) = Y$ ):

$$\llbracket \text{n}_{\text{kind reading}} \rrbracket^{c_i, l_i} = \langle \mathbf{n}, \text{IND}_k(\mathbf{n})(l_i)(c_i) \rangle_{\langle k \times \langle k, t \rangle \rangle} \quad (20)$$

$$\llbracket \text{kind of} \rrbracket = \lambda \mathcal{K}_{\langle k \times \langle k, t \rangle \rangle} \lambda c \langle \pi_1(\mathcal{K}), \pi_2(\mathcal{K})(c) \rangle \quad (21)$$

Since kind counting contexts are mappings from sets of subkinds (at some level) to maximally disjoint sets of subkinds (at that level), counting contexts can be stacked. Applying a specific counting context to an overlapping set of subkinds evaluated at the null counting context, returns a disjoint set of subkinds. For kinds denoted by mass nouns, therefore, the kind extracting expression operation, in effect, replaces the null counting context,  $c_0$ , with the counting context of utterance for the kind-extracting expression. This allows the counting of subkinds. For instance, for *kind of furniture* in (22):

$$\begin{aligned} \llbracket \text{kind of furniture} \rrbracket^{c_i, l_j} &= \llbracket \text{kind of} \rrbracket^{c_i} (\llbracket \text{furniture} \rrbracket^{c_i, l_j}) \\ &= \llbracket \text{kind of} \rrbracket (\llbracket \text{furniture} \rrbracket^{c_i, l_j}(c_i)) \\ &= \lambda \mathcal{K}. \lambda c. \langle \pi_1(\mathcal{K}), \pi_2(\mathcal{K})(c) \rangle (\langle \mathbf{furn}, \text{IND}_k(\mathbf{furn})(l_j)(c_0) \rangle)(c_i) \\ &= \lambda c. (\langle \mathbf{furn}, \text{IND}_k(\mathbf{furn})(l_j)(c_0)(c) \rangle)(c_i) \\ &= \langle \mathbf{furn}, \text{IND}_k(\mathbf{furn})(l_j)(c_0)(c_i) \rangle \\ &= \langle \mathbf{furn}, \text{IND}_k(\mathbf{furn})(l_j)(c_i) \rangle \end{aligned} \quad (22)$$

The context of evaluation for the kind extracting expression applies to the counting base and enforces the extensional resolution of overlap among subkinds in that context. This prevents multiple, and possibly inconsistent, category assignments to ordinary individuals, e.g., one chair *simultaneously* realising two different subkinds, **kitchen furniture** and **dining room furniture**, for instance, *in the same context at the same time*; of course, one and the same chair can be categorised as a kitchen chair in one context, and a dining room chair in another context.

## 4.2. Restrictions on subkind coercion

Subkind coercion, we assume, is one possible strategy for resolving a type-mismatch such as the one created by applying a numerical expression directly to a mass noun. One way of attempting to resolve this mismatch is to access the subkind structure in the kind reading of the mass noun's lexical entry and attempt to enumerate these subkinds. However, this strategy can only be successful if the kind interpretation of the noun has a disjoint subkind structure. If it does not, the grammatical counting operation is not defined. For example, for an expression  $\mathcal{K}_{\langle k \times \langle k, t \rangle \rangle}$ , the type for a kind-interpretation of a noun, applying a numerical expression such as *three*, will have the result shown in (23).

$$\llbracket \text{three} \rrbracket(\mathcal{K}) = \begin{cases} \langle \pi_1(\mathcal{K}), |\pi_2(\mathcal{K})| = 3 \rangle & \text{presupposing } \pi_2(\mathcal{K}) \text{ is disjoint} \\ \perp & \text{otherwise} \end{cases} \quad (23)$$

This will give different results for nouns such as *rice* compared to nouns such as *furniture*. Nouns like *rice* have an extensionally disjoint subkind structure at each level of categorisation. Therefore, if one coerces *rice* as a result of direct numerical modification, the felicitous reading will be to enumerate subkinds. This is the reading for sentences such as (2b). Nouns like *furniture* do not have an extensionally disjoint subkind structure at each level of categorisation. Therefore, if one coerces *furniture*, as a result of direct numerical modification, there will not be a felicitous reading that enumerates subkinds. This explains the infelicity of sentences such as (4b) and (4c).

Furthermore, this will give different results for mass nouns such as *transport* compared to count nouns such as *vehicle*. On the assumption that, in English, the pluralisation of count nouns licenses a kind shifting operation (Chierchia, 1998), counting of subkinds is felicitous because, although **vehicle**, like **transport**, has an overlapping subkind structure, the lexical entry for *vehicle* is not, as a count noun entry, saturated with the null counting context whereas the lexical entry for *transport*, as a mass noun entry is saturated with the null counting context. This means that in every context of utterance, the overlap between subkinds for **vehicle** is resolved by the counting context of use. On the other hand, the saturation of the lexicon with the null counting context for *transport* means that extensional overlap between subkinds is not resolved. This explains the felicity of examples such as (5a) and the infelicity of examples such as (5b).

## 5. Conclusions and comparisons with other accounts

### 5.1. An alternative account: Grimm and Levin (2016)

As far as we know, there is only one other account (Grimm and Levin, 2016) that tries to accommodate the data we have considered here. Grimm and Levin emphasise that collective artefact (*furniture*-like) nouns and their purported subordinate terms do not stand in a well formed taxonomic relation *viz.* they do not participate in the kind-subkind relations necessary to form a well-formed taxonomy. For example, in well formed taxonomies, subkinds inherit all properties from superkinds. Take the kind **apple**, the subkind **green apple** and the subsubkind **granny smith**. Green apples have all the properties of apples, and Granny Smiths have all the properties of green apples. The inheritance relation is transitive. Collective artefacts do not preserve property inheritance. The reason for this, on Grimm and Levin's (2016) analysis, derives from

their claim that denotations of collective artefact nouns include (potential) associated events. For example, part of the lexical semantics of *furniture* is that items in the denotation of *furniture* potentially participate in furnishing events, or at least has the potential to serve this function. This is meant to contrast with expressions such *chair*, the denotata of which participate in sitting-on events. The result is that “ $\llbracket \text{chair} \rrbracket \not\subseteq \llbracket \text{furniture} \rrbracket$ , even though chairs (in stereotypical worlds) always satisfy the associated event of furniture.” and “*Furniture*-like nouns and their constituent entities have different associated events, and therefore do not participate in the sub-/super-kind relation necessary to form an artifactual taxonomy.” (Grimm and Levin, 2016). To take another example, *furniture* is for furnishing spaces and mirrors are a subkind of furniture, however, mirrors are not all for furnishing spaces. Compact make-up mirrors and telescope mirrors, for instance, do not share this function.

We have made no mention, in our account, of associated events, but we do not see any reason why there should not be an event-related component in the analysis of kinds denoted by artefact nouns. It strikes us as plausible that, if events are a part of the lexical semantics for artefact denoting nouns, then reference to event types may well underspecify extensions in a way that will give rise to extensional overlap in subkinds. In this sense, our account and Grimm and Levin’s may well be compatible. Further work must be done to establish the veracity of this possibility, however.

## 5.2. Conclusions

The crucial difference between *furniture*- and *rice*-like nouns, on our account, is that subkinds of *furniture*-like nouns extensionally overlap with respect to their constituent subordinate entities, i.e., ‘lower’ subkinds and ordinary individuals. *Furniture*-like nouns do not lack subkinds entirely (pace Grimm and Levin (2016)), but their taxonomies are defective, and so inconsistent with well-formed taxonomies. This is not the case for prototypical mass nouns like *water* or granular nouns like *rice*, which have taxonomic subkinds whose members we view as conceptually not overlapping.

The crucial difference between *furniture*- and *vehicle*-like nouns, on our account, is that, as mass nouns, *furniture*-like nouns are indexed to the null counting context ( $c_0$ ) whereas count nouns like *vehicle* are indexed to the counting context of utterance. This means that when interpreted with kind readings, despite the fact that both kinds of nouns denote extensionally overlapping subkind structures, the subkinds of *vehicle*-like nouns are countable because the counting context of utterance forces a choice which resolves this overlap. In context, we are forced to decide if some vehicles are trucks or vans. The result of this choice determines whether there are two kinds of vehicles or just one.

The indexing of mass nouns to the null counting context explains why a simple ‘kind of’ coercion is insufficient for object mass nouns: they have overlapping taxonomic (sub)kinds. The coercion operation consists of accessing, and attempting to enumerate, the subkind structure in the lexical entry. Counting subkinds is only then possible if the subkinds at some level are extensionally

disjoint. This contrasts with the explicit use of a kind extracting expression such as *kind of* which also provides a counting context of utterance that resolves extensional overlap.

# Bounded rationality and logic for epistemic modals<sup>1</sup>

Satoru SUZUKI — *Komazawa University, Japan*

**Abstract.** Kratzer (1991) provides *comparative epistemic modals* such as ‘at least as likely as’ with their models in terms of a *qualitative ordering*. Yalcin (2010) shows that Kratzer’s model does *not validate* some intuitively *valid* inference schemata and *validates* some intuitively *invalid* ones. He adopts a model based directly on a *probability measure* for comparative epistemic modals. His model does *not* cause this problem. However, as Kratzer (2012) says, Yalcin’s model seems to be *unnatural* as a model for comparative epistemic modals. Holliday and Icard (2013) prove that not only a *probability measure model* but also a *qualitatively additive measure model* and a *revised version of Kratzer’s model* do not cause Yalcin’s problem. Suzuki (2013) proposes a logic the model of which reflects Kratzer’s intuition above, does not cause Yalcin’s problem, and has *no limitation of the size* of the domain. In the models of Holliday and Icard (2013) and Suzuki (2013), the *transitivity* of probabilistic indifference is valid. The transitivity of probabilistic indifference can lead to a *sorites paradox*. The *nontransitivity* of probabilistic indifference can be regarded as a manifestation of *bounded rationality*. The *aim* of this paper is to propose a new version of *complete logic*—Boundedly-Rational Logic for Epistemic Modals (BLE)—the model of the language of which has the following *three* merits: (1) The model reflects *Kratzer’s intuition* above in the sense that the model should not be based directly on probability measures, but based on qualitative probability orderings. (2) The model does not cause *Yalcin’s problem*. (3) The model is *boundedly-rational* in the sense that the transitivity of probabilistic indifference is not valid. So it does not invite the *sorites paradox*.

**Keywords:** bounded rationality, epistemic modal, just noticeable difference, modal logic, representation theorem, semiorordered qualitative probability, sorites paradox

## 1. Motivation

Kratzer (1991) provides *comparative epistemic modals* such as ‘at least as likely as’ with their models in terms of a *qualitative ordering* on propositions derived from a qualitative ordering on possible worlds. Yalcin (2010) shows that Kratzer’s model does *not validate* some intuitively *valid* inference schemata and *validates* some intuitively *invalid* ones. He adopts a model based directly on a *probability measure* for comparative epistemic modals. His model does *not* cause this problem. However, as Kratzer (2012) says, ‘Our semantic knowledge alone does not give us the *precise quantitative notions of probability and desirability* that mathematicians and scientists work with’, Yalcin’s model seems to be *unnatural* as a model for comparative epistemic modals. Holliday and Icard (2013) prove that not only a *probability measure model* but also a *qualitatively additive measure model* and a *revised version of Kratzer’s model* do not cause Yalcin’s problem. Suzuki (2013) proposes a logic the model of which reflects Kratzer’s intuition above, does not cause Yalcin’s problem, and has *no limitation of the size* of the domain.

Generally, the standard models of social sciences are based on *global rationality* that requires

an *optimising behavior*. But according to Simon (1982a, b, 1997), cognitive and information-processing constrains on the capabilities of agents, together with the complexity of their environment, render an optimising behavior an *unattainable ideal*. Simon dismisses the idea that agents should exhibit global rationality and suggests that they in fact exhibit *bounded rationality* that allows a *satisficing behavior*. If an agent has only a *limited* ability of discrimination, he may be considered to be only *boundedly rational*. In the models of Holliday and Icard (2013) and Suzuki (2013), the *transitivity* of probabilistic indifference is valid. The following example shows that the transitivity of probabilistic indifference can lead to a *sorites paradox*:

**Example 1 (Sorites Paradox)** Suppose that a prep-school has 1000 candidates, and that a staff member of the school arranges them in order of the average of examination results:  $c_1$  (top),  $c_2, \dots, c_{1000}$  (bottom), and that, for any  $i$  ( $1 \leq i \leq 999$ ),  $c_i$  will pass the university entrance exam as likely as  $c_{i+1}$  for him, and that  $c_1$  will pass it by far more likely than  $c_{1000}$  for him. Then if probabilistic indifference were transitive,  $c_1$  would result in passing it as likely as  $c_{1000}$  for the staff member.

The *nontransitivity* of probabilistic indifference can be regarded as a manifestation of *bounded rationality*. An agent has only a limited ability of discrimination. The psychophysicist Fechner (1860) explains this limited ability by the concept of a *threshold of discrimination*, that is, *just noticeable difference* (JND). Given a measure function  $f$  that an examiner could assign to a boundedly rational examinee for an object  $a$ , its JND  $\delta$  is the *lowest intensity increment* such that  $f(a) + \delta$  is recognized to be higher than  $f(a)$  by the examinee. We can consider a JND from a *probabilistic* point of view. Domotor and Stelzer (1971) introduce the concept of *semiordeed qualitative probability* that can provide a qualitatively probabilistic counterpart of a JND.

The *aim* of this paper is to propose a new version of *complete* logic—Boundedly-Rational Logic for Epistemic Modals (BLE)—the model of the language of which has the following *three* merits:

1. The model reflects *Kratzer's intuition* above in the sense that the model should not be based directly on probability measures, but based on qualitative probability orderings.
2. The model does not cause *Yalcin's problem*.
3. The model is *boundedly-rational* in the sense that transitivity of probabilistic indifference is not valid. So it does not invite the *sorites paradox* in Example 1.

The structure of this paper is as follows. In Section 2, we show a representation theorem by Domotor and Stelzer (1971) related to a normalized JND. In Subsection 3.1, we define the language  $\mathcal{L}_{\text{BLE}}$  of BLE. In Subsection 3.2, we define a structured model  $\mathfrak{M}$  of  $\mathcal{L}_{\text{BLE}}$ , provide BLE with a truth definition at  $w \in W$  in  $\mathfrak{M}$ , define the truth in  $\mathfrak{M}$ , define validity, provide BLE with some truth conditions in terms of a probability measure, justify the (in)validity of Yalcin's formulae in BLE, and show the invalidity of the transitivity of probabilistic indifference in BLE. In Subsection 3.3, we provide BLE with its proof system. In Subsection 3.4, we show the

soundness and completeness theorems of BLE. In Section 4, we finish with brief concluding remarks.

## 2. Representation theorem for $\succ$

Domotor and Stelzer (1971) prove the following theorem in which  $\delta$  is interpreted to mean a *normalized JND*:

**Theorem 1 (Representation Theorem for  $\succ$ , Domotor and Stelzer (1971))** *Suppose that  $W$  is a nonempty finite set of possible worlds, and that  $\mathcal{F}$  is the Boolean algebra of subsets of  $W$ , and that  $\succ$  is a binary relation on  $\mathcal{F}$ . Then there exists a finitely additive probability measure  $P : \mathcal{F} \rightarrow \mathbb{R}$  and  $\delta \in \mathbb{R}$  satisfying*

$$A \succ B \text{ iff } P(A) \geq P(B) + \delta,$$

where  $0 < \delta \leq 1$  iff the following conditions are met:

1. **Nontriviality:**  $W \succ \emptyset$ .
2. **Irreflexivity:** Not  $(A \succ A)$ , for any  $A \in \mathcal{F}$ .
3. **Dominance:** For any  $A, B, C \in \mathcal{F}$ , if  $A \subseteq B$ , then if  $C \succ B$ , then  $C \succ A$ .
4. **Semi-Scottness:** For any  $n \geq 1$  and any  $A_1, \dots, A_n, B_1, \dots, B_n, C_1, \dots, C_n, D_1, \dots, D_n \in \mathcal{F}$ , if for any  $i < n$ ,  $(A_i \succ B_i \text{ and not } (C_i \succ D_i))$ , then if  $A_n \succ B_n$ , then  $C_n \succ D_n$ , given that

$$\bigcup_{1 \leq i_1 < \dots < i_k \leq n} ((A_{i_1} \cup D_{i_1}) \cap \dots \cap (A_{i_k} \cup D_{i_k})) = \bigcup_{1 \leq i_1 < \dots < i_k \leq n} ((B_{i_1} \cup C_{i_1}) \cap \dots \cap (B_{i_k} \cup C_{i_k}))$$

holds for any  $k$  with  $1 \leq k \leq n$ .

**Remark 1 (Semi-Scottness)** *Intuitively, the part after ‘given that’ of Semi-Scottness means that for any  $w \in W$ ,  $w$  is in exactly as many  $A_i \cup D_i$ ’s as  $B_i \cup C_i$ ’s.*

## 3. Boundedly-rational Logic for Epistemic Modals (BLE)

### 3.1. Language

We define the language  $\mathcal{L}_{\text{BLE}}$  of BLE as follows:

**Definition 1 (Language)** *Let  $\mathcal{S}$  denote a set of sentential variables,  $\Box$  a unary sentential operator, and  $>$  a binary sentential operator. The language  $\mathcal{L}_{\text{BLE}}$  of BLE is given by the following BNF grammar:*

$$\varphi ::= s \mid \top \mid \neg\varphi \mid (\varphi \wedge \varphi) \mid (\varphi > \varphi) \mid \Box\varphi$$

such that  $s \in \mathcal{S}$ .

- $\perp, \vee, \rightarrow$  and  $\leftrightarrow$  are introduced by the standard definitions.
- $\varphi > \psi$  is interpreted to mean that  $\varphi$  is more likely than  $\psi$ .
- $\varphi \geq \psi := \neg(\psi > \varphi)$ .
- $\varphi \geq \psi$  is interpreted to mean that  $\varphi$  is at least as likely as  $\psi$ .
- $\varphi \approx \psi := \neg(\varphi > \psi) \wedge \neg(\psi > \varphi)$ .
- $\varphi \approx \psi$  is interpreted to mean that  $\varphi$  is as likely as  $\psi$ .
- $\triangle \varphi := \varphi > \neg \varphi$ .
- $\triangle \varphi$  is interpreted to mean that probably  $\varphi$ .
- $\square \varphi$  is interpreted to mean that it must be that  $\varphi$ .
- $\diamond \varphi := \neg \square \neg \varphi$ .
- $\diamond \varphi$  is interpreted to mean that it might be that  $\varphi$ .

### 3.2. Semantics

We define a *structured model*  $\mathfrak{M}$  of  $\mathcal{L}_{\text{BLE}}$  as follows:

**Definition 2 (Model)**  $\mathfrak{M}$  is a quadruple  $(W, R, \rho, V)$  in which

- $W$  is a non-empty set of possible worlds,
- $R$  is a binary epistemic accessibility relation on  $W$ ,
- $\rho$  is a finitely additive semiordered qualitative probability space assignment that assigns to each  $w \in W$  a finitely additive semiordered qualitative probability space  $(W_w, \mathcal{F}_w, \succ_w)$  in which
  - $W_w := \{w' \in W : R(w, w')\}$ ,
  - $\mathcal{F}_w$  is the Boolean algebra of subsets of  $W_w$  with  $\emptyset$  as zero element and  $W_w$  as unit element, and
  - $\succ_w$  is a finitely additive semiordered qualitative probability ordering relative to  $w \in W$  on  $\mathcal{F}_w$  that satisfies all of Nontriviality, Irreflexivity, Dominance, and Semi-Scottness of Theorem 1, and

- $V$  is a truth assignment to each  $s \in \mathcal{S}$  for each  $w \in W$ .

We provide BLE with the following truth definition at  $w \in W$  in  $\mathfrak{M}$ , define the truth in  $\mathfrak{M}$ , and then define validity as follows:

**Definition 3 (Truth and Validity)** *The notion of  $\varphi \in \Phi_{\mathcal{L}_{\text{BLE}}}$  being true at  $w \in W$  in  $\mathfrak{M}$ , in symbols  $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \varphi$ , is inductively defined as follows:*

- $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} s$  iff  $V(w)(s) = \text{true}$ .
- $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \top$ .
- $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \neg\varphi$  iff  $(\mathfrak{M}, w) \not\models_{\mathcal{L}_{\text{BLE}}} \varphi$ .
- $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \varphi \wedge \psi$  iff  $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \varphi$  and  $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \psi$ .
- $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \varphi > \psi$  iff  $\llbracket \varphi \rrbracket_w^{\mathfrak{M}} \succ_w \llbracket \psi \rrbracket_w^{\mathfrak{M}}$ , where  $\llbracket \varphi \rrbracket_w^{\mathfrak{M}} := \{w' \in W_w : (\mathfrak{M}, w') \models_{\mathcal{L}_{\text{BLE}}} \varphi\}$ .
- $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \Box\varphi$  iff for any  $w'$  such that  $R(w, w')$ ,  $(\mathfrak{M}, w') \models_{\mathcal{L}_{\text{BLE}}} \varphi$ .

If  $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \varphi$  for any  $w \in W$ , we write  $\mathfrak{M} \models_{\mathcal{L}_{\text{BLE}}} \varphi$  and say that  $\varphi$  is true in  $\mathfrak{M}$ . If  $\varphi$  is true in all models of  $\mathcal{L}_{\text{BLE}}$ , we write  $\models_{\mathcal{L}_{\text{BLE}}} \varphi$  and say that  $\varphi$  is valid.

The next corollary follows from Definitions 1 and 3.

**Corollary 1 (Truth Condition of  $\varphi \approx \psi$  and Truth Condition of  $\triangle\varphi$ )**

- $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \varphi \approx \psi$  iff  $\llbracket \varphi \rrbracket_w^{\mathfrak{M}} \sim_w \llbracket \psi \rrbracket_w^{\mathfrak{M}}$ , where  $\llbracket \varphi \rrbracket_w^{\mathfrak{M}} \sim_w \llbracket \psi \rrbracket_w^{\mathfrak{M}} := \text{not } (\llbracket \varphi \rrbracket_w^{\mathfrak{M}} \succ_w \llbracket \psi \rrbracket_w^{\mathfrak{M}} \text{ and not } (\llbracket \psi \rrbracket_w^{\mathfrak{M}} \succ_w \llbracket \varphi \rrbracket_w^{\mathfrak{M}}))$ .
- $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \triangle\varphi$  iff  $\llbracket \varphi \rrbracket_w^{\mathfrak{M}} \succ_w \overline{\llbracket \varphi \rrbracket_w^{\mathfrak{M}}}$ .

Then the next corollary follows from Theorem 1 and Corollary 1.

**Corollary 2 (Truth Conditions by Probability Measure)** *For any  $w \in W$ , there exists  $P_w : \mathcal{F} \rightarrow \mathbb{R}$  and such  $\delta$  that  $0 < \delta \leq 1$  satisfying*

- $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \varphi > \psi$  iff  $P_w(\llbracket \varphi \rrbracket_w^{\mathfrak{M}}) \geq P_w(\llbracket \psi \rrbracket_w^{\mathfrak{M}}) + \delta$ .
- $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \varphi \approx \psi$  iff  $P_w(\llbracket \psi \rrbracket_w^{\mathfrak{M}}) - \delta < P_w(\llbracket \varphi \rrbracket_w^{\mathfrak{M}}) < P_w(\llbracket \psi \rrbracket_w^{\mathfrak{M}}) + \delta$ .
- $(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \triangle\varphi$  iff  $P_w(\llbracket \varphi \rrbracket_w^{\mathfrak{M}}) \geq \frac{1+\delta}{2}$ .

**Remark 2 (Logic of Inexact Knowledge)** *In BLE the truth clause of the epistemic necessity*

operator  $\Box$  is not based on a semiordered qualitative probability ordering. In BLE the truth clause of  $\Box\varphi$  is given in Definition 3 as follows:

$$(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{BLE}}} \Box\varphi \text{ iff, for any } w' \text{ such that } R(w, w'), (\mathfrak{M}, w') \models_{\mathcal{L}_{\text{BLE}}} \varphi.$$

On the other hand, Suzuki (2016) proposes a new version of complete logic—*Logic of Inexact Knowledge* (LIK)—the model of the language of which can reflect Williamson (1994)’s arguments on inexact knowledge in the sense that the truth condition of the knowledge operator  $K$  ( $K\varphi := \varphi \approx \top$ ) is given in terms of a semiordered qualitative probability ordering as follows:

$$(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{LIK}}} K\varphi \text{ iff } \llbracket \varphi \rrbracket^{\mathfrak{M}} \sim_w W.$$

So, by virtue of Theorem 1, for any  $w \in W$ , there exists  $P_w : \mathcal{F} \rightarrow \mathbb{R}$  and such  $\delta$  that  $0 < \delta \leq 1$  satisfying

$$(\mathfrak{M}, w) \models_{\mathcal{L}_{\text{LIK}}} K\varphi \text{ iff } 1 - \delta < P_w(\llbracket \varphi \rrbracket^{\mathfrak{M}}) \leq 1.$$

We can also construct BLE on the basis of this idea.

Yalcin (2010) presents the following list of *intuitively valid* formulae (V1)–(V11) and *intuitively invalid* formulae (I1) and (I2):

- (V1)  $\Delta\varphi \rightarrow \neg\Delta\neg\varphi$ .

(If probably  $\varphi$ , then it is not probable that not  $\varphi$ .)

- (V2)  $\Delta(\varphi \wedge \psi) \rightarrow (\Delta\varphi \wedge \Delta\psi)$ .

(If probably ( $\varphi$  and  $\psi$ ), then (probably  $\varphi$  and probably  $\psi$ ).)

- (V3)  $\Delta\varphi \rightarrow \Delta(\varphi \vee \psi)$ .

(If probably  $\varphi$ , then probably ( $\varphi$  or  $\psi$ ).)

- (V4)  $\varphi \geq \perp$ .

( $\varphi$  is at least as likely as  $\perp$ .)

- (V5)  $\top \geq \varphi$ .

( $\top$  is at least as likely as  $\varphi$ .)

- (V6)  $\Box\varphi \rightarrow \Delta\varphi$ .

(If it must be that  $\varphi$ , then probably  $\varphi$ .)

- (V7)  $\triangle\varphi \rightarrow \diamond\varphi$ .

(If probably  $\varphi$ , then it might be that  $\varphi$ .)

- (V8)  $(\varphi \rightarrow \psi) \rightarrow (\triangle\varphi \rightarrow \triangle\psi)$ .

(If (if  $\varphi$ , then  $\psi$ ), then (if probably  $\varphi$ , then probably  $\psi$ ).)

- (V9)  $(\varphi \rightarrow \psi) \rightarrow (\neg\triangle\psi \rightarrow \neg\triangle\varphi)$ .

(If (if  $\varphi$ , then  $\psi$ ), then (if it is not probable that  $\psi$ , then it is not probable that  $\varphi$ ).)

- (V10)  $(\varphi \rightarrow \psi) \rightarrow (\psi \geq \varphi)$ .

(If (if  $\varphi$ , then  $\psi$ ), then ( $\psi$  is at least as likely as  $\varphi$ ).)

- (V11)  $(\psi \geq \varphi) \rightarrow (\triangle\varphi \rightarrow \triangle\psi)$ .

(If ( $\psi$  is at least as likely as  $\varphi$ ), then (if probably  $\varphi$ , then probably  $\psi$ ).)

- (V12)  $(\psi \geq \varphi) \rightarrow ((\varphi \geq \neg\varphi) \rightarrow (\psi \geq \neg\psi))$ .

(If ( $\psi$  is at least as likely as  $\varphi$ ), then (if ( $\varphi$  is at least as likely as not  $\varphi$ ), then ( $\psi$  is at least as likely as not  $\psi$ )).)

- (I1)  $((\varphi \geq \psi) \wedge (\varphi \geq \chi)) \rightarrow (\varphi \geq (\psi \vee \chi))$ .

(If (( $\varphi$  is at least as likely as  $\psi$ ) and ( $\varphi$  is at least as likely as  $\chi$ )), then ( $\varphi$  is at least as likely as ( $\psi$  or  $\chi$ )).)

- (I2)  $(\varphi \approx \neg\varphi) \rightarrow (\varphi \geq \psi)$ .

(If ( $\varphi$  is as likely as not  $\varphi$ ), then ( $\varphi$  is at least as likely as  $\psi$ ).)

We justify the (in)validity of Yalcin's formulae in BLE as follows:

**Proposition 1 (Justification of Yalcin's Formulae)** *BLE validates all of (V1)–(V12) and validate neither (I1) nor (I2).*

Moreover, in BLE, the transitivity of probabilistic indifference is not valid:

**Proposition 2 (Invalidity of Transitivity of Probabilistic Indifference)**

$$\not\models_{\mathcal{L}_{\text{BLE}}} ((\varphi \approx \psi) \wedge (\psi \approx \chi)) \rightarrow (\varphi \approx \chi).$$

So the *sorites paradox* in Example 1 does not appear in BLE.

### 3.3. Syntax

The proof system of BLE consists of the following:

#### Definition 4 (Proof System)

##### Axioms

- All tautologies of classical sentential logic,
- $\Box(\varphi \rightarrow \psi) \rightarrow (\Box\varphi \rightarrow \Box\psi)$  (K),
- $(\Box(\varphi_1 \leftrightarrow \varphi_2) \wedge \Box(\psi_1 \leftrightarrow \psi_2)) \rightarrow ((\varphi_1 > \psi_1) \leftrightarrow (\varphi_2 > \psi_2))$   
(Replacement of Known Equivalents on  $>$ ),
- $\top > \perp$  (Syntactic Counterpart of **Nontriviality**),
- $\neg(\varphi > \varphi)$  (Syntactic Counterpart of **Irreflexivity**), and
- $$\left( \bigvee_{1 \leq i_1 < \dots < i_k \leq n} ((\varphi_{i_1} \vee \tau_{i_1}) \wedge \dots \wedge (\varphi_{i_k} \vee \tau_{i_k})) \right) \\ \leftrightarrow \left( \bigvee_{1 \leq i_1 < \dots < i_k \leq n} ((\psi_{i_1} \vee \chi_{i_1}) \wedge \dots \wedge (\psi_{i_k} \vee \chi_{i_k})) \right) \\ \rightarrow \left( \bigwedge_{i=1}^{n-1} ((\varphi_i > \psi_i) \wedge \neg(\chi_i > \tau_i)) \rightarrow ((\varphi_n > \psi_n) \rightarrow (\chi_n > \tau_n)) \right),$$
  
for any  $n \geq 1$  and any  $k$  with  $1 \leq k \leq n$   
(Syntactic Counterpart of **Semi-Scottness**).

##### Inference Rules

- $$\frac{\varphi \rightarrow \psi}{(\chi > \psi) \rightarrow (\chi > \varphi)}$$
 (Syntactic Counterpart of **Dominance**),
- Modus Ponens, and
- Necessitation.

A proof of  $\varphi \in \Phi_{\mathcal{L}_{BLE}}$  is a finite sequence of  $\mathcal{L}_{BLE}$ -formulae having  $\varphi$  as the last formula such that either each formula is an instance of an axiom or it can be obtained from formulae that appear earlier in the sequence by applying an inference rule. If there is a proof of  $\varphi$ , we write

$\vdash_{\text{BLE}} \varphi$ .

**Remark 3 (Infinite Schema)** *The syntactic counterpart of Semi-Scottness is an infinite schema of axioms for any  $n \geq 1$  and any  $k$  with  $1 \leq k \leq n$ .*

### 3.4. Metalogic

On the basis of Segerberg (1971) and Gärdenfors (1975), we can prove the soundness and completeness theorems of BLE:

**Theorem 2 (Soundness)** *For any  $\varphi \in \Phi_{\mathcal{L}_{\text{BLE}}}$ , if  $\vdash_{\text{BLE}} \varphi$ , then  $\models_{\mathcal{L}_{\text{BLE}}} \varphi$ .*

**Theorem 3 (Completeness)** *For any  $\varphi \in \Phi_{\mathcal{L}_{\text{BLE}}}$ , if  $\models_{\mathcal{L}_{\text{BLE}}} \varphi$ , then  $\vdash_{\text{BLE}} \varphi$ .*

## 4. Concluding Remarks

In this paper, we have proposed a new version of *complete* logic—Boundedly-Rational Logic for Epistemic Modals (BLE)—the model of the language of which has the following *three* merits:

1. The model reflects *Kratzer's intuition* above in the sense that the model is not based directly on probability measures, but based on qualitative probability orderings.
2. The model does not cause *Yalcin's problem*.
3. The model is *boundedly-rational* in the sense that the transitivity of probabilistic indifference is not valid. So it does not invite the *sorites paradox* in Example 1.

# Positive vs. negative inversion exclamatives<sup>1</sup>

Ai TANIGUCHI — *Michigan State University*

**Abstract.** Not all exclamatives intensify in the same way. In this paper, I examine the semantics of positive inversion exclamatives (e.g., *boy, is he an idiot!*) and negative inversion exclamatives (e.g., *isn't he an idiot!*) in English, and propose that the source of the strengthened meaning is distinct in each construction. The difference, moreover, is derivable from each sibling's question counterpart. I therefore adopt the exclamatives-as-questions approach in my analysis, although I abandon domain widening as the mechanism responsible for their out-of-the-norm meaning. I analyze inversion exclamatives as self-answered polar questions. In the positive variant, the sentence-initial particle *boy* provides the pure “extreme degree” reading canonically associated with exclamatives. Negative inversion exclamatives owe their intensity to the polarity emphaser *VERUM*, which is inherited from negative polar questions. At a broader level, the similarities and differences between positive inversion exclamatives, negative inversion exclamatives, and their question counterparts highlight a basic question of form and meaning with respect to sentential classes — what are exclamatives, are they questions, and what do they do? The convergence sheds light on what “exclamatives” as a natural class are, and the divergence tells a story of the diverse ways in which language can encode intensity.

**Keywords:** exclamatives, inversion exclamatives, polar questions, intensification, degrees, verum.

## 1. Introduction

This paper concerns the semantics of two types of inversion exclamatives in English: positive inversion exclamatives (Pos-Ex) and negative inversion exclamatives (Neg-Ex), both exemplified below.

- |                           |                                  |
|---------------------------|----------------------------------|
| (1) Boy, is Misty grumpy! | (positive inversion exclamative) |
| (2) Isn't Misty grumpy!   | (negative inversion exclamative) |

What makes (1) and (2) exclamative constructions is that they both somehow intensify *grumpy*, the predicate at hand. This intensity is often modeled as *degree* intensification in the literature; that is, (1) and (2) both mean ‘Misty is very grumpy.’ I argue that this is not the case. While Pos-Ex's genuinely have a degree interpretation, Neg-Ex's involve *epistemic* intensification in which the truth of a proposition is emphasized. I propose that the semantics of inversion exclamatives derive from inversion questions, which naturally accounts for the subtly different behavior of the positive vs. negative siblings.

---

<sup>1</sup>I would like to thank all the wonderful people that have helped me at various stages of this project: Marcin Morzycki, Alan Munn, Cristina Schmitt, Mutsuko Endo-Hudson, Abhi Parekh, Adam Gobeski, Ai Kubota, Alicia Parrish, Cara Feldscher, Chris Bartoluzzi, Curt Anderson, Grant Rodgers Kemp, Josh Herrin, Tess Huelskamp, and the rest of my colleagues at MSU. I am also grateful for the guidance I have received from the following linguists I have crossed paths with: Alexis Wellwood, Ezra Keshet, Jessica Rett, Kyle Rawlins, Nick Fleisher, Paul Portner, Thomas Grano, Tim Leffel, and Tim Hunter. Many thanks to the audience at Sinn und Bedeutung 21 for the invaluable comments as well. All errors are my own.

§2 will outline empirical observations about positive and negative inversion exclamatives, focusing on how they differ. §3 gives an overview of the existing accounts of exclamatives, and why they do not extend straightforwardly to the present phenomena. §4 elaborates on the tools necessary to analyze inversion exclamatives, such as the semantics of polar questions. My analysis will be presented in §5, and §6 provides a discussion for potential future work.

## 2. Data

### 2.1. Positive inversion exclamatives

The form of Pos-Ex's resemble their question counterpart, positive inversion questions (polar questions); the resemblance is highlighted in (3).

- (3) a. Boy, is Ash immature! (positive inversion exclamative)  
 b. Is Ash immature? (positive inversion question)

True polar questions have rising intonation, but Pos-Ex's have a falling intonation. That Pos-Ex's are not information-seeking can further be shown by their lack of answerability, as in (4). True questions can of course be answered as in (5).

- (4) A: Boy, is Ash immature! (5) A: Is Ash immature?  
 B: ?? Ash is immature. B: Ash is immature.

One property of Pos-Ex's is that they are only compatible with gradable predicates, that is, predicates with inherent scales associated with them:

- (6) a. Boy, is she { whiny / a genius / an idiot / a Pokémon fan }!  
 b. ?? Wow, is that { a teacher / a salad / a raspberry / dead }!

Note that the pre-sentential particle *boy* and the like are obligatory. As (7) shows, the exclamative is highly degraded without some sort of particle preceding it.

- (7) a. Boy/man/damn/wow/god do you run fast!  
 b. ?? Do you run fast!

As a spoiler alert, the particle will be directly responsible for the facts in (6). But first, let us contrast the Pos-Ex data with Neg-Ex's.

### 2.2. Negative inversion exclamatives

Like Pos-Ex's, Neg-Ex's have a question counterpart, which I will call negative inversion questions (also called biased polar questions). The two are identical on the surface (8a-b), except for intonation (sentence-final fall for the exclamative, rise for the question).

- (8) a. Isn't Ash immature! (negative inversion exclamative)  
 b. Isn't Ash immature? (negative inversion question)

The falling intonation on Neg-Ex's is accompanied by prosodic focus on the subject (i.e., *isn't [Ash]<sub>F</sub> immature!*) (Taniguchi, 2016). Readers should keep this intonation in mind in order to block the irrelevant question interpretation in the examples that follow.

Like Pos-Ex's, Neg-Ex's are compatible with gradable predicates:

- (9) Isn't she { whiny / a genius / a Pokémon fan }

Non-gradable predicates, however, have a peculiar status with Neg-Ex's. They are acceptable in most cases, as long as a *pejorative* reading can be construed from the predicate. The nuance is a subtle but a consistent one. In (10a) for example, the meaning of the exclamative is that she is *over-teacherly*. Similarly in (10b), being a linguist is taken to be a bad thing.

- (10) a. Isn't she a teacher! (... she's constantly telling people facts and quizzing them afterwards!)  
 b. Isn't he a linguist! (... he's always asking for grammaticality judgments, even during faculty meetings!)

It should be noted that there is also a "motherese" reading of Neg-Ex's: we can imagine (10a-b) being used in reference to a child acting like a teacher or a linguist (the interjection *aww* may help bring out this interpretation). This interpretation is not an insult *per se*, but nevertheless has a demeaning quality.

This brings us to a point about gradable predicates that Neg-Ex's select for. We've seen that the most natural examples of Neg-Ex's are pejorative; this applies to the gradable predicates as well. With inherently pejorative labels, the examples in (11) are sincere insults. The meliorative predicates in (12), however, are insincere: they are *sarcastic*, thereby being pejorative.

- (11) a. Aren't you an idiot!  
 (... driving while playing a game on your phone?!)  
 b. Isn't he a jerk!  
 (... he made a little girl cry!)
- (12) a. Isn't he a genius!  
 (... he tried to charge his phone in the microwave?!)  
 b. Aren't you lucky!  
 (... 5 exams in one day!)

Note that Pos-Ex's do not have this sarcasm effect for meliorative predicates; the examples in (13) are both sincere.

- (13) a. Boy, is he a genius!  
 (... I can't believe he invented wireless phone chargers!)  
 b. Damn, are you lucky!  
 (... your exams were cancelled?!)

The contrast between Pos-Ex's and Neg-Ex's is illustrated below. The context in which you might say *isn't this fantastic!* is a situation in which things aren't fantastic at all, e.g., (14b); it is infelicitous in opposite cases like (15b). Although you can always force a sarcastic reading for Pos-Ex's, it is by no means the default reading — making the neutral reading of (14a) unnatural.

- (14) (You spill coffee right before a job interview.)  
 a. ?? Boy, is this fantastic!  
 b. Well isn't this fantastic!
- (15) (Free upgrade to business class on an international flight.)  
 a. Boy, is this fantastic!  
 b. ?? Well isn't this fantastic!

Curiously, when a pejorative/sarcastic reading is not possible with a predicate (e.g., *salad*), the Neg-Ex induces a state-the-obvious effect:

- (16) Isn't that a salad! (... lettuce, tomatoes, onions, cheese, croutons, the works!)  
 'that salad has a lot of salad properties'

I can imagine exclaiming this in reference to a giant salad with lots of ingredients in it. The effect can be approximated as 'having a lot of salad properties', 'a very salad-y salad', or perhaps 'no doubt a salad.'

The next natural question is this: are Pos-Ex's and Neg-Ex's the same, as long as the predicate is pejorative? The answer is no. Here is one such example. The assumption is that running out of milk while pouring a glass is surely *inconvenient*, but not *very* inconvenient.

- (17) (You run out of milk while you're pouring a glass.)  
 a. Well isn't this inconvenient!  
 b. ?? Boy, is this inconvenient!

My judgment is that the Pos-Ex in (17b) is overly dramatic. It has the same sense of infelicitousness as saying *this is very inconvenient* in this context. In my analysis, this will follow from the fact that Pos-Ex's have a degree component to them. Neg-Ex's on the other hand clearly cannot mean *very*. The source of intensification is hard to articulate, but I think what is helpful here is the *no-doubt-a-salad salad* example from before: running out of milk while pouring a glass is *for sure* inconvenient for the pourer, even if it is not *very* inconvenient. This difference between certainty vs. degree extremity is what separates the two inversion exclamatives.

### 3. Previous accounts of exclamatives

Modeling the intensified degree reading of WH-exclamatives has been the objective of many studies (Grimshaw, 1979; Gutiérrez-Rexach, 1996; Portner and Zanuttini, 2000; Zanuttini and Portner, 2003; Castroviejo Miró, 2006, 2008b; Rett, 2008; Abels, 2010; Rett, 2011; Chernilovskaya and Nouwen, 2012; Delfitto and Fiorin, 2014: and many more), but how inversion exclamatives intensify — from both descriptive and theoretical perspectives — has played a relatively minor role in painting a more general picture of what the exclamative force is (see Rett (2008, 2011) for a brief discussion on Pos-Ex's; for Neg-Ex's, see Taniguchi (2016)).

In this section I will provide an overview of two popular theories regarding exclamatives, which will be useful for approximating where my analysis falls in the debate concerning the semantics of exclamatives: *exclamatives are questions* vs. *exclamatives are degree constructions*. Both approaches ultimately face difficulty with accounting for exclamatives that do not have a degree interpretation, i.e., Neg-Ex's.

#### 3.1. Exclamatives are questions

In what I call the *question approach* to exclamatives, the semantics of exclamatives derive from actual questions. A WH-Exclamative (WH-Ex) like *How tall Steve is!* therefore underlyingly has the semantics of the question *How tall is Steve?* (Gutiérrez-Rexach, 1996; Zanuttini and Portner, 2003; Chernilovskaya, 2010). I will outline Zanuttini and Portner (2003)'s approach specifically here.

Assuming a Hamblian semantics of questions, the denotation of *How tall is Steve?* is the set of possible answers to this question. For any average person, this might range from 5ft to 6ft, for example:

$$(18) \quad \llbracket \text{How tall is Steve?} \rrbracket = \{ 5'0'', 5'1'', 5'2'' \dots 5'10'', 5'11'', 6'0'' \}$$

The fact that exclamatives have this question semantics clashes with the traditional observation that exclamatives are also factive: they embed under factive predicates (e.g., *know*) but not under non-factive predicates (e.g., *don't know*), at least under the degree interpretation of the WH-clause (Grimshaw, 1979; Abels, 2010). This is shown in (19), with *very* helping to bring out the exclamative interpretation.

- (19) a. I know how (very) tall John is  
b. # I don't know how (very) tall John is

This means that exclamatives are factive questions — and factive questions are uninformative: you are essentially asking a question while knowing the answer. Zanuttini and Portner (2003) propose that *domain widening* is responsible for making exclamatives informative. What sets exclamatives apart from questions is the inclusion of an exceptional alternative that would not normally be in the domain: the domain *widens* to include an exceptional answer to the question.

Under the same context of Steve's possible height, we may consider 6'5" as an answer, for example:

$$(20) \quad \llbracket \text{How tall Steve is!} \rrbracket = \{ 5'0'', 5'1'', 5'2'' \dots 5'10'', 5'11'', 6'0'', \mathbf{6'5''} \}$$

This widening effect is responsible for the deviation-from-the-norm reading, and makes an otherwise defective question utterance-worthy. One criticism of the domain widening approach has been that it overgeneralizes: it does not specify what the source of the exceptionality is for the exceptional alternative. For example, it is not able to bar *how tall Steve is!* from meaning 'Steve's height (5'11") is the same number as my street number (511),' despite the arguable noteworthiness of such a coincidence.

For more immediate purposes, it is not immediately clear how domain widening would apply to to exclamatives with yes/no question forms, since yes/no questions have a strictly binary set of answers —  $p$  or  $\neg p$  — which is unwidenable:

$$\begin{aligned} (21) \quad & \text{a. } \llbracket \text{Is he an idiot?} \rrbracket = \left\{ \begin{array}{l} \text{He is an idiot} \\ \text{He is not an idiot} \end{array} \right\} \\ & \text{b. } \llbracket \text{Boy, is he an idiot!} \rrbracket = \left\{ \begin{array}{l} \text{He is an idiot} \\ \text{He is not an idiot} \\ ??? \end{array} \right\} \\ (22) \quad & \text{a. } \llbracket \text{Isn't he an idiot?} \rrbracket = \left\{ \begin{array}{l} \text{He is an idiot} \\ \text{He is not an idiot} \end{array} \right\} \\ & \text{b. } \llbracket \text{Isn't he an idiot!} \rrbracket = \left\{ \begin{array}{l} \text{He is an idiot} \\ \text{He is not an idiot} \\ ??? \end{array} \right\} \end{aligned}$$

Even if we were to somehow propose a widening mechanism for polar questions, since both negative and positive inversion questions would have the same set of answers, this predicts Neg-Ex's and Pos-Ex's to have the same semantics. This lack of variability is problematic if we are to model attested differences between the two constructions.

### 3.2. Exclamatives are degree constructions

A competing position is that exclamatives do not have the semantics of questions, but rather, that there is a degree morpheme responsible for the exclamative interpretation (Castroviejo Miró, 2006, 2008b, a; Rett, 2011; Wood, 2014)<sup>2</sup>. I will summarize Rett (2011) as an example here.

For Rett, exclamatives encode two two illocutionary operators: an exclamation force operator (E-FORCE) and a degree measurement operator (M-OP):

<sup>2</sup>Castroviejo Miró (2008b) and Wood (2014) do incorporate questions into their analyses, although a degree morpheme, rather than domain widening, is ultimately responsible for the degree interpretation of exclamatives for them.

$$(23) \quad \text{M-OP: } \lambda d \lambda P \lambda x. P(x) \wedge \mu(x) = d$$

- (24) E-FORCE( $p$ ), uttered by  $\text{SPKR}_C$ , is appropriate in a context  $C$  if  $p$  is salient and true in  $w_C$ . When appropriate, E-FORCE( $p$ ) counts as an expression that  $\text{SPKR}_C$  had not expected that  $p$ .

E-FORCE adds the evaluative content of the exclamative: it encodes the speaker's surprise about a degree that holds for some property. This accounts for the degree interpretation of exclamatives like *How tall Steve is!*, where the speaker is surprised by Steve's height (i.e., he is very tall). One advantage of strictly tying the exclamative force to degrees in this way is that non-degree interpretations of surprise can be ruled out. Even if it is surprising that Steve's height (5'11") matches my street number (511), "Steve's height = my street number" does not fall on a scale; it is not a degree, therefore it cannot be the target of surprise for exclamatives.

M-OP is necessary when the predicate to be exclaimed about lacks a scale. For example, *what a teacher!*, where *teacher* is not gradable. M-OP gives predicates like *teacher* a contextually determined scale; the scale of *amazingness* for a teacher for example. Her example, *What desserts John baked!*, with the help of M-OP, may mean 'what delicious desserts John baked' if the context is appropriate. The derivation for *What desserts John baked!* is shown below.

- (25) What desserts John baked!
- a.  $\llbracket \text{M-OP desserts} \rrbracket = \lambda d. \lambda x. \text{desserts}'(x) \wedge \mu(x) = d$
  - b.  $\llbracket \text{What desserts John baked} \rrbracket$   
 $= \lambda d. \exists x [\text{baked}'(j, x) \wedge \text{desserts}'(x) \wedge \mu(x) = d]$

M-OP first makes *desserts* gradable, and assigns it a scale (e.g., deliciousness) and gives it a degree argument. At this point a degree  $d'$  would be provided by the context, leaving the unbound expression  $\exists x [\text{baked}'(j, x) \wedge \text{desserts}'(x) \wedge \mu(x) = d']$ . This is existentially closed by E-FORCE, which also adds the illocutionary force of speaker surprise:

- (26) a.  $p = \exists x [\text{baked}'(j, x) \wedge \text{desserts}'(x) \wedge \mu(x) = d']$   
 b. E-FORCE( $p$ ) counts as an expression if  $\exists d'$  such that  $s_C$  had not expected that  $d' \in D$   
 c. Existential closure via E-FORCE:  $\exists d'. \exists x [\text{baked}'(j, x) \wedge \text{desserts}'(x) \wedge \mu(x) = d']$  +  
 Illocutionary force "speaker didn't expect  $p$ "

*What desserts John baked!* therefore means that the speaker is surprised that the desserts John baked are so delicious (or whatever contextually salient property). Rett speculates how E-FORCE and M-OP might apply to Pos-Ex's<sup>3</sup> as well:

- (27) Wow, did Sue win that race!

She observes that (27) does not express speaker surprise about *Sue* winning the race, which is an individual-oriented reading. It has an event-oriented reading: the manner in which Sue won the race is noteworthy. Following this, she analyzes Pos-Ex's as an exclamation about

<sup>3</sup>She calls them *inversion exclamatives*.

eventualities, which inherit degreehood from M-OP. She remains agnostic as to why inversion exclamatives specifically care about eventualities. Tying inversion exclamatives to eventualities poses an issue, however, since some states<sup>4</sup> are incompatible with Pos-Ex's:

- (28) a. Boy, is Ash an idiot!  
 b. # Boy, is she a teacher!  
 c. # Boy, did she hold that baby!

(28a) is unproblematic: the state of Ash being an idiot is remarkable and surprising in some way. The contrast in (28b) and (28c) are problematic, since under this analysis M-OP should still kick in to assign these eventualities a degree — but it does not. In other words, why can't (28b) and (28c) mean that the way she is a teacher or the way she held the baby is remarkable?

Contrasting Neg-Ex's with Pos-Ex's is also not easy under this account, which posits that the source of variation between different exclamative constructions is what M-OP targets. If Pos-Ex's scalarize eventualities, then what do Neg-Ex's scalarize? Borrowed unmodified, it is not obvious how M-OP would be manipulated to distinguish the two inversion exclamatives.

My proposal is closest to the question approach, although I abandon domain widening as the mechanism responsible for the intensificative meaning of inversion exclamatives. I will argue that a morpheme inherent to Pos-Ex's and a separate morpheme underlying Neg-Ex's are each responsible for generating the distinct intensificative effect for each construction. As a bonus point, analyses for both of them will derive from their question counterparts, which I will pick up as a tool for my analysis in the following section.

## 4. Tools

### 4.1. The question counterparts

I will be assuming the standard treatment of the semantics of questions as a set of possible answers (Hamblin, 1973; Karttunen, 1977). That is, the meaning of a polar question like *did Ash win?* will be treated as the set of the possible answers to this question, namely, *Ash won* and *Ash did not win*:

- (29) a. Did Ash win?  
 b. {**win**(a), ¬**win**(a)}

Compositionally, one might imagine an interrogative force head that turns its propositional complement into such a question. For explicitness, I will treat the interrogative force as an instruction to add a question to the set of questions under discussion (QUDs) in the discourse. This is shown in (30).

<sup>4</sup>Assuming eventualities to include events and states.

- 1233

The denotation for *Ash* [*did*]<sub>F</sub> *win* — a *verum*-focused sentence — then would simply be FOR-SURE-CG(*Ash won*), in other words, ‘*Ash won* should be added to the CG.’ This is one way of modeling the sentiment of ‘*p* is definitely true.’

*Didn't Ash win?* is the question version of FOR-SURE-CG(*Ash won*) according to Romero and Han; the pre-posed negation signals the presence of a VERUM operator.<sup>5</sup> That is, *Didn't Ash win?* decomposes into  $\llbracket Q \text{ VERUM } \text{Ash won} \rrbracket$ . This is shown below.

(35) Didn't Ash win?

- a.  $\llbracket \text{Didn't Ash win?} \rrbracket = \llbracket Q \text{ VERUM } \text{Ash won} \rrbracket$
- b.  $= \lambda p. \text{QUD} + \{p, \neg p\}(\text{VERUM } \text{Ash won})$
- c.  $= \text{QUD} + \{\text{VERUM } \text{Ash won}, \neg \text{VERUM } \text{Ash won}\}$
- d.  $= \text{QUD} + \{\text{FOR-SURE-IN-CG}(\text{Ash won}), \neg \text{FOR-SURE-CG}(\text{Ash won})\}$   
‘Add this to the QUD: Are we for sure putting *Ash won* in the CG?’

Romero and Han's explanation of the speaker bias goes like this. Making reference to meta-discourse pieces like the CG is a marked move, and should be avoided if necessary. VERUM makes reference to the CG. A context in which such a move is necessary is when the speaker believes one of the answers is true, but there is evidence that another discourse participant does not share this belief. In this way, the negative inversion question becomes a necessary halt to the discourse to set things straight, to check that everyone is on the same page. But this only arises if the speaker has a bias in the first place.

## 4.2. Man

I will briefly outline an additional tool here: the obligatory sentence-initial particle in Pos-Ex's (e.g., *boy* is he an idiot!). I take this to be the same creature as McCready (2008)'s *man*. These particles can precede normal propositions as well:

(36) Man, Ash is immature!

‘Ash is very immature (and I have strong feelings about this)’

Suppressing the discussion of the emotive/attitudinal content associated with the particle (see McCready (2008) for an analysis), what *man* roughly is is a long-distance *very*. It means that *immature* holds to a high degree in this case.

The issue is that *man* takes a propositional complement, which is not gradable. What is gradable is the predicate that is inside. To bridge this gap, McCready proposes a type shifter: SD (for *sentence degree*), shown below.

<sup>5</sup>Possibly mood agreement; or, VERUM could be directly encoded in the negation. I remain agnostic about the status of the negation.

- (37)  $\llbracket \text{SD} \rrbracket = \lambda p \lambda d. p(d)$  (McCready, 2008)  
 where  $\lambda d. p(d)$  is a set of degrees that satisfy a gradable predicate in  $p$ ; undefined if no such predicate.

For example,  $\llbracket \text{SD} \rrbracket(\text{Ash is immature})$  would return  $\lambda d. \text{immature}(\text{Ash})(d)$ . If on the other hand the proposition were *this is non-refundable*, the type shifting would be unsuccessful since *non-refundable* is not gradable. This prevents *boy* from being able to apply to non-gradable predicates (e.g., #Boy, this is non-refundable!).

Once a gradable predicate is extracted from the proposition, *man* just has to say ‘very’ of it. One formulation of this is shown in (38);  $\gg$  should be read as ‘exceeds by a large amount.’ Note that this is a large simplification of McCready’s account.

- (38)  $\llbracket \text{man/boy/damn/shit/god/jesus} \rrbracket = \lambda D_{\langle d, \langle s, t \rangle \rangle}. \exists d. D(d) \wedge d \gg \text{standard}_C(D)$   
 (modified from McCready (2008))

This is equivalent to the denotation of *very*. McCready has a discussion of this degree modification being at the expressive level, but I will suppress the multidimensional nature of *man/boy* for the sake of simplicity here. I will return to this point in my discussion later in the paper, however.

## 5. Analysis

Here is what we are trying to account for:

1. Inversion exclamatives look like inversion questions, but aren’t answerable
2. Positive inversion exclamatives are incompatible with non-gradable predicates
3. Negative inversion exclamatives don’t mean ‘very,’ but rather ‘I am certain.’

My proposal for #1 above is that exclamatives *are* questions — just self-answered ones. I propose an exclamative operator EX-OP, akin to the question operator Q. EX-OP is exactly like Q, except that the answer is provided:

- (39)  $\llbracket \text{EX-OP} \rrbracket = \lambda p \lambda w. \{p, \neg p\} + \text{QUD}_w \wedge p(w)$   
 ‘Turn  $p$  into a polar question, and simultaneously answer affirmatively’

This allows for exclamatives to take on the role of a question and an assertion simultaneously.

Let us step through a Pos-Ex example to illustrate this. *Boy, is Ash immature!* has the base proposition *Ash is immature*, to which EX-OP applies:

- (40)  $\llbracket \text{is Ash immature!} \rrbracket = \llbracket \text{EX-OP Ash is immature} \rrbracket =$   
 $\lambda w. \{ \mathbf{immature}(\mathbf{a}), \neg \mathbf{immature}(\mathbf{a}) \} + \text{QUD}_w \wedge \mathbf{immature}_w(\mathbf{a})$   
 ‘Is Ash immature? Yes, Ash is immature.’

At this point, this is utterly uninformative: what is the point of a self-answered polar question? To make this mini self-monologue informative, we must intensify the answer.<sup>6</sup> This is why *boy* and the like are obligatory for this construction. Its contribution (with the help of SD) is articulated below.

- (41)  $\llbracket \text{SD} \rrbracket (\text{EX-OP Ash is immature})$   
 $= \lambda d [\lambda w. \{ \mathbf{immature}(\mathbf{a}), \neg \mathbf{immature}(\mathbf{a}) \} + \text{QUD}_w \wedge \mathbf{immature}_w(\mathbf{a})](d)$   
 $\rightsquigarrow \lambda d \lambda w. \mathbf{immature}_w(\mathbf{a})(d)$   
 ‘the set of degrees that satisfy **immature**(a)’

- (42)  $\llbracket \text{boy} \rrbracket (\llbracket \text{SD EX-OP Ash is immature} \rrbracket)$   
 $= \exists d. \lambda w. \mathbf{immature}_w(\mathbf{a})(d) \wedge d \gg \mathbf{standard}_C(\mathbf{immature})$   
 ‘Ash is very immature’

In other words, *boy, is Ash immature!* ends up meaning ‘Is Ash immature? He is immature. Very immature.’ This easily explains why Pos-Ex’s are only compatible with gradable predicates: their incompatibility with non-gradable predicates reduces to *boy*’s incompatibility with such predicates.

If *boy* is the culprit in Pos-Ex’s, the morpheme responsible for the intensified reading in Neg-Ex’s is VERUM. The connection is intuitive if we assume that exclamatives derive from questions: if *Isn’t Ash immature?* decomposes into  $\llbracket \text{Q VERUM Ash is immature} \rrbracket$ , then *Isn’t Ash immature!* breaks down into  $\llbracket \text{EX-OP VERUM Ash is immature} \rrbracket$ . Let’s see how this works.

- (43)  $\llbracket \text{isn’t Ash immature!} \rrbracket = \llbracket \text{EX-OP VERUM Ash is immature} \rrbracket$   
 a.  $\llbracket \text{VERUM Ash is immature} \rrbracket$   
 b.  $= \lambda w. \forall w' \in \text{EPI}_{\text{SPKR}}(w) \cap \text{CONV}_{\text{SPKR}}(w) [\mathbf{immature}(\mathbf{a}) \in \text{CG}_{w'}]$   
 $\rightsquigarrow \text{FOR-SURE-CG}(\text{Ash is immature})$   
 ‘We should add *Ash is immature* to the common ground’  
 c.  $\llbracket \text{EX-OP} \rrbracket (\text{VERUM Ash is immature})$   
 d.  $= \lambda w. \{ \text{FOR-SURE-CG}(\mathbf{immature}_w(\mathbf{a})), \neg \text{FOR-SURE-CG}(\mathbf{immature}_w(\mathbf{a})) \} + \text{QUD}_w \wedge$   
 $\text{FOR-SURE-CG}(\mathbf{immature}_w(\mathbf{a}))$   
 ‘Should we add *Ash is immature* to the common ground? Yes, we should.’

This translates into the speaker’s strong conviction that Ash is immature. How is this different from *Ash* [*is*]<sub>F</sub> *immature*, which also asserts FOR-SURE-CG(Ash is immature)? I think this may have to do with the fact that *verum* focus is infelicitous out-of-the-blue (Gutzmann and Castroviejo Miró, 2011). For example, if you meet Ash for the first time and simply want to express how certainly immature he is, (44) is very strange.

<sup>6</sup>This is the same line of reasoning as Zanuttini and Portner (2003)’s motivation for domain widening.

- (44) (You meet a guy named Ash. He keeps on launching spitballs at people with a straw.)  
 ??Ash [is]<sub>F</sub> immature!

Gutzmann and Castroviejo Miró (2011) propose that this is because in order for *verum*(p) to be felicitous, *whether p* must be in the QUD in the first place. The intuition is that when you are very sure of something, there must be a reason to assert that; otherwise, just *p* would suffice. One way to make “I am sure” felicitous out of the blue is to turn it into a Neg-Ex, which has an implicit question component to it. Since you’ve snuck “are we sure?” into the QUD with it, you are able to assert “I am sure.” I suggest that this is why Neg-Ex, even as a self-answered question, is informative. This explains why *Isn’t Ash immature!* in the same context as (44) would be completely natural for expressing how blatantly immature Ash is.

## 6. Discussion

An observant reader may have noticed that my analysis has not yet explained why Neg-Ex’s and pejorativity go hand-in-hand. A disappointed reader will hereby learn that I do not have a good explanation for it. I do, however, have some speculations. One interesting property of Neg-Ex’s is that the negation must be preposed:

- (45) a. Isn’t he an expert!  
       ≈ ‘He’s not really an expert’  
       b. # Is he not an expert!

As it turns out, many insults occur at the left edge. A kind of exclamative that uses the indefinite *some* normally expresses the noteworthiness of the NP at hand, but when *some-NP* is preposed, it takes on a markedly pejorative flair:

- (46) *Some*-exclamatives (Anderson, 2016)  
       a. He is some expert!  
           ‘He is a noteworthy expert’  
       b. Some expert he is!  
           ‘He’s not really an expert’

Another pejorative construction is the *schm*-reduplication, which conveys a dismissal (pejorative) attitude towards the reduplicant. Interestingly, *schm*-reduplication must also be preposed:

- (47) *Schm*-reduplication (Grohmann and Nevins, 2004)  
       a. Expert-schmexpert, his facts are half-assed!  
       b. # He is an expert-schmexpert

Given these facts, I do entertain the idea of *n’t* in Neg-Ex’s occupying a position responsible for pejorative mood (e.g., PejP in Grohmann and Nevins (2004)). Much more work is needed in this area to confirm or refute this hypothesis. I leave this for future research.

Another issue concerns the level of meaning of *boy/man* and VERUM, which are both crucial ingredients in my analysis. One crucial property of the intensificative nature of pre-sentential particles like *man* is that their meaning is not at-issue; they are expressive particles (McCready, 2008). One way to test at-issue-ness is to see if the relevant part of the meaning can be contradicted:

- (48) A: Man, Ash is immature!  
       B: That's not true, Ash is not immature.
- (49) A: Man, Ash is immature!  
       B: ?? That's not true, Ash is not *very* immature.

When you respond *That's not true!* to *Man, Ash is immature*, what you are saying is false is the propositional content 'Ash is immature,' not the *very*-ness contributed by *man*. This suggests that the intensification via *man* does not have truth-conditional meaning. Rather, it has *expressive* meaning, a dimension separate from at-issue meaning (Potts, 2007).

Similarly, more recent takes on VERUM have shown that its meaning is also not at-issue (Gutzmann and Castroviejo Miró, 2011).

- (50) A: Ash [is]<sub>F</sub> immature!  
       B: That's not true, Ash is not immature.
- (51) A: Ash [is]<sub>F</sub> immature!  
       B: That's not true, you're not certain that Ash is immature. (You just told me a second ago that you weren't sure if he was immature or not)

My judgment is that *that's not true* cannot be targeting the speaker certainty contributed by VERUM. Following the same line of intuition, Gutzmann and Castroviejo Miró (2011) propose a multidimensional semantics of VERUM. What this suggests is that inversion exclamatives may be expressive as well. An explicitly multidimensional treatment of inversion exclamatives has yet to be proposed, but may be fruitful given the insight from the pieces we are playing with. I leave this for future research.

This work opens up the question of what exclamatives are as a sentence type. Exclamatives exclaim, but how? In the case of positive and negative inversion exclamatives, assuming a question semantics of exclamatives gives us a natural account of the subtle differences in the way they intensify meaning. EX-OP turns a proposition into a question and an assertion at the same time. This leads to intensification because without it, a self-answered question is not informative. EX-OP is where these exclamatives converge, but the intensification that results from it is not necessarily limited to degree intensification as often assumed in the literature. Exclamatives are a more heterogenous class than one might imagine, and the semantic microvariation across exclamative subconstructions are crucial for understanding what the common mechanism across all of them are. My proposal is a simple one of form and meaning: exclamatives look like questions so questionhood must be tied to the intensity they evoke. Although not explicitly discussed here, I would expect WH-exclamatives to tell a similar story. A broader

examination of exclamative types will provide a more generalizable understanding of the exclamative force; this seems to me the logical next step in this project.

## 7. Conclusion

In this paper, I have analyzed the semantics of positive inversion exclamatives (Pos-Ex's) and negative inversion exclamatives (Neg-Ex's). The empirical finding is that Pos-Ex's denote the intensification of degrees while Neg-Ex's express intensified certainty. Neg-Ex's involve the polarity emphaser VERUM, which it inherits from its question cousin. Pos-Ex's intensify via the obligatory sentence-initial particle *boy*, a degree modifier. The common denominator between the two inversion exclamatives is EX-OP, which encodes exclamative meaning: a question-assertion combination. From this analysis we gain two things: exclamatives are non-information-seeking questions, and different subconstructions of exclamatives have different — but predictable — ways of intensifying. This discussion provides a lens into how natural language encodes noteworthiness and intensity, and relating interrogatives to exclamatives for untangling intensification becomes a broader project of the link between form and meaning.

## “No, I AM”: What are you saying “no” to?<sup>1</sup>

Ye TIAN — *Laboratoire de linguistique formelle, CNRS, Université Paris-Diderot*

Jonathan GINZBURG — *Laboratoire de linguistique formelle, CNRS, Université Paris-Diderot*

**Abstract.** The English particle “no” can be used in a variety of contexts. We propose that “no” is three ways ambiguous, distinguished by the type of antecedent utilized: explicit, implicit and exophoric. The second type—“no” with an implicit antecedent—addresses a grounding misalignment caused by sources such as speaker’s bias. This type of “no” cannot be used bare. The current semantic theories on “no” as an answer particle to negative polar questions and assertions claim that “no” is ambiguous between confirming and rejecting the polar question or assertion. The preceding negative polar question or assertion licenses and therefore provides the content for “no” in answers like “No, I AM”. We argue instead that the ambiguity arises from whether “no” is picking an explicit antecedent—the queried proposition—or an implicit one—the questioner’s bias. We offer three predictions and show that even positive antecedents with implied bias may license the “No, I AM” type of answer; in dialogue, bare “no”s only pick up explicit antecedents; the strength of the bias in a negative question influences the rate of the second type of “no” uses. We formalize our account in the KoS framework (Ginzburg, 2012). Our analysis highlights the importance of potential mismatches between the information states of different conversational participants in meaning resolution.

**Keywords:** No, negation, dialogue, non-sentential utterance, polarity particle, KoS

### 1. Introduction

The English polarity particle “no” has several uses: to reject a positive assertion or polar question (example (1)), and to confirm a negative assertion or polar question (example (2)); it can correct a misinterpretation (example (4)); it can be used in the context of agreement (example (5)); and it can be used as a “stop” interjection (example (6)).

- (1) -A: John likes chocolate. / Does John like chocolate?  
-B: No, he doesn’t.
- (2) -A: John doesn’t like chocolate. / Does John not like chocolate?  
-B: No, he doesn’t.
- (3) -A: You don’t use any credit cards, I don’t imagine.  
-B: No, of course I use [them].  
(Switchboard sw3332A-ms98)
- (4) -A: How’s your girlfriend?  
-B: she is no longer my girlfriend.

-A: Ah, I’m so sorry.

-B: No. She is my wife now.

- (5) -A: I think they should also respect the sanctity of the American home, whether it be in a house or in an apartment.  
 -B: Yeah, yeah, no, I agree with you there.  
 (Switchboard sw-058-2015)

- (6) (A child is about to touch the socket) Adult: No!

The multiple facets of “no” are seldom addressed together. The literature coverage is split between the answer particle uses of “no”, addressing examples (1), (2) and (3), and the “discourse marker” uses of “no”, addressing examples (4) and (5).

### 1.1. “No” as an answer particle

Data like examples (1), (2) and (3) are of interest to semanticists who try to account for the ambiguity of “no” as an answer particle. It has been observed that in English, “no” appears in both responses that confirm a negative assertion or polar question, and those that reject one. Some language have an unambiguous negative particle. For example, the French particle “non” can only be used to refer to a negative situation, thus confirming a negative question or rejecting a positive one. A separate particle, “si” takes care of rejecting negative assertions/polar questions (Roelofsen and Farkas (2015)). In line with the proposal of Pope and Katz (1976), Roelofsen and Farkas propose that polar particles have two types of features, ABSOLUTE and RELATIVE. ABSOLUTE features ([+]/[-]) mark a response clause as positive or negative. [-] is marked compared to [+]. RELATIVE features ([AGREE]/[REVERSE]) mark a response as agreeing with or reversing the antecedent. [REVERSE] is more marked than [AGREE]. When “no” answers a negative polar question, the ABSOLUTE feature confirms the queried negative proposition, while the RELATIVE feature rejects the queried negative proposition. Both possibilities can be realized but the latter (rejection) is more marked.

Krifka (2013) proposes that polar questions are anaphors that pick up a salient propositional discourse referent (propDR), introduced by the antecedent. “Yes” asserts a propDR and “no” asserts its negation. A negative assertion or polar question introduces two propDRs: a positive one (more salient) and a negative one. For example, the utterance “Two plus two isn’t five.” introduces the propDRs “Two plus two is five” and “Two plus two isn’t five”. Thus, when the antecedent is negative, “no” can negate the positive propDR and therefore confirms it, or negate the negative propDR and therefore rejects it. The former is preferred as the positive propDR is more salient. Under the theories of both Krifka (2013) and Roelofsen and Farkas (2015), the content of “no” is provided by the preceding negative assertion or polar question.

## 1.2. “No” as a discourse marker

A separate set of studies on “no” come from the field of Conversational Analysis, which analyzes the “discourse marker” uses of “no”, aiming at explaining examples like (4) and (5). Lee-Goldman (2011) proposes that “no” can be used as a discourse marker to mark topic shift, to correct misunderstanding and to manage disagreement. Schegloff (2001) proposed a specific use of “no”: to mark the transition from non-serious to serious talk. BurrIDGE and Florey (2002) study the uses of “yeah-no” in Australian English, and propose that “yeah-no” is a discourse marker with three functions—propositional, textual and expressive. Propositional “yeah no” indicates both assent and dissent; textual “yeah no” provides cohesion, and expressive “yeah no” is used to express politeness. These Conversational Analysis approaches to “no” list its functions, but do not propose any underlying mechanism linking these uses.

## 2. Our proposal: argumentation

Building on earlier proposals (Ginzburg and Sag, 2000; Cooper and Ginzburg, 2011), we propose that “no” can be ambiguous because it can pick up different types of antecedents—explicit, implicit or exophoric:

1. **“No” with an explicit antecedent, can be used as a bare particle:** used to respond to an explicit polar question or assertion (Ginzburg and Sag, 2000; Cooper and Ginzburg, 2011). When the antecedent is positive, “no” negates it, as in (1). When the antecedent is negative, “no” reaffirms it, as in (2). In English, “nope” is a specialized lexical item with this meaning.
2. **“No” with an implicit antecedent, cannot be used as a bare particle:** used to correct a **grounding misalignment** between the interlocutors. In such situations, speaker A assumes that a proposition *p* is in the common ground or can enter the common ground. Speaker B disagrees with this assumption, detects the grounding misalignment, and uses “no” to reject that *p* is in the common ground. The source of the grounding misalignment is implicit, such as an epistemic bias (example (3)), an interpretation (example (4)), an expectation (example (5), more details on this later). Note that “no” does not assert the negation of the misaligned proposition *p*, but merely asserts that *p* should not be in the common ground. Therefore, speaker B must provide extra information to fix the misalignment in a complement clause.
3. **“No” with exophoric antecedent, can be used as a bare particle:** used as an interjection to address an exophoric event with a potential outcome, as in example (6) (Cooper and Ginzburg, 2011).

Importantly, we argue that the ambiguity of “no” as an answer to negation assertions or polar questions lies in the types of the antecedent it picks up. “No” in answers like “No, I’m not.” (or the “ABSOLUTE” feature in Roelofsen and Farkas (2015)) refers to an explicit antecedent introduced by the preceding negative assertion or polar question, while those in answers like “No, I AM” (the “RELATIVE” feature in Roelofsen and Farkas (2015)) refers to an implicit

antecedent: the bias of the question poser. This analysis resembles Krifka (2013)’s analysis of the meaning of “wrong”. He proposes that the particles “right” and “wrong” do not pick up a propositional discourse referent, but a discourse referent introduced by a speech act. The words “right” and “wrong” evaluate this referent as being justified or not. Like “no” with an implicit referent, “right” and “wrong” can only answer biased questions.

We argue that the “No, I AM” uses as in example (3) is not licensed by the preceding negative assertion or polar question, but by a bias of the question poser, grouped together with the “discourse marker” uses such as (4) and (5). In (3), “no” is licensed by speaker bias. A expects that B does not use credit cards, and proposes to enter this proposition into the common ground. B uses “no” to reject this expectation. In (4), “no” is licensed by implied misunderstanding. A’s utterance “Ah, I’m so sorry” implies an interpretation that B has split up with his girlfriend. B uses “no” to reject this interpretation, and then corrects the misalignment with the clause “she is my wife now”. In (5), what “no” rejects is more elusive. In this example, A implies that her opinion regarding the “American home” is exclusive to herself. B uses “yeah” to agree with the content of A’s utterance, and then uses “no” to cancel the assumption that the belief is exclusive to A, communicating that in fact the opinion is shared.<sup>2</sup> In all these cases, the first speaker (speaker A) implies that there is a proposition  $p$  which A believes is in, or can enter the common ground. The interlocutor B uses “no” to assert that  $p$  cannot enter the common ground. Thus this type of “no” does not pick up the proposition introduced by the immediate preceding utterance itself, but addresses a piece of belief of the interlocutor which causes a grounding misalignment. Due to the implicitness of the antecedent, the second type of “no” cannot be used bare, but must be followed by a clause that corrects the misalignment.

Let us analyse another example.<sup>3</sup> Context: A and B submitted a paper to a journal. After they submitted, they found a big mistake in the argument. They expect that the reviewers will catch the mistake and that the paper will be rejected. Then they get a notification from the journal. A reads the email, which includes a summary of the reviewer reports, and then tells B that the paper has been accepted with minor revisions.

- (7) -B: Did none of the reviewers spot our mistake?  
 -A: No, some of them DID, but the editor still decided to accept the paper with minor revisions.

One might argue that in this example, B’s bias/expectation was that some of the reviewers did spot the mistake, so by uttering “no”, A did not reject this expectation, but rather confirmed it. So it cannot be that “no” is used here to signal rejection of an implicit bias. Still, it is licensed. Therefore, the fact that the preceding polar question provides a negative explicit antecedent seems crucial.

<sup>2</sup>We do not claim that this is the meaning of “no” in all “yeah-no” sequences, nor do we claim that “yeah-no” somehow functions together as a discourse marker, countering Burridge and Florey (2002). We believe that the antecedents of “yeah” and “no” are resolved independently. Often, “yeah” expresses agreement/ compliance, but “no” can be used to refer to an explicit antecedent, for example “(SP:PS0FP) Jonathan. Don’t keep doing that. (SP:PS0FR) (unclear) (SP:PS0FX) Yeah (unclear) (SP:PS0FP) (shouting) Yeah no don’t.” (BNC KCT); or to an implicit antecedent like (5).

<sup>3</sup>We thank an anonymous SuB21 reviewer for suggesting this example.

We argue that in this example, “no” still picks up an implicit antecedent. It illustrates that a speaker’s biases can have different sources. Sudo (2013) discusses two sources of biases associated with polar questions: epistemic and evidential. An epistemic bias is one where the question poser has a prior expectation towards a proposition, but there is no immediate evidence in the common ground supporting this proposition. In English, the profile of the presence of a positive epistemic bias and the absence of an evidential bias is often communicated using high-negation polar questions, such as “Won’t the reviewers spot our mistake?”, implying that the speaker expects that reviewers will spot their mistake. On the other hand, an evidential bias is one where there is immediate evidence in the common ground (available to both conversational participants) which supports a proposition. The profile of the presence of a negative evidential bias and presence or absence of a clashing epistemic bias is often communicated using low-negation polar questions, such as “The reviewers didn’t spot our mistake?/ Did they not spot our mistake?”. (7) communicates a negative evidential bias that “the reviewers did not spot our mistake” and a clashing positive epistemic bias that the speaker previously expected otherwise. The evidential bias (that no one spotted the mistake) was indirectly supported by the fact that the paper was accepted. Speaker A’s response “No, some of them DID” corrects B’s evidential bias.

### 3. Our proposal: Formalization

To formalize our proposal, let us first review the features that need to be captured. We have proposed three types of “no”s, distinguished by the type of contextual antecedent they utilize. As a novel contribution, we propose a type of “no” used when there is a *grounding misalignment*, referring to a belief proposition of the interlocutor. To capture this, we need a semantic framework that (a) centralizes the role of context, as the meaning of “no” is partially supplied (and disambiguated) by the context; (b) represents *separate* contexts for each conversation participant; and (c) has significant internal structure by means of which it represents content other than the illocutionary content of the utterance. These features are best handled by semantic theories rooted in dialogue.

#### 3.1. KoS

KoS—a toponym, not an acronym—for recent surveys, see Ginzburg and Fernández (2010); Ginzburg (2012, 2016), for motivation of its view of grammar, see Ginzburg and Poesio (2016)) is a theory that combines an approach to semantics inspired by situation semantics and dynamic semantics with a view of interaction influenced by Conversational Analysis. On the approach developed in KoS, there is actually no single context—instead of a single context, analysis is formulated at a level of information states, one per conversational participant. Each information state consists of two ‘parts’, a private part and the dialogue gameboard that represents information that arises from publicized interactions. We focus on the dialogue gameboard. For current purposes, it will be sufficient to assume a simplified specification of its *type* as given in (8)<sup>4</sup>—the *sprk;addr* fields allow one to track turn ownership, *Facts* represents conversationally

<sup>4</sup>The relevant notion of ‘type’ is drawn from Type Theory with Records, for which see Cooper and Ginzburg (2015).

shared assumptions, *Moves* represents the contents of moves that have been grounded, *QUD* tracks the questions currently under discussion:

(8)  $DGBType =_{def}$

$$\left[ \begin{array}{l} \text{spkr} : \text{Ind} \\ \text{addr} : \text{Ind} \\ \text{utt-time} : \text{Time} \\ \text{c-utt} : \text{addressing}(\text{spkr}, \text{addr}, \text{utt-time}) \\ \text{Facts} : \text{Set}(\text{Proposition}) \\ \text{Moves} : \text{list}(\text{illocutionaryProposition}) \\ \text{QUD} : \text{poset}(\text{Question}) \end{array} \right]$$

Lexical entries and grammar rules interface with the DGB by specifying values that the latter needs to instantiate via a field ‘dgb-params’. Thus, for instance, a lexical entry for a greeting word such as “hi” involves a specification for the initial context of a conversation, one in which no moves have been made and no issues introduced:

(9)  $\left[ \begin{array}{l} \text{phon} : \text{hi} \\ \text{cat.head} = \text{interj} : \text{syncat} \\ \text{dgb-params} : \left[ \begin{array}{l} \text{spkr} : \text{IND} \\ \text{addr} : \text{IND} \\ \text{utt-time} : \text{TIME} \\ \text{Moves} = \langle \rangle : \text{list}(\text{LocProp}) \\ \text{qud} = \{ \} : \text{set}(\text{Question}) \end{array} \right] \\ \text{cont} = \text{Greet}(\text{spkr}, \text{ind}, \text{utt-time}) : \text{IllocProp} \end{array} \right]$

### 3.2. Three times “no”

Working backwards from the last example we discussed in Section 1, we first specify the type of “no” used as an interjection (the third type in Section 2). This type of “no”, arguably, has ontogenetic priority. The context is one in which there is a potential state of affairs or *outcome* (in example (6), the potential outcome would be the child touching the socket). “No” expresses a negative volition to this *outcome*. It is both used in addressing young children and by young children gesturally (Morgenstern et al. (2016)). Cooper and Ginzburg (2011) propose the following lexical entry for this use:

(10) **“No” with exophoric antecedent**

$$\left[ \begin{array}{l} \text{phon : no} \\ \text{cat.head = interjection : syncat} \\ \text{dgb-params = } \left[ \begin{array}{l} \text{o : Outcome} \\ \text{spkr : Ind} \end{array} \right] \text{ : RecType} \\ \text{cont = } \neg \text{Want}(\text{spkr}, \text{o}) \text{ : Prop} \end{array} \right]$$

Now to address the “discourse marker” uses and “no” used to reject negative assertions or polar questions, “no” with implicit antecedent presupposes that there is a misalignment between the Dialogue Gameboards of the two conversational participants. One participant believes (or has high confidence) that a proposition  $r$  should be in the common ground, but the other participant believes otherwise. The belief proposition  $r$  can be introduced by biased question forms (example (3)), implicatures (example (4)), attitude verbs, e.g. “I think” (example (5)), prosody or even nonverbal means like facial expressions. The meaning of this type of “no” is represented as follows. The addressee (previous speaker) believes  $r$ , and the current speaker uses “no” to assert that  $r$  is not true.

(11) **“No” with implicit antecedent**

$$\left[ \begin{array}{l} \text{phon : no} \\ \text{cat.head = interjection : syncat} \\ \text{dgb-params : } \left[ \begin{array}{l} \text{spkr : Ind} \\ \text{addr : Ind} \\ \text{c : addressing}(\text{spkr}, \text{addr}) \\ \text{r : Prop} \\ \text{c1 : Believe}(\text{addr}, \text{r}) \end{array} \right] \\ \text{content = } \neg \text{r} \end{array} \right]$$

Lastly, we address the examples of “no” used as an answer particle that rejects a positive question or confirms a negative one. The context of this use of “no” is its most ubiquitous in adult use, namely bare, as a response particle. It presupposes that in the context, the current Question Under Discussion (max-QUD) is a polar question.<sup>5</sup> “No” always denotes a negative proposition: it negates the queried proposition if the max-QUD is positive, and is identical to the queried proposition if the max-QUD is negative. We propose the following lexical entry for this use, which refines earlier proposals in Ginzburg and Sag (2000); Cooper and Ginzburg (2011).

<sup>5</sup>Ginzburg (2012) proposes that an assertion  $p$  gives rise to the QUD *whether p*. Therefore, this account assumes that the max-QUD after both a polar question and an assertion is a PolQuestion.

## (12) “No” with explicit antecedent

|   |                                                                                |   |
|---|--------------------------------------------------------------------------------|---|
| [ | phon : no                                                                      | ] |
|   | cat.head = interjection : syncat                                               |   |
|   | ARG-ST = $\langle \rangle$ : elist(synsem)                                     |   |
|   | dgb-params.max-qud : PolQuestion                                               |   |
|   | cont : NegProp                                                                 |   |
|   | c1: (cont = maxqud( $\langle \rangle$ )) $\vee$                                |   |
|   | $maxqud(\langle \rangle) ; NegProp \wedge cont = \neg maxqud(\langle \rangle)$ | ] |

## 4. Three predictions and their evaluation

Our theory makes three predictions:

**Prediction I:** Even positive assertions ( $p$ ) or polar questions ( $p?$ ) can license the “No, I Am” type of answers, as long as the speaker implies a bias that is different from  $p$ .

Consider this example, a group of friends are talking about who should cook for the party. Most of them eat meat, and they each propose what they would cook. Amie, who is vegetarian, says “well I can do tofu burgers and soya pudding. I bet you are all excited about that!”. In this context, one can say “No, I AM. That will be interesting!”. Here, “no” is used with a positive clause, as a response to a positive antecedent. This is not allowed under current semantic theories.<sup>6</sup>

**Prediction II:** Without the help of prosody, when “no” is used as a bare particle following a negative assertion or polar question, it can only pick up an explicit antecedent (interpreted as confirmation).

To evaluate this prediction, we conducted a corpus study, looking at responses to negative polar questions in the Switchboard Dialogue Act Corpus (Jurafsky et al., 1997). Negative polar questions are rare compared to positive ones, at a ratio of 1:13. Looking at answers to negative polar questions (summarized in Table 1), we found that confirming answers out-ratio rejecting answers at 5.8:1, higher than the ratio of 2:1 following positive questions, suggesting that negative questions are more biased. When a negative question *is* rejected, most often no particle was used at all. In such cases answers containing “no” are much more likely to be a confirmation than a rejection. Bare “no”s are used only to confirm (as seen in examples (13) and (14)). They do not seem to cause confusion, as we found no clarification questions following bare “no”s. The corpus data supports our prediction that bare “no”s follow negative assertions or polar questions can only pick an explicit antecedent.

<sup>6</sup>It has been pointed out to us that this example is compatible with Krifka (2013), if we assume that an ironic utterance  $p$  introduces *not p* as a discourse referent. This argument does not contradict our analysis that here “no” picks up an implicit antecedent.

- (13) -A: Didn’t like it?  
 -B: No.  
 (Switchboard sw\_0143\_2290)

- (14) A: But, I mean, it doesn’t give you trouble?  
 -B: No.

| Total                          | 128 (76%)    | 22 (13%)  | 19 (11%)     |

Table 1: Distributions of “No” and “Yes” particles used in confirming or rejecting answers to negative polar questions—data from Switchboard

A similar point was made by Roelofsen and Farkas (2015), who noticed that when answering negative assertions or polar questions, bare particle responses are considerably less felicitous than ones accompanied by an answer clause (illustrated in example (15)). Kramer and Rawlins (2012) tested the interpretation of bare particle responses in different contexts, and found that in response to a negative polar question, both bare “yes” and bare “no” are more often interpreted as confirming the negative question than rejecting it.

- (15) -A: Did Peter not pass the text? / Peter didn’t pass the test.  
 -B: ?No. / No, he didn’t pass. / No, he DID pass.

**Prediction III:** Biased negative polar questions can license the “No, I AM” type of answers (the “RELATIVE” use), but neutral questions cannot.

Under our theory, in answers to negative polar questions, the second type of “no” (the “RELATIVE” feature under Roelofsen and Farkas (2015)) is licensed not by the explicit question itself, but by the speaker bias that is often present when a negative question is posed. Therefore, in contexts where the question poser is neutral, we should not expect this type of answer. We ran a production experiment testing whether the strength of the speaker bias in a negative polar question influences the ratio of “RELATIVE” use of “no”. The prediction is that the weaker the speaker bias, the fewer the “No, I AM” type answers.

**Participants:** 50 participants were recruited via Amazon Mechanical Turk. We did not specify any native language requirements, but instead asked them to say what their native language(s) is/are. In this experiments, all 50 participants indicated that English was their native language. There were 28 females and 22 males. The average age was 33 years.

**Design and materials:** We constructed two dialogues, each containing two negative polar questions and three positive polar questions as fillers. The following turn of these questions is left empty, and participants are asked to freely fill the empty lines so that the dialogue sounds

coherent and natural. The first dialogue is between the character Charlotte and a health worker who is conducting a survey in the community. The second dialogue is between Charlotte and a newly acquainted friend. In each dialogue, we tried to make one negative question weakly biased/neutral, while the other strongly biased. To create the context for a weakly biased question, we made the negative proposition salient in the context, but imply that the questioner is genuinely ignorant of the answer. To create the context for a strongly biased question, we planted indirect and insufficient evidence which suggest that the queried negative proposition might be true. The experimental questions are:

- (16) Dialogue 1 background information: A health worker came to the community to talk to the residents because there is a worry concerning a minor infectious disease. However people who have had chickenpox have a reduced chance of contracting it.  
*(The health worker introduces herself and the purpose of the survey, then asks a question about where they lived and whether they have young children.)*  
 -Health worker: You probably have heard that, if you have never had chickenpox, you are more likely to get infected. **Have you not had chickenpox before?** *(weakly biased question)*  
 -Charlotte: *(answer to be filled by participant).*  
 ...  
 -Health worker: Ah you guys just moved here, I see. **So is your nationality not American?** *(strongly biased question)*  
 -Charlotte: *(answer to be filled by participant).*  
 ...
- (17) Dialogue 2 background information: You are chatting with a new friend who you recently met in the local market. Her name is Sarah, and she is an American woman with a young child.  
*(The two characters first exchange greetings.)*  
 -Sarah: Oh, I took my baby to the nursery this morning, and guess what I saw, a kid with chickenpox! And the child rubbed his face all over me!  
 -Charlotte: Haha, that's not nice. Now you stay away from me!  
 -Sarah: Oh my god, **have you not had chickenpox before?** *(strongly biased question)*  
 -Charlotte: *(answer to be filled by participant).*  
 -Sarah: Then you are safe! You won't get it again.  
 ...  
*(The two characters chat about childcare and then start chatting about housing)*  
 -Sarah: We don't own our apartment and our landlord is sometimes too strict about what I can and cannot do. What about you? Do you own your apartment? **Do you not own your apartment ?** *(weakly biased question)*  
 -Charlotte: *(answer to be filled by participant).*  
 -Sarah: Ah that makes life easier.  
 ...

**Results:** we counted answers containing the second type of “no” (the “RELATIVE” uses), for example “No, I am American”, “No, I have!”, “No, I’ve gotten it before but I was really young.”. When the bias is weak, there were 5 such answers, constituting 5.2% of all answers; when the bias is strong, there were 32 such answers, constituting 32.7% of all answers. The difference is significant under a  $\chi^2$  test:  $\chi^2 = 272.15$ ,  $p < 2.2\text{e-}16$ , suggesting that the strength of epistemic bias influences the licensing of the second type (the “RELATIVE” use) of “no”.

## 5. Conclusions

The English particle “no” can be used in a variety of conversational contexts. So far, no analyses have been offered that cover all uses of “no”. We propose that “no” is ambiguous with three meanings, distinguished by the type of antecedent utilized: explicit, implicit and exophoric. The second type—“no” with an implicit antecedent—addresses a grounding misalignment caused by sources such as speaker’s bias. This type of “no” cannot be used bare. The current semantic theories on “no” as an answer particle to negative polar questions and assertions claim that “no” is ambiguous between confirming and rejecting the polar question or assertion. The preceding negative polar question or assertion licenses and therefore provides the content for “no” in answers like “No, I AM”. We argue instead that the ambiguity arises from whether “no” picks up an explicit antecedent—the queried proposition—or an implicit one—the questioner’s bias. We formalize our account in the KoS framework (Ginzburg, 2012). We offer three predictions and show that even positive antecedents with implied bias may license the “No, I AM” type of answer; in dialogue, bare “no”s only pick up explicit antecedents; the strength of the bias in a negative question influences the rate of the second type of “no” uses. Our analysis highlights the importance of potential mismatches between the information states of different conversational participants in meaning resolution.

Important future work involves a comprehensive corpus study to test the coverage of our account and for the implicit antecedent use—a characterization of how such antecedents can be detected.

# Japanese alternative questions and a unified in-situ semantics for *ka*<sup>1</sup>

Wataru UEGAKI — *Leiden University*

**Abstract.** In Japanese, the interpretation of a clause involving a *wh*-item and the Q-particle *ka* is conditioned by the syntactic position of *ka*. In a parallel fashion, we observe that the syntactic position of *ka* conditions the interpretation of a disjunctive construction of the form  $\alpha$ -*ka*  $\beta$ -*ka*. We propose a two-tier alternative semantics for *wh+ka* and *ka*-disjunction that accounts for the parallel syntactic conditioning effect in a unified fashion.

**Keywords:** *ka*, Q-particle, *wh*-indefinites, *wh*-questions, disjunction, alternative semantics

## 1. Introduction

The goal of this paper is to provide a concrete semantics for the Japanese Q-particle *ka* that properly accounts for its use in questions, indefinites and disjunctions in a unified fashion. The Japanese particle *ka* is interesting in the context of the cross-linguistic compositional semantics of indefinites, *wh*-questions and disjunctions (Szabolcsi, 2015) since its interpretation is tightly connected with the syntactic environments in which it occurs, as will be discussed shortly below. A number of proposals have been proposed to capture this connection between the syntactic environment in which *ka* occurs and its interpretation (e.g., Hagstrom, 1998; Shimoyama, 2006; Slade, 2011). However, none of the current compositional semantic analysis of *ka* can successfully capture the fact that the semantic contribution of *ka* is conditioned by its syntactic position in its *disjunction use* in a way parallel to how its semantic contribution is conditioned in the *wh+ka* construction. This paper argues that this parallel pattern straightforwardly falls out from the combination of (a) an extension of the alternative-semantic analysis of in-situ *wh*-questions and Q-particles (Shimoyama, 2006; Beck, 2006; Kotek, 2014) and (b) the Junction-based analysis of disjunction following den Dikken (2006); Mitrovič and Sauerland (2014); Szabolcsi (2015).

## 2. The position of *ka* and its semantic contribution

### 2.1. *wh+ka*

The interpretation of a Japanese sentences involving a *wh*-item and *ka* depends on the syntactic position of *ka* (Kuroda, 1965; Hagstrom, 1998). When *ka* directly attaches to the *wh*-phrase, the *wh-ka* complex functions as an indefinite. On the other hand, when *ka* is in a sentence-final position, the sentence constitutes a *wh*-question. This can be seen in the following examples:

---

<sup>1</sup>I would like to thank Maria Aloni, Lisa Cheng, Floris Roelofsen, Uli Sauerland, Yasutada Sudo, Satoshi Tomioka and anonymous reviewers for *Sinn und Bedeutung* 21 for valuable comments and discussion on earlier versions of this paper. A part of the research leading to this paper is financially supported by Japan Society for the Promotion of Science Postdoctoral Research Fellowship for Young Scientists and JSPS KAKENHI Grant-in-Aid No. 15J00143. All errors are my own.

- (1) a. [DP Dare-**ka** ] -ga hashitta.  
           who-KA -NOM ran  
           ‘Someone ran.’ (∃-statement)
- b. [CP Dare-ga hashitta-**ka** ] (oshiete)  
           who-NOM ran-KA tell  
           ‘(Tell me) who ran.’ (Wh-Question)

Here, the embedding verb *oshiete* ‘tell me’ is added in (1b) since the clause-final *ka* is most natural in embedded contexts for stylistic reasons. In an unembedded clause, *no* is used instead of *ka* in informal speech. In an unembedded formal speech, *ka* is attached to the polite form of the verbal complex.<sup>2</sup>

## 2.2. *ka*-disjunctions

Another empirical domain in which *ka* appears is disjunction. Example (2) shows that *ka* can attach to each disjunct in a disjunction (optionally to the second disjunct).<sup>3</sup> I will call this construction *ka*-DISJUNCTION.

- (2) Taro-ga [DP Hanako-**ka** (matawa) Jiro-**ka**]-o mita.  
       Taro-NOM Hanako-KA or Jiro-KA-ACC saw.  
       ‘Taro saw Hanako or Jiro.’ (∨-statement)

An additional coordinator (in this case *matawa*) can be inserted between the two disjuncts marked by *ka*, and there are several phonologically explicit disjunctive coordinators with different syntactic and semantic properties. In this paper, I will leave out discussion of *ka*-disjunctions involving an explicit coordinator for reasons of space.

One of the empirical contributions of this paper is to establish that the interpretation of a *ka*-disjunction is dependent on the syntactic position of *ka* in each disjunct, in a way parallel to how the interpretation of a *wh+ka* construction is dependent on the syntactic position of *ka*. The parallel is summarized in the following table.

<sup>2</sup>For some speakers, the *wh*-item and *ka* can be separated within a DP that functions as an indefinite. The following example from Yatsushiro (2009) illustrates this:

- (1) [ Dare-o hihanshita gakusei ]-**ka**-ga taihosareta.  
       who-ACC criticized student -KA-NOM be.arrested.  
       ‘A student or other who had criticize someone was arrested’

In this example, *ka* is separated from the *wh*-item *dare* itself, and the *who* subject DP ending with *ka* receives an interpretation as an existential quantifier over students who criticized someone.

<sup>3</sup>I will assume that the presence and the absence of the second *ka* does not have a semantic consequence, unlike the contrast between simplex and complex disjunctions in French (e.g., Spector, 2014). This is confirmed by informal judgment reports by native speakers. Furthermore, a controlled experiment by Sauerland and Yatsushiro (2016) has not revealed any significant difference in judgment patterns between the single-*ka* and the double-*ka* disjunctions.

|     |                                          |                          |                      |
|-----|------------------------------------------|--------------------------|----------------------|
| (3) | <b>the <i>ka</i>-phrase is...</b>        | <b>smaller than a CP</b> | <b>CP</b>            |
|     | <i>wh+ka</i>                             | existential quantifier   | <i>wh</i> -question  |
|     | $\alpha$ - <i>ka</i> $\beta$ - <i>ka</i> | declarative disjunction  | alternative question |

Let me elaborate this empirical claim in some detail. First of all, the dependence of the interpretation of *wh+ka* on the syntactic position of *ka*, exemplified in (1) above, can be described as in the first row of table (3). The syntactic category of the *wh+ka* phrase is a *DP* in (1a), where *ka* attaches to the *wh*-phrase *dare* directly and *dare-ka* serves as the external argument of the verb *hashitta* ‘ran’. This *wh-ka* phrase functions as an indefinite/existential quantifier. On the other hand, the *wh+ka* phrase in (1b) is a whole CP which by itself expresses a question (modulo stylistic anomaly) and can be embedded under clause-embedding predicates such as *oshiete* ‘tell me’. In this case, the *wh*-phrase functions as a *wh*-word in a *wh*-question.

Turning now to *ka*-disjunctions, it is known that *ka*-disjunctions can coordinate (at least) DPs, TPs as well as CPs (Kishimoto, 2013; Uegaki, 2014; Miyama, 2015).<sup>4</sup>

- (4) [<sub>DP</sub> Hanako-*ka* Jiro-*ka*]-*ga* hashitta.  
 Hanako-KA Jiro-KA-NOM ran.  
 ‘Either Hanako or Jiro ran’. (✓V-statement)  
 \*‘Which is true: Hanako ran or Jiro ran?’ (\*AltQ)
- (5) [<sub>TP</sub> [Hanako-*ga* hashitta-**ka**] [Jiro-*ga* hashitta-**ka**]] mitai-*da*.  
 Hanako-NOM ran-KA Jiro-NOM ran-KA MODAL-COP  
 ‘It seems that Hanako ran or Jiro ran.’ (✓V-statement)  
 \*‘Which seems to be true: Hanako ran or Jiro ran?’ (\*AltQ)
- (6) [<sub>CP</sub> [Hanako-*ga* hashitta-mitai-**ka**] [Jiro-*ga* hashitta-mitai-**ka**]] (*oshiete*).  
 Hanako-NOM ran-MOOD-KA Jiro-NOM ran-MOOD-KA tell  
 ‘(Tell me) which is true: It seems that Hanako ran or it seems that Jiro ran?’ (✓AltQ)  
 \*‘(Tell me) it seems that Hanako ran or it seems that Jiro ran.’ (\*V-statement)

Following Kishimoto (2013), I take the positioning of a modal such as *mitai* ‘seem’, which is in a functional projection outside TP, as indicating the syntactic category of *ka*-disjunctions. When the modal is outside the *ka*-disjunction involving tensed predicates, as in (5), its syntactic category is TP. On the other hand, when the modal is inside the *ka*-disjunction, as in (6), or when there is no overt modal item in the sentence as in (7) below, its syntactic category is CP.

- (7) [<sub>CP</sub> [Hanako-*ga* hashitta-**ka**] [Jiro-*ga* hashitta-**ka**]] *oshiete*.  
 Hanako-NOM ran-KA Jiro-NOM ran-KA tell  
 ‘Tell me which is true: Hanako ran or Jiro ran?’ (✓AltQ)

<sup>4</sup>Kishimoto (2013) discusses cases where *ka*-disjunctions apparently coordinate vPs in the surface, but he concludes that they are in fact TP disjunctions based on evidence pertaining to scope with respect to negation.

What is crucial here is that the interpretation of a *ka*-disjunction is a disjunctive statement in both (4) and (5) whereas it is an AltQ in (6) and (7). In other words,  $\alpha$ -*ka*  $\beta$ -*ka* becomes a question with  $\alpha$  and  $\beta$  as alternatives only when it is a CP coordination (Uegaki, 2014).

In sum, *ka*-disjunctions are interpreted as disjunctions without the question force when they are sub-CP-coordinations while they are interpreted as AltQs with each disjunct as alternatives when they are CP-coordinations. This parallels the behavior of *wh+ka* constructions as summarized in the table in (3).

### 3. An analysis in a two-tier alternative semantics

Our proposal employs two-tier alternative semantics (Rooth, 1985) for in-situ *wh*-questions (Beck, 2006; Kotek, 2014). The gist of the analysis is the following: *ka* introduces a *set of alternatives* in its ordinary-semantic value, but only specific predicates—which I will call SET-COMPATIBLE PREDICATES—semantically combine with such a set. Set-compatible predicates include predicates embedding interrogative CPs, such as *oshier* ‘tell’, and the disjunctive coordinator. As a result, a semantic composition of a *ka*-phrase and a set-incompatible predicate requires that the set denoted by the former be ‘flattened’ into an *existential meaning*. This is what happens when *ka* is introduced below CPs. A predicate or operator embedding a *ka*-phrase below the CP level is always set-incompatible except for the disjunctive coordinator. Thus, when *ka*-phrases are smaller than CPs, they are ‘trapped’ inside a non-incompatible predicate and receive an existential meaning. Formally, the flattening effect is implemented with a cross-categorical existential closure  $\exists$ .

#### 3.1. *wh+ka*

Below, I illustrate this system using a simple fragment that captures the basic data discussed in the previous section. First, let us consider the case of the *wh+ka* construction, repeated below.

- (1) a. [<sub>DP</sub> dare-**ka**]-ga hashitta.  
       who-KA-NOM ran.  
       ‘Someone ran.’ (∃-statement)
- b. [<sub>CP</sub> dare-ga hashitta-**ka**]  
       who-NOM ran-KA  
       ‘(Tell me) who ran?’ (Wh-Question)

In the two-tier alternative-semantic analysis of in-situ *wh*-questions developed by Beck (2006) and Kotek (2014), lexical items have ORDINARY and ALTERNATIVE-SEMANTIC VALUES (hereafter O-VALUES and ALT-VALUES). For instance, the semantic values of *ka*, *dare* ‘who’ and *hashitta* ‘ran’ each look like the following:

- (8) a.  $\llbracket \alpha \text{ ka} \rrbracket^o = \llbracket \alpha \rrbracket^{alt}$  b.  $\llbracket \alpha \text{ ka} \rrbracket^{alt} = \{ \llbracket \alpha \rrbracket^{alt} \}$
- (9) a.  $\llbracket \text{dare} \rrbracket^o = \text{undefined}$  b.  $\llbracket \text{dare} \rrbracket^{alt} = \{x \mid x \in \text{human}\}$

- (10) a.  $\llbracket \text{hashitta} \rrbracket^o = \lambda x_e \lambda w_s. \mathbf{ran}(x, w)$     b.  $\llbracket \text{hashitta} \rrbracket^{alt} = \{ \lambda x_e \lambda w_s. \mathbf{ran}(x, w) \}$

Here, *ka* is defined as an operator that simply ‘copies’ the alt-value of its prejacent to the o-value. A *wh*-item like *dare* has an undefined o-value while it introduces a set of alternatives in the alt-value. A set-incompatible predicate like *hashitta* has a standard denotation as a function from individuals to truth values in the o-value while its alt-value is the singleton set consisting of the o-value.

Except for *ka*, which has a syncategorematic definition, semantic values are composed according to either one of the following two rules:

(11) a. **Functional Application (FA)**

If the node  $\alpha$  has  $\{\beta, \gamma\}$  as the set of its daughters and  $\llbracket \beta \rrbracket^o \in D_\sigma$  and  $\llbracket \gamma \rrbracket^o \in D_{\langle \sigma, \tau \rangle}$ , then  $\llbracket \alpha \rrbracket^o$  is defined only if both  $\llbracket \alpha \rrbracket^o$  and  $\llbracket \beta \rrbracket^o$  are. In this case,  $\llbracket \alpha \rrbracket^o = \llbracket \gamma \rrbracket^o(\llbracket \beta \rrbracket^o)$ .

b. **Point-wise Functional Application (PWFA)** (Hamblin, 1973)

If the node  $\alpha$  has  $\{\beta, \gamma\}$  as the set of its daughters and  $\llbracket \beta \rrbracket^{alt} \subseteq D_\sigma$  and  $\llbracket \gamma \rrbracket^{alt} \subseteq D_{\langle \sigma, \tau \rangle}$ , then  $\llbracket \alpha \rrbracket^{alt} = \{ a \mid \exists f \in \llbracket \gamma \rrbracket^{alt} \exists b \in \llbracket \beta \rrbracket^{alt} [a = f(b)] \}$ .

### 3.1.1. *Wh*-questions

Given this setup adopted from Beck (2006) and Kotek (2014),<sup>5</sup> we can already account for the interpretation of the *wh*-question in (1b). Below is a simplified LF tree for (1b) with annotation of the two kinds of semantic values for each node. The notation  $\langle a, b \rangle$  indicates that the node’s o-value is *a* while its alt-value is *b*.

What is crucial above is that the alternatives introduced by *dare* is passed up via an application of PWFA in the alternative-semantic dimension, until the top-level *ka* returns it as the o-value (Beck, 2006). As a result, the sentence receives the standard proposition-set denotation for *wh*-questions (Hamblin, 1973; Karttunen, 1977) as its o-value.

<sup>5</sup>More precisely, I here adopt Kotek’s (2014) definition of the Q-particle, instead of that by Beck (2006), who defines the alt-value of  $\alpha$  *ka* as equivalent to its o-value. See Kotek (2014) for independent motivations for adopting this particular definition in relation to the treatment of multiple *wh*-questions in English. For the purpose of this paper, adopting Kotek’s (2014) definition enables a simpler compositional system.

### 3.1.2. Excursus: Yes/No-questions and the semantics of complementizers

It is important to note at this point that *ka* defined in (8) is also the one that appears as the sentence-final particle in Yes/No-questions (YNQs), as exemplified in (13). The analysis predicts the following *o*-value for (13) in (14).

- (13) Hanako-ga hashitta-ka?  
 Hanako-NOM ran-KA  
 ‘Did Hanako run?’

$$(14) \llbracket (13) \rrbracket^o = \{\lambda w. \mathbf{ran}(\mathbf{h}, w)\}$$

The singleton-set denotation for YNQs as exemplified above is different from the more standard bipolar denotation (Hamblin, 1973; Karttunen, 1977), which would be the following two-membered set in the case of (13).

$$(15) \{\lambda w. \mathbf{ran}(\mathbf{h}, w), \lambda w. \neg \mathbf{ran}(\mathbf{h}, w)\}$$

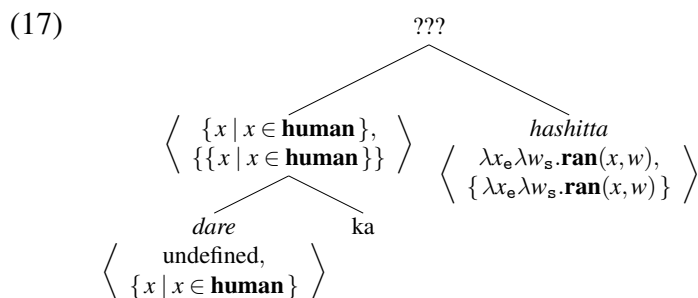

Versions of the singleton analysis of the semantics of YNQs are maintained by authors such as Roberts (2012); Pruitt and Roelofsen (2011); Biezma and Rawlins (2012); Roelofsen and Farkas (2015), and its empirical motivations come from biased polar questions, the interpretation of response particles and the selectional property of dubitative predicates, among others. In many of these analyses, the singleton denotation is mapped to the corresponding bipolar denotation by an extra operation in order to capture the fact that polar questions license negative responses. In this paper, I follow Roelofsen and Farkas (2015) in positing an interrogative operator  $\langle ? \rangle$  on the top of *ka* in interrogative clauses, whose role is to *ensure* multiplicity of alternatives. Syntactically, I will assume that  $\langle ? \rangle$  is in the complementizer position, above *ka*. The semantics of this operator looks like the following:

$$(16) \llbracket \langle ? \rangle \rrbracket^o = \llbracket C_{\text{int}} \rrbracket^o = \lambda Q_{\{p\}} \cdot \begin{cases} Q & \text{if } |Q| > 1 \\ Q \cup \{\neg \bigcup Q\} & \text{if } |Q| = 1 \end{cases}$$

Applying this operator to (13), we get the bipolar denotation:  $\{\lambda w. \mathbf{ran}(\mathbf{h}, w), \lambda w. \neg \mathbf{ran}(\mathbf{h}, w)\}$ . The operator does not have an effect when it applies to *wh*-questions that already involve multiple alternatives. Type-wise,  $\langle ? \rangle$  can only combine with a set of propositions. On the other hand, when a complement clause is declarative, the declarative operator is in the complementizer position, which is semantically an identity function for propositions. The declarative complementizer is realized as *to* in an embedded clause while it is phonologically null in the matrix clause. That is,  $\llbracket C_{\text{decl}} \rrbracket^o = \lambda p_p. p$

### 3.1.3. Indefinites

Let us now turn to how we derive the existential statement in (1a). The first thing to note is that, without any additional mechanisms, the semantic composition does not go through due to type-mismatch. This is so since neither FA nor PWFA can combine the semantic values of *hashitta* with the semantic values of *dare-ka*. This is seen in the following uninterpretable LF.

Here, the operation of existential closure that I mentioned above comes into play. Specifically, I propose that there is a following operator that turns a set in the o-value dimension into the corresponding existential quantifier.<sup>6</sup>

- (18) a.  $[\exists]^o = \lambda Q_{\{\sigma\}} \begin{cases} \lambda w_s. \exists p \in Q[p(w)] & \text{if } \sigma = p \\ \lambda P_{\langle \sigma, p \rangle} \lambda w_s. \exists x \in Q[P(x)(w)] & \text{otherwise} \end{cases} \quad (p := \langle s, t \rangle)$
- b.  $[\exists]^{alt} = \{[\exists]^o\}$
- c.  $\sigma$  is any type, and  $\{\sigma\}$  is the type for the set of  $\sigma$ -type objects. I assume a formal distinction between sets and characteristic functions. Thus,  $\{\sigma\}$  is a distinct type from  $\langle \sigma, t \rangle$ .<sup>7</sup>

This operator can be applied to *dare-ka* in (17). As a result, we derive the existential statement as in the following LF:

Thus, we can capture the fact that (1a) is an existential statement rather than a *wh*-question. The only way in which the semantic composition of *dare-ka* ‘who-KA’ and *hashitta* ‘ran’ goes through is to turn the the o-value of the former into an existential quantifier by  $\exists$ . The same mechanism applies to other cases where a non-inquisitive predicate combine with a *ka*-phrase.

<sup>6</sup>The operation of existential closure is employed in alternative semantics by Kratzer and Shimoyama (2002) and Biezma and Rawlins (2012) (among others) although the operation always applies at the clausal level. Here,  $\exists$  is defined as a cross-categorical operator which can apply clause-internally. In this sense, the operation is close to the non-inquisitive closure ! in Inquisitive Semantics (Ciardelli et al., 2013).

<sup>7</sup>Yatsushiro (2009) uses the notation  $\langle \sigma \backslash t \rangle$  to denote the same type.

Note, however, that the introduction of  $\exists$  creates a potential problem. The *wh*-question interpretation of (1b) itself could now be turned into an existential statement if  $\exists$  is freely available and applied to the whole sentence. However, it is plausible to assume that an operator like  $\exists$  is *not* freely available. I claim that the application of  $\exists$  is allowed only when it is necessary for the semantic composition to go through, as stated in the following constraint:

- (20) The application of  $\exists$  is allowed only as a repair of a type-mismatch.

This constraint prohibits the application of  $\exists$  to the whole sentence of (1b). Since LF (12) of (1b) does not suffer from any type-mismatch, the application of  $\exists$  is disallowed. Hence, the sentence lacks an interpretation as the existential statement.

This is true also when (1b) is embedded under question-embedding predicates since there would be no type-mismatch between question-embedding predicates and (1b). I analyze all question-embedding predicates as a set-compatible predicate, i.e., as selecting for a set of propositions, both in the o-value and in the alt-value. For instance, the semantic values of *oshier(u)* ‘tell/teach’ look like the following:

- (21) a.  $\llbracket \text{oshier} \rrbracket^o = \lambda Q_{\{p\}} \lambda x \lambda w. \text{tell}(x, Q, w)$     b.  $\llbracket \text{oshier} \rrbracket^{alt} = \{ \lambda Q_{\{p\}} \lambda x \lambda w. \text{tell}(x, Q, w) \}$

Thus, the set of propositions in the o-value and the alt-value of an interrogative CP can be combined with the question-embedding predicate via FA and PWFA. Hence, there is no type-mismatch and the existential closure by  $\exists$  does not occur. I claim that there is no set-compatible predicate in Japanese other than interrogative-CP-embedding predicates like (21), disjunctive coordinators such as the disjunctive coordinator and  $\exists$  itself. Thus, any case in which a *ka*-phrase combines with items other than these operators at LF involves existential closure.

This system captures the fact that the position of *ka* conditions the interpretation of a *wh+ka* construction, as we saw in the previous section. When the *ka*-phrase together with  $C_{int}$  forms a whole CP, it would receive the interpretation as the set of propositions, i.e., a question, whether or not it is embedded by a question-embedding predicate. This is because there would be no type-mismatch in the semantic composition. On the other hand, when the *ka*-phrase forms a DP, the set of alternatives it denotes in the o-value cannot participate in the semantic composition unless it is flattened into a non-set. Because, as I claimed above, there is no set-compatible predicate that can syntactically combine with a DP, except for disjunctive coordinators, which I turn to in the next section.

### 3.2. *ka*-disjunctions

In this section, I will argue that the generalization about the effect of the position of *ka* on the interpretation of *ka*-disjunctions can be captured as a natural extension of the system outlined above, once we take into account an appropriate syntax for disjunctions. Following the structure of complex coordinations adopted in the literature on the cross-linguistic syntax and semantics of coordinations (den Dikken, 2006; Slade, 2011; Mitrović and Sauerland, 2014; Szabolcsi,

2015), I assume that *ka*-disjunctions involve a Junction head (hereafter J) with *ka*-phrases both in its internal argument position and in the specifier. The structure is schematized as follows:

$$(22) \quad [_{JP} [_{XP} \alpha \text{ ka}] [_{J'} J [_{XP} \alpha \text{ ka}]]]$$

The disjunctive J head is realized either as *matawa* or *soretomo*, or is phonologically null. I treat disjunctive J as denoting the set-union operation in the o-value, as given in (23a) below, while its alt-value is defined in terms of generalized disjunction (Partee and Rooth, 1983).

$$(23) \quad \begin{array}{ll} \text{a. } \llbracket J \rrbracket^o = \lambda X_{\{\sigma\}} \lambda Y_{\{\sigma\}}. X \cup Y & \text{b. } \llbracket J \rrbracket^{alt} = \{ \lambda X_{\{\sigma\}} \lambda Y_{\{\sigma\}}. \{ \iota X \sqcup \iota Y \} \}^8 \\ \text{c. } \iota X \text{ is defined only if } X \text{ is a singleton set. If defined, } \iota X \text{ is the unique member of } X. \\ \text{c. } X \sqcup Y = \begin{cases} X \vee Y & \text{if } X \text{ and } Y \text{ are of type } \tau \\ \lambda Z_{\sigma}. X(Z) \vee Y(Z) & \text{if } X \text{ and } Y \text{ are of type } \langle \sigma, \tau \rangle \end{cases} \end{array}$$

As concrete examples, we have the following semantic derivations of two examples of *ka*-disjunctions: the DP disjunction *Hanako-ka Jiro-ka* and the clausal disjunction *Hanako-ga hashitta-ka Jiro-ga hashitta-ka*. As one can see from the following LFs, the analysis derives two-membered sets consisting of (the o-values of) its disjuncts (i.e.,  $\alpha$  and  $\beta$  in the schema in (22)) as the semantic values of a *ka*-disjunction as a whole.<sup>9</sup>

$$(24) \quad \begin{array}{ll} \text{a. } \llbracket [\text{Hanako-ka } [\emptyset \text{ Jiro-ka}]] \rrbracket^o = \{ \lambda P.P(\mathbf{j}), \lambda P.P(\mathbf{h}) \} \\ \quad \llbracket [\text{Hanako-ka } [\emptyset \text{ Jiro-ka}]] \rrbracket^{alt} = \{ \{ \lambda P.P(\mathbf{j}) \vee P(\mathbf{h}) \} \} \\ \text{b. } \llbracket [[\text{H.-ga hashitta}] \text{ ka}] [\emptyset [[\text{J.-ga hashitta}] \text{ ka}]] \rrbracket^o = \{ \lambda w.\mathbf{ran}(\mathbf{j}, w), \lambda w.\mathbf{ran}(\mathbf{h}, w) \} \\ \quad \llbracket [[\text{H.-ga hashitta}] \text{ ka}] [\emptyset [[\text{J.-ga hashitta}] \text{ ka}]] \rrbracket^{alt} = \{ \{ \lambda w.\mathbf{ran}(\mathbf{j}, w) \vee \mathbf{ran}(\mathbf{h}, w) \} \} \end{array}$$

We have now already accounted for the AltQ interpretation for clausal *ka*-disjunctions. As can be seen in (24b), a clausal *ka*-disjunction receives as its o-value a set of two propositions, each contributed by the clausal disjuncts. This is precisely the standard semantic denotation for AltQs (Karttunen, 1977; Biezma and Rawlins, 2012).<sup>10</sup> In other words, the AltQ interpretation is analyzed as the union of the singleton interpretations of the question nucleus of two YNQs (Uegaki, 2014). Similar analyses of AltQs are maintained by Pruitt and Roelofsen (2011) for English, Gračanin-Yuksek (2014) for Turkish and Mayr and Zuchewicz (2015) for Polish.

<sup>8</sup>The alt-value of J is defined this way so that the alternatives in the alt-value do not involve the same alternatives as in the o-value, but rather are ‘reset’ to a singleton. This is empirically necessary because clause-final *ka* above a *ka*-disjunction cannot project an alternative question, but rather an Y/N-question:

(i) [ Hanako-**ka** Jiro-**ka** ]-ga hashitta-**ka** oshiete.  
Hanako-KA Jiro-KA -NOM ran-KA tell.  
‘Tell me whether or not either Hanako or Jiro ran’ (Y/NQ)

<sup>9</sup>I assume that a type-lifting from type  $\sigma$  to type  $\langle \langle \sigma, p \rangle, p \rangle$  is available. The type-lifting applies to the denotations of *Hanako* and *Jiro* in (24a) for them to be coordinated by  $\emptyset$  (Partee and Rooth, 1983).

<sup>10</sup>I assume that the exclusivity presupposition of AltQs—the presupposition that only one of the alternatives is true—is guaranteed by an additional operator, following Pruitt and Roelofsen (2011) and Biezma and Rawlins (2012). In the current setup, it can be added to the contribution of  $\langle ? \rangle$ , introduced in (16).

Furthermore, given the mechanism of semantic composition and the repair of the type-mismatch in terms of  $\exists$  described in the previous section, we can also account for the fact that *ka*-disjunctions syntactically smaller than the complement of  $C^{11}$  end up receiving an existential/declarative disjunctive interpretation. The explanation is exactly parallel to that of the existential interpretation of *wh+ka*. When a *ka*-disjunction is smaller than the complement of  $C$ , it has to be semantically combined with a sub-CP predicate/operator. Given the assumption that any such sub-CP operator (other than the  $J$  head and  $\exists$ ) is set-incompatible, the  $o$ -value of a *ka*-disjunction cannot be directly combined with them. It would result in a type-mismatch.

For example, when the DP-disjunction in (24a) appears in a sentence such as the following repeated from the previous section,  $\exists$  repairs the type-mismatch between the disjunction and the verb *hashitta*, as shown in (25).

- (4) [DP Hanako-ka Jiro-ka]-ga hashitta.  
Hanako-KA Jiro-KA-NOM ran.  
'Either Hanako or Jiro ran'.

- (25) a.  $\llbracket \llbracket \text{Hanako-ka} \oslash \text{Jiro-ka} \rrbracket \exists \text{ hashitta} \rrbracket^o = \lambda w. \mathbf{ran}(\mathbf{j}, w) \vee \mathbf{ran}(\mathbf{h}, w)$   
b.  $\llbracket \llbracket \text{Hanako-ka} \oslash \text{Jiro-ka} \rrbracket \exists \text{ hashitta} \rrbracket^{alt} = \{ \lambda w. \mathbf{ran}(\mathbf{j}, w) \vee \mathbf{ran}(\mathbf{h}, w) \}$

#### 4. Existential closure at the clausal level

One of the predictions of the analysis developed so far is that clauses ending with *ka* would receive an existential meaning under proposition-embedding predicates, as the existential closure would kick in to rescue the type-mismatch. In fact, this is not what we see empirically. Clauses ending with *ka* are generally ungrammatical under proposition-embedding predicates like *shinjiru* 'believe' and *mitai* 'seem'. In this section, I will detail the data of *ka*-ending clauses embedded under proposition-embedding predicates, and offer an explanation of the pattern based on independent reasons. I will also point out grammatical examples of embedded *ka*-clauses which have existential interpretations in the way predicted by the current analysis.

The analysis presented up to this point has problems with the following examples, where clauses (specifically CPs and TPs) ending with *ka* are embedded under the proposition-taking predicates *shinjiteiru* 'believe' and *mitai(-da)* 'seem'. The sentences are ungrammatical although the analysis predicts an existential interpretation of the complements.<sup>12</sup>

<sup>11</sup>Here, I say 'complement of  $C$ ' instead of 'CP' because I assume the existence of the complementizer above a clausal JP (see Section 3.1.2). That is, a clausal JP would have the following structure in an interrogative CP.

(i) [CP [JP [ $\alpha$ -ka] [J [ $\beta$ -ka]]]  $\langle ? \rangle$ ]

<sup>12</sup>The exact location of the existential closure in (26a) would be different depending on the type of the complementizer. If the complementizer is the declarative complementizer *to*, it would be applied right below the complementizer since it denotes the identity function over propositions (see Section 3.1.2). On the other hand, if the complementizer is the interrogative complementizer  $\langle ? \rangle$  defined in (16), the existential closure would be applied right above the complementizer. Either way, the predicted meaning would be equivalent to that of (27a), modulo the existential presupposition for the latter case, which will be discussed below.

- (26) a. \*Hanako-wa [ dare-ga hashitta-**ka** (da) -to/⟨?⟩ ] shinjiteiru.  
 Hanako-TOP who-NOM ran-KA COP COMP<sub>DECL</sub>/COMP<sub>INT</sub> believe  
 Intended: 'Hanako believes that someone ran.'
- b. \* [ dare-ga hashitta-**ka** ] mitai da.  
 who-NOM ran-KA seem COP  
 Intended: 'It seems that someone ran.'

What makes the problem puzzling is the fact that the following sentence is grammatical with the same existential interpretation as predicted for (26a).

- (27) a. Hanako-wa [ dare-**ka**-ga hashitta-to ] shinjiteiru.  
 Hanako-TOP who-KA-NOM ran-COMP<sub>DECL</sub> believe  
 'Hanako believes that someone ran.'
- b. [ dare-**ka**-ga hashitta ] mitai da.  
 who-NOM ran-KA seem COP  
 'It seems that someone ran.'

The only difference would be when the existential closure is applied. In (27a), it is at the DP level while in (26a), it is at the CP/TP level.

#### 4.1. A blocking-based account

Despite the appearance of the problem, the ungrammaticality of existential closure at the clausal level in (26) receives a natural explanation in terms of BLOCKING (Aronoff, 1976). The notion of blocking in morphology is employed to account for a lack of certain form in a paradigm, when there is a more optimal competing synonymous form. For example, the form *\*badder* is ungrammatical insofar as it would mean the same thing as *worse*, because it is blocked by the more optimal competitor *worse* (Kiparsky, 2004). The notion of blocking is extended to syntax and semantics by Atlas and Levinson (1981); Horn (1984) and Blutner (2000), and applied to empirical domains such as the interpretation of lexical and periphrastic causation (McCawley, 1978), pronominal reference and presupposition projection. The general idea in these applications of blocking is the same as that of blocking in morphology: a form is blocked if there is another form with the equivalent interpretation that can be achieved more economically, either from rational pragmatic perspectives or processing perspectives. This idea is formulated in terms of neo-Gricean pragmatics by Atlas and Levinson (1981); Horn (1984) and in terms of bi-directional OT by Blutner (2000).

I propose that a similar account can be made for the badness of (26): they are blocked by the corresponding competitors in (27). The additional claim behind this proposal is that the forms in which *ka* locally attaches to a *wh*-item, such as (27), are more economical than the corresponding forms in which *ka* attaches to a clause, such as (26). The rationale for this claim is the following: when *ka* directly attaches to a *wh*-item, the syntactic and semantic features of the *ka*-ending DP itself guarantee that it has to be existentially closed since such forms cannot

be in an argument position of set-compatible predicates.<sup>13</sup> On the other hand, the features of a *ka*-ending clause itself do not determine if it has to be existentially closed or not. Whether it has to be existentially closed depends on the presence and absence of an embedding set-incompatible predicate. In this sense, a *ka*-ending DP is by itself essentially disambiguated into an existential interpretation while a *ka*-ending clause is itself ambiguous. Given that existence of local ambiguity in a sentence leads to processing cost and danger of miscommunication even when the form is ultimately disambiguated ('garden-path' effect; Bever 1970), we can conclude that the forms involving CP-*ka* count as more costly than the forms involving DP-*ka* for the purpose of blocking. Thus, theories of blocking extended to syntactic forms as mentioned above would account for the badness of (26) as a result of blocking from (27).

#### 4.2. Clause-level existential quantification in CP adjuncts

This analysis makes a crucial prediction due to the fact that the mechanism of blocking relies on the existence of a semantically equivalent competitor. That is, the existential closure at the clausal level would be allowed if the resulting interpretation cannot be derived from a simpler competitor. In this section, I will provide data showing that this prediction is borne out. The relevant examples involve CP adjuncts, such as the following:

- (28) a. [ Dare-ga kita-kara-**ka** ] Taro-wa yorokondeita.  
           who-NOM came-because-KA Taro-TOP was.happy  
           'For some person *x*, because *x* came, Taro was happy.' (‘because’-clause)
- b. [ Dare-ni au-tame-**ka** ] Taro-wa hayaku daigaku-ni kita.  
           who-DAT meet-in.order.to-KA Taro-TOP early university-GOAL came.  
           'For some person *x*, to meet *x*, Taro came.' (purpose-clause)

The interpretations of these examples are derived from the application of the existential closure to the whole adjunct CP. The existential closure is triggered by the fact that the coordinators *kara* ‘because’ and *tame* ‘in order to’ denote relations between two propositions (of type  $\langle p, \langle p, p \rangle \rangle$ ); the adjunct CPs ending with *ka* would denote a type  $\{ \langle p, p \rangle \}$  object, which is incompatible with the propositional main clause. This type-mismatch is resolved by applying the existential closure to the adjunct CPs. The following LF tree illustrates the derivation of the *ka*-ending *because*-clause in (28a), together with the existential closure.

<sup>13</sup>This can be further argued for as follows: Syntactically, since a *wh-ka* phrase has the distribution of DPs, it cannot appear as the clausal complement of CP-embedding predicates. Furthermore, since *wh-ka* denotes non-singletons, it cannot be combined with the disjunctive coordinators  $\emptyset$ . It is only CP-embedding predicates and disjunctive coordinators that are set-compatible. Hence, a *wh-ka* phrase can only combine with set-incompatible predicates. Moreover, although some set-compatible CP-embedding predicates can be combined with DPs under a Concealed Question interpretation (e.g., *wakaru*, ‘figure out’; Baker 1968), a *wh-ka* phrase would merely denote a set of individuals in the domain of the *wh*-item, which would not warrant a concealed question interpretation under theories of concealed questions (Heim, 1979; Frana, 2010; Aloni and Roelofsen, 2011).

These meanings are combined with the type-lifted meaning of the main clause in the following:

- (30) a.  $\llbracket \text{Taro-wa yorokon-deita} \rrbracket^o = \lambda g_{\langle p,p \rangle} \lambda w. g(\lambda w'. \text{happy}(\mathbf{t}, w'))(w)$   
 b.  $\llbracket \text{Taro-wa yorokon-deita} \rrbracket^{alt} = \{ \lambda g_{\langle p,p \rangle} \lambda w. g(\lambda w'. \text{happy}(\mathbf{t}, w'))(w) \}$
- (31) a.  $\llbracket (28a) \rrbracket^o = \lambda w. \exists f \in \{ \lambda q_p \lambda w. \text{because}(\lambda w'. \text{came}(x, w'), p, w) \mid x \in \text{hum} \} [f(\lambda w''. \text{happy}(\mathbf{t}, w''))(w)]$   
 $= \lambda w. \exists x \in \text{hum} [\text{because}(\lambda w''. \text{happy}(\mathbf{t}, w''), \lambda w'. \text{came}(x, w'), w)]$   
 b.  $\llbracket (28a) \rrbracket^o = \{ \lambda w. \exists x \in \text{hum} [\text{because}(\lambda w''. \text{happy}(\mathbf{t}, w''), \lambda w'. \text{came}(x, w'), w)] \}$

Why is the existential closure at the CP-level in (28) allowed unlike the *ka*-ending *wh*-clauses under *believe*? In fact, the grammaticality of (28) is exactly what is predicted by the blocking account. Their variants with the alternative form *dare-ka*, as in (32), do *not* have the same interpretations as (28). The relevant coordinators ‘believe’ and ‘in order to’ take scope below the existential in (28) while they take scope above the existential in (32), given the surface position of *ka* and the relevant coordinators.

- (32) a. [ Dare-**ka**-ga kita-kara ] Taro-wa yorokondeita.  
 who-KA-NOM came-because Taro-TOP was.happy  
 ‘Because someone came, Taro was happy.’ (‘because’ >  $\exists$ )
- b. [ Dare-**ka**-ni au-tame ] Taro-wa hayaku daigaku-ni kita.  
 who-KA-DAT meet-in.order.to Taro-TOP early university-GOAL came.  
 ‘Taro came early to the university to meet someone.’ (‘in order to’ >  $\exists$ )

Since a form is blocked only if the simpler competitor has the same interpretation, the blocking does not apply to (28), and hence they are grammatical.

On the other hand, the following examples where *ka* appears right below the relevant coordinators are ungrammatical.

- (33) a. \*[Dare-ga kita-**ka**-kara ] Taro-wa yorokondeita.  
 who-NOM came-KA-because Taro-TOP was.happy  
 ‘Because someone came, Taro was happy.’  
 b. \*[Dare-ni au-**ka**-tame ] Taro-wa hayaku daigaku-ni kita.  
 who-DAT meet-KA-in.order.to Taro-TOP early university-GOAL came.  
 ‘To meet someone, Taro came.’

This is as expected since they have the same interpretations as the sentences in (32). The sentences in (32) block those in (33), making the latter ungrammatical.

#### 4.3. *ka*-disjunction under proposition-taking predicates

The blocking account for the ungrammaticality of *ka*-ending CPs under proposition-embedding predicates discussed above also applies to *ka*-disjunctions. For example, the ungrammaticality of (34) is explained by blocking from the simpler competitor involving a DP-*ka*-disjunction in (35).

- (34) \*Taro-wa [ Hanako-ga hashitta-ka Ø Jiro-ga hashitta-ka ⟨?⟩ ] shinjiteiru.  
 Taro-TOP Hanako-NOM ran-KA Jiro-NOM ran-KA C<sub>int</sub> believe  
 Intended: ‘Taro believes that either Hanako ran or Jiro ran.’  
 (35) Taro-wa [ [ Hanako-ka Ø Jiro-ka ]-ga hashitta-to ] shinjiteiru.  
 Taro-TOP Hanako-KA or Jiro-KA -NOM ran-C<sub>decl</sub> believe  
 ‘Taro believes that either Hanako ran or Jiro ran.’

Furthermore, importantly, exactly the same prediction as in the *wh*-case holds in the disjunction case. That is, the blocking does not occur when there is no semantically equivalent alternative. Again, we can see this in examples involving CP adjuncts:

- (36) Taro-wa [ Hanako-ga kita-kara-**ka** Ø Jiro-ga kita-kara-**ka** ]  
 Taro-TOP Hanako-NOM came-because-KA Jiro-NOM came-because-KA  
 yorokondeita.  
 was.happy  
 ‘Taro was happy either because Hanako came or because Jiro came.’ (∨ > ‘because’)

Just as in the *wh* case, the crucial reason why (36) is not blocked is that it lacks a more economical alternative *with the equivalent interpretation*. An alternative with the DP-sized *ka*-disjunction below would lead to a distinct interpretation where the disjunction scopes below ‘because’.

- (37) Taro-wa [ [ Hanako-**ka** Ø Jiro-**ka** ]-ga kita-kara ] yorokondeita.  
 Taro-TOP Hanako-KA or Jiro-KA -NOM came-because believe  
 ‘Taro was happy because either Hanako or Jiro came.’ (‘because’ > ∨)

Thus, the parallelism between *wh+ka* and *ka*-disjunctions manifests itself here as well.

#### 4.4. Summary

To summarize Section 4, the existential closure at the clausal level is in principle possible, but some *ka*-ending clauses where existential closure could be applied are made ungrammatical for an independent reason, i.e., blocking from the more optimal *wh-ka* local sequence. This account predicts that existential closure at the clausal level is possible if there is no competitor with the same interpretation. It was shown that this prediction is borne out in the domain of CP adjuncts. Existential closure above CP-adjuncts is possible since the sentences with lexical competitors would have different interpretations.

The possibility of analyzing sentences like (28) and (36) is another advantage of the current analysis over previous approaches. Previous approaches such as Hagstrom (1998) and Shimoyama (2006) make a binary distinction between the DP-internal existential *ka* and the question particle *ka* in the complementizer position. The empirical coverage of such accounts does not encompass the existential interpretation of *ka*-ending clauses discussed in this section, as well as the detailed patterns about when it is disallowed.

### 5. Conclusions

In this paper, I proposed a unified analysis of indefinites, *wh*-questions and disjunctions involving the particle *ka* in Japanese. According to the analysis, *ka* is analyzed as an operator that always projects a set of alternatives in the ordinary-semantic dimension. The crucial claim is that this set has to be turned into an existential quantifier by the operation of existential closure if and only if it cannot by itself enter the semantic composition with the rest of the sentence without a type-mismatch. This accounts for the fact that *wh+ka* is interpreted as an indefinite when it forms a sub-CP phrase while it is interpreted as a *wh*-question when it forms a matrix CP, or a CP embedded by a question-embedding predicate.

Furthermore, employing the Junction-based syntactic analysis of disjunctions (den Dikken, 2006; Mitrović and Sauerland, 2014; Szabolcsi, 2015), this analysis can be extended to disjunctions of the form  $\alpha\text{-}ka\ \beta\text{-}ka$ . According to this analysis,  $\alpha\text{-}ka\ \beta\text{-}ka$  denotes the set  $\{\llbracket\alpha\rrbracket, \llbracket\beta\rrbracket\}$  in the ordinary-semantic dimension. This analysis offers a natural account of the fact that the interpretation of  $\alpha\text{-}ka\ \beta\text{-}ka$  depends on the syntactic size of the *ka*-phrases, in a way parallel to how the interpretation of *wh+ka* depends on its syntactic size. When  $\alpha\text{-}ka\ \beta\text{-}ka$  is of a sub-CP size, it is type-shifted into the disjunctive meaning. When  $\alpha\text{-}ka\ \beta\text{-}ka$  is of a CP size, it is interpreted as an alternative question.

Note that this proposal is a conservative extension of existing proposals which have been argued for from independent grounds. The unified analysis of indefinites and questions in terms of the notion of alternatives has been extensively defended at least since Kratzer and Shimoyama (2002), and the extension of this program to the JP structure is undertaken by Mitrović and Sauerland (2014) and Szabolcsi (2015). The role of Q-particle as an operator that brings the

alt-value of the prejacent to the o-value is proposed by Beck (2006) and Kotek (2014), and is shown to have further positive consequences for independent empirical problems such as the intervention effect and the interpretation of multiple *wh*-questions. Two things set the current proposal distinct from existing proposals: (i) the adoption of the above semantics for the Q-particle for its *clause-internal* use, not only for its *clause-final* use; and (ii) the employment of type-compatibility and existential closure in the account of the interpretations of *ka*-ending phrases. Throughout the body of the paper, I have argued that addition of these two claims have far-reaching consequences, including a unified analysis of indefinites and *wh*-questions, an account of the parallelism between *wh+ka* and *ka*-disjunctions, and an analysis of the existential interpretations of some *ka*-ending clauses.

# On the similarity between *unless* and *only-if-not*<sup>1</sup>

Ekaterina VOSTRIKOVA — *University of Massachusetts Amherst*

**Abstract.** This paper discusses the semantics of *unless*-conditionals and compares them to *only-if-not*-conditionals. I propose that the meaning of *unless*-conditionals can be derived from the same ingredients as the meaning of *only-if-not*-conditionals: a negative conditional (where conditionals are understood as restrictors on quantifier domains as in the Kratzer-Lewis tradition) and an exhaustifier that, like *only*, negates all of the focus alternatives for a modal claim built by substitution of the element marked with focus with other elements of the same semantic type (but unlike *only* also asserts its prejacent). I propose that the two constructions are similar in the following sense. First, in both cases a negative conditional and the exhaustifier are separated syntactically. Secondly, focus alternatives are constructed in the same way: a set of focus alternatives for a proposition denoted by an *if*-clause (or a complement of *unless*) includes any other possible proposition. I suggest that this way of constructing alternatives resolves a long-standing puzzle about *only* with conditionals: it allows us to derive the right interpretation for *only* with conditionals in a compositional manner without making any special assumptions about the nature of the covert modal.

**Keywords:** *only*, conditionals, Conditional Excluded Middle, *unless*, exceptives

## 1. Introduction

In this paper I will discuss the semantics of *unless*-conditionals and compare them to *only-if-not*-conditionals (1).

- (1) a. Unless it rains, the party will be outside.  
b. Only if it does not rain, will the party be outside.

The analysis I propose is built on the idea that *unless* means (almost) the same thing as *only if not* (Clark and Clark, 1977: 457; Quirk, Greenbaum, Leech, and Svartvik, 1972: 746) or rather *if and only if not* (Comrie, 1986: 79). I will argue that there is an advantage in analyzing these two constructions in a similar way syntactically. I will suggest that the meaning of *unless*-conditionals can be derived from two ingredients: a negative conditional statement and an unpronounced exhaustifier that has a meaning similar to *only*.

The approach I suggest is a modified version of von Stechow's (1994) approach to *unless*-conditionals, according to which they are exceptive constructions in a modal domain: *unless* subtracts a set denoted by its complement from a domain of a modal operator (*unless* acts like *if not* in a Kratzer-Lewis system (Lewis, 1975; Kratzer, 1978, 1986), where conditionals restrict domains of modal operators) and states that subtraction of any alternative proposition makes the quantificational claim false.

---

<sup>1</sup> I would like to thank Seth Cable and Rajesh Bhatt for their help with this project. I am also grateful to Barbara Partee, Ilaria Frana, Vincent Homer, Angelika Kratzer, Petr Kusliy, Sakshi Bhatia, Yutaka Ohno, Jyoti Iyer, Tony Smith, Leland Kusmer, and the audience of SuB 21 for their helpful comments and suggestions.

Building on the recent proposals made for *but*-exceptives (Gajewski, 2008, 2013; Hirsch, 2016), I suggest that domain subtraction and exhaustification should be separated syntactically. I will argue that this separation provides an explanation for weak NPI-licensing in *unless*-clauses. I suggest that *unless* marks its complement with focus and is obligatorily c-commanded by “O”, which is identical to *only* except that it asserts its prejacent. “O” applies to an entire clause with a modal operator and negates all the alternatives for this clause that are built by substitution of the element marked with focus (the complement of *unless*) by its alternatives. The crucial aspect of the proposed analysis is that the set of alternatives for the complement of *unless* includes all possible propositions. I will show how this approach explains the known differences between *unless* and *if not*.

There is a long-standing puzzle about deriving the meaning of exhaustifiers like *only* with conditionals in a compositional manner (Barker, 1993; von Fintel, 1997; Herburger, 2015). Since “O”, like *only*, involves negation of focus alternatives, the same puzzle arises for the proposed theory of *unless*-conditionals. There are two solutions to this puzzle proposed in the literature and both of them involve a special stipulation about the nature of the covert modal. According to the first one, bare conditionals obey the principle of Conditional Excluded Middle (Barker 1993; von Fintel 1997), and according to the second one, the covert modal obligatorily changes its modal force and becomes an existential quantifier under negative operators like *only* (Herburger, 2015).

I will show that it is possible to resolve the puzzle of *only* with conditionals without appealing to any special stipulation by extending my analysis of *unless*-conditionals to regular conditionals with *only*. I will argue that the right interpretation for those sentences follows naturally if we allow the set of possible alternatives for a proposition denoted by an *if*-clause to include not only the proposition itself and its negation (as it standardly assumed), but any possible proposition.

The discussion will go as follows. In Section 2 I will introduce the properties of *unless*-conditionals and von Fintel’s analysis of them. I will propose my analysis for *unless*-conditionals. I will suggest separating domain subtraction and exhaustification syntactically. In Section 3 I will discuss the puzzle posed by combining *only* with conditionals and the Conditional Excluded Middle (CEM) as a solution to this problem. I will show that the analysis of *unless*-conditionals suggested here (as well as von Fintel’s analysis of *unless*-conditionals) is not compatible with CEM. In Section 4 I will propose a novel solution to the problem of *only* with conditionals: I will extend the core idea of von Fintel’s approach to *unless*-conditionals to *only-if*-conditionals and allow the set of alternatives for a proposition denoted by an *if*-clause to include any other possible proposition. In Section 5, I will discuss the consequences and predictions of the suggested approach. Section 6 concludes.

## 2. The semantics of *unless*-conditionals

### 2.1. *Unless* is not equivalent to *if not*.

*Unless*-conditionals express a negative condition and their meaning is close to *if not*. The similarity between *unless* and *if not* can be demonstrated by the following pair of sentences (2)a and (2)b.

- (2) a. Unless it rains, the party will be outside.  
 b. If it does not rain, the party will be outside.

However, Geis (1973) in his classic paper provided several arguments against the idea that *unless* is equivalent to *if not*. The first argument given by Geis is that two *unless*-clauses cannot be coordinated (3). Two *if*-clauses – positive or negative – can be coordinated, as shown in (4).

(3) \*Unless it rains and unless I am sick, the party will be at my house.

(4) If it does not rain and if I am not sick, the party will be at my house.

Geis also shows that *unless* does not combine with operators like *only*, *even*, and *except* ((5) and (6)), unlike negative *if*-clauses ((7) and (8)).

(5) \*The party will be outside only unless it rains.

(6) \*The party will be outside even/except unless the weather is good.

(7) The party will be outside only if it does not rain.

(8) The party will be outside even/except if the weather is not good.

Another difference between *if-not*- and *unless*-clauses noticed by Geis is their ability to host NPIs. Geis argued that NPIs are not licensed in *unless*-clauses at all. However, von Stechow (1994) showed that this is true only for strict NPIs like *yet* (9); weak NPIs like *anyone* can be licensed in *unless*-clauses (11).

(9) \*Ivan will be upset **unless** Bill has come **yet**.

(10) Ivan will be upset **if** Bill has **not** come **yet**.

(11) **Unless anyone** objects, we must move on.

Another contrast between *if not* and *unless* is that *then* is not allowed in consequents of *unless*-conditionals (12) (Fretheim, 1977; von Stechow, 1994).

(12) Unless it rains, (\*then) the party will be outside.

(13) If it does **not** rain, then the party will be outside.

Following Geis, we can conclude that *unless* is not equivalent to *if not*, and any semantic theory of *unless* should explain the differences between *unless* and *if not* that we observe here.

## 2.2. *Unless* as an exceptive construction

Von Fintel (1994) proposed that *unless* makes the following contribution to the meaning of a sentence (14).

$$(14) \quad [[ [s [s \text{ unless } \alpha] [s Q_C \beta]] ]]^g = T \text{ iff } g(C_1)(w) - [[\alpha]]^g \subseteq [[\beta]]^g \text{ \& } \\ \forall Y ( (g(C_1)(w) - Y \subseteq [[\beta]]^g) \rightarrow [[\alpha]]^g \subseteq Y ) \} \\ \text{where } [[\alpha]]^g = \{w: [[\alpha]]^{g,w} = T\}$$

In (14)  $Q_C$  stands for a universal modal operator.<sup>2</sup> Its index  $C$  is a covert domain restriction variable: it denotes a function that applies to a world and returns a set of worlds accessible from that world.  $\alpha$  is a complement of *unless*; it is interpreted a set of possible worlds that is subtracted from the domain of the modal operator.  $\beta$  is the constituent that denotes a set of worlds that the modal takes as its second argument.

The first conjunct in (14) is a modal claim, where the denotation of  $\alpha$  is subtracted from the domain of the modal quantifier. The second conjunct is the exhaustification or the leastness condition. It universally quantifies over possible propositions (sets of possible worlds) that can be subtracted from the domain of the modal operator instead of the proposition denoted by the original complement of *unless*. It states that if the resulting modal claim is true, then the original subtracted set is a subset of this set of possible worlds.

In other words, it negates all the resulting modal claims with exception of those that are already entailed by the original modal claim. The modal operator is assumed to be a universal quantifier. The structural position of the original restrictor  $R$  is in an upward entailing context (as it is under negation and in the restrictor of a universal quantifier). If  $R$  is substituted by its superset, the resulting modal claim will be entailed by the original modal claim, therefore its negation will contradict the original claim. This semantics predicts that two *unless*-clauses cannot be coordinated. The clause in (14) says that the set denoted by  $\alpha$  is the unique minimal set subtraction of which from the domain of the modal operator makes the quantificational claim true. There cannot be two such unique sets.

## 2.3. Separating domain subtraction from exhaustification syntactically

One of the properties of *unless*-clauses is their ability to host weak NPIs (15).

(15) **Unless anyone** objects, we will move on.

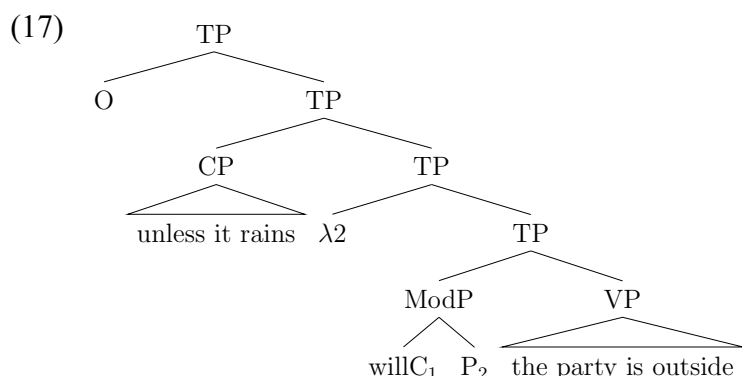

This fact is not predicted by von Fintel's approach, where the domain subtraction and exhaustification are done in one step. The reason for this is the first conjunct of the formula in (14) that simply expresses the domain subtraction. The structural position of the constituent  $\alpha$

<sup>2</sup> *Unless*, due to its semantics, cannot apply to existential modals (von Fintel, 1994). The assumption is that in cases where an existential modal is overtly present in a sentence, *unless* operates on an unpronounced universal modal and an existential takes scope below it.

is not in a downward entailing context, because it is in the restrictor of the universal quantifier and under negation.

To account for the fact that weak NPIs are licensed in *unless*-clauses I propose that domain subtraction and exhaustification should be separated syntactically, as shown in (17). I will make the simplifying assumption that syntactically a modal forms a constituent with a variable of type  $\langle s, t \rangle$ . The value of this variable is provided by the *unless*-clause via the mechanism of lambda abstraction.

(16) Unless it rains, the party will be outside.

*Unless* subtracts its complement (a proposition) from a domain of a modal operator (18) (thus an *unless*-clause is equivalent to a negative *if*-clause in the Kratzer-Lewis tradition (Lewis, 1975; Kratzer, 1978, 1986), where conditionals restrict domains of various operators).

(18)  $[[\text{unless } \alpha]]^{w,g} = \{w_1: w_1 \notin [[\alpha]]^g\}$

(19) For any sets of worlds  $P$  and  $Q$ ,  $[[\text{will}_{C_1}]]^{w,g}(P)(Q) = T$  iff  $g(C_1)(w) \cap P \subseteq Q$  (where  $C_1$  is a variable standing for an accessibility function from worlds to sets of worlds).

*Unless* marks its complement with focus and must be c-commanded at LF by “O”.<sup>3</sup> The set of focus alternatives for a proposition  $p$  includes any other possible proposition. (The advantages of constructing alternatives in such a way will be shown in Section 4.) “O” c-commands the entire sentence containing an *unless*-clause. “O” has exactly the same semantics as *only* except that it asserts its prejacent (Chierchia, 2013) (20). It states that for each set of worlds such that it is a member of the set of focus alternatives of the original sentence and the world of evaluation is one of them, the set of worlds denoted by the original sentence is a subset of it. It essentially negates each of the focus alternatives except for the ones that are entailed by the original sentence. It also states that the evaluation world is a member of the set denoted by the original sentence; that is, it asserts its prejacent.

(20) “O”:  $[[O \alpha]]^{w,g} = T$  iff  $\forall r [(r \in [[\alpha]]^g_f \ \& \ w \in r) \rightarrow [[\alpha]]^{w,g} \subseteq r] \ \& \ [[\alpha]]^{w,g}$

<sup>3</sup> The reasons why “O” is chosen as an exhaustifier and not the leastness operator are given in the Appendix.

Under the assumption that *only* also c-commands the entire sentence, *unless*-conditionals are structurally parallel to *only-if-not*-conditionals.

(21)

Because “O”, unlike *only*, asserts its prejacent, *only-if-not*-conditionals are not predicted to be completely semantically equivalent to *unless*-conditionals. However one part of their meaning is predicted to be the same, namely the one that comes from negation of all alternatives that are formed by substitution of a conditional clause by its alternatives.

### 3. The problem of *only if*

In this section I will introduce the puzzle posed by applying of exhaustifiers like *only* (or “O”) to conditionals.

#### 3.1. The problem of *only* with bare conditionals

Deriving the meaning of *only* with conditionals in the absence of an overt modal operator (so-called bare conditionals) in a compositional manner is not an easy task. To see why, let us consider what *only* and *if* mean independently.

According to the standard assumptions about the semantics of *only*, it applies to a proposition (its prejacent) and negates all of the contextually relevant alternative propositions derived by substitution of the element marked with focus in the original sentence with elements of the same semantic type (Rooth, 1985). Thus the claim in (22) is true if and only if each of the claims in (23) is true.

(22) Only John came to the party.

(23) Bill did not come, Mary did not come, Jack did not come, etc.

Our goal is to derive the meaning of an *only if* claim, like the one in (24), by using the same ingredients: *only* and focus alternatives for its prejacent.

(24) Only if the queen is home, is the flag up.

The meaning of (24) can be roughly paraphrased as (25).

(25) In **all** worlds in which the queen is **not** home, the flag is **not** up.

Thus the result of applying *only* to a bare conditional seems to be a modal claim where the modal has the universal force, the restrictor is the negation of the original *if*-clause in (24) and the scope is the negation of the original scope.

There are two major problems with (24) that are extensively discussed in the literature. The first one is that (24) does not seem to presuppose that if the queen is home, the flag is up, even though normally *only* presupposes its prejacent (McCawley, 1974). The second problem is that it is not clear how to derive (24) from (25) given our standard assumptions about the semantics of conditionals and *only* (Barker, 1993; von Fintel, 1997; Herburger, 2015). I will set the first issue aside in this paper and focus on the second problem.

The prejacent of *only* in (26) taken by itself seems to be a universal modal assertion.

(26) If the queen is home, the flag is up.

The meaning of (26) (the prejacent) is something like (27), which I will represent as (28).<sup>4</sup>

(27) In **all** worlds where the queen is home, the flag is up.

(28)  $[[ (27) ] ]^{g,w}$  is T iff  $P \subseteq Q$   
 where  $P = \{w: \text{the queen is home in } w\}$  and  $Q = \{w_1: \text{the flag is up in } w_1\}$

*Only* negates all of the alternatives for its prejacent that are created by substitution of the focused element with other expressions of the same type. The focused element in this case is the *if*-clause (the meaning of which I represented with P). Since our goal is to get a modal claim with a restrictor that is the negation of the original restrictor, the alternative we are particularly interested in is the one given in (29). Under the assumption that the set of focus alternatives for a proposition only includes the proposition itself and its negation, this is the only alternative that can be negated without contradicting the original claim.

(29)  $P' \subseteq Q$   
 (where P' stands for a complement of P, the original set)

Negation of this universal claim will result in an existential claim that can be paraphrased as (30). This is not the desired result, because (30) is too weak.

(30) In **some** worlds where the queen is **not** home, the flag is **not** up.

In what follows, I will review one of the existing solutions to this puzzle, according to which the covert modal operator obeys the principle of conditional excluded middle (CEM). I will show that the semantics for *unless*-conditionals developed here, as well as the semantics of *unless*-conditionals suggested by von Fintel, is not compatible with this principle. I will

<sup>4</sup> This semantics for conditionals completely ignores an accessibility relation. I omit the accessibility relation only for simplicity of exposition. (I make a simplifying assumption here that all worlds are accessible from all worlds.) In the Appendix, I show that my result holds in case we add an accessibility relation.

propose a novel solution to this puzzle that does not appeal to this principle and does not postulate any other special property of bare conditionals, but rather changes the way we construct the set of focus alternatives for a conditional clause.

### 3.2. Conditional excluded middle as a possible solution for the *only-if* puzzle

One of the existing solutions to this puzzle adopts the idea that bare conditionals obey the principle of conditional excluded middle (CEM) (Barker, 1993; von Fintel, 1994, 1997). In a theory-neutral way the principle of CEM can be expressed as follows: two claims “if  $p$ ,  $q$ ” and “if  $p$ , not  $q$ ” cannot both be false.<sup>5</sup> The exact realization of this principle depends on the approach to the semantics of conditionals that one adopts. Von Fintel (1994) develops the idea that the covert universal modal operator that bare conditionals restrict – the generic operator – carries a homogeneity presupposition. A very simplified<sup>6</sup> semantics for GEN is given in (31).

- (31) For any sets of worlds  $A$  and  $B$ ,  $[[\text{GEN}]]^{\text{g,w}}(A)(B)$  is defined only if  $A \subseteq B \vee A \subseteq B'$ .  
If defined  $[[\text{GEN}]]^{\text{g,w}}(A)(B)$  is T iff  $A \subseteq B$ .

Because of the homogeneity presupposition GEN is predicted to obey CEM (32). Essentially the higher scope negation over GEN is interpreted as the lower scope negation operating only on the proposition in scope of GEN.

- (32) CEM for GEN:  $\neg [[\text{GEN}]]^{\text{g,w}}(A)(B) \Leftrightarrow [[\text{GEN}]]^{\text{g,w}}(A)(\neg B)$

This solves the puzzle of *only* with bare conditionals in the following way. *Only* negates the only alternative given in (33). The homogeneity presupposition says that both (33) and (34) cannot be false, thus negation of (33) entails that (34) must be true.

- (33)  $P' \subseteq Q$

- (34)  $P' \subseteq Q'$

This is exactly the desired result, since (34) can be paraphrased as (35).

- (35) In **all** worlds where the queen is **not** home, the flag is **not** up.

### 3.3. CEM as a problem for the analysis of *unless*-conditionals

The semantics for *unless*-conditionals developed in Section 2.3, as well as the semantics suggested by von Fintel (1994) introduced in Section 2.2, is not compatible with CEM. It essentially involves negation of all the alternatives built by substitution of the complement of *unless* with a different proposition. If we consider the claim in (36), then the set of negated

<sup>5</sup> For arguments against CEM see Leslie (1997).

<sup>6</sup> This semantics is simplified because it completely ignores the accessibility relation or the selection function that von Fintel uses to restrict the domain of GEN and account for the fact that GEN only makes a claim about relevant normal situations.

alternative modal claims will include things like the ones given in (37), because the list of the alternatives for a complement of *unless* includes any other possible proposition (that is not a superset of the original proposition).

(36) Unless it rains, the party will be outside.

(37)  $\{\neg [g(C_1)(w_0) - \{w_1: \text{I call my mom in } w_1\}] \subseteq \{w_1: \text{the party is outside in } w_1\}],$   
 $\neg [g(C_1)(w_0) - \{w_1: \text{John is late in } w_1\}] \subseteq \{w_1: \text{the party is outside in } w_1\}],$   
 $\neg [g(C_1)(w_0) - \{w_1: \text{it snows in } w_1\}] \subseteq \{w_1: \text{the party is outside in } w_1\}], \text{ etc.}\}$   
 (where  $C_1$  stands for a contextually determined accessibility function)

If the high scope negation is interpreted as the low scope negation (because of CEM) we will end up with truth-conditions that involve a set of universal claims like the ones in (38). The claims listed in (38) are clearly not a part of what (36) means.

(38) In **all** worlds in which I don't call my mom, the party is **not** outside,  
 In **all** worlds in which John is not late, the party is **not** outside,  
 In **all** worlds in which it does not snow, the party is **not** outside, etc.

Moreover, the set of possible alternatives for the complement of *unless* includes all possible propositions, thus it will include not only the proposition denoted by *it snows*, but also the proposition denoted by its negation *it does not snow*. Putting those two propositions instead of the original complement of *unless* and negating the resulting modal claims by CEM is equivalent to saying that the party is not outside in all possible worlds (39). This contradicts the original modal claim that states that the party is outside in all worlds where it does not rain.

(39) In **all** worlds in which it does **not** snow, the party is **not** outside.  
 In **all** worlds in which it **snows**, the party is **not** outside.

This line of argumentation shows that the semantics for *unless*-conditionals suggested in this paper is not compatible with the principle of Conditional Excluded Middle that has been argued to be necessary to solve the problem of *only-if*-conditionals. In the next section I will show that CEM is not needed to solve the *only if* puzzle.

#### 4. How to construct the alternatives for conditionals: *only if* without CEM

In this section I will show that we can derive the meaning of conditionals with exhaustifiers like *only* in a compositional manner if we drop the assumption that the set of focus alternatives for a proposition (denoted by an *if*-clause) includes only the proposition itself and its negation. I will show that if we allow this set to include any other possible proposition, the problem of *only if* can be solved without CEM or any special stipulations about the nature of the covert modal.

Let us go back to our example (24) (repeated as (40)). Its prejacent expresses the modal claim in (41).

(40) **Only if** the queen is home, is the flag up.

(41)  $P \subseteq Q$

Where  $P = \{w: \text{the queen is home in } w\}$ ,

$Q = \{w_1: \text{the flag is up in } w_1\}$ .

*Only* will negate all of the alternatives for this sentence that are created by substitution of the focused element with other expressions of the same type except for those that are entailed by the original sentence. The focused element in this case is the *if*-clause that I represented by  $R$ . Normally, *only* is represented as a quantifier over propositions or sets of worlds, as in (42). The contribution of *only* is to say that, for every proposition in the set of focus alternatives, if that alternative is true then it is entailed by the original sentence.<sup>7</sup>

(42)  $[[\text{Only } \alpha]]^{w,g} = T \text{ iff } \forall r [(r \in [[\alpha]]^g_f \& w \in r) \rightarrow [[\alpha]]^g \subseteq r]$

In our case, whether a particular alternative is entailed by the original claim depends solely on the properties of its restrictor, because the alternatives differ from the original claim only with respect to their restrictor.

The universal quantifier is downward entailing on its first argument. Therefore the alternatives that are created by substitution of  $R$  by a subset of  $R$  are entailed by the original claim and cannot be negated by *only*. All other alternatives are negated.

Given this, we can represent the contribution of *only* by quantifying over alternative restrictors. We need to say that for every alternative restrictor, if it makes the quantification claim true, then this restrictor is a subset of the original restrictor. The formula in (43) says exactly the same thing as *only* applied to this particular modal construction.

It specifies the exact form of the alternatives (the antecedent of the material implication in (43)). It also specifies what it means for a resulting alternative quantificational claim to be entailed by the original one (the consequent of the material conditional in (43)): its restrictor is a subset of the original restrictor. This is because all and only quantificational claims with restrictors that are subsets of the original restrictor are entailed by the original quantificational claim.

(43)  $\forall Y (Y \subseteq Q \rightarrow Y \subseteq P)$

Based on this way of representing the contribution of *only*, it can be shown that negation of all of the alternatives for (41) (with the exception of those that are entailed by the original sentence) entails that in all worlds in which the flag is not up, the queen is not home. The relevant proof is given in (44).

<sup>7</sup> In set talk: for any set of worlds if it is a member of the set of focus alternatives and the actual world is a member of this set, then the set of worlds denoted by the original sentence is its subset.

- (44) a.  $\forall Y (Y \subseteq Q \rightarrow Y \subseteq P) \Rightarrow$   
 b.  $Q \subseteq P \Leftrightarrow$   
 c.  $P' \subseteq Q'$   
 (where  $P'$  stands for the complement set of  $P$  and  $Q'$  stands for the complement set of  $Q$ , following the standard notation.)

The claim in (44)c can be paraphrased as (45).

- (45) In **all** worlds where the queen is **not** home, the flag is **not** up.

The proof in (44) shows that if we take focus alternatives for a proposition denoted by an *if*-clause to be any possible proposition and negate all alternatives for an entire conditional (excluding the ones that are entailed by the original claim), we get the desired interpretation for *only* with bare conditionals.

## 5. The results of the suggested approach

In this section I will discuss the meaning of *unless*-conditionals and *only-if-not*-conditionals that is predicted by the approach suggested in this paper. I will also show that this approach explains the properties of *unless*-conditionals discussed in Section 2.

### 5.1. The predicted meaning of *unless*-conditionals and *only-if-not*-conditionals

The predicted meaning of (46) is given in (47). The first conjunct in (47) comes as a result of negating of all the alternatives for a modal claim. As was shown above, negation of all the alternatives in this case gives us the universal claim with the restrictor being the negation of the original restrictor and the scope being the negation of the original scope.<sup>8</sup> The second conjunct is the prejacent of “O” (and the *unless*-clause is interpreted as a negative *if*-clause).

- (46) Unless it rains, the party will be outside.

- (47)  $[[ (46) ]]^{\mathbf{g}, w_0} = \text{T}$  iff  $\mathbf{g}(C_1)(w_0) \cap \{w: \text{it rains in } w\} \subseteq \{w: \text{the party is outside in } w\}'$   
 &  $\mathbf{g}(C_1)(w_0) \cap \{w: \text{it rains in } w\}' \subseteq \{w: \text{the party is outside in } w\}$

The predicted meaning of (48) is given in (49). This is the result of exhausting the alternatives. The semantics for *only if not* does not contain the second conjunct because *only* does not assert its prejacent.

- (48) Only if it does not rain, will the party be outside.

- (49)  $[[ (48) ]]^{\mathbf{g}, w_0} = \text{T}$  iff  $\mathbf{g}(C_1)(w_0) \cap \{w: \text{it rains in } w\} \subseteq \{w: \text{the party is outside in } w\}'$

<sup>8</sup> Here I introduce the accessibility relation. The proof that was given in Section 4 ignored it. I demonstrate that adding the accessibility relation will give the same result in (47) in the Appendix.

The universal claim in (49) is the shared part of the meaning of the *unless*-conditional in (46) and *only-if-not*-conditional in (48). By making *only if not* and *unless* structurally and semantically similar this approach correctly predicts that (46) and (48) are very close in meaning. *Unless*-conditionals are predicted to be closer to *if-and-only-if*-conditionals, due to the fact that “O” asserts its prejacent and *only* does not.

## 5.2. Explaining the properties of *unless*-conditionals

### 5.2.1. Weak NPI licensing in *unless*-clauses

Weak NPIs are licensed in *unless*-clauses, as we saw before in (11) (repeated here as (50)).

(50) Unless **anyone** objects, we must move on.

Under the standard account NPIs like *any* and *ever* require downward entailing (DE) environments (Fauconnier, 1975, 1978; Ladusaw, 1979). To explain the ability of *unless*-clauses to host weak NPIs, I will adopt the environment-based approach to NPI licensing (Chierchia, 2004; Gajewski, 2005; Homer, 2011), according to which an NPI is licensed if there is a constituent containing that NPI which is the proper environment for that NPI.

For example, in (51) *any* is licensed, even though if we consider the entire sentence the position of *any* is not in DE context. Two DE operators – the lower clause negation and *no one* – make the environment of *any* upward entailing. However, there is a constituent in the sentence such that it is a proper environment for the NPI – the embedded negative sentence (this constituent is underlined in (51)).

(51) **No** one thinks that John has **not** done any work.

According to the account proposed in this paper the exhaustifier “O” and domain subtraction are separated syntactically. The constituent where *any* is licensed in (64) is the *unless*-clause itself, interpreted as *if not*. Thus the NPI licenser in this case is the negation or domain subtraction.

### 5.2.2. No licensing of strict NPIs: bi-clausal structure of *unless*-clauses

Strict NPIs, like *in years*, are not licensed in *unless*-clauses, see (52).

(52) \*Unless John has visited Mary **in years**, I am happy. (Geis, 1974)

However, negation is known to license strict NPIs. To account for the strict NPI facts in *unless*-clauses, I suggest that *unless*-clauses have a more complex structure than they appear to have. I propose that *unless*-clauses consist of two clauses: they have a structure similar to “if it is **not** the case **that p**”.

*In years* is not licensed if it is separated from negation by a finite clause boundary, as shown in (53). As (54) shows, this is not a problem for *any*. I propose that *in years* is not licensed in (52) for the same reason it is not licensed in (53): in both cases *in years* appears in a positive

clause. Negation is too high to license the strict NPI. The schematic representation of the syntactic structure of an entire *unless*-conditional like (55) is given in (56). The *unless*-clause is marked in bold. This is the constituent in which weak NPIs are licensed.

(53)\*It is **not** true **that** John has visited Mary **in** years.

(54) It is **not** true **that** John talked to **anyone**.

(55) Unless anyone objects, we will go on.

(56) [TP O [CP [CP **un** [PolP **less** [vP  $\emptyset$  [CP [ $\emptyset$ <sub>Com</sub> **anyone objects** ]]]] [TP we will<sub>C1</sub> go on]]

The evidence in favor of this syntactic structure comes from the historical development of *unless*-conditionals. The *unless*-construction originates from *on lesse that*, *lesse than*, or *in/on/of lesse than* (one relevant example from Traugott (1997) is given in (57)).

(57) That thar sholde no Statut no Lawe be made, **oflasse than** they yeaf thereto their assent.  
That no statute nor law should be made **unless** they gave their consent to it.  
(1414 Parl<sub>t</sub> [HC] as cited by Traugott (1997) (her example (14c))

Thus at some point the domain subtraction was overtly separated from its complement by a finite clause boundary. I suggest that even though this clause boundary is not expressed overtly any longer in present-day English, native speakers are still sensitive to its presence.

### 5.2.3. *Unless* with *even* and *only*

I proposed that *unless* marks its complement with focus and is obligatorily c-commanded by a focus sensitive operator “O”. This provides a natural explanation for the fact that *unless*-clauses cannot be associated with focus sensitive operators like *even* and *only*.

Elements that are already associated with one focus sensitive operator cannot be associated with another one (60). Thus the restriction observed in (58) is the same as the one observed in (59) and (60).

(58)\*The party will be outside only unless it rains.

(59)\*The party will be outside only only if it does not rain.

(60)\*Bill gave flowers even only to Sue.

### 5.2.4. Coordination facts

The fact that two *unless*-clauses cannot be coordinated follows from the semantics proposed in this paper. Given this analysis, there predicted to be a conflict between the meaning of the first conjunct (“unless John leaves today I will leave”) and the meaning of the second conjunct (“unless Joe leaves today I will leave”) in (61).

(61) \*Unless John leaves today and unless Joe leaves today, I will leave.

“O” negates all of the focus alternatives for the modal claim in the first conjunct. One of the alternatives for the complement of *unless* in the first conjunct is the proposition denoted by *Joe leaves today*. Thus the list the alternatives that “O” negates will include the modal claim in (62). “O” asserts its prejacent. The contribution of the prejacent of “O” in the second conjunct is given in (63). Negation of (62) directly contradicts (63). Conjunction of two *unless*-clauses will always result in a contradiction of this sort.

(62)  $\neg [g(C_1)(w_0) \cap \{w: \text{Joe leaves today in } w\}] \subseteq \{w: \text{I leave in } w\}$

(63)  $[g(C_1)(w_0) \cap \{w: \text{Joe leaves today } w\}] \subseteq \{w: \text{I leave in } w\}$

#### 5.2.5. *Then* in *unless*-clauses

*Then* is ungrammatical in both (64) and (65).

(64) \***Unless** it rains, then the party will be outside.

(65) \***Only** if it does not rain, then the party will be outside.

I will adopt the proposal by Iatridou (1994) and von Stechow (1994), according to which conditionals with *then* are examples of the left-dislocation construction. There are restrictions on what kind of items can be left-dislocated and those restrictions explain ungrammaticality of *then* in such conditionals.

An example of the left-dislocation construction is given in (66). In (66) a DP *the girls you invited* is left-dislocated. It is followed by a full clause, the subject position of which is occupied by the resumptive pronoun *they*. This pronoun picks up the same group of individuals as the left-dislocated DP (*the girls you invited*).

(66) The girls you invited, they are interesting.

Iatridou (1994) and von Stechow (1994) point out that focus sensitive operators like *only* and *even* cannot be associated with left-dislocated items ((67), (68)).

(67) \***Only** the girls you invited, they're interesting.

(68) ??**Even** the girls you invited, they're interesting.

Treating conditionals with *then* as examples of the left-dislocation construction allows us to reduce the restriction observed in (64)-(65) to the restriction observed in (67)-(68).

## 6. Conclusion

In this paper I offered an analysis of *unless*-conditionals, which is built on the observation going back to the work of Comrie (1986) that *unless*-conditionals mean the same thing as *if*

*and only if not*. I suggested an approach that takes this idea literally and derives the meaning of *unless*-conditionals from a negative conditional, focus alternatives and an operator “O” that is exactly like *only* except that it asserts its prejacent.

I argued that there is a parallelism between *only-if-not*- and *unless*-conditionals. First of all, in both cases a negative condition (interpreted as a restrictor on a universal modal) and exhaustification are contributed by two items separated syntactically. This provides an explanation for weak NPI licensing in *unless*-clauses. Secondly, the list of alternatives for *unless*-conditionals and for *only-if-not*-conditionals that are negated by an exhaustifier is constructed in the same way. I suggested that a set of alternatives for a proposition denoted by an *if*-clause or by a complement of *unless* has to include all possible propositions. I showed that this way of constructing alternatives provides a natural solution to the problem of *only* with bare conditionals. In this way, this proposal derives the right interpretation for conditionals with *only* in a compositional manner without any stipulations about the nature of the covert operator that conditionals restrict.

## Appendix. The leastness condition vs “O”.

In this appendix I would like to demonstrate two things. The first is that the result of using “O” is predicted to be slightly different than the result of using the leastness condition proposed by von Fintel (1994) (reviewed in Section 2.2). The second one is that if a modal has a complex restrictor that includes an accessibility relation, the result of negating alternatives for this modal claim formed by substitution of a proposition denoted by an *if* or *unless*-clause with any other possible proposition will give us the right interpretation for the sentence. I will demonstrate this using the example in (1).

- (1) a. Unless it rains, the party will be outside.  
 b. LF:  $[_{TP3} O [_{TP2} [_{CP} \text{unless it rains}] [\lambda 1 [_{TP1} \text{the party} [will_{C2} P_1] \text{be outside}]] ] ]$

We can represent the meaning of the prejacent of “O” in (1) (evaluated in the actual world) as in (2).

- (2)  $[[TP_2]]^{w_0.g} = T \text{ iff } R-Q \subseteq P$   
 $R := \{w: w \text{ is accessible from } w_0\}, Q := \{w: \text{it rains in } w\}, P := \{w: \text{the party is outside in } w\}$

Von Fintel (1994) shows that the result of applying the leastness condition to the set  $Q$  in this modal claim (given in (3)a) is equivalent to (3)b.

- (3) a.  $\forall Y (R - Y \subseteq P \rightarrow Q \subseteq Y)$   
 b.  $Q \subseteq P' \cap R$   
 All the worlds where it rains are **the accessible worlds** where the party is **not** outside.

The problem with (3)b is that the accessibility relation appears on the wrong side. If the relevant accessibility relation is, for example, epistemic, then (3)a entails that every world where it rains is a world that is compatible with what is known. That is too strong. There might be worlds where it rains and the Earth is flat and those are not compatible with what is known.

The result of negating alternatives with “O” is given in (4), which is the desired result (“O” also asserts its prejacent, but right now we are focusing only on the result of negating alternatives).

- (4)  $Q \cap R \subseteq P'$   
 All **accessible worlds** where it rains are the worlds where the party is **not** outside.

Here is the reason why “O” and “leastness” give different results. All modal claims that are formed by substitution of the original subtracted set  $R$  by its superset are indeed entailed by the original modal claim. However, they are not the only ones that are entailed. It can happen that subtracting a set of worlds will give us a modal claim with an empty set as the restrictor. This modal claim is entailed by the original one, but this subtracted set does not have to be a superset of  $R$ . We can demonstrate this scenario on the following model (5). A modal claim (6) is true in this model.

- (5)  $U := \{a, b, c, d, e\}$ ,  $R := \{a, b, c\}$ ,  $Q := \{b, d\}$ ,  $P := \{a, c, e\}$

- (6)  $R - Q \subseteq P \Leftrightarrow \{a, c\} \subseteq \{a, c, e\}$

Let’s consider an alternative modal claim where the subtracted set is  $\{a, b, c\}$  (7). This universal claim is true, because its restrictor is empty.

- (7)  $R - \{a, b, c\} \subseteq P$

The leastness condition tells us that if the resulting alternative is true, then the new subtracted set is a superset of the original one. Thus it should be the case that  $\{b, d\} \subseteq \{a, b, c\}$ , but it is not true. Therefore, some of the resulting modal claims are entailed by the original one, but the subtracted set is not a superset of the original one.

The actual result of negating all of the alternatives, except for the ones that are already entailed by the original modal claim (the result of applying “O” – again, ignoring the asserted prejacent) is given in (8).

- (8)  $\forall Y [((R - Y) \subseteq P) \rightarrow ((R - Y) \subseteq (R - Q))]$

The formula says that if the quantificational claim is true, then the entire new restrictor is a subset of the original restrictor (because the universal quantifier is downward entailing on its first argument). We can simplify this formula.

(9) Step 1: The left side inside the square brackets:

$$\begin{aligned} R-Y \subseteq P &= P' \subseteq (R-Y)' \text{ by contraposition} \\ &= P' \subseteq (R \cup Y) \text{ by DeMorgan's law} \\ &= (P' \cap R) \subseteq Y \text{ by the following equivalence: for any } A, B: \\ &\quad A \subseteq (B \cup C) = A \cap B' \subseteq C \end{aligned}$$

(10) Step 2: The right side inside the square brackets:

$$\begin{aligned} (R-Y) \subseteq (R-Q) &= (R-Q)' \subseteq (R-Y)' && \text{by contraposition} \\ &= (R' \cup Q) \subseteq (R' \cup Y) && \text{by DeMorgan's law} \\ &= ((R' \cup Q) \cap R) \subseteq Y && \text{for any } A, B: A \subseteq (B \cup C) = A \cap B' \subseteq C \\ &= ((R' \cap R) \cup (Q \cap R)) \subseteq Y && \text{by distributive laws} \end{aligned}$$

(11) Step 3: Putting the results together:

$$\begin{aligned} \forall Y ((P' \cap R) \subseteq Y \rightarrow ((R' \cap R) \cup (Q \cap R)) \subseteq Y)^9 &= \\ ((R' \cap R) \cup (Q \cap R)) \subseteq (P' \cap R) &\Rightarrow \text{because the universal quantifier is DE on its first} \\ \text{argument} & \\ (Q \cap R) \subseteq (P' \cap R) &= \text{All accessible worlds where it rains are worlds where the party is} \\ \text{not outside.} & \\ \text{This is the desired result.} & \end{aligned}$$

The same result is predicted if *only* negates all of the alternatives for a negative conditional clause. Thus (12) is predicted to have the following truth-conditions.

(12) Only if it does not rain, will the party be outside.

(13)  $[[ (12) ] ]^{w_0, g} = T$  iff  $(Q \cap R) \subseteq (P' \cap R)$  where  $R := \{w: \text{is accessible from } w_0\}$ ,  
 $Q := \{w: \text{it rains in } w\}$ ,  $P := \{w: \text{the party is outside in } w\}$

<sup>9</sup> The following equivalence is used here: for any sets A and B:  $\forall Y (A \subseteq Y \rightarrow B \subseteq Y) = B \subseteq A$

# Cointensional questions, fragment answers, and structured meanings<sup>1</sup>

Andrew WEIR — NTNU Norwegian University of Science and Technology

**Abstract.** I discuss ‘cointensional questions’, questions which appear to have the same sense as each other, e.g. *how many fives ten contains* and *how many times ten contains five*. Fragment answers are sensitive to the distinction in form between these questions: the first of these can be answered by *two* but not *twice*, and vice-versa for the second. I argue that this casts light on the identity condition in (clausal) ellipsis, and in particular, requires a semantics for questions and focus which is more structured than propositional/Hamblin alternatives. Building on a proposal in Krifka (2006), I propose that the *backgrounds* of short answers must be in a subset relation to the background of their antecedent questions. I show that this proposal makes additional welcome predictions, capturing so-called ‘inheritance of content’ effects in clausal ellipsis.

**Keywords:** fragment answers, ellipsis, identity in ellipsis, structured meanings, questions, focus, inheritance of content

## 1. Introduction

This paper considers the data in (1)–(4).

- (1) Q: How many signals did the machine send?  
a. (i) It sent TWO signals. (ii) TWO (signals).  
b. (i) ?It sent a signal TWICE. (ii) \*TWICE.
- (2) Q: How many times did the machine send a signal?  
a. (i) ?It sent TWO signals. (ii) \*TWO (signals).<sup>2</sup>  
b. (i) It sent a signal TWICE. (ii) TWICE.
- (3) Q: How often did the train take on water?  
a. (i) It took on water TWICE. (ii) TWICE.  
b. (i) ?It took on water in TWO PLACES. (ii) ?\*In TWO PLACES.
- (4) Q: In how many places did the train take on water?  
a. (i) ?It took on water TWICE. (ii) \*TWICE.  
b. (i) It took on water in TWO PLACES. (ii) In TWO PLACES.

The questions in (1) and (2) seem to have the same sense: assuming a machine that sends signals sequentially, then if one knows the answer to (1), one knows the answer to (2), and vice versa. The same is true, assuming a train that makes a straight journey from A to B and only stops at any water stop once, for (3) and (4). I will call such pairs of questions *cointensional*.

<sup>1</sup>Thanks to reviewers for and attendees at SuB 21 for helpful comments. All errors are mine.

<sup>2</sup>Note that *two* on its own is not ungrammatical here if it can be interpreted as *two times*. I pick *two* because of the existence of *twice*, which blocks *two times* (or at least makes the latter unnatural).

This paper seeks to explain a mystery posed by cointensional questions, namely the asymmetry between the (i) answers – ‘full’ or clausal answers – and the (ii) answers, variably called in the literature ‘short answers’, ‘term answers’ or ‘fragment answers’. The acceptability of the (i) answers, in all cases, shows that it is possible (if sometimes mildly degraded) to answer a question ‘indirectly’ with a full clausal answer – that is, with an answer which does not match the antecedent question in form, but which nevertheless ‘answers’ the question in some broader sense. However, this possibility is not open to the fragment answers in (ii). It is ungrammatical, as the diacritics in (1)–(4) indicate, to use a fragment answer to answer a question ‘indirectly’, even if the corresponding full answer makes a coherent contribution to the discourse, and even if the answer to the question is (intuitively) reconstructable from the fragment.

The paper considers two main theoretical issues: the nature of the link between fragment answers and clausal answers, and the proper analysis of questions and focus structures. Many analyses of fragment answers, so-called sententialist analyses (e.g. Morgan (1973); Merchant (2004); Reich (2007); Weir (2014b) a.o.), propose to derive fragment answers directly from the clausal answers via a process of clausal ellipsis; roughly speaking, deleting everything in the clausal answer except for a focused constituent (or a constituent containing the focus; for syntactic restrictions on this process, see Merchant (2004); Krifka (2006); Weir (2014b, 2015)). By contrast, nonsententialist analyses (e.g. Stainton (1998, 2006a, b); Ginzburg and Sag (2000); Culicover and Jackendoff (2005); Jacobson (2016) a.o.) propose that short answers are generated ‘directly’, without accompanying sentential structure.

- (5) How many times did the machine send a signal?  
 a. TWICE. (nonsententialist)  
 b. ~~The machine sent a signal~~ TWICE. (sententialist)

There is a considerable amount of syntactic support for sententialist analyses, at least in clear-cut cases of answers to linguistically-expressed questions, such as those in (1)–(4).<sup>3</sup> However, on the face of it, data like those in (1)–(4) pose a problem for sententialist analyses; if the fragment answers are reductions of the clausal answers, why are some fragment answers unacceptable when their corresponding clausal answers are acceptable?

This paper locates the problem in the semantic identity condition that is operative in clausal ellipsis. The proposal is that the kind of semantic identity that is required between an elided clause and its antecedent is such as to enforce the kind of form-matching effects shown in (1)–(4). It will furthermore be shown that the kind of semantic identity condition required implies that questions and focus structures, at least at some level of their interpretation, must be more structured or ‘categorical’ in their meaning than a denotation based on propositional alternatives/Hamblin sets, as proposed by Hausser (1983); von Stechow (1990); Krifka (2001, 2006); Jacobson (2016) a.o. Furthermore, the analysis will be extended to capture two further phenomena associated with fragment answers, and clausal ellipsis more generally (e.g. sluicing). Firstly, the analysis is extended to ‘inheritance of content’ effects (Chung et al. (1995); Romero

<sup>3</sup>Antecedentless fragments, such as those discussed in Stainton (2006b) – e.g. *Fire!* or *A coffee, please* – pose further complications and may not ultimately be amenable to a sententialist analysis, as Merchant (2010) discusses, though see Weir (2014b):ch. 3 for a contrary view. I put these cases aside in this paper.

(1998); Barros (2013); Weir (2014a, b); Jacobson (2016) a.o.) illustrated in (6), (7); fragment answers (*John and Bill* and *Jane Austen* respectively below) obligatorily ‘inherit’ restrictions from the antecedent sentence, while this does not necessarily occur in the full answers:

- (6) (Jacobson (2016)’s (14), adapted)  
Which math students left the party early?  
a. John and Bill left the party early, but they’re not math students.  
b. John and Bill, #but they’re not math students.
- (7) (from Weir (2014b):60, originally from Jeremy Hartman p.c.)  
Which Brontë sister wrote *Emma*?  
a. Jane Austen wrote *Emma*, you idiot.  
b. #Jane Austen, you idiot. (entails that Jane Austen is a Brontë sister)

Secondly, the analysis also captures the (related) fact that, while a fragment can provide a ‘more specific’ (i.e. with a more specific NP restriction) answer than the question contains (8), the inverse (9a, b) is not possible, even if the full clausal answer is acceptable (9c, d). See Barros (2013) for discussion of similar facts with respect to sluicing.

- (8) Which pastries did John eat? – Some croissants.
- (9) Which pastries did John eat?  
a. #Nothing.  
b. #All the food on the table.  
c. He ate nothing.<sup>4</sup>  
d. He ate all the food on the table.

The paper proceeds as follows. Section 2 lays out some of the background issues: why a sententialist account of fragment answers is to be preferred on syntactic grounds, and some existing approaches to the semantic identity condition on clausal ellipsis. Section 3 discusses how the data discussed above pose a problem for many extant theories of this semantic identity condition. Section 4 argues that these facts should not be captured by reference to a syntactic or LF-isomorphism condition on ellipsis (such as those proposed by Chung (2013); Merchant (2013); Griffiths and Lipták (2014); Thoms (2015) a.o.). Section 5 makes the proposal that the semantic condition on clausal ellipsis must make reference to a structured semantic object, building on proposals by Krifka (2006), while section 6 provides a technical implementation of how this is done in the syntax. Section 7 proposes a modification to Krifka’s proposal, which maintains the essential feature of capturing the data in (1)–(4), and has the additional benefit of capturing the ‘inheritance of content’ effects discussed above. Section 8 concludes.

<sup>4</sup>*He didn’t eat anything* is better here, but the fragment answer *anything* is out for independent reasons (as the putatively elided clause, *he ate x*, contains no negator to license the NPI). The clausal answer in (9c) is nevertheless grammatical.

## 2. Fragments, ellipsis, and the semantic antecedence condition

I start from the position that, at least in question-answer sequences like that in (10), the fragment answer is derived via clausal ellipsis as in (11); and concretely, I adopt Merchant (2004)'s proposal that the fragment moves to a left-peripheral position prior to ellipsis of the rest of the clause (although we will see a refinement of this position in sections 4 and 6).

(10) What did John eat? – Chips.

- (11) a. ~~John~~ ate chips.  
b. [<sub>CP</sub> Chips<sub>1</sub> [<sub>TP</sub> ~~John~~ ate ~~t<sub>1</sub>~~]]

Clausal structure can be diagnosed, for example, by the presence of binding and Case connectivity effects in the fragment (i.e. the fragment shows the binding and Case properties that it would in the full clause; Merchant (2004)). The existence of a movement dependency can be diagnosed by the existence of 'stranding' effects; for example, in languages in which prepositions must obligatorily be pied-piped along with their arguments, prepositions are also obligatory in the corresponding fragment answers (Merchant (2001, 2004)'s P-stranding generalization; see also Weir (2014b)). Space precludes a detailed defense of the sententialist position over 'bare' or 'subsentential' analyses, in which fragment answers are generated without clausal structure; on the basis of the evidence presented by the above authors, I assume that clausal ellipsis is indeed implicated in the creation of fragment answers.<sup>5</sup>

As in all cases of ellipsis, some kind of matching or identity relation must hold between the elided clause and some antecedent. One familiar candidate for such a condition is Merchant (2001)'s e-GIVENness:

- (12) a. A clause may be elided if it is e-GIVEN.  
b. A clause A is e-GIVEN if there is an antecedent clause E such that  $F\text{-clo}(A) \iff F\text{-clo}(E)$ .  
c. The focus closure (F-clo) of a clause is the denotation of that clause with all focused elements replaced by variables, and all variables (that is, traces plus focused elements which have been replaced) having been existentially closed.

This would rule in ellipses such as (11b) by matching two IPs which both contain existentially closed traces in object position:

- (13) a. What did [<sub>IP</sub> John eat t]? – Chips [<sub>IP</sub> John ate t]  
b.  $\exists x. \text{John ate } x \iff \exists y. \text{John ate } y$

This condition is likely too liberal; recent work on clausal ellipsis (e.g. Reich (2007); Ander-

<sup>5</sup>The claim made in this paper can be understood as a weaker, conditional one; *if* one accepts a sententialist/ellipsis view of fragments, *then* one will also have to accept a semantic condition on clausal ellipsis along the lines proposed here. It should be noted also that one of the main proponents of the nonsententialist view, Robert Stainton (e.g. Stainton (1998, 2006a, b)), has as his main concern antecedentless or discourse-initial fragments, and accepts that in question-answer sequences, fragments may be derived elliptically from full clauses.

Bois (2010, 2014); Barros (2014); Weir (2014a, b); Collins et al. (2015)) has been converging on the position that clausal ellipsis cannot find its antecedent simply anywhere in the preceding discourse, but must rather find its antecedent in the Question under Discussion (Roberts, 1996).<sup>6</sup> Reich (2007) proposes, for example, that the focus-semantic value of an elided clause, understood as a set of propositional alternatives (Rooth, 1985) must be equal to the value of the Question under Discussion, also understood as a set of propositional alternatives (Hamblin denotation for questions):

- (14) What did John eat? — ~~John~~ ate chips.  
 a.  $\llbracket \text{QUD} \rrbracket = \llbracket \text{What did John eat?} \rrbracket = \{\text{John ate chips, John ate cake, } \dots\}$   
 b.  $\llbracket \text{John ate [chips]}_F \rrbracket^f = \{\text{John ate chips, John ate cake, } \dots\}$   
 $\llbracket \text{QUD} \rrbracket = \llbracket \text{John ate [chips]}_F \rrbracket^f$ , so ellipsis is licensed.

I will assume, again without much discussion, that the Question under Discussion (or something very like it, such as the concept of ‘live issue’ in Inquisitive Semantics) is the anaphoric ‘target’ for the identity relation in clausal ellipsis; the reader is referred to the authors above for support for this position.

### 3. The problem for propositional alternatives

Many of the semantic accounts founder on the data presented in (1)–(4); the examples in (1) and (2) are repeated here:

- (15) Q: How many signals did the machine send?  
 a. (i) It sent TWO signals. (ii) TWO (signals).  
 b. (i) ?It sent a signal TWICE. (ii) \*TWICE.
- (16) Q: How many times did the machine send a signal?  
 a. (i) ?It sent TWO signals. (ii) \*TWO (signals).  
 b. (i) It sent a signal TWICE. (ii) TWICE.

The problem here is that, on a Hamblin-alternatives view of questions (and of focus), the questions in (15) and (16) above denote the same sets of sets of worlds, and so do the focus values of the answers.

- (17) a.  $\llbracket \text{How many signals did the machine send?} \rrbracket$   
 b.  $\llbracket \text{the machine sent [two]}_F \text{ signals} \rrbracket^f$   
 c.  $\{p \mid \exists d. p = \lambda w'. \text{ the machine sent } d\text{-many signals in } w'\}$   
 d.  $\{\text{the machine sent one signal, the machine sent two signals, } \dots\}$   
 e.  $\{\text{the machine sent a signal once, the machine sent a signal twice, } \dots\}$   
 f.  $\{p \mid \exists d. p = \lambda w'. \text{ the machine sent a signal } d\text{-many times in } w'\}$   
 g.  $\llbracket \text{the machine sent a signal [twice]}_F \rrbracket^f$   
 h.  $\llbracket \text{How many times did the machine send a signal?} \rrbracket$

<sup>6</sup>AnderBois (2010, 2014)’s argument that clausal ellipsis is anaphoric to the ‘live issue’ can be seen as a variant on this, although the implementation in terms of Inquisitive Semantics is rather different.

The key point is that if the machine sent two signals, then it also sent a signal twice; if the machine sent a signal three times, then it also sent three signals; and so on. If we understand questions and focus-semantic values to consist of sets of sets of worlds (propositional alternatives), then each of (17a–h) is the same object: the same set of sets of worlds. But this is a problem for the semantic conditions reviewed in section 2. These semantic conditions rely on a characterization of focus-alternatives as being sets of propositions; if the sets of propositions denoted by two clauses (such as *the machine sent TWO signals* and *the machine sent a signal TWICE*) are identical, then from the point of view of these semantic identity conditions, ‘mismatch’ answers should be possible, such as the below discourse. Here Reich (2007)’s condition, where the QUD has to be identical to the focus value of the answer, is used to illustrate; but the same problem will afflict any condition that uses propositional alternatives in its formulation.

(18) How many signals did the machine send? — ~~\*The machine sent a signal~~ TWICE.

(19)  $\llbracket \text{How many signals did the machine send?} \rrbracket = \llbracket \text{the machine sent a signal [twice]}_F \rrbracket^f$   
so ellipsis should be licensed in (18), contrary to fact.

One might initially think that the examples have not been constructed carefully enough; perhaps the set of worlds in which the machine sends two signals is not quite the same set of worlds in which the machine sends a signal twice. (Perhaps the machine can send two signals simultaneously.) Such a semantic difference between the two answers would be enough to cause the semantic conditions discussed above not to be met. However, we can illustrate the problem in general terms by using mathematical examples, such as (20), (21).

(20) Q: How many fives does ten contain?  
a. (i) Ten contains TWO fives. (ii) TWO (fives).  
b. (i) ?Ten contains five TWICE. (ii) \*TWICE.

(21) Q: How many times does ten contain five?  
a. (i) ?Ten contains TWO fives. (ii) \*TWO (fives).  
b. (i) Ten contains five TWICE. (ii) TWICE.

Because mathematical truths are assumed to hold at all possible worlds, we can be sure that the question and all of the answers above denote the same sets of sets of worlds (that is, the singleton set containing the set of all possible worlds). Despite the fact that the questions and the focus values of the answers in (20) and (21) are all cointensional, the same problem recurs: ‘mismatches’ of this sort are forbidden, as shown above.

It should be noted that this is not quite the same problem as classic cases of hyperintensionality, which demonstrate that a possible-worlds semantics for propositions is insufficient; e.g. the failure of (22a) to entail (22b), even though both of the clauses embedded under ‘know’ should denote the same sets of sets of worlds (i.e. the singleton set containing the set of all possible worlds).

- (22) a. Little Johnny knows that two plus two makes four.  
 b. Little Johnny knows that the square root of 169 is 13.

The examples in (1)–(4) differ from examples like those in (22) because the questions, and their answers, in (1)–(4) really do appear, at least on the face of it, to have the same sense. For example, they can be substituted, *salva veritate*, under a verb like *know* in a way that the mathematical statements in (22) cannot.

- (23) a. John knows how often the train took on water.  
 b. John knows in how many places the train took on water.<sup>7</sup>
- (24) a. John knows how many fives ten contains.  
 b. John knows how many times ten contains five.

Despite the fact that these questions and answers seem in some way to share the same sense, that identity does not suffice for ellipsis matching in (1)–(4). One obvious way to explain the failure of ellipsis in these examples would be to suggest that there is a *syntactic* difference between the elided clause and the antecedent, combined with the idea that the identity condition in ellipsis is (partially or wholly) syntactic in nature. In the next section I will argue that, even if one agrees that there is a syntactic component to ellipsis identity, this will not suffice to solve the problem that cointensional questions pose.

#### 4. Not due to syntactic isomorphism or LF-parallelism

On the face of it, the alternations discussed here look rather similar to other cases that have been discussed in the literature, where the propositional semantics of the antecedent and elided clauses are the same but the syntax is different. Examples include voice mismatches (Merchant, 2013) and argument structure mismatches (Chung, 2013; Merchant, 2013). In such cases also, clausal ellipsis (sluicing, fragments) is not licensed.

- (25) *Voice mismatches* (Merchant, 2013)  
 a. \*Someone ate the cake, but we don't know by who ~~the cake was eaten~~.  
 b. \*Who ate the cake? — By John ~~the cake was eaten~~.  
 c. \*The cake was eaten, but we don't know who ~~ate the cake~~.
- (26) *Argument structure mismatches*  
 a. \*It's known that they sent someone a silly message, but it's unclear to who they ~~sent a silly message~~. (Chung, 2013: ex. 6)  
 b. \*They embroidered something with peace signs, but I don't know on what they ~~embroidered peace signs~~. (Merchant, 2013: ex. 43)

<sup>7</sup>One might again contest such examples by saying that there are situations which tease them apart; for example, if there is only one water stop on the track (which the train might have stopped at several times going forward and back), (23b) might be true (John knows there's only one place), but (23a) false. Again, the mathematical example in (24) is given to show that the problem is a general one, independent of the problems that might be found for specific examples.

It has been argued that the failure of such mismatches is due to a syntactic isomorphism condition in ellipsis. For example, Chung (2013) proposes that elided clauses must be identical to their antecedents in argument structure and the presence of Case-assigning heads. I do not want to argue against a syntactic identity condition in ellipsis (over and above the semantic identity condition to be developed in this paper) to capture these data; the cases discussed by Chung and Merchant are convincing in this respect. But I believe that this is not what is going wrong in the examples in (1)–(4). Consider the antecedent and ungrammatical elided clause (assuming movement of the fragment) that cause problems in (1), for example.

- (27) a. [<sub>CP</sub> How many signals<sub>i</sub> [<sub>TP</sub> the machine [<sub>VP</sub> [<sub>VP</sub> send t<sub>i</sub> ] ]]]  
 b. \*[<sub>CP</sub> Twice<sub>i</sub> [<sub>TP</sub> the machine [<sub>VP</sub> [<sub>VP</sub> send a signal ] t<sub>i</sub> ]]]

We can see two potential ‘mismatches’ here; firstly, the antecedent has a trace (of *how many signals*) where the elided clause has an indefinite (*a signal*); and the elided clause has a trace (of *twice*) where the antecedent has nothing. However, these cannot be what is ruling this question-answer pair out; similar ‘mismatches’ do not trouble clausal ellipsis in other cases. As discussed by (Merchant, 2001: 202ff), there are in general many cases where an antecedent for clausal ellipsis contains a trace in a position where a trace could not be in the elided clause. Merchant’s strategy to deal with such cases is to assume that a pronoun is present in the ellipsis site, and it seems difficult to credit an alternative to this in cases such as the below.

- (28) The FBI knows [which truck<sub>i</sub> they rented t<sub>i</sub>], but figuring out [from whom<sub>j</sub> they rented ~~it~~<sub>j</sub>] has proven difficult. (Merchant, 2001: 206)

- (29) What did he eat t<sub>i</sub>, and why ~~did he eat it~~<sub>i</sub>?

- (30) A: That natto, he ate t<sub>i</sub>. B: Yes – with chopsticks ~~he ate it~~<sub>i</sub>

The point can be generalized with indefinites in predicative position:

- (31) Such a man<sub>i</sub>, John might become t<sub>i</sub>.  
 a. Tom, too. (=Tom<sub>j</sub> t<sub>j</sub> ~~might become such a man~~ too)  
 b. ... but I couldn’t tell you when<sub>j</sub> ~~he might become such a man~~ t<sub>j</sub>

- (32) What kind of man might John become t<sub>i</sub>?  
 And when<sub>j</sub> ~~might he become such a man~~ t<sub>j</sub>?

Such cases indicate that a trace can clearly antecede something contentful in an elided clause.<sup>8</sup> Moreover, (31) and (32) appear to indicate that the contentful constituent in the elided clause can potentially be a full indefinite, not ‘merely’ a pronoun, given the degraded nature of (33b) on the relevant reading:

<sup>8</sup>One could argue that the moved phrase in the antecedent clause is subject to reconstruction, allowing matching; but then this should be available in cases like (27) as well.

- (33) What kind of man might John become?  
 a. And when might he become such a man?  
 b. ??And when might he become one?  
 (only: when might he become a man, not: when might he become such a man)

Any putative ban on a trace anteceding a non-trace cannot therefore account for the badness of the cases under discussion here, as there is evidence against the existence of such a ban. The ‘inverse’ problem – that a trace is present in the elided clause that is not present in the antecedent – is also present in the example in (27).<sup>9</sup> But this also is not generally a problem for clausal ellipsis; this is simply so-called ‘sprouting’.

- (34) He’s dancing, but I don’t know [with who]<sub>i</sub> ~~he’s dancing~~  $t_i$ .

- (35) He ate natto. — Yes, [with chopsticks]<sub>i</sub> ~~he ate natto~~  $t_i$ .

Examples like (34) and (35) show that we cannot locate the problem simply in the fact that the elided clause contains a trace that the antecedent does not contain.

A somewhat different kind of syntactic isomorphism has been proposed by many authors in the form of ‘(LF) Parallelism’ (Fiengo and May (1994); Fox and Lasnik (2003); Griffiths and Lipták (2014); Thoms (2015) a.o.). Under this conception, what is relevant in ellipsis identity is syntactic identity at LF up to variables, and correspondence at LF between the scopes of ellipsis remnants and of their antecedents; any variable-binding relationships should be identical between antecedent clause and elided clause.<sup>10</sup> This captures, for example, the fact that the indefinite correlates of *wh*-remnants in sluicing take wide scope, in parallel with the *wh*-phrase:

- (36) Most people ate something, but I don’t know what ~~most people ate~~  $t$ .

- (37) a. Antecedent LF: something 1 [most people ate  $t_1$ ]  
 b. Elided clause: what 1 [most people ate  $t_1$ ]

The LF of the antecedent and elided clause are identical, up to the identity of the binders, and so ellipsis is licensed. It might be thought that an LF Parallelism constraint of this sort can explain why the mismatch cases in (1)–(4) are ungrammatical. In particular, the variable-binding relations in ‘mismatch’ cases differ: in (38) a trace is being bound in object position in the antecedent but in adjunct position in the elided clause, and vice versa in (39).

<sup>9</sup>This is true if we assume movement of the fragment. This view will be discussed and (partially) revised below and in section 6. However, the key point here is just that arguments and adjuncts can ‘sprout’ under ellipsis, without any corresponding antecedent, so that by itself should not cause a problem for the ‘mismatch’ cases under discussion here.

<sup>10</sup>The term ‘Parallelism’ is somewhat ambiguous. The literature is agreed that, as a matter of *interpretation*, elided clauses must have the same scope relations as their antecedents. What is not clear is whether this is enforced only at the level of semantic interpretation, or whether it is a *syntactic* constraint at LF, concerning the positions of variables and their binders. (An indefinite could for example have a ‘wide-scope’ interpretation by dint of being the only scope-bearing element in the sentence, without actually taking syntactic scope at LF.) Here I am discussing this latter understanding of Parallelism as a basically syntactic (LF-level) constraint.

- (38) a. How many signals 1 [the machine [<sub>VP</sub> [<sub>VP</sub> send t<sub>1</sub> ] ] ]  
 b. Twice 1 [~~the machine~~ [<sub>VP</sub> [<sub>VP</sub> send a signal] t<sub>1</sub> ] ]
- (39) a. How often 1 [the machine [<sub>VP</sub> [<sub>VP</sub> send a signal] t<sub>1</sub> ] ]  
 b. Two signals 1 [~~the machine~~ [<sub>VP</sub> [<sub>VP</sub> send t<sub>1</sub> ] ] ]

There are two reasons not to believe that this is the problem in the cases under discussing here, however. The first is that the examples in (3) and (4), repeated below, seem to involve binding into the same position, namely a vP-level adjunct; so it is not clear that a failure of binding parallelism alone should be the culprit.

- (40) a. How often did the train take on water? – \*In two places ~~the train took on water~~.  
 b. In how many places did the train take on water? – \*Twice ~~the train took on water~~.
- (41) a. How often 1 [the train [<sub>VP</sub> [<sub>VP</sub> took on water] t<sub>1</sub> ] ]  
 b. In two places 1 [the train [<sub>VP</sub> [<sub>VP</sub> took on water] t<sub>1</sub> ] ]

The second counterargument is that it is not clear that fragments move at LF in the way that the LF Parallelism account would suggest. Weir (2014b, 2015) provides a number of arguments that fragments do move (in the way proposed by Merchant (2004) and discussed in section 2) – but only at PF, not at LF. The most important of these arguments is the availability of NPI fragments (see also den Dikken et al. (2000); Valmala (2007)).

- (42) a. I know what John did buy, but what didn't he buy? — Any wine.  
 b. Which of these computers should I not touch? — Any of them!

As NPIs must be in the scope of their licenser at LF, and never take wide scope, then the LF movement which Parallelism accounts appeal to is not available for fragments like (42). It is therefore not clear that Parallelism is to be correctly understood as a *syntactic* constraint on ellipsis. However, I wish to argue for a version of the leading idea of the LF Parallelism approach – that a condition on ellipsis is that lambda abstractions in the antecedent and the elided clause must 'match' in some way. However, I argue that this is not to be located in the syntax, but rather in a more structured *semantics* for questions and focus structures.

## 5. The solution: congruence with structured meanings

In this section I will argue for two main conclusions:

- (a) Questions, and focus structures, must be understood (at some level of semantic representation) to have a more structured, 'categorical'-style denotation than Hamblin sets of propositional alternatives, as in for example Hausser (1983); von Stechow (1990); Krifka (2001, 2006); Jacobson (2016).

- (b) It is this structured meaning, or a part of it, which (the semantic component of) the identity condition on clausal ellipsis makes reference to.<sup>11</sup>

The proposal I would like to make here builds directly on a proposal in Krifka (2006). Krifka proposes that questions, and focus structures (e.g. answers to questions), have the structured denotations shown in (43) and (44) below (after Krifka's (77, 78) respectively).<sup>12</sup>

- (43)  $\llbracket \text{who}_i \text{ John introduced } t_i \text{ to Sue} \rrbracket$   
 $= \langle \text{PERSON}, \lambda x. \text{introduced}(\text{sue})(x)(\text{john}) \rangle$   
 where PERSON is the alternatives that the question word can range over.
- (44)  $\llbracket \text{John introduced } [\text{Bill}]_F \text{ to Sue} \rrbracket$   
 $= \langle \text{bill}, A, \lambda x. \text{introduced}(\text{sue})(x)(\text{john}) \rangle$   
 where A is the focus alternatives (in the sense of Rooth (1985), and possibly restricted by context) to the focused term (i.e. here  $A = \text{ALT}(\llbracket \text{Bill} \rrbracket) = \{\text{Tom}, \text{Mary}, \text{Harry}, \dots\}$ )

Following the literature on structured-meaning approaches to focus and questions, call the lambda-terms in (43) and (44) the *backgrounds* of the question and the focus structure. Given these denotations, Krifka proposes the question-answer congruence condition in (45) (Krifka's (79), adapted).

- (45) A question-answer pair  $\langle W, B \rangle - \langle F, A, B' \rangle$  is congruent iff:  
 $B = B'$  and  $W \subseteq A$  (or  $W = A$ ).  
 If congruent, the answer asserts  $B(F)$ .

Furthermore, Krifka states that 'the identity of backgrounds allows for short, or term answers, in which the background of the answer is deleted' (p. 130). The requirement that the backgrounds – that is, the lambda abstractions created by abstracting over the *wh*-term in the question and the focused term in the answer, respectively – must be identical is not met in the case of the cointensional questions. Crucially, even though the intensions/senses of cointensional questions are the same, their structured meanings are not; in particular, the backgrounds in the 'mismatch' cases are different, if we assume that the background in a case like (46) is a lambda-abstraction over signals, and the background in a case like (47) is a lambda-abstraction over intervals of time.

<sup>11</sup>This formulation contains two caveats. Firstly, as discussed in section 4, I do not want to make the strong assertion here that the identity condition on ellipsis is purely semantic; there may also be a syntactic component to it, as proposed in Chung (2013); Merchant (2013) a.o. Secondly, the proposals made here are made only for *clausal* ellipsis, and not for other forms of ellipsis such as verb phrase ellipsis, which seem to have different antecedence conditions (see e.g. discussion in AnderBois (2010); Weir (2014b)).

<sup>12</sup>These denotations have been adapted from the originals in two ways. Firstly, the interpretations Krifka gives to these structures is not strictly speaking the structured denotation itself, but rather the speech act which contains this structured denotation as content; but I have suppressed this distinction here (and in subsequent discussion). Secondly, and more importantly, Krifka presents the denotation in (44) as the interpretation of a logical form which contains movement of the focused phrase; however, as discussed in section 4, I do not want to assume that fragments (or foci in general) move at LF in this way. I will discuss the matter of how exactly the lambda term in (44) should be created in section 6; for the present I simply assume that the structured denotation in (44) can be derived in some way or another.

- (46) Question: How many signals did the machine send?  
Background:  $\lambda x$ . the machine sent  $x$ ,  $x$  a signal
- (47) Question: How many times did the machine send a signal?  
Background:  $\lambda t$ . the machine sent a signal at interval  $t$

The corresponding focus-structures will have the same lambda abstractions as their backgrounds:

- (48) Answer: The machine sent [TWO signals]<sub>F</sub>.  
Background:  $\lambda x$ . the machine sent  $x$ ,  $x$  a signal
- (49) Answer: The machine sent a signal [TWICE]<sub>F</sub>.  
Background:  $\lambda t$ . the machine sent a signal at interval  $t$

The key point here is that if (46) is answered with (49), or (47) with (48), the backgrounds will not match. Adopting Krifka's question-answer congruence condition in (45) as a condition on clausal ellipsis therefore captures the data in (1)–(4).<sup>13</sup> Additional support for this comes from some cases where such 'mismatches' are possible. A *how many* or *how often* question does not always have to receive a numerical short answer, as long as the background of the answer is a lambda-abstraction which matches the background of the question (i.e. abstracts over a variable in the same position), as (50) and (51) illustrate.

- (50) How many people came to the party? (Weir, 2014b: 79)  
a. Six (people).  
b. John, Paul, George, Sarah, Mary and Helen.  
(background in both cases:  $\lambda x$ .  $x$  came to the party)
- (51) In how many places did the train take on water?  
a. Three (places).  
b. Cleveland, Albany and Springfield.  
(background in both cases:  $\lambda x$ . the train took on water in  $x$ )

## 6. Implementation

How do we get access to backgrounds in focus and question structures? That is, how do we create the lambda abstractions involved? Krifka proposes that this is done via movement: *wh*-words and foci move at LF, and this movement creates a lambda abstraction in the normal way (following e.g. Heim and Kratzer (1998)'s rule of Predicate Abstraction).

- (52) LF: [Who 1 [did John introduce  $t_1$  to Sue]]  
Background:  $\lambda x$ . John introduced  $x$  to Sue

<sup>13</sup>Krifka's proposal is actually intended to be a condition on question-answer congruence generally, not just in elliptical structures. That seems too strong, given that full clausal 'mismatches' are only mildly degraded (*How many signals did the machine send? — ?It sent a signal TWICE*), even though their backgrounds do not appear to match.

- (53) LF: [Bill 1 [John introduced  $t_1$  to Sue]]  
 Background:  $\lambda x$ . John introduced  $x$  to Sue

I assume that this is indeed how backgrounds are created in *wh*-questions. However, given the evidence reviewed in section 4 that fragments do not move at LF (Weir, 2014b, 2015), I do not wish to derive the backgrounds of the answers via LF movement as such. In this section I wish to sketch a method of obtaining the same effect – i.e. the creation of a lambda abstraction over the focused phrase, but without actual syntactic movement of that phrase.<sup>14</sup>

I propose that a Focus head is inserted in the clausal left periphery, co-indexed with the focused phrase in the clause (see Constant (2014) for a similar recent proposal for a contrastive topic head; on the technology of focus indices, see Kratzer (1991)). This Foc head, furthermore, is endowed with an [E] feature (Merchant, 2001) which enforces the semantic condition on clausal ellipsis as a presupposition; this Foc<sub>[E]</sub> head has a syncategorematic interpretation when it combines with a TP, given in (54).<sup>15</sup>

- (54) **Implementation of ellipsis condition on E-feature (to be refined)**  
 Let  $n$  be an index. Then,  
 $\llbracket \text{Foc}_{[E]n} \text{ TP} \rrbracket = \llbracket \text{TP} \rrbracket$ , iff there is an antecedent question/Question under Discussion whose background is equal to  $\llbracket n \text{ TP} \rrbracket$ ; otherwise undefined.

The interpretation of  $\llbracket n \text{ TP} \rrbracket$  is given by the rule of Trace Conversion (Fox, 2002):

- (55)  $\llbracket [n \text{ } [\dots \text{XP}_n \dots]] \rrbracket$   
 $= \lambda x$ .  $\llbracket [\dots \text{XP} \dots] \rrbracket$ , where the head of XP is replaced by the head  $the_x$ ,  
 where  $\llbracket the_x \rrbracket = \lambda P.ty.[P(y) \wedge y = x]$

So, for example, the structure in (56a) is interpreted as in (56b):

- (56) a. [3 [the machine sent [two signals]<sub>3</sub>]]  
 b.  $\lambda x$ . the machine sent  $the_x$  signals  
 $= \lambda x$ . the machine sent  $ty$ . [signal( $y$ )  $\wedge y = x$ ]  
 $\approx \lambda x$ . the machine sent the signals which are  $x$

And the structure in (57) – i.e. the structure underlying the elliptical answer *two signals* – is interpreted as shown. (The [E]-feature prompts ellipsis of the clause, as in Merchant (2001), and the focused phrase will move at PF to a left-peripheral position to escape ellipsis; see Weir (2014b, 2015) for details.)

<sup>14</sup>But this is not crucial for the rest of the analysis being presented here. Readers who are unconvinced by the arguments against the movement of fragments, and/or who wish to assume that foci move at LF, can continue to assume this, and can assume that focus backgrounds are created by movement (which is indeed perhaps an easier way to do it than the proposal here). What will be key, though, is the appeal to mechanisms of Trace Conversion discussed below.

<sup>15</sup>It may seem to be a disadvantage of the proposal that it requires the syncategorematic rule in (54). However it should be noted that Merchant (2001)'s original [E]-feature also in effect has to be interpreted syncategorematically, as Weir (2014b):319 discusses.

- (57)  $\llbracket [\text{Foc}_{[E]_3} [\text{the machine sent} [\text{two signals}]_3] ] \rrbracket$   
 $= \llbracket \text{the machine sent two signals} \rrbracket$   
 iff there is an antecedent question/Question under Discussion whose background is equal to  $[\lambda x. \text{the machine sent the signals which are } x]$

The presupposition in (57) will be met if the antecedent question has the background ‘ $\lambda x. \text{the machine sent the signals which are } x$ ’, but not if it has the background ‘ $\lambda t. \text{the machine sent the signals at interval } t$ ’, capturing the data in (1)–(4).

## 7. Refining the matching condition

Krifka’s matching condition therefore captures the data this paper began with. I wish here, however, to propose a modification to Krifka’s proposal, while retaining the core idea that it is the backgrounds of question and answer which are important in clausal ellipsis. The necessary refinement comes from question-answer pairs such as the below, from Jacobson (2016).

- (58) Which math students came to the party?  
 a. John and Bill came to the party, but they’re not math students.  
 b. John and Bill (#but they’re not math students)

As can be seen, the full clausal answer in (58a) does not commit the speaker to John and Bill’s being math students. That is, the restriction of the question is not necessarily inherited in a full clausal answer. By contrast, in a fragment answer, the restriction of the question is obligatorily inherited (and see Chung et al. (1995) for similar data for sluicing).

The question-answer congruence proposal made in Krifka (2006) does not quite capture this. Let us suppose first that the restrictions in the questions and answers are encoded in the way that Trace Conversion would deliver, as below:

- (59) a. Q: Which math students came to the party?  
 b. B:  $\lambda x. \text{the math students who are } x \text{ came to the party}$
- (60) a. A:  $[\text{John and Bill}]_F$  came to the party  
 b. B’:  $\lambda x. \text{John and Bill, who are } x, \text{ came to the party}$

Saying that these backgrounds have to match is too strong a condition. This would require that the partial function which maps math students to True if they came to the party and False otherwise, is identical to the partial function which maps  $\{\text{John, Bill}\}$  to True if they came to the party and False otherwise; that is, it would entail not merely that John and Bill are math students, but that they are the only math students. To avoid this problem, we could try removing the restriction within the lambda term, making the backgrounds in both cases ‘ $\lambda x. x \text{ came to the party}$ ’, but we then need to understand why the short answer in (58b) is restricted to math students. The second clause of Krifka’s condition, which states that the range of the *wh*-word in the question must be a subset of the focus-alternatives of the focused term in the answer (‘ $W \subseteq A'$ ’ in (45)), does not quite capture this; in fact it is not clear that we wish to impose this

precise condition on question-answer congruence, at least not in this form, given the availability of generalized quantifiers as the focused phrase in answers:

- (61) Which pastries did John eat? — (A lot of croissants, but) fewer than three danishes.

Here, the set of alternatives to the focused phrase (*fewer than three danishes*) presumably contains generalized quantifiers, as in (62).

- (62)  $\text{ALT}(\llbracket \text{fewer than three danishes} \rrbracket)$   
 $= \{ \llbracket \text{fewer than three croissants} \rrbracket, \llbracket \text{more than three danishes} \rrbracket, \llbracket \text{five croissants} \rrbracket, \dots \}$

The contents of the set in (62) are of the wrong type for the ‘ $W \subseteq A'$ ’ condition to be met; in (61), this would require the set of entities denoted by  $\llbracket \text{pastries} \rrbracket$  to be a subset of the set in (62), but (62) is a set of generalized quantifiers, not entities.

I propose a solution to the above which comprises two main ingredients. Firstly, I assume that backgrounds of questions and of focus structures are indeed structured in the way in which Trace Conversion would deliver, that is, they are partial functions of the kind in (59), (60). Secondly, I propose that the background-matching condition on clausal ellipsis is as in (63).

- (63) **Background-matching condition on clausal ellipsis (final version)**  
 Given a question with background  $Q$  and an answer with background  $A$ , the answer can be elided (up to the focused phrase) only if  $A \sqsubseteq Q$ .

Where ‘ $\sqsubseteq$ ’ is a notion of generalized entailment defined over functions:

- (64)  $A \sqsubseteq B \iff \forall x. A(x) \rightarrow B(x)$

It is probably easiest to understand this definition in terms of set talk; the definition states that, understood extensionally as sets, the background of the answer must be a subset of the background of the question. This can then be encoded in the Foc head/[E]-feature as follows, a revision of (54):

- (65) **Implementation of ellipsis condition on E-feature (final version)**  
 Let  $n$  be an index. Then,  
 $\llbracket \text{Foc}_{[E]n} \text{ TP} \rrbracket = \llbracket \text{TP} \rrbracket$ , iff there is an antecedent question/Question under Discussion with background  $B$  such that  $\llbracket n \text{ TP} \rrbracket \sqsubseteq B$ ; otherwise undefined.

Such a condition captures the cases discussed by Jacobson (2016). The backgrounds of the question and answer are as shown in (66) and (67) respectively:

- (66) Question: Which math students came to the party?  
 Background:  $\lambda x$ . the math students who are  $x$  came to the party

- (67) Answer: [John and Bill] ~~came to the party~~  
 Background:  $\lambda x$ . John and Bill who are  $x$  came to the party

If it is a condition on clausal ellipsis that the elided clause's background must be a subset of the antecedent question – i.e. the background in (67) is a subset of the background in (66), or equivalently, satisfying the predicate in (67) entails satisfying the predicate in (66) – then this forces John and Bill to be math students. The same effect can be seen in the below case, which is simply ungrammatical (from Weir (2014b):60, originally due to Jeremy Hartman p.c.)

- (68) Which Brontë sister wrote *Emma*?  
 a. Jane Austen wrote Emma, you idiot.  
 b. #Jane Austen, you idiot.
- (69) Background of question:  $\lambda x$ . the Brontë sister who is  $x$  wrote *Emma*  
 Background of answer:  $\lambda x$ . Jane Austen who is  $x$  wrote *Emma*  
 Background of A  $\not\sqsubseteq$  background of Q, so ellipsis is not licensed.

Such a subset condition also captures the fact that one can move from 'superset' NP restrictors in a question to 'subset' restrictors in the fragment, but not vice versa, as (70) and (71) show:

- (70) Q: Which pastries did John eat? (Background:  $\lambda x$ . John ate the pastries which are  $x$ )  
 A: Three croissants ~~John ate~~. (Background:  $\lambda x$ . John ate the croissants which are  $x$ )  
 Background of A  $\sqsubseteq$  background of Q, so ellipsis is licensed.
- (71) Q: Which pastries did John eat? (Background:  $\lambda x$ . John ate the pastries which are  $x$ )  
 A: \*Nothing ~~John ate~~. (Background:  $\lambda x$ . John ate the thing which is  $x$ )  
 Background of A  $\not\sqsubseteq$  background of Q, so ellipsis is not licensed.<sup>16</sup>
- (72) Q: Which pastries did John eat? (Background:  $\lambda x$ . John ate the pastries which are  $x$ )  
 A: \*All the food at the buffet ~~John ate~~.  
 (Background:  $\lambda x$ . John ate the food at the buffet which is  $x$ )  
 Background of A  $\not\sqsubseteq$  background of Q, so ellipsis is not licensed.

Note in these cases that full clausal answers are possible; in other words, the problem is not that the answer is per se incoherent, but rather that some condition proprietary to short answers/clausal ellipsis is not met.

- (73) Which pastries did John eat?  
 a. John ate NOTHING.  
 b. John ate ALL THE FOOD AT THE BUFFET.

<sup>16</sup>Note also that the condition proposed in Jacobson (2016), which proposes that the background of the question must compose with the denotation of the fragment, does not quite capture this data (although it captures the data in (66) and (68)). The fragment *nothing* (i.e. ' $\lambda P.\neg\exists x.P(x)$ ') could compose with the question's background here (which would result in the proposition ' $\neg\exists x$ . John ate the pastries which are  $x$ ', i.e. that John didn't eat any pastries). What goes wrong in (71) rather seems to be the fact that the backgrounds are not in the proper subset relation.

The background-matching condition proposed here is argued to be proprietary to clausal ellipsis, and so captures this asymmetry.

## 8. Conclusion

In this paper, I have argued that cointensional questions and their short answers pose a challenge to semantic conditions on ellipsis that work only at the level of propositional alternatives. I have argued, following Krifka (2006), that the correct account of such cases requires a structured-meaning treatment of questions and focus structures; and have proposed an implementation of a semantic matching constraint: the focus background of an answer must entail/be a subset of the background of the antecedent question.

# An attention-based explanation for some exhaustivity operators<sup>1</sup>

Matthijs WESTERA — *ILLC, University of Amsterdam*

**Abstract.** A well-known challenge for accounts of exhaustivity implications is the *granularity problem*: that adding a non-weakest disjunct to an utterance (e.g., “or both”) may prevent exhaustivity implications. Recent approaches to this problem apply exhaustivity operators either globally, i.e., to the disjunction as a whole, or locally, i.e., to each disjunct separately. This paper seeks to contribute to a better understanding of the operators employed in the globalist strand, which, contrary to globalists’ aims, have not thus far been given any sort of pragmatic motivation. To that end this paper demonstrates that these operators can be derived, wholly or in part, from a pragmatic theory: *Attentional Pragmatics* (Westera, 2017). The theory centers on the assumption that speakers should not only assert all relevant propositions they hold true, but also draw attention to all relevant propositions they consider possible. This assumption, suitably formalized, overcomes the granularity problem. The current paper formally derives an exhaustivity operator from Attentional Pragmatics and proves that it is in important respects conservative with regard to existing operators.

**Keywords:** exhaustivity, Hurford disjunction, granularity, Attentional Pragmatics, globalism/localism, innocent exclusion, minimal worlds.

## 1. Introduction

Adding a non-weakest disjunct can affect the exhaustivity implications of an utterance:

- (1) A: Who (of John, Mary and Bill) is at the party?
  - a. B: John is there. *(implied: not Mary, not Bill)*
  - b. B: John is there, or both John and Mary. *(implied: ~~not Mary~~, not Bill)*

This poses a challenge for traditional pragmatic accounts of exhaustivity, which are based on considerations of informational strength, i.e., the Gricean maxim of Quantity (e.g., Horn 1972; Gazdar 1979; Schulz and Van Rooij 2006; Spector 2007; Geurts 2011). The reason is that considerations of informational strength alone are arguably unable to distinguish between examples like (1a) and (1b). After all, the most straightforward semantic informational contents (i.e., literal sentence meanings) and hence primary informational intents (i.e., speaker meanings) for (1a) and (1b) would correspond to the classical meanings of their closest translations into predicate logic,  $Pj$  and  $Pj \vee (Pj \wedge Pm)$  – but these are classically (informationally) equivalent. I will call this the **granularity problem**: the traditional, information-based pragmatic approach is too coarse-grained to see the difference between (1a) and (1b).

The granularity problem was noted already by Gazdar (1979), and several approaches have been explored. Gazdar tried to solve it by assuming that utterances have “clausal” implications, to the effect that a speaker should be uncertain about any embedded clause of an uttered

---

<sup>1</sup>I am very grateful to J. Groenendijk and F. Roelofsen for valuable commentary on all iterations of this work, and to the audiences and reviewers of Logic in Language and Conversation (Utrecht) and Sinn und Bedeutung. Financial support from the Netherlands Organization for Scientific Research (NWO) is gratefully acknowledged.

sentence, e.g., the disjuncts of a disjunction. However, besides overgenerating clausal implications, the pragmatic explanation for clausal implications relies on the assumption that both embedded clauses and their negations are always relevant, a type of symmetry that is not plausible (Horn, 1989) and that leads to the well-known symmetry problem (Kroch, 1972). More recent approaches can be divided into two main branches:

- **Localist:** exhaustivity operators are applied to each disjunct (e.g., Chierchia et al. 2012), potentially motivated pragmatically by considerations of redundancy (e.g., Katzir and Singh 2013; Ciardelli and Roelofsen 2016).
- **Globalist:** an exhaustivity operator is applied only globally, to the disjunction as a whole, but the operator is a more sophisticated one that somehow has access to the individual disjuncts (Schulz and Van Rooij 2006; Alonso-Ovalle 2008). No pragmatic motivation for these operators has been given.

The current paper aims to mend the gap in the globalist approaches, by outlining a pragmatic motivation for an adequate exhaustivity operator. To that end I adopt the theory of Attentional Pragmatics (Westera 2017), which defines a set of maxims that govern not only information sharing, but also attention sharing – a promising approach because while (1a) and (1b) are informationally equivalent, they are arguably attentionally distinct.

The theory of Attentional Pragmatics is summarized in section 2; section 3 derives a new exhaustivity operator from this theory; and section 4 demonstrates its (partial) conservativeness with regard to existing operators. Section 5 concludes.

## 2. Attentional Pragmatics (summary of Westera 2017)

### 2.1. Framework and formalism

For a clear exposition it is necessary that I summarize the conceptual and formal pragmatic framework adopted in Westera 2017. A core assumption is the following:

**Assumption 1.** Speakers have certain communicative intentions, e.g., to share a piece of information, the objects of which are called “intents”.

Intents are to be distinguished from the (semantic) *contents* of a sentence. This distinction is adopted from Bach and Harnish 1979, and it generalizes Grice’s (1989) distinction between *speaker meaning* and *sentence meaning*. In this paper I will say only very little about semantic contents; I will just presuppose that an adequate semantics exists which, through the maxim of Manner, delivers the assumed intents. Another core assumption is the following:

**Assumption 2.** A goal of making a certain piece of information common ground is not pursued on its own, but as part of what is called a “theme”: a set of propositions that share a certain subject matter and that each ought to be made common ground.

Themes are more commonly called “questions under discussion”, but this gives rise to a poten-

tially harmful confusion between questions as discourse goals, as utterances, as meanings of interrogative sentences and as meanings of embedded interrogative-like constructions.

The assumed intents and themes for the relevant examples, as well as the conversational maxims, will be specified in *Intensional Logic* (Montague, 1973), albeit with doxastic rather than alethic modality and with some additional notation conventions. I refer to the exposition in Gamut 1991 (vol.2) for the basic formalism. As a brief reminder: the operators  $\wedge$  and  $\vee$  signify abstraction over and application to worlds, which will be used in this paper almost exclusively to switch between propositions and their truth values, i.e.,  $\wedge\phi$  can generally be read as “(the proposition) that  $\phi$ ”, and  $\vee p$  as “the proposition  $p$  is true here”. To illustrate, the formula  $\Box(Pj \wedge \mathcal{T}_0(\wedge Pj))$  might express that the speaker takes herself to know that John is at the party and that the proposition that John is at the party is an element of the main theme.

As is common, expressions of certain relevant types will be distinguished typographically. Besides using lowercase for individual constants/variables ( $a, b, c, \dots$  of type  $\langle e, t \rangle$ ) and uppercase for predicates ( $A, B, C, \dots$  of type  $\langle e, t \rangle$ ), I will use lowercase calligraphic constants/variables for propositions ( $\mathcal{a}, \mathcal{b}, \mathcal{c}, \dots$  of type  $\langle s, t \rangle$ ) and uppercase calligraphic for sets of propositions ( $\mathcal{A}, \mathcal{B}, \mathcal{C}, \dots$  of type  $\langle \langle s, t \rangle, t \rangle$ ). Furthermore, as a notational convention, for all unary, first-order predicate constants  $P$ , I may write, e.g.,  $Pjmb$  to mean  $Pj \wedge Pm \wedge Pb$ . In addition, it will occasionally be convenient to conceive of functions of type  $\langle a, t \rangle$  as sets of things of type  $a$ , and to use the usual set-theoretical operations and relations within the object language (these can be defined as mere notational shorthands; Zimmermann 1989). Lastly, for any set-type expression  $X$  I will write  $X^\cap$  to mean the closure of  $X$  under intersection.

In order to formalize the theory, type-theoretical expressions will be interpreted on a subclass of *admissible models*, designed so as to interpret certain constants in a certain way, e.g., the constant I-RELATION will be interpreted basically as the Gricean maxim of I(nformational)-Relation (cf. Montague’s meaning postulates). Admissible models must also validate the KD45 belief axioms, plus *intent introspection* and *theme introspection*, which ensure that the speaker knows the interpretations of constants denoting intents and themes of the utterance (e.g.,  $p_0$  for the main informational intent, i.e., what is asserted) – I leave their definitions implicit. Thus:

**Definition 1** (Admissible model). A model  $\mathbf{M}$  (or  $\langle \mathbf{M}, w_0 \rangle$ ) is an *admissible model* iff:

1.  $\mathbf{M}$  validates (makes true in all its worlds) the KD45 belief axioms;
2.  $\mathbf{M}$  validates intent and theme introspection; and
3.  $\mathbf{M}$  validates the definitions of the maxims, to be given below.

And it is an admissible model *for a given example* if, and only if, in addition:

4.  $w_0$  validates all formal statements given in the example (in a gray box); and
5.  $W$  is sufficiently large, that is, every contingent first-order formula that can be constructed from only constants used in the example, variables, connectives and quantifiers, is true in some  $w \in W$ .

Admissible models for a given example enable us to instantly formalize the relevant parts of a

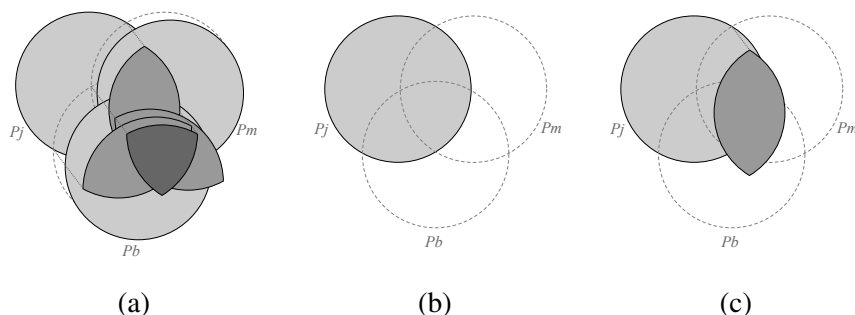

Figure 1: The theme and attentional intents of (2a), (2b) and (2c).

given example and prove potentially interesting things about it, e.g., that an utterance complies with the Gricean maxim of Relation, which is the case if in all admissible models for the example the constant I-RELATION returns true in the actual world, when applied to the relevant intents and themes, and given the beliefs and goals of the speaker.

On top of the common assumption that utterances have themes and intents, we need a particular type of intent to solve the granularity problem (building on Ciardelli et al. 2009):

**Assumption 3.** Utterances have *attentional intents*. An attentional intent is a non-empty set of propositions to which a speaker intends to draw the audience's attention.

Note that an utterance may draw attention to many things, propositions and otherwise, including (but not limited to) everything explicitly mentioned in the utterance – but not everything will be part of what the speaker *intended* to draw attention to, i.e., part of the attentional intent. Note furthermore that the assumption that utterances have attentional *intents* does not commit one to the assumption of a corresponding dimension of attentional semantic *content*. In Westera 2017 it is shown that attentional intents can typically be clearly conveyed without such an enriched semantic dimension, simply on the basis of the informational contents of all uttered constituents.

To illustrate, and also to get acquainted with the formalism, let us consider the intents and themes of (1) with which this chapter started, repeated here as (2):

- (2) a. A: Who (of John, Mary and Bill) is at the party?

$$\mathcal{T}_0 = \{\wedge Pj, \wedge Pm, \wedge Pb\}^\cap \quad \mathcal{A}_0 = \{\wedge Pj, \wedge Pm, \wedge Pb\}^\cap$$

- b. B: John is at the party.

$$\mathcal{T}_0 = \{\wedge Pj, \wedge Pm, \wedge Pb\}^\cap \quad p_0 = \wedge Pj \quad \mathcal{A}_0 = \{\wedge Pj\}$$

- c. B: John is at the party, or John and Mary.

$$\mathcal{T}_0 = \{\wedge Pj, \wedge Pm, \wedge Pb\}^\cap \quad p_0 = \wedge Pj \quad \mathcal{A}_0 = \{\wedge Pj, \wedge Pjm\}$$

For each utterance  $\mathcal{T}_0$  denotes the main theme,  $p_0$  the main informational intent (what is as-

serted) and  $\mathcal{A}_0$  the main attentional intent. Recall that  $\{\dots\}^\cap$  is a notational shorthand for closure under intersection. For independent motivation of the assumed themes and intents I refer to Westera 2017. The assumed attentional intents of (2a), (2b) and (2c) are depicted, from left to right, in figure 1. This type of pictorial representation will be relied upon again further below. In it, each attentional intent is depicted as a Venn diagram on the set of all possible worlds, based on the three atomic propositions of John's, Mary's, and Bill's presence (the circles). Overlapping propositions in the attentional intent – the gray regions – are pulled apart in a third dimension, towards the reader as it were, for clearer presentation.

## 2.2. Maxims governing informational intents

Recall that the maxims are defined by fixing the interpretation of a number of designated constants in the class of admissible models. The *I(nformation)-maxims* closely resemble Grice's (1989, ch.2) maxims (except Manner, which will not play an explicit role in this paper). Grice's informal approach can of course be formalized in different ways, and for a motivation of the following definition I refer to Westera 2017 (e.g., it predicts the right distribution of intonational cues of maxim violations; cf. Westera 2013):

### Definition 2.

1. I-QUALITY( $p$ ) =  $\Box^\vee p$   
“Intend to share only information you take to be true.”
2. I-RELATION( $p, \mathcal{T}$ ) =  $\mathcal{T}(p)$   
“Intend to share only information that is thematic.”
3. I-QUANTITY( $p, \mathcal{T}$ ) =  $\forall q \left( \left( \begin{array}{c} \text{I-QUALITY}(q) \wedge \\ \text{I-RELATION}(q, \mathcal{T}) \end{array} \right) \rightarrow (p \subseteq q) \right)$   
“Intend to share all thematic information you take to be true.”

From this definition we can derive some general results, e.g., that a speaker will always know whether a given intent complies with the I-maxims or not, and that if there exists a compliant intent then it is the only one. We can also compute more concrete predictions, e.g.:

**Fact 1.** For all admissible models  $\langle \mathbf{M}, w_0 \rangle$  for example (2b):

$$\mathbf{M}, w_0 \models \text{I-QUANTITY}(p_0, \mathcal{T}_0) \rightarrow (\neg \Box Pm \wedge \neg \Box Pb)$$

This I-Quantity implication is the starting point of traditional pragmatic accounts of exhaustivity implications. However, since it is (correctly) predicted for (2b) and (2c) alike, it does not provide us with a handle for distinguishing them – this is the granularity problem. Note, furthermore, that the absence of belief ( $\neg \Box Pm$ ) does not entail a belief to the contrary ( $\Box \neg Pm$ ), i.e., exhaustivity. This is the well-known *epistemic step*, which elsewhere I have argued is a genuine empirical problem for the standard, I-Quantity-based recipe for exhaustivity (Westera 2014).

### 2.3. Maxims governing attentional intents

The *A(attention)-maxims* follow the same general recipe as the I-maxims, except for the addition of the maxim of A-Parsimony, which I will briefly motivate shortly:

**Definition 3.**

1. A-QUALITY( $\mathcal{A}$ ) =  $\forall a(\mathcal{A}(a) \rightarrow \Diamond^\vee a)$   
“Intend to draw attention only to propositions that you consider possible.”
2. A-RELATION( $\mathcal{A}, \mathcal{T}$ ) =  $\forall a(\mathcal{A}(a) \rightarrow \mathcal{T}(a))$   
“Intend to draw attention only to thematic propositions.”
3. A-PARSIMONY( $\mathcal{A}, \mathcal{T}$ ) =  $\forall a \left( (\mathcal{A}(a) \wedge \text{A-QUALITY}(\{a\})) \rightarrow \Diamond \left( \bigvee a \wedge \forall b \left( \left( \begin{array}{c} b \subset a \wedge \\ \text{A-RELATION}(\{b\}, \mathcal{T}) \end{array} \right) \rightarrow \neg^\vee b \right) \right) \right)$   
“Intend to draw attention to a proposition only if, if you consider it possible, you consider it possible independently of any more specific thematic proposition(s).”
4. A-QUANTITY( $\mathcal{A}, \mathcal{T}$ ) =  $\forall a \left( \left( \begin{array}{c} \text{A-QUALITY}(\{a\}) \wedge \\ \text{A-RELATION}(\{a\}, \mathcal{T}) \wedge \\ \text{A-PARSIMONY}(\{a\}, \mathcal{T}) \end{array} \right) \rightarrow \mathcal{A}(a) \right)$   
“Intend to draw attention to all thematic propositions you consider independently possible.”

Again some general results can be proven, e.g., that a speaker will always know whether the A-maxims are complied with, and that if there is a compliant attentional intent then it is the only one. As on the informational side, for a motivation of this particular definition of the maxims I refer to Westera 2017. I will here summarize only the motivation for A-Parsimony. Consider a speaker B who believes that if John and Mary are at the party, then so is Bill (i.e.,  $\Box(Pjm \rightarrow Pb)$ ). Now, consider the following two utterances made by this speaker:

- (3) a. B: John is at the party, or John, Mary and Bill.

$$\begin{array}{lll} \Box(Pjm \rightarrow Pb) & & \\ \mathcal{T}_0 = \{\wedge Pj, \wedge Pm, \wedge Pb\}^\cap & \mathcal{A}_0 = \{\wedge Pj, \wedge Pjmb\} & p_0 = \wedge Pj \end{array}$$

- b. (?) B: John is there, or John and Mary, or John, Mary and Bill.

$$\begin{array}{lll} \Box(Pjm \rightarrow Pb) & & \\ \mathcal{T}_0 = \{\wedge Pj, \wedge Pm, \wedge Pb\}^\cap & \mathcal{A}_0 = \{\wedge Pj, \wedge Pjm, \wedge Pjmb\} & p_0 = \wedge Pj \end{array}$$

I take it that the utterance in (3b) is intuitively quite strange: why, given B’s beliefs, did B include the middle disjunct – or, in terms of attentional intents, why did B intend to draw attention to John and Mary’s joint presence ( $\wedge Pjm$ )? The maxim of A-Parsimony predicts precisely this strangeness: drawing attention to John and Mary’s joint presence is not parsimonious, i.e., superfluous, because B does not consider it possible independently of the presence of all three of them ( $\wedge Pjmb$ ). More precisely, it can be proven for (3b) that the attentional intent violates

Figure 2: The theme, attentional intents and exhaustivity implications of (2b) and (2c).

either A-Quality, if  $\wedge Pjmb$  is not in fact considered possible, or A-Parsimony, if it is and  $\wedge Pjm$  is not possible independently of it. In contrast, for (3a) there does exist an admissible model in which all the maxims are complied with.

### 3. Deriving an exhaustivity operator

I will first apply the maxims to some concrete examples, before presenting a general result and a derivative exhaustivity operator. Consider once again the contrast with which this chapter started, with the assumed themes and intents as given in (2), repeated here:

- (2) a. A: Who (of John, Mary and Bill) is at the party?

$$\mathcal{T}_0 = \{\wedge Pj, \wedge Pm, \wedge Pb\}^\cap \quad \mathcal{A}_0 = \{\wedge Pj, \wedge Pm, \wedge Pb\}^\cap$$

- b. B: John is at the party.

$$\mathcal{T}_0 = \{\wedge Pj, \wedge Pm, \wedge Pb\}^\cap \quad p_0 = \wedge Pj \quad \mathcal{A}_0 = \{\wedge Pj\}$$

- c. B: John is at the party, or John and Mary.

$$\mathcal{T}_0 = \{\wedge Pj, \wedge Pm, \wedge Pb\}^\cap \quad p_0 = \wedge Pj \quad \mathcal{A}_0 = \{\wedge Pj, \wedge Pjm\}$$

The exhaustivity implication we wish to derive for (2b) is that B believes that Mary and Bill are not at the party ( $\Box \neg Pm, \Box \neg Pb$ ). For (2c) we want to derive the same for Bill ( $\Box \neg Pb$ ), but not for Mary – with regard to Mary we may want to derive merely that the speaker does not consider Mary’s presence possible independently of John’s ( $\Box(Pm \rightarrow Pj)$ ). The desired implications are depicted schematically in figure 2, which is identical to figure 1 given earlier except for the bold outlines, which contain those worlds that the exhaustivity implications would exclude from the speaker’s doxastic state. Formally, exhaustivity follows from the assumption that B takes her attentional intent to comply with A-Quantity ( $\Box \text{A-QUANTITY}(\mathcal{A}_0, \mathcal{T}_0)$ ). That is, for (2b), as depicted in figure 2(b), we get:

**Fact 2.** For all admissible models  $\langle \mathbf{M}, w_0 \rangle$  for (2b):

$$\mathbf{M}, w_0 \models \Box \text{A-QUANTITY}(\mathcal{A}_0, \mathcal{T}_0) \rightarrow (\Box \neg Pb \wedge \Box \neg Pm)$$

Figure 3: The theme, attentional intent and exhaustivity implication of example (4).

And for (2c), as depicted in figure 2(c), we get:

**Fact 3.** For all admissible models  $\langle \mathbf{M}, w_0 \rangle$  for (2c):

$$\mathbf{M}, w_0 \models \Box \text{A-QUANTITY}(\mathcal{A}_0, \mathcal{T}_0) \rightarrow (\Box \neg Pb \wedge \Box (Pm \rightarrow Pjm))$$

And there exists such a model where:

$$\mathbf{M}, w_0 \not\models \Box \text{A-QUANTITY}(\mathcal{A}_0, \mathcal{T}_0) \rightarrow \Box \neg Pm$$

Instead, for all admissible models for (2c) we have:

$$\mathbf{M}, w_0 \models \Box \text{A-QUALITY}(\mathcal{A}_0) \rightarrow \neg \Box \neg Pm$$

Here the implication that Mary's presence is not possible independently of John's ( $\Box (Pm \rightarrow Pjm)$ ) derives from A-Quantity's conditioning on A-Parsimony: B didn't draw attention to Mary's presence, so she must not consider it possible independently of John and Mary's joint presence. But note that, in this case, the same can be inferred from I-Quality: believing that John is at the party ( $\Box Pj$ ) entails believing that he is if Mary is ( $\Box (Pm \rightarrow Pjm)$ ). Thus, for (2c) A-Parsimony is not strictly necessary. But it does make a difference for the variant in (3a) given earlier, repeated here in (4) (though without the particular beliefs):

(4) B: John is at the party, or John, Mary and Bill.

$$\mathcal{T}_0 = \{\wedge Pj, \wedge Pm, \wedge Pb\}^\cap$$

$$p_0 = \wedge Pj$$

$$\mathcal{A}_0 = \{\wedge Pj, \wedge Pjmb\}$$

Figure 3(a) and (b) depict the assumed theme and the attentional intent, in which the bold outline again contains those worlds excluded by the exhaustivity implication from B's doxastic state. The implication is that, according to B, Mary or Bill can be at the party only if everyone is. Unlike before, this implication follows from A-Quantity and not from I-Quality (since  $\Box \vee Pj$  does not entail  $\Box (Pm \rightarrow Pjmb)$ ). Hence, A-Parsimony does occasionally make a difference.

To derive a more general result, let us restrict our attention to cases where the theme has the property of *chain completeness*, which means that for every chain of ever more specific, thematic propositions, their infinitary intersection is also thematic. The role of this restriction is clarified in the proof in the appendix. The following result obtains:

**Fact 4.** For all admissible models  $\mathbf{M}$ , for arbitrary constants  $\mathcal{A}_i$  and  $\mathcal{T}_j$ , where the theme denoted by  $\mathcal{T}_j$  is chain-complete:

$$\mathbf{M} \models \Box \text{A-QUANTITY}(\mathcal{A}_i, \mathcal{T}_j) \rightarrow \forall a \left( (\mathcal{T}_j(a) \wedge \neg \mathcal{A}_i(a)) \rightarrow \Box(\neg^\vee a \vee \exists b(\mathcal{A}_i(b) \wedge (b \subset a) \wedge^\vee b)) \right)$$

And if in  $\mathbf{M}$  the speaker's beliefs are accurate (factivity), then:

$$\mathbf{M} \models \Box \text{A-QUANTITY}(\mathcal{A}_i, \mathcal{T}_j) \rightarrow \forall a \left( (\mathcal{T}_j(a) \wedge \neg \mathcal{A}_i(a)) \rightarrow (\neg^\vee a \vee \exists b(\mathcal{A}_i(b) \wedge (b \subset a) \wedge^\vee b)) \right)$$

In words: compliance with A-Quantity implies that, for every proposition that is thematic and to which no attention is intended to be drawn, the speaker must think that it does not obtain or that, if it does obtain, a more specific proposition obtains to which attention is intended to be drawn.

We can define a notational shorthand for the second result of fact 4, namely by taking its intension ( $^\wedge$ ), while making sure through abstraction and application that the intent and theme constants are interpreted in the initial world of evaluation. We then get:

**Definition 4.** For  $\mathcal{A}$  and  $\mathcal{T}$  any constant or variable of type  $\langle\langle s, t \rangle, t\rangle$ , let the following notational shorthand be defined:

$$\text{EXH}(\mathcal{A}, \mathcal{T}) \stackrel{\text{def}}{=} \lambda \mathcal{T}' \left( \lambda \mathcal{A}' \wedge \forall a \left( (\mathcal{T}'(a) \wedge \neg \mathcal{A}'(a)) \rightarrow (\neg^\vee a \vee \exists b(\mathcal{A}'(b) \wedge (b \subset a) \wedge^\vee b)) \right) (\mathcal{A}) \right) (\mathcal{T})$$

Note that this exhaustivity operator is not a substantive assumption of the theory, but a mere notational shorthand for the exhaustivity implications that are predicted by the theory anyway, at least in admissible models, given factivity and compliance with A-Quantity. The operator can also be formulated in the metalanguage, in a more set-theoretical fashion (parameters  $\mathbf{M}, w, g$  for the interpretation function  $[\cdot]$ , omitted for readability, are the same throughout):

**Fact 5.** For arbitrary constants or variables  $\mathcal{A}$  and  $\mathcal{T}$ :

$$[\text{EXH}(\mathcal{A}, \mathcal{T})] = \bigcap_{\substack{a \in [\mathcal{T}] \\ a \notin [\mathcal{A}]}} (\bar{a} \cup \bigcup_{\substack{b \in [\mathcal{A}] \\ b \subset a}} b)$$

This obtains fairly directly, and I will omit a formal proof: the universal quantifier in definition 4 corresponds here to generalized intersection; negation to complementation, disjunction to union and existential quantification to generalized union. To illustrate, notice that the complements of the bold outlines in figures 2 and 3 given earlier correspond precisely to the sets of worlds characterized by the exhaustivity operator, when applied to the relevant themes and intents.

Figure 4: The theme and attentional intent (with exhaustivity implication) of (5B).

To illustrate the operator, let us consider a slightly more elaborate example:

(5) A: How many kids does John have?

B: John has one, three, or five kids.

$$\begin{aligned} \mathcal{T}_0 &= \{^K0, ^K1, ^K2, ^K3, ^K4, \dots\} & \mathcal{A}_0 &= \{^K1, ^K3, ^K5\} \\ p_0 &= ^K1 \quad (\text{equivalent to } ^K(K1 \vee K3 \vee K5)) \end{aligned}$$

I assume an “at least”-interpretation of numerals for the sake of illustration (the structure of interest can be replicated without numerals). The theme and the attentional intent of (5B) are depicted in figure 4. The striped regions together contain the worlds that are excluded by the operator (like the bold outlines before). The outcome of the operator can be computed as follows, now writing bare numerals  $n$  as a shorthand for  $^K n$ :

$$\begin{aligned} \text{EXH}(\mathcal{A}_0, \mathcal{T}_0) &= (\bar{0} \cup 1 \cup 3 \cup 5) \cap (\bar{2} \cup 3 \cup 5) \cap (\bar{4} \cup 5) \cap \bar{6} \cap \bar{7} \cap \dots \\ &= 1 \cap (\bar{2} \cup 3) \cap (\bar{4} \cup 5) \cap \bar{6} \\ &= (1 \cap \bar{2} \cap \bar{4} \cap \bar{6}) \cup \dots \cup (1 \cap 3 \cap \bar{4} \cap \bar{6}) \cup \dots \cup (1 \cap 3 \cap 5 \cap \bar{6}) \\ &= (1 \cap \bar{2}) \cup (3 \cap \bar{4}) \cup (5 \cap \bar{6}) \end{aligned}$$

The last line says that John has exactly one, exactly three, or exactly five kids.

#### 4. (Partial) conservativeness with regard to existing operators

The current exhaustivity operator is motivated pragmatically. In contrast, existing operators tend to have been motivated either only descriptively (Groenendijk and Stokhof, 1984; Alonso-Ovalle, 2008) or, in part, in terms of I-Quantity (as in Schulz and Van Rooij 2006; Spector 2007); and sometimes they are conceived of as grammatical devices (e.g., Fox, 2007; Chierchia et al., 2012; Katzir and Singh, 2013). Different motivations may justify different applications of the operator, and hence lead to different empirical predictions even if the operators would be equivalent when regarded purely as abstract mathematical objects. Nevertheless, let us compare the current operator to previous ones at this abstract, mathematical level. I will consider three operators:

1. the *minimal worlds* operator  $\text{EXH}_{\text{mw}}$  discussed in Spector 2016 (attributed to Spector 2007 and Schulz and Van Rooij 2006);
2. the *innocent exclusion* operator  $\text{EXH}_{\text{ie}}$  from Alonso-Ovalle 2008 (based on the notion of innocent exclusion from Fox 2007); and
3. the *dynamic* operator  $\text{EXH}_{\text{dyn}}$  from Schulz and Van Rooij 2006.

I will also discuss the grammatical approach, which applies an operator like  $\text{EXH}_{\text{mw}}$  to each disjunct separately. Correspondences between these operators and the current one will be stated only for cases in which (i) application of the current operator is warranted, and (ii) the other operator was intended to apply. Condition (i) is satisfied in *operable models*:

**Definition 5** (Operable model). An admissible model  $\langle \mathbf{M}, w_0 \rangle$  is *operable* if and only if the speaker's beliefs are accurate (factivity), in  $w_0$  the relevant intents comply with the maxims relative to the relevant themes, and the set of thematic propositions in  $w_0$  is chain-complete.

Although I will state (partial) correspondences to each of the aforementioned operators, for reasons of space a proof will be given (in the appendix) only for the third.

First, the **minimal worlds** operator (Schulz and Van Rooij, 2006; Spector, 2007, 2016) can be defined in the current framework by temporarily adding  $\text{EXH}_{\text{mw}}$  to the language, with the following semantics (as before, the omitted parameters of  $[\cdot]$  are the same everywhere):

**Definition 6.** For arbitrary constants/variables  $p$  and  $\mathcal{T}$ , let:

$$[\text{EXH}_{\text{mw}}(p, \mathcal{T})] \stackrel{\text{def}}{=} \{w \in [p] \mid \text{there is no } w' \in [p] \text{ such that:} \\ \{a \mid a \in [\mathcal{T}], w' \in a\} \subset \{a \mid a \in [\mathcal{T}], w \in a\}\}$$

That is, the proposition denoted by  $p$  must be true in the relevant worlds  $w$ , together with a set of other thematic propositions that is *minimal* compared to the sets of true thematic propositions in other worlds  $w'$  in which the proposition denoted by  $p$  is true. The minimal worlds operator aligns with the current operator if the attentional intent is a singleton set:

**Fact 6.** Take any utterance with intents denoted by  $p_i$  and  $\mathcal{A}_j$  such that  $\mathcal{A}_j = \{p_i\}$  is true, and theme denoted by  $\mathcal{T}_k$ . For any admissible, operable model  $\langle \mathbf{M}, w_0 \rangle$  for such an utterance:

$$\mathbf{M}, w_0 \models \text{EXH}_{\text{mw}}(p_i, \mathcal{T}_k) = p_i \cap \text{EXH}(\mathcal{A}_j, \mathcal{T}_k)$$

This result shows that the operators align when attention does not really make a difference. I refer to Spector 2016 for a detailed comparison of the operator  $\text{EXH}_{\text{mw}}$  to other existing operators from Krifka 1993 and Fox 2007. None of these operators can distinguish between (1a) and (1b) with which this chapter started – this is the granularity problem.

Second, the **innocent exclusion** operator of Alonso-Ovalle (2008) is formulated in terms of *Alternative Semantics*, but it can be readily applied to attentional intents. It relies on a set IE of *innocently excludable* propositions, a notion adopted from Fox 2007:

**Definition 7.** For  $A$  a set of propositions, and  $A^\cap$  its closure under intersection, let:

$$\text{IE}(A) \stackrel{\text{def}}{=} \{a \in A^\cap \mid \text{for all } b \in A, \text{ any way of excluding from } b \text{ as many} \\ a' \in A^\cap \text{ as consistency allows, excludes also } a\}$$

In terms of innocent exclusion, the operator is defined as follows:

**Definition 8.** For an arbitrary constant/variable  $\mathcal{A}$ :

$$[\text{EXH}_{\text{ie}}(\mathcal{A})] \stackrel{\text{def}}{=} \bigcup [\mathcal{A}] \cap \bigcap_{a \in \text{IE}([\mathcal{A}])} \bar{a}$$

This operator aligns with the current one with regard to (1a) and (1b) (i.e., (2b,c)). However, for the variant “John, or John, Mary and Bill” in (4) it fails to predict exhaustivity. One problem is that Alonso-Ovalle does not derive the theme from some preceding question, but computes it from the utterance itself by taking the set of disjuncts and closing this set under intersection. A more serious problem is that his operator never excludes *part* of a proposition, like in (4) the part of the proposition denoted by  $^{\wedge}P_{jm}$  that is not contained in the proposition denoted by  $^{\wedge}P_{jmb}$  – after all, a proposition is not “innocently excludable” if it contains a proposition that isn’t. Still, for a restricted set of cases our operators are formally equivalent:

**Fact 7.** Take any utterance with intents denoted by  $p_i$  and  $\mathcal{A}_j$  and theme denoted by  $\mathcal{T}_k$  s.t.:

- $p_i = \bigcup \mathcal{A}_j$ ;
- $\mathcal{T}_k = \mathcal{A}_j^{\cap}$ ; and
- $\forall a((\mathcal{T}_k(a) \wedge \neg \mathcal{A}_j(a)) \rightarrow \neg \exists b(b \subset a \wedge \mathcal{A}_j(b)))$ .

For any admissible, operable model  $\langle \mathbf{M}, w_0 \rangle$  for such an utterance:

$$\mathbf{M}, w_0 \models \text{EXH}_{\text{ie}}(\mathcal{A}_j) = (p_i \cap \text{EXH}(\mathcal{A}_j, \mathcal{T}_k))$$

The third bullet excludes cases like (4), where mere parts of propositions need to be excluded.

Third, the **dynamic** operator  $\text{EXH}_{\text{dyn}}$  of Schulz and Van Rooij 2006 is in a way a modification of the “minimal worlds” operator  $\text{EXH}_{\text{mw}}$ , the difference being that  $\text{EXH}_{\text{dyn}}$  does not minimize the set of true thematic propositions among *all* worlds in the informational intent, but only within certain subsets. I will bypass the details of how they determine these subsets, a matter for which they use *dynamic semantics* – in a nutshell, they compare only world-assignment pairs that share the same assignment (discourse referents). At least for disjunctive utterances, which they assume introduce a discourse referent for each disjunct, this amounts simply to comparing only worlds within some proposition in the attentional intent. Hence, for present purposes their operator can be (re)defined as follows:

**Definition 9.** For arbitrary constants/variables  $\mathcal{A}$ , and  $\mathcal{T}$ , let:

$$[\text{EXH}_{\text{dyn}}(\mathcal{A}, \mathcal{T})] = \{w \mid \text{for some } a \in [\mathcal{A}]: w \in a \text{ and there is no } w' \in a \\ \text{s.t. } \{b \mid b \in [\mathcal{T}], w' \in b\} \subset \{b \mid b \in [\mathcal{T}], w \in b\}\}$$

Whether this definition corresponds exactly to theirs depends on the degree to which the current attentional intents align with what they consider to be discourse referents – a matter which I

defer to Westera 2017. But as it is defined here the operator  $\text{EXH}_{\text{dyn}}$  can distinguish between (1a) and (1b), as well as account for (4) – indeed, our operators align quite generally:

**Fact 8.** Take any utterance with intents denoted by  $p_i$  and  $\mathcal{A}_j$  and a theme denoted by  $\mathcal{T}_k$ , and for which the following is true:

- $p_i = \bigcup \mathcal{A}_j$ ; and
- $\mathcal{T}_k = \mathcal{T}_k^\cap$ .

For any admissible, operable model  $\langle \mathbf{M}, w_0 \rangle$  for such an utterance:

$$\mathbf{M}, w_0 \models \text{EXH}_{\text{dyn}}(\mathcal{A}_j, \mathcal{T}_k) = (p_i \cap \text{EXH}(\mathcal{A}_j, \mathcal{T}_k))$$

This highlights that the contribution of this paper is not the exhaustivity operator in itself but its derivation from Attentional Pragmatics. In contrast, Schulz and Van Rooij offer only a partial explanation for their operator – they do not motivate its sensitivity to discourse referents, which is precisely what gives it an edge over the other operators. The part which they do motivate (basically  $\text{EXH}_{\text{mw}}$ ) relies on I-Quantity, and hence runs into the granularity problem.

Lastly, let us consider the **grammatical approach** to exhaustivity, which assumes that operators like  $\text{EXH}_{\text{mw}}$  are covertly applied to each disjunct separately. The dynamic operator  $\text{EXH}_{\text{dyn}}$ , by virtue of its definition, effectively “exhaustifies” each individual disjunct in a similar fashion. Hence, fact 8 entails a correspondence also between the current operator (as well as  $\text{EXH}_{\text{dyn}}$ ) and the grammatical approach. Nevertheless, Attentional Pragmatics *doesn’t* predict, unlike the grammatical approach, that individual disjuncts are interpreted exhaustively. Roughly, the difference between our approaches can be paraphrased as follows:

(6) B: John, or John, Mary and Bill.

a. **Grammatical approach:** John *and no one else* was there, or John, Mary and Bill.  
 $(Pj \wedge \neg Pm \wedge \neg Pb) \vee Pjmb)$

b. **Attentional Pragmatics:** John was there, or John, Mary and Bill – *and if Mary or Bill was there then everyone was.*  $((Pj \vee Pjmb) \wedge ((Pm \vee Pb) \rightarrow Pjmb))$

Although the two paraphrases (and formulae) are classically, informationally equivalent, only (6a) involves the exhaustive interpretation of an individual disjunct. What this shows is that some at first sight “local” exhaustivity effects can be predicted by a globalist pragmatic theory – of course provided it is sensitive to some dimension of speaker meaning that, while global, reflects the syntactic structure of the uttered sentence more closely than informational intents do (cf. Simons 2011). This doesn’t mean that Attentional Pragmatics can account for *all* purportedly local exhaustivity effects – such effects may well be a mixed bag (Geurts, 2011). Nor does a formal correspondence mean that Attentional Pragmatics and the grammatical approach make the same predictions – this depends, after all, on where and when the grammatical approach predicts that operators be inserted, and what their sets of formal alternatives are.

Several proponents of the grammatical approach have proposed that local exhaustification is driven by considerations of redundancy (e.g., Katzir and Singh 2013; essentially following Hurford 1974). They note that, in cases like (6), the stronger disjunct does not contribute to the

information conveyed by the utterance *unless* the weaker disjunct is interpreted exhaustively. However, as Ciardelli and Roelofsen (2016) demonstrate, this explanation may fail when one's semantics/pragmatics is more fine-grained than the traditional, information-only picture: for instance, constituents that are informationally redundant can still make an attentional difference. Indeed, according to Attentional Pragmatics the second disjunct in (6) isn't redundant, and as a consequence this theory is incompatible with redundancy-based accounts of local exhaustification in such disjunctions. Note that this doesn't mean that redundancy has no role to play in pragmatics. For one, informational redundancy may still play a role in *conjunctions* where one conjunct entails the other (because from I-Quality and A-Parsimony it follows that the attentional intent may rationally contain only the conjunction as a whole). Moreover, the maxim of A-Parsimony essentially bans an *attentional* kind of redundancy.

## 5. Discussion

According to Attentional Pragmatics, exhaustivity implications arise not from the assumption that a rational speaker asserts all thematic propositions believed to be true, nor from local exhaustification driven by considerations of redundancy, but from the assumption that a rational speaker draws attention to all thematic propositions believed to be possible. This new perspective provides a globalist pragmatic solution to the granularity problem, one which the current paper captured in an operator. It also solves several other problems for the standard, information-based approach; I refer to Westera 2017 for an application to the occurrence of exhaustivity in cases where I-Quantity does not apply (hints, questions) and cases where the opinionatedness assumption is explicitly denied, as well as a solution to the symmetry problem. If valid, this attentional approach mandates a thorough revision of the literature on exhaustivity.

At a purely technical level, the current paper may seem to suggest that the required revision is rather minimal: the operator derived from Attentional Pragmatics is, as a purely formal device, in important respects conservative with regard to operators from the literature. However, the range of circumstances in which its application is pragmatically warranted is more restricted than the frequent reliance on exhaustivity operators in the literature seems to require. It excludes, for instance, the local operators that grammaticalists assume, but also certain global occurrences. For instance, Schulz and Van Rooij (2006) seek to apply their operator directly to conditional answers to unconditional questions, and to modalized answers to non-modalized questions, but these are cases for which in the current approach no "operable" admissible models exist: conditional/modal answers cannot compliantly address the theme introduced by unconditional/non-modal questions, hence we must not seek to directly apply our operator to them. These cases must be analyzed, rather, as involving a *theme shift*, to be explained by a separate "theme pragmatics" (Westera, 2017), i.e., a theory of how conversational goals are prioritized and organized into themes. The current maxims, in contrast, constrain only which intentions are rational *given* a theme, i.e., a set of goals.

More generally, the restrictions on the current operator's applicability reflect that it abbreviates only a rather small part of a pragmatic theory. The operator of Schulz and Van Rooij seems more ambitious; they motivate it by stating that "none of these [previously proposed] theories gives a satisfying explanation for why the scope of exhaustive interpretation should be restricted

to those cases that they can actually handle” (p.8). But the converse is true as well: none of these existing theories, including Schulz and Van Rooij’s, gives a satisfying explanation for why the cases that their operators appear to handle are cases that they *should* handle. If all you have is a hammer, everything looks like a nail (e.g., Maslow, 1966). By acknowledging the limited applicability of the current exhaustivity operator, and the unknown applicability of existing ones, we may begin to see subtle differences between different types of exhaustivity-like inferences, and between the types of conversational goals that are normally served by conditional and unconditional answers or plain and modalized answers.

## Appendix. Proofs of facts 4 and 8

**Proof of fact 4:** Take an arbitrary admissible model  $\mathbf{M}$  in which  $\mathcal{T}_j$  complies with the chain completeness restriction. Take an arbitrary world  $w$  in this model. Suppose that the speaker takes A-Quantity to be complied with, i.e.,  $\mathbf{M}, w \models \Box \text{A-QUANTITY}(\mathcal{A}_i, \mathcal{T}_j)$ . Given intent and theme introspection, this means that A-Quantity is actually complied with in  $w$ :

$$\mathbf{M}, w \models \forall a \left( \left( \begin{array}{c} \text{A-QUALITY}(\{a\}) \wedge \\ \text{A-RELATION}(\{a\}, \mathcal{T}_j) \wedge \\ \text{A-PARSIMONY}(\{a\}, \mathcal{T}_j) \end{array} \right) \rightarrow \mathcal{A}_i(a) \right) \quad (1)$$

Take an arbitrary function  $g$  that assigns to  $a$  a thematic proposition, i.e., suppose that:

$$\mathbf{M}, w, g \models \mathcal{T}_j(a) \quad (2)$$

Suppose, furthermore, that no attention is drawn to  $a$  in  $w$ :

$$\mathbf{M}, w, g \models \neg \mathcal{A}_i(a) \quad (3)$$

Since  $\mathcal{A}_i(a)$  is false in  $w$ , the antecedent in (1) cannot be true either, hence at least one of its conjuncts must be false. A-Relation cannot be blamed, because the proposition denoted by  $a$  is thematic in  $w$  (from supposition (2)), so it must be either A-Quality or A-Parsimony. Let us explore the latter.

Suppose that the singleton intent denoted by  $\{a\}$  does not comply with A-Parsimony in  $w$ , i.e.,  $\mathbf{M}, w, g \models \neg \text{A-PARSIMONY}(\{a\}, \mathcal{T}_0)$ . This amounts to:

$$\mathbf{M}, w, g \models \Diamond^\vee a \wedge \Box (\vee a \rightarrow \exists b (b \subset a \wedge \mathcal{T}_0(b) \wedge \vee b)) \quad (4)$$

It follows that there exists a world  $w'$  that is belief-accessible from  $w$ , such that the proposition assigned to  $a$  is true in  $w'$ , and, by the second conjunct, some stronger proposition can be assigned to  $b$  that is true and thematic in  $w'$ . This means that in the original world  $w$ , the proposition assigned to  $b$  must be considered possible and, by theme introspection, thematic. Hence, we have:

$$\mathbf{M}, w, g \models \exists b (b \subset a \wedge \mathcal{T}_0(b) \wedge \Diamond^\vee b)$$

Since this stronger proposition  $b$  is thematic and possible, A-Quantity (which is complied with according to (1)) requires that it be an element of the attentional intent denoted by  $\mathcal{A}_i$  in  $w$ , unless A-Parsimony prevents this, i.e., unless there is an even stronger thematic and possible

proposition (say,  $c$ ), independently of which  $b$  in turn is not considered possible. And so on, potentially *ad infinitum*.

To curb this potential infinitude, assume that the set of thematic propositions is *chain-complete*, i.e., that for every chain of increasingly specific thematic propositions  $a_0, a_1, \dots$  (i.e., such that every  $a_{i+1} \subset a_i$ ), their infinitary intersection  $\bigcap \{a_0, a_1, \dots\}$  is also thematic. This guarantees that there exists a maximally specific thematic and possible proposition, and according to A-Quantity that must be an element of the attentional intent denoted by  $\mathcal{A}_i$ . This means that we can strengthen supposition (4) by adding the conjunct  $\mathcal{A}_i(b)$ , which after dropping the conjunct  $\mathcal{T}_0(b)$  yields the following:

$$\mathbf{M}, w, g \models \Diamond^\vee a \wedge \Box(\vee a \rightarrow \exists b(b \subset a \wedge \mathcal{A}_i(b) \wedge \vee b))$$

This was derived, recall, from the supposition that the singleton intent denoted by  $\{a\}$  does not comply with A-Parsimony in  $w$ , i.e., that A-Parsimony is the reason why the proposition assigned to  $a$  is not an element of the attentional intent denoted by  $\mathcal{A}_i$ . The other possible reason was A-Quality, i.e.,  $\neg\Diamond^\vee a$ . Hence, we can conclude the disjunction of these two reasons:

$$\begin{aligned} \mathbf{M}, w, g &\models \neg\Diamond^\vee a \vee (\Diamond^\vee a \wedge \Box(\vee a \rightarrow \exists b(b \subset a \wedge \mathcal{A}_i(b) \wedge \vee b))) \\ \text{which implies: } \mathbf{M}, w, g &\models \Box(\neg\vee a \vee \exists b(b \subset a \wedge \mathcal{A}_i(b) \wedge \vee b)) \end{aligned}$$

By retracting suppositions (2) and (3) we obtain:

$$\mathbf{M}, w \models \forall a \left( (\mathcal{T}_j(a) \wedge \neg\mathcal{A}_i(a)) \rightarrow \Box(\neg\vee a \vee \exists b(\mathcal{A}_i(b) \wedge b \subset a \wedge \vee b)) \right)$$

And by retracting supposition (1), i.e., that A-Quantity is (believed to be) complied with, we obtain the first result in fact 4. The second result directly derives from this through factivity.

The restriction to chain-complete themes is only a presentational choice, that allows a simpler formulation of the main result. It is not indicative of, say, some sort of defect in the maxims. I don't think that, relative to a theme like that is not chain-complete, a speaker could rationally behave differently from what the current maxims predict, namely, to not draw attention to any particular proposition in the chain. If anything, a rational speaker may want to consider switching to a chain-complete theme instead.

**Proof of fact 8:** We prove the equivalence of the two operators by proving inclusion right-to-left and then left-to-right. First right-to-left: in an arbitrary admissible, operable model  $\langle \mathbf{M}, w_0 \rangle$  of the specified type of utterance, take a world  $w \in [p_i \cap \text{EXH}(\mathcal{A}_j, \mathcal{T}_k)]_{\mathbf{M}, w_0, g}$ . Given that  $p_i = \bigcup \mathcal{A}_j$  is true in  $w_0$ , there must be some  $a \in [\mathcal{A}_j]_{\mathbf{M}, w_0, g}$  such that  $w \in a$ . Moreover, given the chain-completeness restriction on themes in operable models, and given compliance with A-Relation, there must be a most specific (strongest, smallest) proposition  $a$  of that sort. From our exhaustivity operator it follows that every thematic proposition to which no attention is drawn is either false in  $w$ , or entailed by this most specific  $a$ . Hence,  $w$  makes the proposition  $a$  true and anything entailed by it, but no other thematic propositions. Within  $a$ , then, there is no  $w' \in a$  where the set of true thematic propositions is smaller than in  $w$ . Hence (by definition)  $w \in [\text{EXH}_{\text{dyn}}(\mathcal{A}_j, \mathcal{T}_k)]_{\mathbf{M}, w_0, g}$ .

Conversely, take an arbitrary world  $w \in [\text{EXH}_{\text{dyn}}(\mathcal{A}_j, \mathcal{T}_k)]_{\mathbf{M}, w_0, g}$ . According to the definition of  $\text{EXH}_{\text{dyn}}$ , there must be some  $a \in [\mathcal{A}_j]_{\mathbf{M}, w_0, g}$  such that  $w \in a$  and  $w$  makes a minimal number of thematic propositions true, compared to other  $w' \in a$ . Given the chain-completeness restriction and compliance with A-Relation, there must be a most specific (strongest, smallest)  $a$  of that sort. Within this most specific  $a$ , any minimal set of true thematic propositions will contain  $a$  and anything entailed by it, but nothing else. (This is because, if a minimal set of true thematic propositions had contained another thematic proposition  $a'$ , then the intersection  $a \cap a'$  would have been thematic as well (by assumption of closure under intersection), and  $a$  would not have been possible independently of these more specific intersections, contrary to A-Parsimony, and would not have been included in the attentional intent.) Hence, this world  $w$  is contained in  $a$ , to which attention is drawn, but in no more specific thematic proposition. By definition, my operator contains all such worlds. Moreover, given that  $p_i = \bigcup \mathcal{A}_j$  is true in  $w_0$ , we have that  $w \in [p_i]_{\mathbf{M}, w_0, g}$ , and hence  $w \in [p_i \cap \text{EXH}(\mathcal{A}_j, \mathcal{T}_k)]_{\mathbf{M}, w_0, g}$ .

## Question agnosticism and change of state<sup>1</sup>

Aaron Steven WHITE — *Johns Hopkins University*

Kyle RAWLINS — *Johns Hopkins University*

**Abstract.** We give an account of the selectional behavior of cognitive change-of-state verbs, such as *decide*, that attempts to reduce this behavior to their change-of-state event structure. In particular, we argue that, if a cognitive verb is change-of-state, it is *Q-agnostic*—i.e. it selects both declarative and interrogative clauses. This augments previous accounts of Q-agnosticism, which have tied the distribution of declarative and interrogative clauses to semantic/pragmatic notions like factivity and veridicality but which fail on nonveridical predicates like *decide*.

**Keywords:** lexical aspect, clause embedding, change of state, factivity, veridicality

### 1. Introduction

A verb's syntactic distribution is sensitive to properties of the class of events that that verb characterizes. However, not all conceivable event properties correlate with syntactic distribution. A major question in the lexical semantics literature is therefore: which event properties impact argument distribution and by what mechanisms (Gruber, 1965; Fillmore, 1970; Zwicky, 1971; Jackendoff, 1972; Grimshaw, 1979, 1990; Pesetsky, 1982, 1991; Pinker, 1989; Levin, 1993)?

For 'action verbs'—e.g. *hit* and *break*—most proposals converge on event properties such as dynamicity, telicity, change of state, and causation (see Levin and Rappaport Hovav 2005 for a review). This set differs radically from the set of properties often proposed to be relevant in determining the distribution of embedded clauses—e.g. representationality (Bolinger, 1968; Stalnaker, 1984; Farkas, 1985; Villalta, 2000, 2008; Scheffler, 2009; Anand and Hacquard, 2013), factivity (Hintikka, 1975), veridicality (Egré, 2008; Spector and Egré, 2015), and a range of other intentional (Moulton, 2009; Rawlins, 2013) and discourse-related properties (Hooper, 1975; Portner and Rubinstein, 2013; Anand and Hacquard, 2014).

In this paper, we give an account of the selectional behavior of cognitive change-of-state predicates, like *decide*. Our main claims are (i) that it is the change-of-state nature of *decide* that determines its selectional behavior and (ii) that our analysis of *decide* can be straightforwardly extended to cover a large range of what we term *Q(uestion)-agnostic* verbs—verbs which take both interrogative and declarative clauses (often termed *responsives* following Lahiri 2002).

In making this proposal, we are responding to prior approaches that attempt to reduce Q-agnosticism to properties such as factivity and veridicality (Egré 2008; cf. Hintikka 1975; Spector and Egré 2015). Verbs like *decide* are well-known counterexamples to these existing proposals, since *decide* is neither factive nor veridical in examples like (1)—decisions may be rescinded or simply not realized—yet it is Q-agnostic.

---

<sup>1</sup>We'd like to thank audiences at Sinn und Bedeutung 21, the JHU Semantics Lab, and the factivity MINSIM workshop at UMD in December 2016 as well as Valentine Hacquard and Pranav Anand for helpful discussion.

- (1) Jo decided (whether) {to leave, she would leave}.

These verbs' status as counter-examples (we argue) has yet to be explained. Indeed, we suggest that the correlation between factivity/veridicality and Q-agnosticism actually obscures the fact that change-of-state is a key property for determining Q-agnosticism.

To carry this argument out, we develop a detailed account of the lexical semantics of *decide*. Our analysis is that deciding characterizes a change from a *pre-state*—which can involve either a set of alternative intentions that the agent is deciding between or a single fixed intention—to a *post-state* where some intention has been fixed on the part of the agent. Declarative complements always characterize the post-state intention, while interrogative complements characterize pre-state intentions involving multiple alternatives.

Much of the technical effort lies in deriving these facts from a core meaning for *decide* in a neo-Davidsonian event semantics with a Hacquardian (2010) approach to eventuality *content*. We suggest that this effort is worth it, since the pattern observed for *decide* generalizes to other cognitive change-of-state-verbs: interrogative clauses consistently characterize pre-state alternatives and declarative clauses consistently characterize post-state propositions.

In a wider context, our aim is to demonstrate that action verbs and clause-embedding verbs might not be so different in the properties that determine the distribution of arguments: properties like change-of-state are relevant to both. This proposal helps to reveal formal similarities between entailments that arise as a consequence of event structure and entailments related to the intentional properties of propositional attitudes. We believe these formal similarities will be useful in unifying theories that rely on event structural properties to explain syntactic distribution and those that rely on intentional properties.

We begin in Section 2 with a discussion of previous proposals that relate Q-agnosticism and veridicality. In Section 3, we apply those previous proposals to nonveridical predicates, showing some further necessary refinements to handle the particular data for *decide*. In Section 4, we present our proposal for *decide* and other change-of-state nonveridicals, as well as a compositional implementation. In Section 5, we conclude with prospects for generalizing our approach to other subclasses of Q-agnostic predicates, including epistemics and communicatives.

## 2. Veridicality, distribution, and interpretation

To begin, we discuss the generalizations that decision verbs are exceptions to, introducing two ways that veridicality and Q-agnosticism are believed to be related: in determining (i) the distribution of interrogatives and declaratives; and (ii) the interpretation of interrogatives.

### 2.1. Veridicality and embedded clause distribution

It has long been known that the distributions of interrogative and declarative embedded clauses are independent. Some clause-embedding predicates only take interrogative complements, such

as *wonder* (2a); some predicates only take declarative complements, such as *believe* (2b); and some predicates take both interrogative and declarative complements, such as *know* (2c).

- |     |    |                                                  |                    |
|-----|----|--------------------------------------------------|--------------------|
| (2) | a. | Jo didn't wonder {*that, whether} Bo was smart.  | <i>Q-accepting</i> |
|     | b. | Jo didn't believe {that, *whether} Bo was smart. | <i>Q-rejecting</i> |
|     | c. | Jo didn't know {that, whether} Bo was smart.     | <i>Q-agnostic</i>  |

The Q-agnostic predicates in particular have been of interest in the syntax and semantics literature, in large part because they bear on a variety of important topics, including the interpretation of questions and the treatment of polysemy (Karttunen, 1977; Groenendijk and Stokhof, 1984; Heim, 1994; Ginzburg, 1995; Lahiri, 2002; George, 2011; Uegaki, 2015); but they are also interesting because a verb's Q-agnosticism appears to be predictable from the sorts of inferences that verb triggers about its embedded clause (cf. Hintikka, 1975).

Specifically, among the well-studied clause-embedding verbs there is a relatively strong correlation between whether a predicate is veridical—i.e. whether it entails the content of its embedded clause—and whether it is Q-agnostic (Egré, 2008). Veridical predicates, like *know*, *realize*, and *prove*, tend to be Q-agnostic (3a), and nonveridical predicates, like *believe*, *think*, and *hope*, tend not to be (3b).

- |     |    |                                                                          |
|-----|----|--------------------------------------------------------------------------|
| (3) | a. | Jo {knows, realized, proved} that Bo is home. $\rightarrow$ Bo is home.  |
|     | b. | Jo {believes, thinks, hopes} that Bo is home. $\nrightarrow$ Bo is home. |

Indeed, Egré (2008) argues that this correlation is perfect: a predicate is Q-agnostic if and only if it is veridical. Defending this claim requires him to explain the apparent Q-agnosticism of two kinds of counterexamples: nonveridical communicative predicates, like *tell* (4a) and *agree* (4b); and nonveridical cognitive predicates, like our key example *decide* (4c), as well as adjectival predicates like *be certain* (4d).<sup>2</sup>

- |     |    |                                                      |
|-----|----|------------------------------------------------------|
| (4) | a. | Jo told Mo {that, whether} Bo was home.              |
|     | b. | Jo agreed with Mo {that, about whether} Bo was home. |
|     | c. | Jo decided {that, whether} she should leave.         |
|     | d. | Jo wasn't certain {that, whether} she should leave.  |

Egré argues that (except for *tell*) none of the predicates in (4) are truly Q-agnostic. Rather, when they take a question, there is really a (sometimes silent) preposition mediating the relationship. Thus, Egré's revised generalization is that only veridicals can take both declaratives and interrogatives *directly*—i.e. without mediation by a preposition. As evidence for this position, he notes that predicates like *agree*, *decide*, and *be certain* all at least can mediate the syntactic relationship between a predicate and an interrogative via a preposition.

- |     |    |                                              |
|-----|----|----------------------------------------------|
| (5) | a. | Jo agreed with Mo about whether Bo was home. |
|     | b. | Jo decided (about) whether she should leave. |

<sup>2</sup>These are counterexamples to the *only if* direction. Egré also discusses counterexamples to the *if* direction, such as *be true* and *be right*. These are not relevant for current purposes.

- c. Jo wasn't certain (about) whether she should leave.

This position is useful for integrating nonveridicals into the standard treatment of embedded interrogatives, which has that embedded interrogatives denote a true answer (Karttunen 1977; Groenendijk and Stokhof 1984; though see Hamblin 1973). We turn to this assumption next.

## 2.2. Veridicality, true answers, and possible answers

Veridicality has also played a key role in explaining the interpretation of embedded interrogatives, in the form of what we will call the *true-answers assumption*—the assumption that embedded interrogatives denote a set of true answers to the question. The true-answers assumption works well for predicates like *know*, which do indeed seem to relate individuals to true answers, and it would seem to connect directly to the above selectional hypothesis. Suppose, by the true-answers assumption, that (6) is true for all Q-agnostics *V*.

### (6) A true-answerhood constraint for Q-agnostics

$$\forall x, Q, w : \llbracket V_{int} \rrbracket^w(Q)(x) \leftrightarrow \exists p \in \text{ANS}_{w@}(Q) : \llbracket V_{decl} \rrbracket^w(p)(x)$$

(cf. Dayal, 1996)

where  $\text{ANS}_w(Q) = \{p \in Q : p(w)\}$

Then, we correctly predict (7) to be infelicitous: what Jo knows cannot fail to be wrong, since what she knows is, by definition, true—and in this case, uniquely true.

- (7) Jo knew whether Bo was home, #but she was wrong.

Just as the veridical selectional hypothesis hits problems for nonveridicals, so of course does the true-answers assumption; these problems have been discussed for predicates like *agree* (8a) and of course *decide* (8b). Intuitively, such verbs do not seem to relate individuals to true answers (Beck and Rullmann, 1999; Lahiri, 2002); people might agree on a falsehood, or decide to do something impossible. If (6) were true for all Q-agnostics, then (8a) and (8b), like (7), should be infelicitous.

- (8) a. Jo and Mo agreed about whether Bo was home, but they were both wrong.  
b. Jo finally decided whether she would leave, but then she changed her mind.

Rather, these predicates seem to relate an individual to something like a *possible answer* (or set thereof): (8a) and (8b) are roughly paraphrasable as (9a) and (9b), respectively.

- (9) a. Jo and Mo agree either that Bo is home or that he isn't.  
b. Jo decided either that she would go or that she wouldn't.

But supposing that the denotation of, e.g., *about* (or its purported silent variant) acts to convert true answers to possible answers, then—on Egré's account—it makes sense that, insofar as a predicate does not relate an individual to true answers, it requires mediation by a preposition. On this view, then, *decide* (etc.) might not be exceptional in either its selectional behavior or

interpretive behavior, and so might be consistent with a version of the true-answers assumption.

We provide two arguments against this treatment of the purportedly exceptional Q-agnostic/Q-selecting verbs. One reason to be doubtful of this story is that at least some nonveridical predicates do not allow mediation by any preposition. For instance, *estimate* is not veridical (10a), and *about* cannot mediate its relationship to a question (10b). Thus, an account such as Egré's needs to stipulate that certain verbs only take silent prepositions, which seems undesirable. We will avoid the assumption of lexically-specific silent pronouns here.

- (10) a. Jo estimated that they would have enough money, but she was wrong.  
 b. Jo was trying to estimate (\*about) whether they would have enough money.

A second problem is that the preposition that overtly mediates such cases most often is *about*; yet there is extensive evidence that *about*-phrases are modifiers of the verbs they combine with—not directly interacting with argument structure at all (Rawlins, 2013). In fact, Rawlins shows that the distribution of *about* is orthogonal to the selection of embedded interrogatives.

This leaves the question of what the interpretation is of the exceptional cases, like *decide* and *estimate*. One tack is to retain the standard approach to embedded questions and assume that, e.g., the predicate itself converts true answers to possible answers (cf. Beck and Rullmann, 1999; Lahiri, 2002). Another option is to say, instead, that all embedded questions denote possible answers and that, e.g., a predicate itself can convert possible answers to true answers (Spector and Egré, 2015). We will start from this second approach here.

Under the assumption that questions denote sets of complete possible answers—i.e. partitions on  $D_s$ —this second approach has the nice consequence that it correctly predicts veridical predicates to always relate individuals to true answers—the true-answerhood property follows from the veridicality entailment or presupposition.<sup>3</sup> To see this, suppose we define (*p*-)veridicality and *q*-veridicality as in (11) and that we replace the true-answerhood constraint in (6) with (12), which implements the possible-answers assumption for Q-agnostics *V*.

- (11) a. P-VERIDICAL(*V*)  $\leftrightarrow \forall x, p, w : \llbracket V_{decl} \rrbracket^w(p)(x) \rightarrow p(w@)$   
 b. Q-VERIDICAL(*V*)  $\leftrightarrow \forall x, Q, w : \llbracket V_{int} \rrbracket^w(Q)(x) \leftrightarrow \llbracket V_{decl} \rrbracket^w(ANS_{w@}(Q))(x)$

- (12) **A possible-answerhood constraint for Q-agnostics**  
 $\forall x, Q, w : \llbracket V_{int} \rrbracket^w(Q)(x) \leftrightarrow \exists p \in Q : \llbracket V_{decl} \rrbracket^w(p)(x)$

From this constraint, one can prove that a verb is *q*-veridical if it is *p*-veridical; see (13).

- (13)  $\forall x, Q : (\llbracket V_{int} \rrbracket^w(Q)(x) \ \& \ \text{P-VERIDICAL}(V)) \rightarrow \exists p \in Q : \llbracket V_{decl} \rrbracket^w(p)(x) \ \& \ p(w@)$   
 $\equiv \exists p \in ANS_{w@}(Q) : \llbracket V_{decl} \rrbracket^w(p)(x)$   
 $\equiv \llbracket V_{int} \rrbracket^w(ANS_{w@}(Q))(x)$

<sup>3</sup>It falters, however, on many communicative predicates like *tell*, which appear to relate individuals to true answers but which are not veridical (though see discussion in Baker, 1968). There are various ways these predicates might be dealt with (Egré, 2008; Anand and Hacquard, 2014; Spector and Egré, 2015).

We follow Spector and Egré 2015 in suggesting that this situation is an improvement over the standard approach, since there are fewer stipulations (*modulo* some that Spector and Egré address), and so for the remainder of the paper, we assume the possible answers interpretation for questions. The next focus is to apply this hypothesis specifically to *decide*: if an interrogative embedded by *decide* denotes a set of possible answers, what does the lexical semantics of *decide* do with them?

### 3. Overgeneration for nonveridicals

We now show how to instantiate the possible-answers assumption into a particular lexical entry for *decide*. We first show that decisions involve the firming of intentions, and then discuss two key kinds of contexts where intentions can change with decisions, involving selection of intentions and changes of intentions; these lead to different selectional behaviors. In this process we make one further, final refinement to the possible-answers constraint.

#### 3.1. Selecting and alternating contexts

First, note that (14) entails (15a) and (15b).

(14) At 3pm, Jo decided to leave at 5pm.

- (15) a. It's false that, before 3pm, Jo intended to leave at 5pm.  
b. It's true that, after 3pm, Jo did intend to leave at 5pm.

Given this evidence, (16) seems to be a good first approximation to the denotation of *decide to*. That is, the decider changes state from not having an intention to having one.

- (16)  $\llbracket \text{decide}_{\text{decl}} \rrbracket^t = \lambda p. \lambda x. \neg \text{INTEND}(x, p, \{t' : t' < t\}) \ \& \ \text{INTEND}(x, p, \{t' : t' > t\})$   
where  $\text{INTEND}(x, p, T) \leftrightarrow x$  intends  $p$  over interval  $T$

The possible-answers assumption allows us to infer from (16) to an interrogative embedding case; assuming the possible-answers constraint in (12), (17) must hold. The prediction is then that *decide whether to VP* entails either that the decider changed from not intending to VP to intending to VP, or they changed from not intending not to VP to intending not to VP.

- (17) **Deciding WH version 1**  
 $\llbracket \text{decide}_{\text{int}} \rrbracket^t(Q)(x) \leftrightarrow \exists p \in Q : \neg \text{INTEND}(x, p, T_{<t}) \ \& \ \text{INTEND}(x, p, T_{>t})$   
where  $T_{<t} \equiv \{t' : t' < t\}$  and  $T_{>t} \equiv \{t' : t' > t\}$

This prediction is borne out: (18) does have an entailment of that form.

- (18) At 3pm, Jo decided whether to leave at 5pm.

Despite this positive prediction, (17) needs one further refinement.

Figure 1: Schematization of selecting and alternating contexts

Note that *decide to VP* can describe two kinds of context: *selecting contexts* and *alternating contexts*. In a *selecting context*, a decider selects an intention from a set of possible intentions. For instance, suppose that, before 3pm, Jo neither intends to leave at 5pm nor intends not to leave at 5pm (schematized in Figure 1). (19) is felicitous in this context.

(19) At 3pm, Jo decided to leave at 5pm.

In an *alternating context*, a decider changes intention from a mutually exclusive intention. For instance, suppose that (19) is true, and thus before 4pm, Jo intends to leave at 5pm. (20) is both felicitous and true in this context.

(20) At 4pm, Jo decided not to leave at 5pm.

Contrast this pattern with *decide whether to*. Like (19), (21a) is a true description of DECISION<sub>1</sub>. But unlike (20), (21b) is infelicitous in the alternating context. Intuitively it implies that Jo hadn't made a decision before 4pm.

- (21) a. At 3pm, Jo decided whether to leave at 5pm.  
b. #At 4pm, Jo decided whether to leave at 5pm.

The pattern seen with *decide* in selecting/alternating contexts is surprising if (17) exhausts the relevant set of entailments—and in particular, if the first conjunct is presupposed—since (17) predicts that (21b) should be true in this context. Indeed, (17) predicts that (20) entails (21b).

This infelicity appears to arise as a consequence of a presupposition failure similar to those found for, e.g., aspectual change-of-state verbs, such as *start* and *stop* (cf. Simons, 2001; Abusch, 2002; Abbott, 2006). For instance, *start p* presupposes  $\neg p$ , but this presupposition can be filtered in ignorance contexts, such as (22).

(22) I don't know if Jo used to smoke, but if she starts smoking, she'll get lung cancer.

We observe a similar pattern for *decide whether to VP* in ignorance contexts. If the speaker is not sure whether Jo already had an intention, (21b) is felicitous, suggesting that there is a similar presupposition being filtered; (23) illustrates such a filtering context.

(23) I don't know if, before 4pm, Jo already either intended to leave at 5pm or intended not to, but if, at 4pm, she decided whether to leave at 5pm, she'll follow through on it.

Thus, just like the aspectuals, it appears that the description of the state prior to the decision (the *pre-state*) is presupposed, and in the case of (21b), this presupposition is not satisfied. This is bolstered by the fact that *not decide to VP* is infelicitous in the context of DECISION<sub>1</sub>.

(24) #At 3:30pm, John didn't decide to leave at 5pm.

Going forward, we thus assume that entailments about the pre-state are presupposed, though for presentational purposes, we write them as conjuncts on par with other predicates of events.

### 3.2. Taking change-of-state seriously

The issue with alternating contexts has a straightforward solution. *Decide whether to VP* does not involve just forming some intention towards an alternative where that was previously lacking, but rather moving from a state where the agent has no intentions towards a set of alternatives, to one where they do have intentions towards some alternative. At a technical level, this amounts to introducing a narrow-scoping existential quantifier into (17). This has the consequence that we now predict (21b) to be a false description of DECISION<sub>2</sub>, since the first conjunct in (25) is false in a context where the decider already has an intention.

(25) **Deciding WH version 2**  

$$\llbracket \text{decide}_{int} \rrbracket^t(Q)(x) \leftrightarrow \neg \exists p \in Q : \text{INTEND}(x, p, T_{<t}) \ \& \ \exists p \in Q : \text{INTEND}(x, p, T_{>t})$$

The point of (25) is not just to fix a data problem, though. Like (16), it takes the general form of a change-of-state predicate—i.e. there is some particular state *R* that does not hold of an individual *x* prior to the change characterized by the predicate that holds after the change. In the case of *decide p*,  $R_p = \lambda x. \text{INTEND}(x, p)$ ; and in the case of, *decide Q*,  $R_Q = \lambda x. \exists p \in Q : \text{INTEND}(x, p)$ . (We suppress time parameters from now on, as they do not matter to our point.)

To summarize, in the interrogative-embedding case, a decision involves a presupposed pre-state entailment with a lack of intention relative to some set of alternatives and a post-state with an intention relative to those alternatives. In the declarative-embedding case, only the post-state is characterized, and the pre-state entailments fall out from there.

## 4. Our proposal

In this section, we present a compositional analysis that captures the interpretive facts presented in Section 3, while also capturing the argument selectional behavior of *decide*.

### 4.1. Generalization

We propose the following generalization: a predicate is Q-agnostic if (a) it is change-of-state and (b) the change it characterizes involves states associated with propositional content. Assuming Egré's generalization is correct, this is corroborated trivially by veridical change-of-

|           | Finite       |                | Control      |                | AcI          |                |

Table 1: The syntactic distribution of nonveridical change-of-state verbs

state predicates like *realize*, *discover*, *find out*, *figure out*, and *prove*; but it is also true of a host of nonveridical change-of-state predicates, such as those listed in Table 1.<sup>4</sup>

Beyond these positive examples, we also find negative examples, like *intend*. *Intend* is neither veridical nor change-of-state, and is not Q-agnostic.

(26) Jo intended (\*whether) to leave.

Such negative examples are not critical for our generalization, but they are interesting for relating our proposal to Egré's (2008) veridicality generalization, discussed in Section 2. Many Q-agnostic predicates, both veridical and nonveridical, are change-of-state, but if one were to focus only on change-of-state predicates that involve changes in epistemic state—e.g. *realize*, *discover*, *find out*, *figure out*, etc.—it would at least be reasonable to say that those ‘inherit’ their Q-agnosticism from the fact that *know* is Q-agnostic. This would in turn explain the correlation between veridicality and Q-agnosticism. But because we do not have similar recourse here—*intend* is not veridical—we must say something else.

What binds the predicates in Table 1 together—to the exclusion of *intend*—is that they all involve selection from a set of mutually exclusive options: deciding involves selecting from a set of possible decisions; a judgment involves selecting from a set of possible judgments; and so

<sup>4</sup>Note that this assumes that the Q-agnostic predicates include all predicates that take both a question and an interrogative, regardless of other syntactic differences between the relevant declarative and interrogative—e.g. tense. For instance, predicates of evaluation like *evaluate*, *appraise*, and *rate* take AcI declaratives but not finite declaratives, despite taking both finite and control interrogatives.

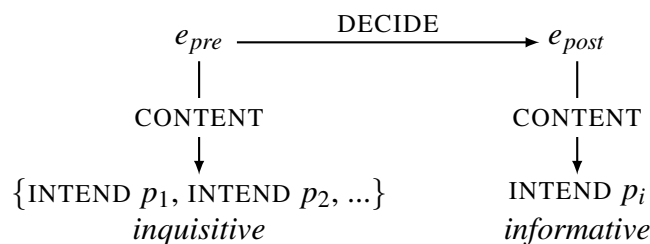

Figure 2: A schematization of decisions in selecting contexts

on. The intuition behind our generalization is that, when taking an interrogative, the predicates in Table 1 use the question denoted by that interrogative to characterize the set of options from which the judger, decider, etc. selects. But when taking a declarative, these predicates use the propositions denoted by that declarative to characterize the selected option.

Figure 2 schematizes this idea for *decide*. We model decisions as three-place relations on eventualities: a *pre-state* (e.g. the decider’s intentional state prior to the decision), the decision itself, and a *post-state* (e.g. the decider’s intentional state after the decision). Then, embedded interrogatives characterize the *inquisitive content* of the pre-state, and embedded declaratives characterize the *informative content* of the post-state (cf. Hacquard, 2010; Rawlins, 2013).

We implement this idea compositionally by combining two recent approaches to verb meaning: (i) Champollion’s (2015) verb-as-event-quantifier approach and (ii) Hacquard’s (2010) neo-Davidsonian event content approach to propositional attitude verbs (cf. Kratzer, 2006; Moulton, 2009; Bogal-Allbritten, 2016).

#### 4.2. Verbs as event quantifiers

In Champollion’s approach, verbs are existential quantifiers over eventualities. For instance, (27) gives his denotation for *kiss* (p. 42, fig. 2).

$$(27) \quad \llbracket \text{kiss} \rrbracket = \lambda f_{\langle vt \rangle}. \exists e : f(e) \ \& \ \text{KISS}(e)$$

Note that this approach assumes that all arguments are severed from the verb (cf. Kratzer, 1996; Borer, 2005; Pietroski, 2005). The denotations of adjuncts as well as the denotations of heads that introduce thematic roles (after combining with their argument) are then treated as (partial) functions from  $D_{\langle vt \rangle t}$  to  $D_{\langle vt \rangle}$ . For example, the THEME role would be introduced via a *th* head.

$$(28) \quad \llbracket [\text{th Jo}] \rrbracket = \lambda V_{\langle \langle vt \rangle t \rangle}. \lambda f_{\langle vt \rangle}. V(\lambda e. f(e) \ \& \ \text{THEME}(e) = j)$$

Important for our purposes is how change-of-state verbs work in this system. Champollion does not treat change-of-state verbs directly, though his denotation for the adverb *alternately* (p. 58, ex. 62), which incorporates change-of-state semantics, contains all the relevant components. We do not repeat his denotation here, since it involves more machinery than we need, rather extracting the relevant pieces to define a basic change-of-state verb *break* in (29).

- (29)  $\llbracket \text{break} \rrbracket = \lambda f_{\langle vt \rangle}. \exists e : f(e) \ \& \ \text{COS}(e, \text{BREAK}, \text{BROKEN})$   
 where  $\text{COS}(e, g, h) \equiv \exists e_1, e_2 : e_1 \supset e \supset e_2 \ \& \ g(e, e_1, e_2) \ \& \ \neg h(e_1) \ \& \ h(e_2)$   
 $e_1 \supset e_2 \equiv \sup \tau(e_1) = \inf \tau(e_2)$  (assuming time is dense)

For the remainder of the paper, we assume that change-of-state verbs have a form parallel to (29). Effectively, to know the denotation for a change-of-state verb, we need to know two things: (i) the eventuality predicate that characterizes the change (e.g. BREAK); and (ii) the eventuality predicate that characterizes the state that changes (e.g. BROKEN). We assume that (i) carries any entailments that are idiosyncratic to a particular kind of state change—e.g. that the holder of the states characterized by (ii) is the same as the patient/theme of the state change.

In certain cases (including *decide* and other Q-agnostic change-of-state predicates), the second component may be supplied by external material. For instance, at least for aspectual verbs like *start* and *stop*, the state that changes appears to be characterized by the embedded clause.

- (30) Jo started to run at 5pm.  $\rightarrow$  Jo was not running before 5pm and was running after 5pm.

Thus, it appears that we need some way of feeding the embedded clause content to the first argument of COS. One way to do this is to assume that *start* maps from event quantifiers to event quantifiers, instead of being an event quantifier itself. This route, the analogue of which we employ for *decide*, is taken in (31a). Assuming for the moment that the infinitival *to* is the identity on event quantifiers (31b), the denotation of the VP headed by *start* in (30) is (31c).

- (31) a.  $\llbracket \text{start} \rrbracket = \lambda V_{\langle \langle vt \rangle t \rangle}. \lambda f_{\langle vt \rangle}. \exists e : f(e) \ \& \ \text{COS}(e, \text{START}, \lambda e_1. V(\lambda e_2. e_1 = e_2))$   
 b.  $\llbracket \text{to run} \rrbracket = \llbracket \text{run} \rrbracket = \lambda f_{\langle vt \rangle}. \exists e : f(e) \ \& \ \text{RUN}(e)$   
 c.  $\llbracket \text{start to run} \rrbracket = \lambda f_{\langle vt \rangle}. \exists e : f(e) \ \& \ \text{COS}(e, \text{START}, \lambda e_1. \exists e_2 : e_1 = e_2 \ \& \ \text{RUN}(e_2))$   
 $= \lambda f_{\langle vt \rangle}. \exists e : f(e) \ \& \ \text{COS}(e, \text{START}, \text{RUN})$

In this case, the predicate that characterizes the state change, START, might enforce identity between the agent of the starting and the agent of the running—insofar as aspectuals are control verbs (see Perlmutter, 1970; Landau, 2001; Wurmbrand, 2001; Grano, 2012).

#### 4.3. Quantification over eventuality contents

In Hacquard's approach, propositional attitude verb denotations have three components: (i) an experiencer thematic role, (ii) a predicate of eventualities, and (iii) a universal quantification over the (intersection of the) contents of the attitude eventuality (cf. Hintikka, 1962). For instance, (32) gives a slightly modified version of her denotation for *believe* (p. 101, ex. 41).

- (32)  $\llbracket \text{believe} \rrbracket = \lambda e. \lambda p. \lambda x. \text{EXP}(e) = x \ \& \ \text{BELIEF}(e) \ \& \ \forall w \in \cap \text{CON}(e) : p(w)$   
 where  $\forall e : \text{CON}(e) = \{p : p \text{ is compatible with the contents of } e\} \ \&$   
 $\forall e : \text{BELIEF}(e) \rightarrow [\text{CON}(e) \equiv \text{DOX}(\text{EXP}(e))]$

Importantly, CON must be defined as a partial function from events to quantifiers over worlds—

i.e. questions—in order to ensure that non-information state events do not end up with contents.

We say that an eventuality  $e$  has (*propositional*) *content* if  $\text{CON}(e)$  is defined. We say that the content of an eventuality is *informative* with respect to a question  $Q$  iff  $\exists p \in Q : \cap \text{CON}(e) \subseteq p$ ; otherwise, it is *non-informative*. In the case where it is non-informative, the question  $Q$  can be viewed as *inquisitive* relative to the content.<sup>5</sup> Since the last conjunct in (32) continues to arise for the change-of-state verbs we are interested in, it is useful to give it the shorthand in (33).

$$(33) \quad \forall e, p : \text{CON}(e) \text{ is defined} \rightarrow \left[ e \xrightarrow{\text{CON}} p \leftrightarrow \forall w \in \cap \text{CON}(e) : p(w) \right]$$

We refer to the relation  $\xrightarrow{\text{CON}}$  as *content entailment* and say that  $e$  *content-entails*  $p$ .

#### 4.4. Merging the approaches

To merge these two approaches, we propose the form in (34a) for a basic stative propositional attitude verb such as *believe* or *intend*.

$$(34) \quad \begin{array}{ll} \text{a.} & \llbracket \text{believe} \rrbracket = \lambda p. \lambda f_{\langle vt \rangle}. \exists e : f(e) \ \& \ \text{BELIEF}(e) \ \& \ e \xrightarrow{\text{CON}} p \\ \text{b.} & \llbracket \text{intend} \rrbracket = \lambda p. \lambda f_{\langle vt \rangle}. \exists e : f(e) \ \& \ \text{INTENTION}(e) \ \& \ e \xrightarrow{\text{CON}} p \end{array}$$

The main difference between this denotation and Hacquard's is the sublexical quantification over eventualities and the lack of an experiencer thematic role. The main difference between this denotation and Champollion's is that propositional attitude verbs take a proposition in addition to an eventuality predicate, which is already plausibly necessary for aspectuals.<sup>6</sup>

Next, we define what it means for an event to content-entail a question. The definition in (35) is effectively a reencoding of the rule in (12) from Section 2. An eventuality content-entails a question just in case that eventuality content-entails some answer to that question—i.e. the content is informative relative to the question.<sup>7</sup>

<sup>5</sup>A different strategy, following Rawlins (2013), would be to allow contents themselves to be of a type that is rich enough to define inquisitiveness (see, e.g., Ciardelli et al. 2013; Rawlins 2013). Here we stick with Hacquard's treatment, where it is always propositional.

<sup>6</sup>Another possible approach is to retain the event quantifier analysis even for propositional attitude verbs and aspectuals and assume, e.g., that complementizers selected by propositional attitude verbs have the form in (i), where  $p$  is contributed by the denotation of the constituent that combines with the complementizer (cf. Kratzer, 2006; Moulton, 2009; White, 2014; Bogal-Allbritten, 2016).

(i)  $\llbracket C_p \rrbracket = \lambda p. \lambda V_{\langle vt \rangle t}. \lambda f_{\langle vt \rangle}. V \left( \lambda e. f(e) \ \& \ e \xrightarrow{\text{CON}} p \right)$

Aspectuals would then need some complementizer that amounts to existential disclosure (Dekker, 1993).

This denotation is analogous to Champollion's thematic role denotations, differing in that Champollion's thematic role takes entity quantifiers whereas ours takes propositions. To make ours fully analogous, we could assume (ii) instead, where  $\mathcal{Q}$  is some first order quantifier.

(ii)  $\llbracket C_{\mathcal{Q}} \rrbracket = \lambda \mathcal{Q}. \lambda V_{\langle vt \rangle t}. \lambda f_{\langle vt \rangle}. V \left( \lambda e. f(e) \ \& \ \mathcal{Q} p \in \mathcal{Q} : e \xrightarrow{\text{CON}} p \right)$

This would imply that complementizers are type-identical to thematic roles, except that they take quantifiers over worlds—i.e. questions—instead of quantifiers over events.

<sup>7</sup>The notion of content-entailment in (35) may or may not be relevant for predicates that only take questions—

$$(35) \quad \forall e, Q : \text{CON}(e) \text{ is defined} \rightarrow \left[ e \xrightarrow{\text{CON}} Q \leftrightarrow \exists p \in Q : e \xrightarrow{\text{CON}} p \right]$$

We use this overloaded version of  $\xrightarrow{\text{CON}}$  to give a straightforward denotation for *decide* with *ad hoc polymorphism*—i.e.  $\llbracket \text{decide} \rrbracket$  is agnostic about the type of its first argument  $R$ .

$$(36) \quad \llbracket \text{decide} \rrbracket = \lambda R_{\tau}. \lambda f_{\langle \text{vt} \rangle}. \exists e : f(e) \ \& \ \text{COS}(e, \text{DECIDE}, \lambda e'. e' \xrightarrow{\text{CON}} R) \\ \text{where } \tau \in \{ \langle st \rangle, \langle \langle st \rangle t \rangle \}$$

The relation  $\text{DECIDE}(e, e_1, e_2)$  must entail at least two things of the eventualities it relates. First, it must entail that  $e_1$  and  $e_2$  are states with intentional contents, i.e. whose contents are sets of propositions characterizing some experiencer's intentions. Second, it must entail that the experiencer of those intentions is the agent/experiencer of the decision  $e$ .

To ensure that  $\llbracket \text{decide} \rrbracket$  combines with a proposition or question, we assume that  $\llbracket \text{to VP} \rrbracket = \lambda w. \llbracket \text{VP} \rrbracket(\lambda e. e \in D_v^w)$ , where  $D_v^w$  is the set of events in world  $w$  (cf. White, 2014). Then, when *decide* takes a declarative, we obtain a denotation of the form in (37).

$$(37) \quad \llbracket \text{decide to leave} \rrbracket = \lambda f_{\langle \text{vt} \rangle}. \exists e : f(e) \ \& \ \text{COS}(e, \text{DECIDE}, \lambda e'. e' \xrightarrow{\text{CON}} R) \\ \text{where } R = \lambda w. \exists e' \in D_v^w : \text{LEAVE}(e')$$

Assuming that the introduction of a subject merely contributes a conjunct  $\text{EXP}(e) = c$  for some constant  $c$  (and ignoring tense),  $\llbracket (37) \rrbracket$  entails (39), which is consistent with the pattern of entailments discussed in Section 3. Keep in mind that for *decide* CON contains propositions describing intentions, so the intersection is the set of worlds compatible with the agent's intentions during that eventuality. The pre-state content does not entail the proposition  $R$  (it may be compatible with it in selecting contexts, or entirely inconsistent in alternating contexts). The post-state's content does entail  $R$ .

$$(38) \quad \text{Jo decided to leave.}$$

$$(39) \quad \exists e, e_1, e_2 : e_1 \supset e \supset e_2 \ \& \ \text{DECIDE}(e, e_1, e_2) \\ \& \ \neg \forall w \in \cap \text{CON}(e_1) : \exists e_3 \in D_v^w : \text{LEAVE}(e_3) \\ \& \ \forall w \in \cap \text{CON}(e_2) : \exists e_4 \in D_v^w : \text{LEAVE}(e_4)$$

When *decide* takes an interrogative, we obtain a denotation of the form in (40).

$$(40) \quad \llbracket \text{decide whether to leave} \rrbracket = \lambda f_{\langle \text{vt} \rangle}. \exists e : f(e) \ \& \ \text{COS}(e, \text{DECIDE}, \lambda e'. e' \xrightarrow{\text{CON}} R) \\ \text{where } R = \{ \lambda w. \exists e'' \in D_v^w : \text{LEAVE}(e''), \lambda w. \neg \exists e'' \in D_v^w : \text{LEAVE}(e'') \}$$

Under the same assumption (and again ignoring tense),  $\llbracket (40) \rrbracket$  entails (42), which is consistent with the pattern of entailments discussed in Section 3.

e.g. *wonder* and *ask*. We remain agnostic about this possibility, since we only intend to treat Q-agnostics here.

(41) Jo decided whether to leave.

(42)  $\exists e, e_1, e_2 : e_1 \supset e \supset e_2 \ \& \ \text{DECIDE}(e, e_1, e_2)$   
 $\& \neg \exists p \in R : \forall w \in \cap \text{CON}(e_1) : p(w)$   
 $\& \exists p \in R : \forall w \in \cap \text{CON}(e_2) : p(w)$   
 where  $R = \{\lambda w. \exists e'' \in D_v^w : \text{LEAVE}(e''), \lambda w. \neg \exists e'' \in D_v^w : \text{LEAVE}(e'')\}$

That is, the pre-state does not content-entail the question, and thus the question  $R$  is inquisitive relative to the pre-state's content (and therefore the agent's intentions at that time); this isn't compatible with an alternating context, but is compatible with a selecting context. The post-state, on the other hand, is informative relative to the question; in other words, the agent's intentions during that state resolve the question completely. We thus capture the full pattern of intuitions for *decide*.

## 5. Conclusion

In this paper, we have given an account of the selectional behavior of cognitive change-of-state verbs, such as *decide*, that attempts to reduce their selectional behavior to their change-of-state event structure. In particular, we argued that, if a cognitive verb is change-of-state, it is *Q-agnostic*—i.e. it selects both declarative and interrogative clauses. This augments previous accounts of Q-agnosticism, which have tied the distribution of declarative and interrogative clauses to semanticopragmatic notions like factivity and veridicality but which run aground on nonveridical predicates like *decide*.

In the remainder of the paper, we briefly consider the prospect of generalizing this approach to other kinds of nonveridical Q-agnostic predicates—e.g. communication predicates like *tell* and *agree*—and relating it to previous theories of Q-agnosticism for veridical predicates.

### 5.1. Nonveridical communicatives

We noted in Section 2 that communication verbs, like *tell* and *agree*, are Q-agnostic but not veridical. There are two fruitful routes for explaining these verbs on our proposal, both of which use Anand and Hacquard's (2014) neo-Davidsonian account of communicative predicates. On their account, communicatives characterize future states of some common ground (cf. Farkas and Bruce, 2009). For instance, (43) gives a modified version of their entry for *claim*.

(43)  $\llbracket \text{claim} \rrbracket = \lambda p. \lambda f_{\langle vt \rangle}. \exists e : f(e) \ \& \ \text{CLAIM}(e) \ \& \ e \xrightarrow{\text{CON}} \lambda w. [\forall w' \in \text{CG}(w) : p(w')]$   
 where  $\forall e : \text{CLAIM}(e) \rightarrow [\text{CON}(e) \equiv \text{GOAL}(e)]$

One possibility, raised by Valentine Hacquard (p.c.), is that a subset of communicative predicates—*tell* but not *claim*—characterize not only future states of the common ground but also the Question Under Discussion of the reported discourse. Then, when such a communicative verb takes a question, that question characterizes that Question Under Discussion.

Another possibility is that, while all communicative predicates characterize future states of the common ground, only a subset characterize a change to that common ground. Insofar as a particular communicative predicate characterizes such a change, e.g. *agree*, our account predicts that those predicates are Q-agnostic.

## 5.2. Cognitive factives

As it stands, our account, in conjunction with Egré's (2008), redundantly predicts change-of-state factives to be Q-agnostic, since they are both veridical and change-of-state.

$$(44) \quad \llbracket \text{realize} \rrbracket = \lambda R_{\tau} . \lambda f_{\langle vt \rangle} . \exists e : f(e) \ \& \ \text{COS}(e, \text{REALIZE}, \lambda e' . e' \xrightarrow{\text{CON}} R) \\ \text{where } \tau \in \{ \langle st \rangle, \langle \langle st \rangle t \rangle \}$$

This raises the possibility that one or the other property is actually relevant in determining their Q-agnosticism. Is it possible to reduce the Q-agnosticism of change-of-state cognitive factives to the fact that they are change-of-state? There are at least two challenges for such a theory. The first is that stative cognitive factives like *know* are Q-agnostic. This means that the theory cannot tie Q-agnosticism too closely to change-of-state. The second challenge is that change-of-state is independent of factivity or veridicality—e.g. compare the factive *find out* to the nonfactive, nonveridical *determine*.

We suggest a generalization of the change-of-state hypothesis—that Q-agnosticism is really a product of having a particular kind of bipartite lexical semantic structure, one relating two encapsulated eventualities. Being change-of-state is one way that a verb can come to have that structure, but not the only one. Kratzer (2002) suggests that factives express relations between entities and facts as well as some auxiliary relation describing, e.g., the entity's beliefs about the fact (*know*) or how the entity came to be related to the fact (*discover*, *realize*, etc.). This contrasts with a nonfactive stative, like *intend*, which does not have such a bipartite structure.

This idea might be implemented using George's (2011) Twin Relations Theory, which similarly treats Q-agnostic predicates like *know* using ad hoc polymorphism. In George's theory, Q-agnostic predicates are constructed from two abstract elementary relations  $R_{\forall}$  and  $R_{\exists}$ . For instance, (45) gives a translation of the relevant relations for *know*,  $\text{KNOW}_{\forall}$  and  $\text{KNOW}_{\exists}$ , into our neo-Davidsonian formalism, and (46) shows how denotations for the declarative-taking and interrogative-taking variants of *know* are built from these relations.

$$(45) \quad \begin{aligned} \text{a. } \text{KNOW}_{\forall} &\equiv \lambda p . \lambda e . \lambda w . \text{BELIEF}(e) \ \& \ \left[ e \xrightarrow{\text{CON}} p \right] \rightarrow p(w) \\ \text{b. } \text{KNOW}_{\exists} &\equiv \lambda p . \lambda e . \text{KNOW}(e) \ \& \ e \xrightarrow{\text{CON}} p \end{aligned}$$

$$(46) \quad \begin{aligned} \text{a. } \llbracket \text{know}_{\text{decl}} \rrbracket^w &= \lambda p . \lambda f . \exists e_1, e_2 : f(e) \ \& \ \text{KNOW}_{\forall}(p)(e_1)(w) \ \& \ \text{KNOW}_{\exists}(p)(e_2) \\ \text{b. } \llbracket \text{know}_{\text{int}} \rrbracket^w &= \lambda Q . \lambda f . \exists e_1, e_2 : f(e) \ \& \ \forall p \in Q : \text{KNOW}_{\forall}(p)(e_1)(w) \\ &\quad \& \ \exists p \in Q : \text{KNOW}_{\exists}(p)(e_2) \end{aligned}$$

Effectively,  $\text{KNOW}_{\forall}$  characterizes the veridical entailments of *know*, while  $\text{KNOW}_{\exists}$  characterizes the asserted content. This theory is straightforwardly portable to change-of-state predicates, such as *decide*.

- (47) a.  $\text{DECIDE}_{\forall} \equiv \lambda p. \lambda e. \lambda e'. e \supset e' \ \& \ \neg \left[ e \xrightarrow{\text{CON}} p \right]$   
 b.  $\text{DECIDE}_{\exists} \equiv \lambda p. \lambda e. \lambda e'. e \supset e' \ \& \ e \xrightarrow{\text{CON}} p$
- (48) a.  $\llbracket \text{decide}_{\text{decl}} \rrbracket^w = \lambda p. \lambda f. \exists e : f(e) \ \& \ \exists e_1, e_2 : \text{DECIDE}(e, e_1, e_2)$   
 $\quad \quad \quad \& \text{DECIDE}_{\forall}(p)(e_1)(e)$   
 $\quad \quad \quad \& \text{DECIDE}_{\exists}(p)(e)(e_2)$   
 b.  $\llbracket \text{decide}_{\text{int}} \rrbracket^w = \lambda Q. \lambda f. \exists e : f(e) \ \& \ \exists e_1, e_2 : \text{DECIDE}(e, e_1, e_2)$   
 $\quad \quad \quad \& \forall p \in Q : \text{DECIDE}_{\forall}(p)(e_1)(e)$   
 $\quad \quad \quad \& \exists p \in Q : \text{DECIDE}_{\exists}(p)(e)(e_2)$

There are two potential upshots to such a reimplementation. First, (48) provides equivalent denotations to those given in Section 4. Second, for *know*, the conjunct containing  $\text{KNOW}_{\forall}$  corresponds to the presupposed content and the conjunct containing  $\text{KNOW}_{\exists}$  corresponds to the asserted content. This may suggest a more general pattern, wherein verbs with bipartite event structures always presuppose some universally quantified presupposition when they take an interrogative clause, be it a presupposition about facts or a presupposition about intentions.

## Only meets vagueness<sup>1</sup>

Katsuhiko YABUSHITA — *Naruto University of Education*

**Abstract.** An *only* sentence is construed to consist of the positive component, also referred to as the *prejacent* and the negative one. It is uncontroversial that the negative component is part of the literal meaning, or entailment of the *only* sentence. More controversial is the status of the prejacent, for it can be canceled (only epistemically, not directly) unlike the negative component; in the literature, it has been analyzed as entailment, presupposition, or conversational implicature. In this paper, novel data on the cancellability of the prejacent will be proffered to indicate that the prejacent is not always cancelable, but is sensitive to the vagueness of the main predicate, suggesting that the cancelability of the prejacent has nothing to do with the semantics of *only* per se. Indeed, couched in a dynamic semantic framework of vagueness, an alternative analysis of an *only* sentence will be presented, in which along with the negative component, the prejacent is part of the literal meaning of the sentence; however, sometimes, it will not be categorically *asserted*, or will be partly revoked as the speaker is aware of the possibility that the object in question does not satisfy the standard of the absolute use of the (vague) main predicate.

**Keywords:** *only*, prejacent, cancelation, vagueness, dynamic semantics

### 1. Introduction

In the literature, it is uncontroversial that the interpretation of an *only* sentence, e.g., (1a) is composed of the positive component also referred to as the *prejacent*, (1b) and the negative component, (1c).

- (1) a. Only John smokes.
- b. John smokes.
- c. Nobody except for John smokes.

Schematically, an *only* sentence, its prejacent and its negative component are represented in terms of background-focus notation as (2a), (2b), and (2c), respectively.

- (2) a. *ONLY* $\langle F, B \rangle$
- b. Prejacent:  $B(F)$
- c. Negative Component:  $\forall x[[x \in ALT(F) \wedge x \neq F] \rightarrow \neg B(F)]$

Controversial is the status of the prejacent—i.e., whether it is an entailment (e.g., Atlas 1993, 1996), a presupposition (e.g., Geurts and van der Sandt 2004; Horn 1969, 1996; Rooth 1985, 1992), or a conversational implicature (e.g., Ippolito 2007; McCawley 1981, van Rooij and Schulz 2007) of an *only* sentence.

---

<sup>1</sup> I would like to thank the audiences of Theoretical Linguistics at Keio (TaLK) 2016 and Sinn und Bedeutung (SuB) 21, especially Joseph DeVeaugh-Geiss, Mira Grubic, Peter Lasersohn, Manfred Krifka, Mats Rooth, Bernard Schwarz and Yasutada Sudo, for their helpful questions, comments and/or suggestions. I'm afraid that those have not been fully incorporated into the current version. All the remaining inadequacies are mine. Last, but not least, thanks to Rob Truswell for editing the current volume as well as being one of the organizers of SuB 21.

One of the most compelling pieces of evidence against the entailment and presupposition approaches is the cancellability of the prejacent observed in, e.g., (3).

- (3) a. Only Mary can speak French ... maybe she cannot.  
b. Only John is tall ... maybe he is not.

However, a look at further data reveals that the prejacent is not always cancelable; it is cancelable only when the main predicate is a vague one as seen in (3) and (4) in conjunction with (5) and (6).

- (4) a. #Only Mary came to the party ... maybe she didn't.  
b. #Only John is married ... maybe he is not.

- (5) a. Mary can speak French very well.  
b. John is very tall.

- (6) a. \*Mary came to the party very much.  
b. \*John is very married.

Data like (3) and (4) together are baffling to all the three existing approaches, for they cannot explain why the prejacent is cancellable sometimes and non-cancellable other times. In this paper, couched in a dynamic semantic framework for vagueness proposed by Barker (2002, 2013), I will present an analysis of the interpretation of an *only* sentence—in which the prejacent is indeed part of the semantic meaning of an *only* sentence but is not (categorically) asserted when the main predicate is a vague one.

Before moving on to the presentation of the current analysis, one more word is in order about the cancelability of the prejacent of an *only* sentence. That is, the prejacent is cancelable only epistemically as seen in the contrast between (7a) and (7b), and unlike the case of the cancellation of a conversational implicature in (7c).

- (7) a. Only Mary can speak French ... maybe, she can't.  
b. #Only Mary can speak French ... she can't.  
c. Mary has three children ... (actually,) she has exactly five children.

## 2. A novel analysis of the cancelability of the prejacent

It has been seen above that the prejacent of an *only* sentence is not always cancelable; the cancellation is possible only if the main predicate of the sentence is a vague one. This certainly suggests that the cancellation has no bearing on the semantics of an *only* sentence, or *only*. Indeed, in the current analysis to be proposed in the following, I will adopt such a semantics for *only* that both the prejacent and the negative component are hardwired in the literal meaning of (an) *only* (sentence), but after the utterance of an *only* sentence, the prejacent can be partly revoked, or can be not categorically asserted as the speaker becomes aware of the possibility that the focused object in question does not satisfy the standard for the absolute use of the (vague) predicate.

## 2.1. Semantics of *only*

Demonstrated by the contrast between (3) and (4), the prejacent of an *only* sentence is not always cancelable; it is cancelable only when the main predicate is a vague one. This strongly suggests that the prejacent is in fact part of the literal meaning of (an) *only* (sentence), but can be canceled (epistemically) from an interaction with vagueness. For the purpose of the present paper, any reasonable semantics of *only* with both the prejacent and the negative component incorporated will do, e.g., van Rooij and Schulz's (2007) *ONLY*, which is actually the penultimate version of their final proposed semantic meaning of *only*.

- (8) Definition (van Rooij and Schulz's (2007) *ONLY*)  
 $ONLY(\langle F, B \rangle) = \{w \in W : F(w)(B(w)) \ \& \ \neg \exists v [F(v)(B(v)) \ \& \ v <_B w]\},$   
 where  $<_B$  is a relation on  $W$  such that  $v <_B w$  iff  $v$  is exactly like  $w$  except that the extension of  $B$  in  $v$  is smaller than that in  $w$ , i.e.,  $B(v) \subset B(w)$ .

According to the definition of the meaning of an *only* sentence, e.g., *Only Mary can speak French*, whose semantic representation in terms of the focus-background notation is  $ONLY(\langle Mary, \lambda x. can \ speak \ French(x) \rangle)$  is the set of possible worlds whose extension of  $\lambda x. can \ speak \ French(x)$  is the set that contains Mary as its sole element; in other words, where Mary and nobody else can speak French. The meaning corresponds with the propositional content composed of both the prejacent and the negative component.

## 2.2. Semantic framework for vagueness: Barker (2002, 2013)

As a general semantic framework for the interpretation of sentences involving vague predicates, I will adopt a dynamic semantic framework proposed by Barker (2002, 2013). In the framework, the utterance of a sentence updates information states, here modeled as sets of ordered pairs of possible worlds and discourses, not just sets of possible worlds, having the schematic form  $\{\langle w, \mathbf{d} \rangle : \dots\}$ . The role of a discourse, among others, is to determine the standard for the absolute use of a vague predicate; that is, given a discourse,  $\mathbf{d}$ , a possible world,  $w$ , and a vague predicate, say *tall*,  $\mathbf{d}(w)(\llbracket tall \rrbracket)$  specifies the standard of tallness in  $w$  and  $\mathbf{d}$ . In the setting, for example, *John is tall* is true in  $\langle w, \mathbf{d} \rangle$ , i.e.,  $\llbracket John \ is \ tall \rrbracket^{w, \mathbf{d}} = 1$  iff the degree of John's height is equal to or greater than the standard of tallness in  $w$  and  $\mathbf{d}$ , which is:

- (9)  $\llbracket John \ is \ tall \rrbracket^{w, \mathbf{d}} = 1$  iff  $\iota e [\llbracket tall \rrbracket^{w, \mathbf{d}}(j)(e)] \geq \mathbf{d}(w)(\llbracket tall \rrbracket)$ ,  
 where  $\iota$  is the iota operator and  $e$  is a degree variable.

And the utterance of a sentence updates a given information state into an information state in whose ordered pairs of possible worlds and discourses the sentence is true, as illustrated with *John is tall* as an example in the following:

- (10)  $C + "John \ is \ tall" = C' = \{\langle w, \mathbf{d} \rangle \in C : \llbracket John \ is \ tall \rrbracket^{w, \mathbf{d}} = 1\} = \{\langle w, \mathbf{d} \rangle \in C : \iota e [\llbracket tall \rrbracket^{w, \mathbf{d}}(j)(e)] \geq \mathbf{d}(w)(\llbracket tall \rrbracket)\}$

The update of an information state by the utterance of an *only* sentence, in this case *Only John is tall*, is illustrated as follows:

$$(11) \ C + \text{"Only John is tall"} = C' = \{ \langle w, \mathbf{d} \rangle \in C : \llbracket \text{Only John is tall} \rrbracket^{w, \mathbf{d}} = 1 \} = \\ \{ \langle w, \mathbf{d} \rangle \in C : \llbracket \text{John is tall} \rrbracket^{w, \mathbf{d}} = 1 \wedge \forall x [x \neq j \rightarrow ie[\llbracket \text{tall} \rrbracket^{w, \mathbf{d}}(x)(e)] < \\ \mathbf{d}(w)(\llbracket \text{tall} \rrbracket)] \} = \{ \langle w, \mathbf{d} \rangle \in C : ie[\llbracket \text{tall} \rrbracket^{w, \mathbf{d}}(j)(e)] \geq \mathbf{d}(w)(\llbracket \text{tall} \rrbracket) \wedge \forall x [x \neq j \rightarrow \\ ie[\llbracket \text{tall} \rrbracket^{w, \mathbf{d}}(x)(e)] < \mathbf{d}(w)(\llbracket \text{tall} \rrbracket)] \}$$

### 2.3. A post-update operation: *On Second Thought* (OST)

When the prejacent of an *only* sentence is canceled, the *only* sentence is characteristically followed by a pause, which is expressed typographically as “...” before the cancelation, as seen in (2) and the examples in the literature in general. I take the pause to signify the speaker’s having second thoughts about the standard for someone or something to be determined to have the property in question, i.e., she has been suspecting that the standard can be more stringent than she originally assumed and has decided to take precautions against such a possibility.

I propose that there should be a post-update operation on information states that will incorporate the possibility that the standard of the property in question is stricter than originally assumed. The operator is a function on information states and properties as its arguments and is named *On Second Thought* (OST).

#### (12) Definition (OST)

$$OST(C', \llbracket B \rrbracket) = \{ \langle w, \mathbf{d}' \rangle : \exists \mathbf{d} [\langle w, \mathbf{d} \rangle \in C' \wedge \mathbf{d}' \geq_{w, \llbracket B \rrbracket} \mathbf{d}] \},$$

where  $C'$  is an information state,  $B$  is the background predicate in question, and  $\geq_{w, \llbracket B \rrbracket}$  is a relation on the domain of discourses,  $D$  such that  $\mathbf{d}' \geq_{w, \llbracket B \rrbracket} \mathbf{d}$  iff  $\mathbf{d}'$  is exactly like  $\mathbf{d}$  possibly except that  $\mathbf{d}'(w)(\llbracket B \rrbracket) \geq \mathbf{d}(w)(\llbracket B \rrbracket)$ .

Given an information state and a property, the application of *OST* on the information state with respect to the property results in an information state such that it contains ordered pairs of a possible world and a discourse that are exactly like ones contained in the input information state with the possible exception that the discourse is stricter with regard to the standard for the absolute use of the property in the world.

Let us see the effects of *OST* on the information state resulting from the utterance of an *only* sentence, e.g., *Only John is tall*, i.e., (11), with respect to the property  $\llbracket \text{tall} \rrbracket$ .

$$(13) \ OST(C + \text{"Only John is tall"}, \llbracket \text{tall} \rrbracket) = OST((10), \llbracket \text{tall} \rrbracket) = \{ \langle w, \mathbf{d}' \rangle : \exists \mathbf{d} [\langle w, \mathbf{d} \rangle \in \\ C \wedge ie[\llbracket \text{tall} \rrbracket^{w, \mathbf{d}}(j)(e)] \geq \mathbf{d}(w)(\llbracket \text{tall} \rrbracket) \wedge \forall x [x \neq j \rightarrow ie[\llbracket \text{tall} \rrbracket^{w, \mathbf{d}}(x)(e)] < \\ \mathbf{d}(w)(\llbracket \text{tall} \rrbracket)] \wedge \mathbf{d}' \geq_{w, \llbracket \text{tall} \rrbracket} \mathbf{d}] \}$$

The resulting information state is such that nobody other than John is tall in all the ordered pairs of possible worlds and discourses that are elements of the information state; in some of the ordered pairs John is tall and in the others John is not tall.

### 2.4. Veltman’s (1996) update semantics

Veltman (1996) developed a dynamic-semantic framework to analyze epistemic modals and default reasoning. Relevant to the following discussion is his analysis of epistemic modals,

especially the epistemic possibility modal ‘*might*’, which I take to model *maybe*, which characteristically appears in the sentences canceling the prejacent of an *only* sentence as in (3).

Here I will introduce a minimum portion of Veltman’s (1996) dynamic-semantic framework that is sufficient for the current issues and is adapted to the terms of the previous sections. Given an information state  $C$  and a sentence  $\phi$ , the update of  $C$  by (the utterance of)  $\phi$  is basically as we have assumed above, i.e., intersecting  $C$  with the propositional content of  $\phi$ ; consequently, the resulting information state is usually a proper subset of  $C$ , as in the cases of, e.g., (10) and (11). One of the exceptional cases is a sentence of the form *might*  $\psi$  with the epistemic operator *might* prefixed. Following is the definition of the update effected by *might*  $\psi$ .

(14) Definition (Update Function of *might*  $\psi$ )

Let  $C$  be an information state and *might*  $\phi$  be a sentence composed of an operator *might* and a sentence  $\psi$ .

$C + \text{might } \psi = C$  if  $C + \psi \neq \emptyset$ . (Otherwise, i.e., if  $C + \psi = \emptyset$ ,  $C + \text{might } \psi = \emptyset$ .)

As is clear from the definition, the update by *might*  $\phi$  is actually not an “update”, for the resulting information state is the same as the input one (or the “absurd” state, i.e.,  $\emptyset$ ). Veltman characterizes the function of *might*  $\phi$  as a *test*, by which you just see if the current information state is compatible with  $\phi$ .

From the perspective of whether someone in a given information state accepts a given sentence and whether the sentence is acceptable to her, the two relations between information states and sentences, i.e. *acceptance* and *acceptable* were defined as follows:

(15) Definition (*Acceptance*)

Let  $C$  be an information state and  $\phi$  be a sentence.  $\phi$  is *accepted* in  $C$  ( $C \Vdash \phi$ ) iff  $C + \phi = C$  (which intuitively says that the propositional information of  $\phi$  is already subsumed by  $C$ ).

(16) Definition (*Acceptable*)

Let  $C$  be an information state and  $\phi$  be a sentence.  $\phi$  is *acceptable* in  $C$  iff  $C + \phi \neq \emptyset$  (which intuitively says that the propositional information of  $\phi$  is not rejected by  $C$ ).

From the definitions of the update function of a sentence of the form *might*  $\phi$ , *acceptance* and *acceptable*, it follows that *might*  $\psi$  is accepted in  $C$  iff  $\psi$  is acceptable in  $C$ .

## 2.5. Veltman’s (1996) *might* for *maybe* and *acceptance* for felicitous continuation

Having reviewed Veltman’s (1996) update semantics, I propose that the modal adverb that characteristically appears with the sentence suspending the prejacent, i.e., *maybe* should be modeled as Veltman’s *might*, and the felicitous continuation as Veltman’s *acceptance*.

### 2.5.1. The case of an *only* sentence with a vague predicate

Let us take *Only John is tall* as an *only* sentence with a vague predicate. As shown above, the information state resulting from updating a given information state  $C$  with the utterance of the sentence is (11), which is reproduced here:

$$(11) \ C + \text{"Only John is tall"} = C' = \{ \langle w, \mathbf{d} \rangle \in C : \llbracket \text{Only John is tall} \rrbracket^{w, \mathbf{d}} = 1 \} = \\ \{ \langle w, \mathbf{d} \rangle \in C : \llbracket \text{John is tall} \rrbracket^{w, \mathbf{d}} = 1 \wedge \forall x [x \neq j \rightarrow ie[\llbracket \text{tall} \rrbracket^{w, \mathbf{d}}(x)(e)] < \\ \mathbf{d}(w)(\llbracket \text{tall} \rrbracket)] \} = \{ \langle w, \mathbf{d} \rangle \in C : ie[\llbracket \text{tall} \rrbracket^{w, \mathbf{d}}(j)(e)] \geq \mathbf{d}(w)(\llbracket \text{tall} \rrbracket) \wedge \forall x [x \neq j \rightarrow \\ ie[\llbracket \text{tall} \rrbracket^{w, \mathbf{d}}(x)(e)] < \mathbf{d}(w)(\llbracket \text{tall} \rrbracket)] \}$$

Then, the information state resulting from the application of *OST* to (11) with respect to the property  $\llbracket \text{tall} \rrbracket$  is (13), which is reproduced here:

$$(13) \ OST(C + \text{"Only John is tall"}, \llbracket \text{tall} \rrbracket) = OST((11), \llbracket \text{tall} \rrbracket) = \{ \langle w, \mathbf{d}' \rangle : \exists \mathbf{d} [ \langle w, \mathbf{d} \rangle \in \\ C \wedge ie[\llbracket \text{tall} \rrbracket^{w, \mathbf{d}}(j)(e)] \geq \mathbf{d}(w)(\llbracket \text{tall} \rrbracket) \wedge \forall x [x \neq j \rightarrow ie[\llbracket \text{tall} \rrbracket^{w, \mathbf{d}}(x)(e)] < \\ \mathbf{d}(w)(\llbracket \text{tall} \rrbracket)] \wedge \mathbf{d}' \geq_{w, \llbracket \text{tall} \rrbracket} \mathbf{d}] \}$$

As (13) is a set of ordered pairs of possible worlds and discourses, in some of which John is not tall, in the others of which John is tall, and in all of which nobody other than John is tall, the following holds:

$$(17) \ OST(C + \text{"Only John is tall"}, \llbracket \text{tall} \rrbracket) (= (13)) + \text{"John is not tall"} \neq \emptyset$$

That is, "John is not tall" is acceptable in  $OST(C + \text{"Only John is tall"}, \llbracket \text{tall} \rrbracket)$ , which, according to the definition of the update function for a sentence of the form *might*  $\psi$ , (15), means the following:

$$(18) \ (13) + \text{might "John is not tall"} = (13)$$

Consequently, according to the definition of *acceptance*, the following holds:

$$(19) \ OST(C + \text{"Only John is tall"}, \llbracket \text{tall} \rrbracket) (= (13)) \Vdash \text{might "John is not tall"} \\ (\text{might "John is not tall" is accepted by } OST(C + \text{"Only John is tall"}, \llbracket \text{tall} \rrbracket).)$$

The result in (19), I contend, models well the felicitousness in continuation observed in (3b). First,  $C + \text{"Only John is tall"}$  represents the speaker's (tentative) assertion that John and nobody else is tall. Second,  $OST(C + \text{"Only John is tall"}, \llbracket \text{tall} \rrbracket)$  corresponds to the state where the speaker has had second thoughts about the standard for the absolute use of the predicate (*be*) *tall*; she has suspected that the standard might be stricter than she originally assumed. Finally, in the resulting state, it holds that *might* "John is not tall" (*maybe, John is not (tall)*), as  $OST(C + \text{"Only John is tall"}, \llbracket \text{tall} \rrbracket) \Vdash \text{might "John is not tall"}$ .

## 2.5.2. The case of an *only* sentence with a non-vague predicate

In the above, we have seen that the suspension of the prejacent of an *only* sentence with a vague predicate can be modeled well—with the identification of *OST* for the speaker's second thoughts on the standard for the absolute use of the vague predicate, Veltman's (1996) *might* for *maybe*, and Veltman's *acceptance* for the felicitousness in continuation with a prejacent-suspending sentence. Now, let us see the case of an *only* sentence with a non-vague predicate, e.g., *Only John is married*.

The information state resulting from updating a given information state  $C$  with the utterance of *Only John is married* is analogous to the case of *Only John is tall*, i.e., (11) and as follows:

$$\begin{aligned}
(20) \quad C + \text{"Only John is married"} = C' = \{ \langle w, d \rangle \in C : \llbracket \text{Only John is married} \rrbracket^{w,d} = 1 \} \\
= \{ \langle w, d \rangle \in C : \llbracket \text{John is married} \rrbracket^{w,d} = 1 \wedge \forall x [x \neq j \rightarrow \\
\iota e [\llbracket \text{married} \rrbracket^{w,d}(x)(e)] < d(w)(\llbracket \text{married} \rrbracket)] \} = \{ \langle w, d \rangle \in \\
C : \iota e [\llbracket \text{married} \rrbracket^{w,d}(j)(e)] \geq d(w)(\llbracket \text{married} \rrbracket) \wedge \forall x [x \neq j \rightarrow \\
\iota e [\llbracket \text{married} \rrbracket^{w,d}(x)(e)] < d(w)(\llbracket \text{married} \rrbracket)] \}
\end{aligned}$$

The result of applying *OST* to (20) with respect to the property  $\llbracket \text{married} \rrbracket$  will be analogous to (13) and as follows:

$$\begin{aligned}
(21) \quad \text{OST}(C + \text{"Only John is married"}, \llbracket \text{married} \rrbracket) = \{ \langle w, d' \rangle : \exists d [\langle w, d \rangle \in C \wedge \\
\iota e [\llbracket \text{married} \rrbracket^{w,d}(j)(e)] \geq d(w)(\llbracket \text{married} \rrbracket) \wedge \forall x [x \neq j \rightarrow \\
\iota e [\llbracket \text{married} \rrbracket^{w,d}(x)(e)] < d(w)(\llbracket \text{married} \rrbracket)] \wedge d' \geq_{w, \llbracket \text{married} \rrbracket} d] \}
\end{aligned}$$

Before proceeding to see the consequences, let me point out a characteristic of non-vague, or definite predicates like *(be) married* with respect to degrees for someone or something to have the denoted property. That is, as a non-vague predicate, there is no vagueness with respect to whether the denoted property is applicable to an object or not. The characteristic is rendered into the following assumption:

(22) Assumption (Binary Degrees for Non-vague Properties)

The possible degrees for something or someone to have the property denoted by a non-vague predicate are binary, e.g., 1 and 0, and the standard for the absolute use of the property is the higher value, in this case, 1.

Given the assumption (22), let us now see if there is any feature with the information state (21) distinct from the information state (13). Indeed, the following holds:

$$\begin{aligned}
(23) \quad \text{OST}(C + \text{"Only John is married"}, \llbracket \text{married} \rrbracket) = \{ \langle w, d' \rangle : \exists d [\langle w, d \rangle \in C \wedge \\
\iota e [\llbracket \text{married} \rrbracket^{w,d}(j)(e)] \geq d(w)(\llbracket \text{married} \rrbracket) \wedge \forall x [x \neq j \rightarrow \\
\iota e [\llbracket \text{married} \rrbracket^{w,d}(x)(e)] < d(w)(\llbracket \text{married} \rrbracket)] \wedge d' \geq_{w, \llbracket \text{married} \rrbracket} d] \} = C + \\
\text{"Only John is married"}
\end{aligned}$$

That is because there are no discourses whose standard for the absolute use of the predicate *(be) married* is higher than those already involved in the information state (10)—with the standard being fixed to the higher degree of the two possible ones in any discourse, as is a consequence of the assumption (22). Consequently, the result of applying *OST* to  $C + \text{"Only John is married"}$  with respect to  $\llbracket \text{married} \rrbracket$  is the same thing as  $C + \text{"Only John is married"}$ ; in other words, the operation of *OST* is vacuous when the predicate is a non-vague one. Being identical to  $C + \text{"Only John is married"}$ , (23) is a set of ordered pairs of possible worlds and discourses such that in all the ordered pairs, John and nobody else is married, from which the following follows:

$$(24) \quad \text{OST}(C + \text{"Only John is married"}, \llbracket \text{married} \rrbracket) + \text{"John is not married"} = \emptyset$$

According to the definition of the relation of *acceptable*, (16), the following holds:

- (25) "*John is not married*" is not acceptable in  $OST(C + \text{"Only John is married"}, \llbracket married \rrbracket)$ .

Thus, according to the definition of the update function of a sentence of the form *might*  $\psi$ , (14) and that of the relation of *acceptance*, it follows that:

- (26)  $OST(C + \text{"Only John is married"}, \llbracket married \rrbracket) \not\models \text{might "John is not married"}$   
 (*might* "*John is not married*" is not accepted by  $OST(C + \text{"Only John is married"}, \llbracket married \rrbracket)$ ).

The result in (26), I contend, models well the non-suspendability of the prejacent and the infelicity of the continuation observed in (4).

### 2.5.3. Outcome of the current analysis

As is demonstrated by the two cases above, in the current analysis the following proposition holds:

- (27) Proposition:  
 Let  $\alpha$  be a proper noun and  $P$  be a predicate.  
 $OST(C + \text{"Only } \alpha P", \llbracket P \rrbracket) \models \text{might } \alpha \text{ not } P$  iff  $P$  is a vague predicate.

With the assumptions in (28), the proposition in (27) characterizes well the facts on the suspendability of the prejacent of *only* sentences observed in (3) and (4).

- (28) a. What is typographically expressed as "... " in examples of the suspension of the prejacent of an *only* sentence in the literature is a representation of the speaker's second thoughts on the standard for the absolute use of the predicate in question; specifically, she suspects that the standard might be stricter than she originally assumed. And the second thought is analyzed as the *OST* operator.  
 b. The epistemic modal that characteristically precedes the sentence suspending the prejacent, i.e., *maybe*, and the felicity in continuation are analyzed as Veltman's (1996) *might* and *acceptance*, respectively.

### 2.6. Horn's (2002) notion of *assertoric inertia*: A precursor?

In the current analysis, the suspendability of the prejacent of an *only* sentence is crucially attributed to the vagueness of the predicate and the speaker's afterthought about the standard for the absolute use of the vague predicate. That is, by the utterance of an *only* sentence with a vague predicate, the prejacent is indeed asserted once. However, for some reason, the speaker can suspect that the standard might be stricter than she originally thought and she weakens the original assertion and accepts the possibility that the prejacent is not true.

In fact, in relation to the suspendability of the prejacent of an *only* sentence, Horn (2002) proposed a notion which appears to be related to the current analysis, i.e. *assertoric inertia*. Drawing on Stalnaker's (1978) notion of assertion of an utterance as an agreement among the interlocutors to update the common ground so that it is compatible with the propositional content of the utterance, Horn introduced the notion of *assertoric inertia*. Something is assertorically

inert when it is entailed but not asserted. He proposed that the prejacent of an *only* sentence should be assertorically inert; hence, it should be suspendable. I would like to point out some problems with Horn's analysis. First, he doesn't propose a formal implementation of the very notion of assertoric inertia. Second, he attributes assertoric inertia of the prejacent to *only* sentences as a construction, or the semantics of *only*; consequently, every instance of the prejacent of an *only* sentence would be predicted to be suspendable. However, the prediction is incompatible with the variability of the suspension of the prejacent—the suspendability of the prejacent is subject to whether the main predicate is vague or not among others. As such, Horn's *assertoric inertia*-based analysis can be said to be empirically inadequate.

### 3. Issues to be addressed

I will conclude this paper by listing some issues to be addressed in the future work:

- In the current work, the cancelability of the prejacent of an *only* sentence is attributed to the speaker's second thought about the standard for the absolute use of a vague predicate, having nothing to do with the semantics of *only* per se. Hence, it will be predicted that "John is tall ... maybe, he isn't" is felicitous. Is this prediction borne out?
- Are there any factors other than vagueness that induce OST? Is OST independently motivated?
- Is there a variant of OST which supposes a more lenient standard instead of a stricter one? If not, why? If there were, the following continuation would be predicted to be felicitous: "Only John is tall ... maybe, some other people are".

# Perspectival plurality, relativism, and multiple indexing<sup>1</sup>

Dan ZEMAN — *University of Vienna*

**Abstract.** In this paper I focus on a recently discussed phenomenon illustrated by sentences containing predicates of taste: the phenomenon of “perspectival plurality”, whereby sentences containing two or more predicates of taste have readings according to which each predicate pertains to a different perspective. This phenomenon has been shown to be problematic for (at least certain versions of) relativism. My main aim is to further the discussion by showing that the phenomenon extends to other perspectival expressions than predicates of taste and by proposing a general solution to the problem raised by it on behalf of the relativist. The core claim of the solution (“multiple indexing”) is that utterances of sentences containing perspectival expressions should be evaluated with respect to (possibly infinite) sequences of perspective parameters. While such a move sounds radical, I argue that the departure from the traditional Kaplanian framework is not as dramatic as it sounds.

**Keywords:** perspectival expressions, relativism, perspectival plurality, multiple indexing

It has recently been argued (Kneer, 2015; Kneer, Vicente and Zeman, 2017) that predicates of taste exhibit what these authors call “perspectival plurality”: the phenomenon whereby sentences containing two or more such predicates have readings according to which each predicate in the sentence needs to be interpreted relative to a different perspective. In addition, the authors mentioned show that this phenomenon amounts to a serious problem for certain versions of relativism about predicates of taste. Despite the fact that neither the phenomenon itself nor the problem it raises have previously received much attention in literature, perspectival plurality is both interesting in its own right and has important consequences for the semantics of predicates of taste.

In this paper I aim to further the discussion in two directions. First, I want to show that the phenomenon of perspectival plurality is exhibited by more expressions than predicates of taste; second, I want to provide a general solution to the problem the phenomenon poses to relativism. In section 1 I introduce perspectival expressions, discuss their main traits, and sketch how relativism, as opposed to contextualism, treats them. In section 2 I illustrate the phenomenon at stake, starting with predicates of taste and then showing that it extends to other expressions as well. Accessing the relevant readings will require quite a bit of contextual set-up, so I will provide that for each of the examples offered. In section 3 I briefly present the problem perspectival plurality raises for certain versions of relativism, with focus on Lasersohn’s view. In section 4 I present the outlines of a relativist solution to the problem,

---

<sup>1</sup> I would like to thank Adrian Briciu, Andrei Moldovan and Agustin Vicente for reading and commenting on a previous version of this paper, as well as the audiences at the 3<sup>rd</sup> workshop of the *Semantic Content and Conversational Dynamics* project, University of Barcelona, the *Pervasive Context* conference, University of Reading and the *1<sup>st</sup> Context, Cognition and Communication* conference, University of Warsaw for their criticisms, comments and suggestions. I must also thank Robert Truswell for giving me the opportunity to publish in these prestigious *Proceedings*. All the remaining errors are, of course, mine. Finally, I acknowledge financial help from the *Semantic Content and Conversational Dynamics* project at the University of Barcelona, the *Lexical Meaning and Concepts* project at the University of the Basque Country and a “Juan de la Cierva” Postdoctoral Fellowship from MINECO.

consisting in the introduction of sequences of perspectives in the circumstance of evaluation. In the final section I discuss how much of a departure my proposal is from the traditional Kaplanian framework. In the last section I summarize and mention some open questions.

## 1. Perspectival expressions, contextualism and relativism

If I ask you whether licorice is tasty, you will answer me immediately. Most probably, you will tell me that licorice is tasty or not *from your perspective*, even if talk of perspectives is not explicit in our exchange. Immediacy and implicitness, however, should not obscure the fact that, in answering my question, licorice is deemed tasty or not *with respect to a perspective*: yours. But your perspective is not the only one that can matter: licorice can be deemed tasty or not from another person's perspective – as when, for example, you talk from your child's point of view (such a use of “tasty” has been called “exocentric”, in contrast to the first, “autocentric” or “egocentric” use – see Lasersohn (2005) and Stephenson (2007) for discussion). On the other hand, in a context in which it isn't clear which is the perspective that matters, asking whether licorice is tasty should be answered with another question: tasty to whom? All these cases seem to point to the same fact: that, in assessing whether licorice is tasty or not, a perspective needs to be supplied. “Tasty” is, in this sense, *perspectival*.

Expressions like “tasty”, “fun”, “delicious”, “disgusting”, “cool” are known as predicates of taste and constitute perhaps the paradigm of perspectival expressions. But they are not the only ones. Aesthetic predicates such as “beautiful”, “ugly”, etc. belong to this category too. According to some, moral predicates such as “good”, “bad” or the moral “ought” are also perspectival in this sense. Furthermore, epistemic modals such as “might”, “must” and the like, as well as epistemic terms such as “knowledge”, “justification” and co. can be classified in this category too. Granted, the sense of “perspective” relevant for each type of expression is different: in the first case being dependent on a perspective is equivalent with being dependent on a standard of taste, in the second with being dependent on an aesthetic standard – a moral standard, a certain body of knowledge, an epistemic standard, in the other cases. Differences between these are surely important, but in what follows I will use “perspective” as an umbrella-term to refer to whatever it is that the semantic interpretation of the expressions at stake depends on. All the expressions mentioned are, in this sense, *perspectival*.<sup>2</sup>

Another characteristic of all the expressions mentioned, one that is intimately connected with their perspectivity, is that sentences in which they appear are *context-sensitive* – in the broad sense that utterances of the same sentence can vary in truth value across contexts. To illustrate, let's focus on predicates of taste for the moment. Suppose Johnny and Tony taste licorice for the first time. Johnny loves it, but Tony is repelled by its taste. Assuming that each utter

### (1) Licorice is tasty

<sup>2</sup> “Perspective” has been used as a technical term to refer to a specific parameter in the circumstance of evaluation (see below) that is postulated by relativists as part of their semantic machinery (e.g., Kölbel, 2004b). Although I will talk about parameters shortly, at the moment I'm using the term in a neutral, intuitive sense – thus trying to be neutral between various semantic views on the expressions in question. “Perspective” also seems to have another, more self-locating use associated with personal pronouns like “I”, adverbs like “here”, “now” and “actually” – see footnote 7 for some discussion.

in separate contexts, intuitively Johnny's utterance of (1) is true in his context and Tony's utterance of (1) is false in her context. The truth value of (1) can thus vary with the context in which it is uttered.

Now, in the contemporary debate about the semantics of predicates of taste, relativism has recently become one of the main contenders. Relativism can be best understood in opposition to its main rival, contextualism, so in order to get clear on relativism's semantic commitments I will introduce the two views in tandem. Under one way of seeing the debate, both contextualism and relativism about predicates of taste are attempts to account for the context-sensitivity (in the broad sense illustrated above) of sentences like (1) via the perspectivity of the predicates themselves. In fact, the main difference between the two views can be expressed by saying that they situate perspectivity in different places in the semantic apparatus. Starting from the familiar Kaplanian framework in which the role of context is to provide both elements in the content of utterances *and* values for the parameters in the circumstance of evaluation (Kaplan, 1989: 525), the difference between contextualism and relativism consists in giving precedence to one of those roles of context over the other with respect to perspectives. Thus, for contextualism, the role of context is to provide the perspectives that enter into the semantic content of utterances like (1) above; for relativism, the role of context is to provide the perspectives that enter into the circumstance with respect to utterances like (1) are evaluated. This difference comes out both in *the type of semantic content the two views postulate* (perspective-specific contents for contextualism, perspective-neutral contents for relativism) and in *the types of parameters that figure in the circumstance* (possible worlds and perhaps other parameters – but no perspectives – for contextualism; possible worlds and perhaps other parameters *plus* perspectives, for relativism). The same holds with respect to the other perspectival expressions mentioned above, for which the formal representation of the corresponding sentences is similar.<sup>3</sup>

There is a lot of variety within both contextualism and relativism. For example, versions of contextualism can differ by postulating different mechanisms by which context provides the perspectives that enter into the content of the relevant utterances. Thus, perspectives can be provided either as a result of satisfying the character of a perspectival expression (understood as in indexical), or as a result of saturating one or more variables for perspectives that such expressions come endowed with, or by means of unconstrained pragmatic processes of the kind appealed to by truth-conditional pragmatic analyses etc. Versions of relativism can differ by conceiving the context which provides the perspectives that enter into the circumstance differently: it could be either the context of use, as in the Kaplanian framework and more orthodox versions of relativism, or the context of assessment, as more radical

<sup>3</sup> Contextualism about predicates of taste has been upheld by Stojanovic (2007), Glanzberg (2007), Cappelen and Hawthorne (2009), Schaffer (2011); contextualism about moral terms has been proposed by Dreier (1990), among others; contextualism (and relativism) about aesthetic terms is discussed in, e.g., Baker (2012); contextualism about epistemic modals has been defended by, e.g., von Fintel and Gillies (2008) and Schaffer (2011), while contextualism about epistemic terms like “know” has been one of the main contenders for a while now, supported by, e.g., DeRose (1992). On the other hand, relativism about predicates of taste has been defended chiefly by Lasersohn (2005, 2008, 2016) and MacFarlane (2014); relativism about moral terms has been defended by, e.g., Brogaard (2008); Kölbel (2004b) holds relativism about the entire evaluative sphere, including the aesthetic; relativism about epistemic modals is defended in Egan, Hawthorne and Weatherston (2005) and MacFarlane (2014); relativism about epistemic terms has been proposed by, e.g., Kompa (2005), MacFarlane (2014).

versions would have it. Finally, as suggested above, variation in both views can come from *whose* perspective is relevant in all contexts – that of the relevant person (usually the speaker), that of a group to which the speaker belongs to or not, or even a generic perspective. However, for the purposes of this paper most differences between contextualist views, as well as those between relativist views, won't matter and will thus be put aside. The only assumption I make concerns the issue of whose perspective is relevant: namely, that this is a matter that depends on the context. I think flexible versions of both contextualism and relativism are better suited to account for the data.

## 2. Perspectival plurality

In the preceding section I contended that one of the main and widely agreed upon features of the expressions investigated is their perspectivality: the fact that we appeal to perspectives for their interpretation. This feature, in turn, is responsible for the expressions' sensitivity to context (in the sense described). Recently, however, a related but much less discussed phenomenon involving such expressions has surfaced in the literature: namely, what Kneer (2015) and Kneer, Vicente and Zeman (2017) call "perspectival plurality". Perspectival plurality consists in the existence of certain readings ("plural readings") of sentences containing two or more perspectival expressions that make appeal to more than one perspective. Perspectival plurality has been brought to the fore by the authors mentioned in connection to predicates of taste; here my aim is to show that it is a more general phenomenon, exhibited by (most of) the perspectival expressions mentioned above, as well as by others. The phenomenon is interesting in its own right, but also relevant in connection to relativism about the relevant expressions because, as I will show in section 3, it is highly problematic for at least certain versions of the view.

As it happens, the plural readings that I want to put forward for consideration are not easily available without a certain amount of contextual setting. I will thus provide such a setting before presenting each example. Starting with predicates of taste, imagine the following scenario: Halloween has just passed, and several families from the neighborhood have gathered together to talk about how they spend the holiday. Naturally, at some point the conversation centers on what their kids did, with parents taking turns to tell the stories involving their offspring. Thus, one parent starts describing what his kid did, other parents following suit. When his turn comes, Johnny's father utters

(2) Johnny played a silly prank and had a lot of tasty licorice.

In this context, the most natural interpretation of the sentence seems to be that, while "tasty" pertains to Johnny's perspective, "silly" doesn't (since Johnny himself thought that the prank was great and had a lot of fun playing it); instead, "silly" is most naturally interpreted as pertaining to the father's perspective. This reading of (2) is a combination of an egocentric use of a predicate of taste ("silly") with an exocentric use ("tasty"). Another interpretation of the sentence is that, while "tasty" pertains to Johnny's perspective, "silly" pertains to the perspective of the neighbor, the victim of the prank (to make this reading more palatable, assume, for example, that the victim has previously complained about Johnny's prank). This latter reading of (2) is a combination of two exocentric uses of the two predicates of taste. I take both readings of (2) to show that predicates of taste exhibit perspectival plurality.

Some readers will no doubt find the reading I'm claiming to be available hard, or even impossible, to get. One reason for that might be connected with finding it difficult to interpret "tasty" as pertaining to Johnny's perspective, and not to the father's or the neighbor's. I acknowledge the difficulty, but I think it can be easily alleviated by stipulating that situation is such that i) that the father in fact doesn't like licorice and ii) this is known to everyone in the audience. So the father couldn't use "tasty" egocentrically – that would amount to him saying something false. It seems to me that in such a situation (2) is clearly (and perhaps uniquely) felicitous. And such a situation doesn't strike me as incredibly far-fetched – in fact, I believe many real world scenarios are precisely like it.<sup>4</sup>

In the reminder of this section I will attempt to show that the same happens with other perspectival expressions. Take, for example, aesthetic predicates. Imagine the context to be similar to the one for the interpretation of (2), but that instead of discussing what their kids did on Halloween, the parents are discussing what they did on their school trip to the art museum. The visit comprised both seeing the main exhibition of the museum and a period of playing time in which kids were mostly drawing or painting. As before, one parent starts describing what his kid did, other parents following suit. When her turn comes, Johnny's mother – a sophisticated art lover – utters

- (3) Johnny drew a nice portrait of the teacher in the play time and saw an exquisite painting in the main exhibition.

In this context, the most natural interpretation of the sentence is such that, while "nice" pertains to Johnny's perspective, "exquisite" doesn't (since he is too little to have an understanding of good art); instead, "exquisite" is most naturally interpreted as pertaining to the mother's perspective. As the first reading of (2) above, this reading is a combination of an egocentric use of an aesthetic predicate ("exquisite") with an exocentric use ("nice"). Another interpretation of the sentence is that, while "exquisite" pertains to the mother's perspective, "nice" pertains to a third person – say, the art teacher who supervised the kids' playing time (to make this reading more palatable, assume, for example, that Johnny's mother has previously reported the teacher's evaluation of Johnny's drawing). This latter reading of (3) is a combination of two exocentric uses of the two aesthetic predicates. I take both readings of (3) to show that aesthetic predicates exhibit perspectival plurality.

Another type of expressions exhibiting perspectival plurality are moral terms. (4) below seems to easily lend itself to a plural interpretation. Imagine the context to be one on which a student is questioned about her knowledge of various moral theories, by having to respond to particular cases. For easiness, the cases are devised so that to involve (symbolic) characters. Thus, one such case involves Immanuel, a notorious Kantian, and Jeremy, a notorious utilitarian. The question in this particular case revolves around the permissibility of lying. So, asked about what the two characters should do, the student answers with

<sup>4</sup> Two remarks. First, it is important to stress that the claim is *not* that (2) cannot have other readings in other contexts (say, one in which both predicates of taste pertain to the father's perspective) but that, *in the context described above* (with or without making the stipulations mentioned), the plural reading of (2) is the most natural one. Second, in making the case for the availability of the plural readings for (2) I'm not relying solely on my own intuitions: in a series of experiments, Kneer (2015) has shown that for similar sentences plural readings are not only available, but the preferred ones in contexts like the ones devised for (2). For many other examples of plural readings of similar sentences, see also Kneer, Vicente and Zeman (2016).

## (4) Jeremy should lie, but Immanuel shouldn't.

In this context, the most natural interpretation of the sentence is such that the first "should" pertains to Jeremy's perspective, while the second "should" to Immanuel's. This is an example in which both moral predicates are used exocentrically, each of them pertaining to a different perspective. I take this reading of (4) to show that moral terms exhibit perspectival plurality.

Sentences containing epistemic modals also seem to admit plural readings. Thus, imagine that Anne and Bob are playing Mastermind. Anne has hidden the pieces and Bob has made his first guess. Immediately after she has given Bob feedback about his guess, Anne departs from the board to get a glass of water. Seeing Bob hold a green piece in his hand and ponder whether to put it on the board or not, Anne comments on his predicament by saying "There might be a green one". Here the "might" pertains to Bob's perspective, since Anne knows very well whether a green piece is among the ones she has hidden or not. But suppose that while she is sure about the green piece, she doesn't remember very well whether a red piece is among the ones hidden too (being away from the board, she cannot currently see it, so she cannot check). She continues the sentence by saying (perhaps only to herself) "and there might be a red one too". This latter "might" doesn't pertain to Bob's perspective as the one before, but to her own instead. Thus, in such a context the most natural interpretation of

## (5) There might be a green one, and there might be a red one too,

is such that the first "might" pertains to Bob's perspective and the second "might" to Anne's. The example is thus one in which an exocentric use of an epistemic modal is combined with an egocentric use. Although the scenario is more complex than the ones before, I take this reading of (5) to show that epistemic modals exhibit perspectival plurality.<sup>5,6</sup>

Judging from the examples above, perspectival plurality seems to be a phenomenon exhibited by a wide range of expressions.<sup>7</sup> The reader might not have accessed the relevant readings of

<sup>5</sup> For other examples, as well as for experimental studies involving epistemic modals that show the preponderance of the plural interpretation, see Kneer (2015).

<sup>6</sup> Plural readings of sentences containing epistemic terms like "know" seem harder to come by. One explanation might be based on Lewis' (1996) observation that once a stricter epistemic standard has been made salient in a context, it is hard to go back to a less strict one. This explanation, however, might not work for cases in which the stricter standard is made salient after the less strict one has. Be that as it may, I don't want to rule out that in suitably constructed contexts plural readings of such sentences are possible, but I also won't try to devise a scenario showing that they are here.

<sup>7</sup> On a broader understanding of "perspective", which captures the semantic dependence of sentences on more objective (self-locating) features of the context, such as time, location and possible world, perspectival plurality is manifest with other expressions too. The following sentences seem to allow plural readings:

- (i) Anne threw a party and Bob got drunk.
- (ii) Every time John visits a city in a foreign country, he goes to all the local bars.
- (iii) Claire like more the books she could have written than the books she wrote.

(i) is often given as an example of temporal anaphora, being interpreted such that the interval of Bob's getting drunk is contained in the interval of Anne's throwing of the party; but there is a reading of (i) according to which the events need not overlap (for example, consider (i) as an answer to the question "what did your friends do this weekend/lately?"). One reading of (ii) is that the countries are foreign with respect to John, while the

the sentences provided as *the most natural ones*, as described. This is fine, since the important fact is that the plural readings of the sentences *exist*, even if are not the most natural or default ones. The reader might also be wary to concede that the phenomenon is present in a particular domain or another. This is fine too, since its presence in some domains and absence in others is enough to establish its existence. Thus, even if plural readings are not perceived as the most natural ones, or are limited to certain domains, the examples above show that there is a phenomenon to be taken into consideration.

### 3. The problem for relativism

Although examples like the above have not been present very much in recent relativist literature, there are a few places where similar examples with plural readings have been discussed.<sup>8</sup> The most comprehensive discussion can be found in Lasersohn (2008). However, Lasersohn doesn't think plural readings are problematic for (his brand of) relativism, because he doesn't think they are available for the sentences he discusses. I will first briefly go through Lasersohn's considerations and then show that he is mistaken.

The context of Lasersohn's discussion is the so-called "argument from binding", made famous by Stanley (2000), and which has prominently figured in the debate between truth-conditional semantics and truth-conditional pragmatics. The argument is used to show that the target expressions have a variable of a certain kind in their syntactic configuration. It is

---

bars are local with respect to the (denizens of the) cities visited by John. Finally, for the interpretation of (iii), while the reference of the second "books" has to be determined with respect to a possible world in which Claire wrote books (as "could" demands), the reference of the first "books" has to be determined with respect to the actual world (see Creswell (1990) for many more examples like this.) I take these readings of (i)-(iii) to show that perspectival plurality (in the extended sense employed in this footnote) appears with other expressions than the ones focused on in section 2. Interestingly, although utterances of "I" in other languages than English (i.e., Amharic) can in the right environments be used to refer to someone else than the speaker (Schlenker, 2003), plural readings involving two occurrences of "I" in such languages are *not* available (Ninan, 2010). There are, however, examples in which various forms of the first person pronoun refer to different "aspects" of the speaker. For instance, imagine that after a certain outcome of a dice during a board game Mary utters:

(iv) I'm going to move myself two fields ahead.

"I" in (iv) refers to Mary as a person, while "myself" to her representation in the game (say, some token of sorts). This seems to me also like an instantiation of the broad phenomenon under discussion here. Finally, the so-called "de se" interpretations of dream reports (Percus and Sauerland, 2005) seem to fall into this category too. In a sentence like

(v) I dreamt that I was marrying my granddaughter

the second "I" refers to the speaker's dream-self, while "my" to the speaker's real self and thus (v) has, according to the two authors, a plural reading according to which the dream-self of the speaker marries his actual self's granddaughter. Importantly, Percus and Sauerland point out that (v) *cannot* have a plural interpretation according to which the real self of the speaker marries the dream-self's granddaughter. This example opens up further issues related to the scope of the phenomenon, its varieties, its presence in more complex constructions like embeddings under various verbs, as well as to the constraints on the interpretation of sentences that have plural readings. I hope to pursue these questions in further research. I thank an anonymous referee for *SuB21* for bringing dream reports to my attention.

<sup>8</sup> Earlier attempts to criticize relativism by appeal to plural readings of similar (but still importantly different) sentences belong to Cappelen and Hawthorne (2009) and Kissine (2012). See Kneer, Vicente and Zeman (2016) for more details.

both an argument that has been applied to a variety of expressions and against several views. Recently, it has been used against relativism about predicates of taste. To illustrate how it works, consider

(6) Everyone got something tasty. (Schaffer, 2011: 194)

When uttered in a context in which each person from a group of people gets something tasty, (6) has a reading according to which the thing each person got is tasty *from the perspective of that person* – that is, a bound reading. Coupled with the principle that “there is no semantic binding without a syntactically bindable variable”, this reading of (6) presumably yields the conclusion that “tasty” has a variable for perspectives in its logical configuration. Given that the presence of such a variable in the logical configuration of “tasty” amounts to a contextualist view, the argument shows that relativism about “tasty” and predicates of taste in general is incorrect.<sup>9</sup>

Lasersohn counters this argument by proposing a different account of binding he dubs “index binding”. In essence, index binding replaces the relevant binding in the object language by binding in the meta-language. According to the proposal, quantifiers can bind both variables in the object language and variables in the meta-language. Although he illustrates how this works using meteorological sentences, in the case of (6) the claim would be that the quantifier “everyone” binds both a variable in the object language and one in the meta-language: the first is the subject variable of the verb “get”, while the second is the variable for perspectives; the first belongs to the object language, the second to the meta-language. Index binding avoids the conclusion of the argument from binding by avoiding binding of perspectives in the object language altogether, and relegating it to the meta-language instead. Thus, there is no need to postulate variables for perspectives in the object language to account for bound readings of sentences like (6). Presumably, a similar story can be told for other perspectival expressions for which the argument from binding can (or has) been devised.

Plural readings come in when Lasersohn worries about the expressive power of index binding. He admits from the outset that

[b]inding the index in this way does not give us the full expressive power of standard variable binding. If, for example, we were to claim that predicates of taste have hidden argument places which can be filled by [variables for perspectives], we should expect to find cases where two of [those variables] both appear free inside the scopes of two different variable-binding operators, each of which binds just one of the [variables]. (Lasersohn, 2008: 325)

To illustrate the worry with an example, consider

---

<sup>9</sup> For the argument to work against relativism, it has to be assumed that context cannot have both the role of providing elements in the content of a given utterance (in the present case, by providing a value to a variable) *and* that of providing elements into the parameters of circumstance. This claim is encapsulated in the principle Recanati (2007: 34) calls “Distribution” and is assumed by Schaffer and other contextualists mounting the argument.

- (7) Every man gave a woman a fun ride and a tasty dish. (Lasersohn, 2008: 325)

If standard variable binding were to apply to (7), it “should have a reading in which the hidden argument for *fun* is bound to *every man*, but the hidden argument for *tasty* is bound by *some woman*” (2005: 325). And, were such a reading available, that would be bad news for index binding. However, Lasersohn further claims,

[(7)] does not have such a reading. It can be interpreted at least three ways: The speaker might be expressing his or her own opinion that the rides were fun and the dishes were tasty, or claiming that the each man gave a ride that was fun for him and a dish that was tasty for him, or that each woman received a ride that was fun for her and a dish that was fun for her; but *the sentence cannot mean that each man gave some woman a ride that was fun for him, and a dish that was tasty for her*. (2008: 325, my emphasis)

The reading Lasersohn claims (7) cannot have is precisely a plural reading, one in which one predicate is bound by a quantifier (thus pertaining to the perspectives of those in the domain of that quantifier), while the other predicate is bound by another quantifier (thus pertaining to the perspectives of those in the domain of the other quantifier). So, Lasersohn brings in plural readings in connection to sentences like (7) to show that, in fact, they are not available. This, in turn, allows him to put to rest worries related to expressive power, and thus to show that index binding yields the right results when it comes to predicates of taste.<sup>10</sup> Presumably, he would employ the same reasoning in connection to other perspectival expressions.

But, as we show in Kneer, Vicente and Zeman (2017), Lasersohn is too quick to dismiss plural readings. First, although it might be that a plural reading of (7) is unavailable in any context, such a reading seems to be available with similar sentences in certain contexts. To stick with predicates of taste for the moment, take the following example, uttered in the same context as that devised for (2):

- (8) Every neighbor let some kids play a silly prank on him and gave them a lot of tasty licorice.

In such a context, the most natural interpretation of (8) is such that, while “tasty” pertains to the perspective of each kid in the range of “some kids”, “silly” pertains to that of each neighbor in the range of “every neighbor” (or to that of the speaker). If this is so, then Lasersohn’s ban on plural readings of sentences like (7) is not mandated.<sup>11</sup> In the same vein, plural readings seem to be available for similar sentences containing the other expressions mentioned above. To illustrate with aesthetic predicates, uttered in the same context as that devised for (3), the most natural interpretation of

- (9) Every teacher showed some kid how to draw a nice portrait of himself and how to appreciate the exquisite paintings in the main exhibition.

<sup>10</sup> He also takes the absence of such readings for (7) to provide an argument against contextualism about predicates of taste. I’m not interested in this aspect here, but see Kneer (2015) for developing this point.

<sup>11</sup> For more similar examples, see Kneer, Vicente and Zeman (2017).

is such that, while “nice” pertains to the perspective of each kid in the range of “some kid”, “exquisite” pertains to that of each teacher in the range of “every teacher” (or to that of the speaker). It is of course possible that such readings are not available for all the expressions mentioned, but the availability of such readings for sentences like (8) and (9) clearly shows that Lasersohn’s ban on plural readings at least for doubly-quantified sentences containing predicates of taste and aesthetic predicates is empirically incorrect.

Second, as I’ve shown in section 2, plural readings are clearly available for simple sentences containing the expressions at stake. True, Lasersohn doesn’t consider such sentences, so a certain amount of speculation is present here. But assuming that Lasersohn is consistent, his ban on plural readings should extend to simple sentences too. One way to avoid this extension is to claim that the problem stems from the account of binding that he proposes. Although index binding has not been received with a lot of sympathy (see, for example, Snyder (2013) for several objections), this is not the case. As we observe in Kneer, Vicente and Zeman (2017), Lasersohn’s ban on plural readings comes from more general considerations having to do with what he takes the commitments of a relativist framework to be. Thus, talking about the absence of plural readings of (7), he writes: “[t]he intuition behind this pattern can perhaps be expressed this way: In a relativist theory, in order to assess a sentence for truth or falsity, one must adopt a stance – that is, *truth assessment is always done from a particular perspective*” (Lasersohn, 2008: 326, my emphasis). Thus, Lasersohn takes this “one sentence – one perspective” principle (what in Kneer, Vicente and Zeman (2017) we call the “Uniqueness of Perspective Constraint”) to be at the heart of a (or at least his) relativist theory. The claim is thus completely general and applies to *all* sentences, regardless of their complexity. For Lasersohn, then, plural readings should be banned across the board. Evidently, this doesn’t bode well with the data.<sup>12</sup>

#### 4. Towards a solution: multiple indexing

In previous sections I’ve shown that the phenomenon of perspectival plurality extends beyond predicates of taste (section 2) and, following previous work, that it poses a serious problem for at least certain versions of relativism (section 3). In this section I sketch a possible solution on behalf of the relativist.<sup>13</sup>

As we have seen in section 1, the main feature of relativism is that it introduces a parameter for perspectives in the circumstance of evaluation/index. Now, the problem posed by perspectival plurality shows that one such parameter is not enough. A natural move, then, would be to postulate more than one parameter for perspectives in the circumstance/index. This is an instance of a more general strategy I call “multiple indexing”.

<sup>12</sup> The extent to which the “one sentence – one perspective” principle is held in relativist quarters is hard to determine, given that not many relativists have addresses the issue. To my knowledge, Lasersohn is the only one who adheres to it explicitly. Kissine (2012) also seems to think that relativists are committed to it. In any case, I’m happy to contend that the problem raised by perspectival plurality is, at limit, only a problem for Lasersohn’s view and for any other relativist view that upholds the principle as a core commitment of the framework.

<sup>13</sup> Due to limitations of space, I’m not able to consider here other possible solutions to the problem. See, however, Kneer, Vicente and Zeman (2017) for a short survey.

Multiple indexing thus consists in the introduction in the circumstance of evaluation/index of more than one parameter *of the same kind*. More precisely, the proposal is that each utterance should be evaluated with respect to *sequences* of such parameters. The idea of a sequence is that it provides an ordering of parameters that are systematically related to the expressions to which they correspond, so that the value of the first parameter of the relevant kind is used to evaluate the first (occurrence of the) expression it corresponds to, the value of the second parameter of the relevant kind is used to evaluate the second (occurrence of the) expression it corresponds to and so on.<sup>14</sup> It is thus a wholesale, global strategy to assess for truth complex sentences by (locally) providing values of the parameters used for the evaluation of each (occurrence of the) expression they correspond to. In our case, the sequence is composed of parameters for *perspectives*, with the result that each parameter will provide a value for the perspective used to evaluate each (occurrence of the) perspectival expression it corresponds to. The strategy helps with perspectival plurality because it allows that, in principle, each (occurrence of a) perspectival expression can be evaluated with respect to a different perspective. This is exactly what cannot happen if one upholds the “one sentence – one perspective” principle considered by Lasersohn to be at relativism’s roots. But it also has no problem with what could be called, in contrast to plural readings, “singular readings”: those that Lasersohn claimed are the only ones available in the case of (7), for example. What happens in such cases is that the values of all the parameters for perspectives are the same – that is, all the perspectival expressions are evaluated with respect to the same value, and, thus, the whole sentence itself.

To illustrate how the strategy is applied, let’s once again focus on predicates of taste and consider the plural reading of (2) made salient in section 2, as well as one of its singular readings – say, the one according to which both “silly” and “tasty” pertain to the speaker’s perspective. Before supplying values for the two parameters for perspectives employed, the template for the truth conditions of (2) looks something like this:

- (10)  $[[\text{Johnny played a silly}^1 \text{ prank and had a lot of tasty}^2 \text{ licorice}]]^{c, w, \langle p1, p2 \rangle} = 1$  iff Johnny played a silly prank in  $w$  according to the value of  $p1$  and had a lot of tasty licorice in  $w$  according to the value of  $p2$ ,

where  $p1$  and  $p2$  are the two parameters for perspectives in the sequence introduced, the superscripts on the two predicates of taste represents the order in which they appear and the co-indexing of the parameters with those superscripts signifies that they correspond to the predicates superscripted ( $pn$  corresponds to  $\Phi^n$ , where  $\Phi$  is a predicate). Once values are given to  $p1$  and  $p2$ , we obtain the two readings of (2) mentioned above. Thus, the plural reading is represented as follows:

- (11)  $[[\text{Johnny played a silly}^1 \text{ prank and had a lot of tasty}^2 \text{ licorice}]]^{c, w, \langle p1[\text{speaker}], p2[\text{Johnny}] \rangle} = 1$  iff Johnny played a silly prank in  $w$  according to the speaker’s perspective and had a lot of tasty licorice in  $w$  according to Johnny’s perspective,

<sup>14</sup> In other words, we define a kind of assignment function (similar to that defined in. e.g., Heim and Kratzer (1998), but on the circumstance side, as it were) that assigns to each occurrence of a perspectival expression the corresponding perspective parameter in the sequence.

where  $pn[v]$  should be read as “ $v$ ’s perspective is the value of the  $pn$ -th parameter for perspectives”, so that the value of  $p1[speaker]$  is the speaker’s perspective and the value of  $p2[Johnny]$  is Johnny’s perspective.<sup>15</sup> The singular reading of (2) mentioned above is represented as follows:

- (12)  $[[Johnny \text{ played a silly}^1 \text{ prank and had a lot of tasty}^2 \text{ licorice}]]^{c, w, \langle p1[speaker], p2[speaker] \rangle}$   
 = 1 iff Johnny played a silly prank in  $w$  according to the speaker’s perspective and had a lot of tasty licorice in  $w$  according to the speaker’s perspective.

The difference in readings is simply the result of giving different values to the sequence of perspectives in the circumstance/index. The framework is flexible enough to capture all the possible plural readings, but also all the possible singular readings of sentences like (2), as well as those of similar sentences comprising the other expressions mentioned.<sup>16</sup>

Now, in representing the abstract truth-conditions of (2) I have used a sequence of perspective parameters with only two elements for convenience. But given the existence – at least in principle – of sentences with an infinite number of perspectival expressions that might admit of plural readings, the two parameters are not enough. So the sequences I propose to introduce will have to be infinite as well. From a formal point of view, this poses no significant problem. Vlach (1973), as well as Cresswell (1990), discuss the possibility of adopting systems with infinite indexing, and the reasons they offer are very similar to those presented in this paper (namely, the need to account for plural readings of sentences containing perspectival expressions, in the broader sense of “perspective” mentioned in footnote 7). Alternatively, one could employ a finite but non-limited sequence of perspective parameters, on the model of Vlach’s system with times (Vlach, 1973, Appendix)). Certain authors (e.g., Rabern, 2012) show that a non-finite number of parameters is in fact *necessary* for semantics. Be that as it may, the point here is that although I have used a sequence with only two perspective parameters, there is no obstacle to using one with infinite parameters. In such a case, every sentence will be relative to an infinite sequence, but the majority of parameters will be idle, since in fact sentences with an infinite number of perspectival expressions will not be uttered. (The idleness of certain parameters is a move already familiar to the relativist, given that there are sentences that don’t contain any perspectival expressions; see Kölbel (2009) for this point.) There is an alternative route, too: instead of taking semantic values to be functions from infinite sequences to truth-values, one can see them as *partial functions* from sequences with a number of parameters  $n$  to truth values, where the partial functions are obtained by imposing the condition that  $n$  is the same as the number of perspectival expressions in the sentence whose semantic value is evaluated for truth.<sup>17</sup>

<sup>15</sup> The representation of the reading of (2) according to which “silly” pertains to the perspective of the neighbor, the victim of the prank, is obtained by replacing the first parameter in the sequence,  $p1[speaker]$ , with  $p1[neighbor]$ .

<sup>16</sup> An important question that can be asked at this point is how exactly are the values of the parameters for perspectives determined in a certain context. I cannot provide a detailed answer here, but the short one is: at least partially, *by the intentions of the speaker*. This has a certain “pragmatic” ring to it; I happily accept that. Providing values for parameters of circumstance has been deemed by several authors (including relativists: see MacFarlane’s (2014) “post-semantics”) as a pragmatic phenomenon.

<sup>17</sup> I’m indebted to David Rey for discussion and suggestions on this point.

As for plural readings of complex sentences with quantifiers like (8), I think there is more than one way to go, depending on the account of binding adopted. One option would be to keep Lasersohn's index binding<sup>18</sup>, but give up the "one sentence – one perspective" principle that comes with it and allowing a quantifier phrase to bind *only* the  $n$ -th parameter for perspectives in the sequence, namely that corresponding to the  $n$ -th predicate in the sentence. Alternatively, the relativist could adopt the view put forward in Zeman (2015), according to which quantifier phrases like "every neighbor" contribute a "for  $x$ " phrase that is construed as a variadic operator of the kind proposed by Recanati (2002). Variadic operators are extensional operators that transform a predicate into another predicate with higher adicity, whose additional argument in a sentence like (8) gets bound by "every neighbor". Deciding which of these two alternatives ultimately serves best the relativist is no doubt important, but for the purposes of this paper such a decision need not be made. In principle, the multiple indexing strategy is independent of the account of binding adopted. To keep things simpler, however, I will illustrate how sentences like (8) are treated by using index binding. This time I will give the truth conditions for three readings of (8), the plural one made salient in section 3 and two singular ones, one in which both "silly" and "tasty" pertain to the speaker's perspective, the other in which they pertain to the range of neighbors quantified over by "every neighbor" (this latter case corresponding to both predicates of taste being bound by the quantifier phrase). Before supplying values for the two parameters for perspectives employed, the template for the truth conditions of (8) is (simplifying greatly)

- (13)  $[[\text{Every neighbor let some kids play a silly}^1 \text{ prank on him and gave them a lot of tasty}^2 \text{ licorice}]]^{c, w, \langle p1, p2 \rangle} = 1$  iff Every neighbor  $x$  let some kid  $y$  play a silly prank on  $x$  in  $w$  according to the value of  $p1$  and  $x$  gave  $y$  a lot of tasty licorice in  $w$  according to the value of  $p2$ .

Once values are given to  $p1$  and  $p2$ , we obtain the three readings of (8) mentioned above. Thus, the plural reading is represented as follows:

- (14)  $[[\text{Every neighbor let some kids play a silly}^1 \text{ prank on him and gave them a lot of tasty}^2 \text{ licorice}]]^{c, w, \langle p1[x], p2[y] \rangle} = 1$  iff Every neighbor  $x$  let some kid  $y$  play a silly prank on  $x$  in  $w$  according to  $x$ 's perspective and  $x$  gave  $y$  a lot of tasty licorice in  $w$  according to  $y$ 's perspective,

where "every neighbor" and "some kids" quantify both over object language variables and over parameters for perspectives in the index, as Lasersohn's index binding requires, with each of them quantifying over one of the parameters in the sequence (the former over  $p1$ , the latter over  $p2$ ).<sup>19</sup> The two singular readings mentioned above are represented by (15) and (16), respectively:

- (15)  $[[\text{Every neighbor let some kids play a silly}^1 \text{ prank on him and gave them a lot of tasty}^2 \text{ licorice}]]^{c, w, \langle p1[x], p[x] \rangle} = 1$  iff Every neighbor  $x$  let some kid  $y$  play a silly prank on  $x$  in  $w$  according to  $x$ 's perspective and  $x$  gave  $y$  a lot of tasty licorice in  $w$  according to  $x$ 's perspective.

<sup>18</sup> Assuming the problems that beset it (Snyder, 2013) are solved.

<sup>19</sup> The representation of the plural reading of (8) according to which "silly" pertains to the perspective of the speaker is obtained by replacing the first parameter in the sequence,  $p1[x]$ , with  $p1[speaker]$ .

- (16)  $[[\text{Every neighbor let some kids play a silly}^1 \text{ prank on him and gave them a lot of tasty}^2 \text{ licorice}]]^{c, w, \langle p1[\text{speaker}], p2[\text{speaker}] \rangle} = 1$  iff Every neighbor  $x$  let some kid  $y$  play a silly prank on  $x$  in  $w$  according to the speaker's perspective and  $x$  gave  $y$  a lot of tasty licorice in  $w$  according to the speaker's perspective.

As before, the difference in readings is simply the result of giving different values to the sequence of perspectives in the circumstance/index. The framework is flexible enough to capture all the possible plural readings, but also all the possible singular readings of sentences like (8), as well as those of similar sentences comprising the other expressions mentioned.

## 5. How unorthodox is multiple indexing?

Naturally, the framework just put forward is liable to a number of objections. For reasons of space, I will address here perhaps the most obvious one: that it is highly unorthodox, in that it departs significantly from the Kaplanian framework in which the debate between relativism and contextualism has been, so far at least, framed. I will try to show that, while it is indeed a departure from the Kaplanian view, the departure is not dramatic.

One source for the feeling of oddness might be the very idea of countenancing *more than one parameters of the same kind* in one's semantic framework. However, this worry is easy to assuage. The Kaplanian framework in which the debate between contextualism and relativism has been cast (and which I take here to be the orthodox view<sup>20</sup>) *already* makes appeal to more than one contextual element of the same kind in the semantic apparatus. For Kaplan (1989), but also for Lewis (1980), many contextual elements are part both of the context of utterance (understood here in a formal sense as a tuple of contextual features – agent, time, location, world) *and* of the circumstance/index (world and time for Kaplan; world, time, location and standards of precision for Lewis). But the need to introduce more than one contextual element of the same kind has been noted even before that: as Kamp (1971), Vlach (1973) and others have shown (in the particular case of time), this is needed for the interpretation of complex sentences in natural language, like “One day, all persons alive now will be dead”. The novelty brought by Kaplan and Lewis was to show that we need to distinguish clearly (on pain of conflating the logically valid with the necessary) between two roles such contextual features play: on one hand, we need them to fix the content of utterances (“context”); on the other, we need them to allow that such content is evaluated at different situations (“circumstance of evaluation”/“index”); no semantic theory is complete without one or the other. So, far from being objectionable, the introduction of two contextual elements of the same kind is, according to Kaplan and Lewis, a requirement for an adequate semantic theory.

Perhaps then one might think that multiple indexing is unorthodox because one might find the idea of introducing more than one parameter of the same kind in *any* side of the context-circumstance/index division odd. This worry is put to rest by attending to the fact that in the Kaplanian framework itself we need to postulate more than one contextual element of the same kind in the context (understood now formally as a tuple of elements, “context”). As

<sup>20</sup> “Unorthodox” views that depart from the Kaplanian framework are not uncommon: for a recent view that reminds one of the old, pre-Kaplanian “index theory” of Lewis (1970), see Stojanovic (2012).

widely known, the focus of Kaplan's main work has been both on what he called "pure indexicals" and on demonstratives. When it comes to the latter, an element that gives the content of a demonstrative has to be introduced in the (formal) context, in the same way in which the speaker has been introduced in order to give the content of a pure indexical like "I". So, besides agent, time, location and possible world, the Kaplanian formal notion of context includes a demonstration<sup>21</sup> that would give the content of the demonstrative in a sentence like "That is a boat". But this cannot be the end of the story, since there are sentences containing two or more demonstratives, such as

(17) That is on top of that,

where the first "that" is accompanied by a demonstration targeting one object and the second "that" by a demonstration targeting another object. In order for (17) to get a content, context has to provide not only one demonstration, but two. That is, we need two elements for demonstrations in the Kaplanian (formal) context. And, given that there are sentences with more than two demonstratives ("That is between that and that"), things are not likely to stop here.

So, then, the remaining source of resistance to multiple indexing is that one finds the idea of introducing more than one parameter of the same kind *in the circumstance/index* side of the aforementioned division itself odd. While this is far from an argument, it pushes the question of the motivations for doing so. Of course, the main claim of this paper is that perspectival plurality is precisely such a motivation. But it is important to note that, in the end, perspectival plurality does very little on top of other arguments for relativism to embrace multiple indexing. In other words, any reason the relativist has to introduce *one* parameter of a certain kind in the circumstance/index can automatically be turned into a reason to introduce *more than one* such parameter by attending to perspectival plurality.

So, what about the actual arguments for introducing one parameter of a certain kind in the circumstance/index? To keep it close to orthodoxy, let's consider Kaplan and Lewis' main reason for drawing the distinction between context and circumstance/index in the first place: namely, the need to separate contextual elements that are *shiftable* from those that are not. Their reasoning was the following: if a contextual element is shiftable, then it becomes part of the circumstance/index; if it's not, then it becomes part of the context. To exemplify, the contextual element that gives the content of a pure indexical like "I" (the speaker) is considered not to be shiftable (in English, anyway). This is usually put by saying that "I" "scopes out" from under various embeddings and always refers to the speaker. However, no such "scoping out" seems to happen in the examples containing perspectival expressions considered in this paper.<sup>22</sup> If anything, perspectives can easily be shifted (the perspective to which "tasty" pertains to in "Licorice is tasty for Johnny" is clearly Johnny's) – and, if

<sup>21</sup> Or a demonstrative intention. On this matter, Kaplan has changed his mind from "Demonstratives" to "Afterthoughts". I myself don't commit to any of these views; I mention demonstrations only to get my point across.

<sup>22</sup> This point is also made in Kneer, Vicente and Zeman (2017). The conclusion drawn there, however, is that multiple indexing is not viable, because the examples dealt with don't contain "reference-fixing expressions" like "now" in Kamp/Vlach sentences. This is a mistake: what such considerations show is at best that a *certain* form of multiple indexing is not viable, one that is different from the present proposal. See the argument below.

perspectival plurality is a real phenomenon, such shifting can take place in more than one direction (a claim that can be further illustrated by making all the perspectives explicit, as in “Licorice is tasty for Johnny, but not tasty for Tony”). So, if one accepts a Kaplan/Lewis-style argument from shiftability to the introduction of parameters for perspectives in the circumstance/index, then perspectival plurality as illustrated in this paper justifies the further step of introducing more than one such parameter – in a way that is entirely coherent with the Kaplanian framework.<sup>23</sup>

Of course, not everyone accepts the argument from shiftability (a.k.a. “the operator argument”), for various reasons. Many authors have questioned its premises, based on considerations having to do with the correct syntactic representation of the sentences at stake (see King (2003), among many others). What’s more, even if the premises at stake are accepted, both their necessity (MacFarlane, 2009) and their sufficiency (Ninan, 2010) for the desired conclusion have been denied. However, the good news for the multiple indexing relativist is that she doesn’t need to rely (and some relativists have explicitly advised against doing so – e.g., MacFarlane (2009)) on this argument. A variety of other motivations for relativism have been given in the literature, from phenomena like “faultless disagreement” (Kölbel, 2004a; Lasersohn, 2005, 2008, 2016), eavesdropping (Egan, Hawthorne and Weatherston, 2005), retraction (MacFarlane, 2014) to arguments of a syntactic nature (Lasersohn, 2009). Some of those arguments might move the reader more than others; discussing their efficacy has not been my purpose here. But the point made above remains: assuming one *already* has arguments, of whatever kind, for the introduction of a certain parameter in the circumstance/index, the phenomenon of perspectival plurality gives one a sufficient reason to introduce more than one such parameter. And given that none of the arguments mentioned is incompatible with the Kaplanian framework, if what I’ve said in this section is on the right track, then multiple indexing is not such a drastic departure from the Kaplanian orthodoxy as one might have initially thought.

## 6. Summary and open questions

I started this paper by focusing on a recently discussed phenomenon illustrated by sentences containing predicates of taste: perspectival plurality. I then showed, following previous work, that this phenomenon creates problems for at least certain versions of relativism. My main aim in the paper was to further the discussion by showing that the phenomenon extends to other perspectival expressions than predicates of taste and by proposing a general solution to the problem raised by it on behalf of the relativist. The core claim of the solution is that utterances of sentences containing perspectival expressions should be evaluated with respect to (possibly infinite) sequences of perspective parameters (that is, multiple indexing). This solution helps with perspectival plurality because, in principle, it allows each (occurrence of a) perspectival expression to be interpreted as pertaining to a different perspective. In the previous section I marshaled some considerations against seeing multiple indexing as a radical departure from the traditional Kaplanian framework.

Now, what I offered here is a mere sketch, rather than a full-fledged theory. But one gets a clear idea of the work to be further done. First, a more precise formalization of the apparatus is required. Second, shielding the view from more objections is crucial. Third, a thorough

<sup>23</sup> I’m indebted to Adrian Briciu for discussion of these intricate issues.

comparison with other possible solutions to the problem posed by perspectival plurality needs to be undertaken. Fourth, the implications for semantics in general and for the debate between contextualism and relativism will need to be made clear. For example, one important question is what type of semantic content we end up countenancing if we adopt such a view, so that to be able to tell what does it mean to assert, have attitudes and communicate such contents. This has obvious consequences for the debate between contextualism and relativism, on which I did not focus here. A key issue to be dealt with in this connection is to ascertain what readings of sentences containing perspectival expressions are allowed and which are not, and see which of the two views best account for the whole range of data. Admittedly, I have here only scratched the surface; progress will be made by a full investigation of the limits and constraints of perspectival plurality. These are all open question that the multiple indexing relativist will need to address.

# Modified numerals revisited: The cases of *fewer than 4* and *between 4 and 8*<sup>1</sup>

Linmin ZHANG — Concordia University, New York University

**Abstract.** There seems an interplay between (i) the interpretation of sentences containing non-increasing modified numerals (e.g., *fewer than 4*, *between 4 and 8*) and (ii) the type of predicates in those sentences. For example, (i) *fewer than 4 boys smiled*, where the predicate is distributive, has no existential entailment, but an upper-bound reading; while (ii) *fewer than 4 boys lifted the piano together*, where the predicate is collective, has an existential entailment, but no upper-bound reading. Following Brasoveanu (2013)'s post-supposition-style account for modified numerals, here I propose that (I) the semantic contribution of non-increasing modified numerals is twofold: (i) introducing a maximal referent as at-issue meaning in the derivation, and (ii) adding a cardinality constraint as a secondary dimension of meaning, and that (II) it is the type of predicates (distributive vs. collective) that determines the scope of maximization and where to evaluate this secondary dimension of meaning – at the sentential level or within a group-denoting DP.

**Keywords:** modified numerals, distributivity, collectivity, maximality, post-supposition.

## 1. Introduction

The semantics of **non-increasing modified numerals** has been a hot topic in current formal linguistic research. It has been noticed for decades that there seems an interplay between the interpretation of sentences containing this kind of modified numerals and the type of predicates therein.

As illustrated in (1), when a **downward-entailing (DE)** modified numeral (here *fewer than 4*) combines with a **distributive** predicate (here *smile*), the sentence has an upper-bound reading, but no existential entailment. I.e., sentence (1) is compatible with a situation in which no boys smiled. In contrast, as illustrated in (2), when *fewer than 4* combines with a **collective** predicate (here *lift the piano together*), the sentence has an existential entailment. I.e., if there were no boys at all involved in piano-lifting, sentence (2) is judged infelicitous according to our intuition. However, if there were two groups, one of 3 boys and the other of 8 boys, and each group collectively lifted the piano, sentence (2) is true and felicitous in this scenario – it simply means that a certain group of fewer than 4 boys collectively lifted the piano. I.e., there is no upper-bound reading for sentence (2): it does not rule out the possibility of more boys involved in piano-lifting.

- (1) Fewer than 4 boys smiled. *smile*: **distributive** predicate  
a. ✓ **Upper-bound reading**: ruling out the possibility of more boys smiling.  
b. # **Existential entailment**: asserting the existence of smiling boys.

---

<sup>1</sup>Lots of thanks to Sam Al Khatib, Chris Barker, Brian Buccola, Dylan Bumford, Lucas Champollion, Chris Davis, Jia Ling, Rick Nouwen, Stephanie Solt, Anna Szabolcsi, Robert Truswell as well as NYU Semantics Group and the reviewers and audience of *Sinn und Bedeutung 21* (SuB 21) for comments, discussions, and support!

- (2) Fewer than 4 boys lifted the piano together. *lift the piano together*: **collective** predicate
- # Upper-bound reading**: ruling out the possibility of more boys involved in piano-lifting.
  - ✓ Existential entailment**: asserting the existence of piano-lifting boys.

Thus (3) summarizes the basic empirical observations with regard to interpreting sentences containing DE modified numerals. This pattern was initially noted in Winter's work (see, e.g., Winter 2001; Ben-Avi and Winter 2003) and much studied recently by Buccola and Spector (see Spector 2014; Buccola 2015a, b; Buccola and Spector 2016; Buccola 2016). As noted in these works, the generalization in (3) can also be extended to the cases of **non-monotone** modified numerals, such as *between 4 and 8* (see (4), except that here there is always an existential entailment).

- (3) Generalization on interpreting sentences containing DE modified numerals:<sup>2</sup>

|                        | Distributive predicate | Collective predicate |
|------------------------|------------------------|----------------------|
| Upper-bound reading    | ✓                      | #                    |
| Existential entailment | #                      | ✓                    |

- (4) *Between 4 and 8* + **distributive / collective** predicates:
- Between 4 and 8 boys smiled.* ✓ Upper-bound reading
  - Between 4 and 8 boys lifted the piano together.* # Upper-bound reading

To account for the pattern shown in (3), Buccola and Spector have proposed an 'over-generation + pragmatic blocking' approach, which, I argue, suffers from empirical and conceptual problems. In this paper, by following Brasoveanu (2013)'s post-supposition-style approach, which was originally developed to analyze the cumulative reading of sentences containing *exactly*-type modified numerals (e.g., *exactly three boys saw exactly five movies*), I propose a purely semantic account that generates exactly the attested readings summarized in (3). In a nutshell, I propose that (I) the semantic contribution of non-increasing modified numerals is twofold: (i) introducing a maximal referent as **at-issue meaning** in the derivation, and (ii) adding a cardinality constraint as a **secondary dimension of meaning**, and that (II) it is the type of predicates (distributive vs. collective) that determines the scope of maximization and where to evaluate this secondary dimension of meaning – at the sentential level or within a group-denoting DP.

Section 2 presents Buccola and Spector (2016)'s 'over-generation + pragmatic blocking' approach that is based on the notion of number-based maximality, and I discuss empirical and conceptual challenges to it. Based on Brasoveanu (2013)'s study, my new account is presented in Section 3. Section 4 discusses cumulative readings. Section 5 discusses another approach developed in Buccola and Spector (2016), which is based on the notion of informativity-based maximality. Section 6 compares the current account with the main idea of Solt (2006). Section 7 concludes the paper.

<sup>2</sup>The lack of existential entailment for distributive-reading sentences with DE quantifiers has also been called *Van Benthem's problem* (see Van Benthem 1986).

## 2. Buccola and Spector (2016)'s 'over-generation + pragmatic blocking' approach

Buccola and Spector (2016) have presented and discussed four specific accounts, each involving some notion of **maximality**. Overall, all these accounts are based on the idea of 'over-generation + pragmatic blocking'. They differ along two parameters: (i) the **type** of maximality (number-based vs. informativity-based) and (ii) the **source** of maximality (lexically encoded vs. non-lexical). In this section, I focus on the two accounts using a number-based maximality operator, and those using an informativity-based maximality operator will be discussed in Section 5.

### 2.1. Buccola and Spector (2016): Number-based maximality operator + pragmatic blocking rule

The basic idea of this approach includes two parts. First, in natural language semantics, there is a maximality operator  $\max$  of type  $\langle dt, d \rangle$  involved in the interpretation of modified numerals. Crucially, there is scope interaction between this operator  $\max$  and existential closure  $\exists$ , leading to potential ambiguity, i.e., over-generating sentence readings. Second, there is a pragmatic rule, which rules out any readings in which the semantic contribution of a numeral  $n$  is trivial.

(5) shows the definition of the number-based maximality operator  $\max$  in Buccola and Spector (2016). Essentially,  $\max$  takes a totally ordered set  $P$  (of type  $\langle dt \rangle$  –  $d$  stands for *degree*, an element in a totally ordered set) as input and returns its upper bound  $n$  (of type  $d$ ) as output. In Buccola and Spector (2016), inputs of  $\max$  are almost always convex sets of natural numbers.<sup>3</sup> To avoid any potential existential entailment problems, Buccola and Spector (2016) assume that an empty set can also serve as the input of  $\max$ , and in this case, the output is simply 0.<sup>4</sup>

$$(5) \quad \text{Number-based maximality operator: } \max \quad \text{Buccola and Spector (2016)}$$

$$\llbracket \max(P_{\langle dt \rangle}) \rrbracket = \begin{cases} \text{un}.P(n) \wedge \forall m[P(m) \rightarrow m \leq n] & \text{if } \exists n P(n) \\ 0 & \text{otherwise} \end{cases}$$

Buccola and Spector (2016) provide two ways to implement  $\max$ : **L(exical)Max** and **SMax**.<sup>5</sup> As (6) shows, within the analysis of LMax,  $\max$  is part of the lexical semantics of *fewer than*. *Fewer than* takes a number  $n$  (of type  $d$ ) as input and returns a generalized quantifier over

<sup>3</sup>Briefly speaking, a **convex** totally ordered set is a totally ordered set  $P$  such that for any elements  $a$  and  $b$  in the set, if  $a \leq b$ , then any element  $x$  such that  $a \leq x \leq b$  is also in the set. E.g.,  $\{x|x > 0\}$ ,  $\{x|x < 4\}$ , and  $\{x|4 \leq x < 8\}$  are all convex sets, while sets such as  $\{x|x \leq 5 \vee x > 8\}$  are not convex.

<sup>4</sup>Notice that if a set has no upper bound (e.g.,  $\{x|x \geq 0\}$ , which has an infinite endpoint) or the upper bound is open (e.g.,  $\{x|0 \leq x < 5\}$ , in which the endpoint 5 is not included), then for any number  $x$  in the set, there is always another number  $y$  such that (i)  $y > x$  and (ii)  $y$  is also in the set. Thus this kind of sets are undefined in Buccola and Spector (2016)'s  $\max$ . In a footnote, Buccola and Spector (2016) mention the maximality failure issue for sentences such as *fewer than 5 prime numbers are odd*, which is intuitively judged false, not undefined, but according to their analysis, the set of numbers  $\lambda n. [\exists x. |x| = n \wedge \text{PRIME-NUMBER}(x) \wedge \text{ODD}(x)]$  is undefined for their  $\max$  in (5). This issue is left unsolved in their paper, but it does not arise with the analysis proposed in this paper (see Footnote 10).

<sup>5</sup>According to Buccola and Spector (2016), SMax can be understood as either SyntacticMax or SeparateMax.

degrees (i.e., something of type  $\langle dt, t \rangle$ ) as output.<sup>6</sup> Since  $\llbracket \text{fewer than } n \rrbracket$  is analyzed as a generalized quantifier, there can be scope interaction between  $\llbracket \text{fewer than } n \rrbracket$  and existential closure  $\exists$  in deriving sentence meanings. (7) shows the derivation of two (potential) readings for the sentence *fewer than 4 boys smiled*. In (7a), *fewer than 4* raises to a position that takes scope over the rest of the sentence. Since  $\max$  takes wider scope over the existential closure and it can potentially return 0 as output, the interpretation thus derived has no existential entailment. In contrast, in (7b), *fewer than 4* raises to a position that is still inside of the scope of existential closure (actually inside of AP), thus the wide scope of existential closure guarantees the existential entailment. Since *smile* is a distributive predicate (see (8a)), the semantic contribution of *fewer than 4* in (7b) is in effect vacuous.

- (6) The implementation of maximality in **LMax**:  
 $\llbracket \text{fewer than } n \rrbracket_{\langle d, \langle dt, t \rangle \rangle} \stackrel{\text{def}}{=} \lambda n_d. \lambda P_{\langle dt, t \rangle}. [\max(P) < n]$
- (7) Using LMax to derive  $\llbracket \text{fewer than 4 boys smiled} \rrbracket$ :
- a.  $\llbracket \text{fewer than 4} \rrbracket$  takes wider scope over  $\exists$ :  $\leadsto$  Upper-bound reading  
 $[\text{fewer than 4}][\lambda n. [\exists [n \text{ boys smiled}]]]$   
 $\Leftrightarrow \max([\lambda n. [\exists x[|x| = n \wedge \text{BOYS}(x) \wedge \text{SMILE}(x)]]] < 4$   
 i.e., the maximal value that is equal to the cardinality of smiling boys is less than 4.
- b.  $\exists$  takes wider scope over  $\llbracket \text{fewer than 4} \rrbracket$ :  $\leadsto$  Existential entailment  
 $[\exists [\lambda x. [\text{fewer than 4}][\lambda n. |x| = n]] \text{boys}] \text{smiled}$   
 $\Leftrightarrow \exists x [\max(\lambda n. |x| = n) < 4 \wedge \text{BOYS}(x) \wedge \text{SMILE}(x)]$   
 $\equiv \exists x [|x| < 4 \wedge \text{BOYS}(x) \wedge \text{SMILE}(x)]$  (see (8a))  
 $\equiv \exists x [\text{BOYS}(x) \wedge \text{SMILE}(x)]$  i.e., there are smiling boys.  $\leadsto$  No upper-bound reading
- (8) **Distributivity**:  $P$  is distributive iff  $\forall x, y [P(x) \wedge y \leq_{\text{part}} x \rightarrow P(y)]$ .
- a.  $\checkmark$  *Smile*: if a group of boys smiled, it follows that each boy smiled.
- b.  $\#$  *Lift the piano together*: if a group of boys collectively lifted the piano, it doesn't follow that a subset of these boys formed a group and lifted the piano together.

The unattested reading shown in (7b) means that insofar as there are smiling boys, there always exists a subset of smiling boys whose cardinality is less than 4. I.e., the numeral 4 can be replaced by any other numerals without affecting the truth condition of this reading. Thus, Buccola and Spector (2016) propose the pragmatic constraint (9) to rule out the reading in (7b).

- (9) Buccola and Spector (2016)'s pragmatic economy constraint:  
 An LF  $\phi$  containing a numeral  $n$  is infelicitous if, for some  $m$  distinct from  $n$ ,  $\phi$  is truth-conditionally equivalent to  $\phi[n \mapsto m]$  (the result of substituting  $m$  for  $n$  in  $\phi$ ).

Similar to (7), (10) illustrates the derivation of two readings for a sentence containing collective

<sup>6</sup>The definition in (6) is slightly different from the one given in Buccola and Spector (2016), which is like this:  $\llbracket \text{fewer than } n \rrbracket_{\langle d, \langle dt, t \rangle \rangle} \stackrel{\text{def}}{=} \lambda n_d. \lambda P_{\langle dt, t \rangle}. \exists m [m < n \wedge \max(P) = m]$ . I.e., in their original definition, there is also an existential closure, the semantic contribution of which is actually vacuous and not motivated in their paper.

predicates. In (10b), since *lift the piano together* is a collective predicate, obviously, if fewer than 4 boys formed a group and lifted the piano together, it doesn't follow that a subset of these boys also formed a group to lift the piano together (see (8b)). Thus, the semantic contribution of *fewer than 4* in (10b) is not trivial, and there is no need to apply the pragmatic rule in (9). In this analysis, (10b) naturally has an existential entailment, but no upper-bound reading. The derivation in (10a) essentially leads to the unattested reading that no groups of boys with a cardinality equal to or larger than 4 lifted the piano together, but in Buccola and Spector (2016), the accounts of LMax and SMax do not include a mechanism to block this unattested reading.

- (10) Using LMax to derive  $\llbracket \text{fewer than 4 boys lifted the piano together} \rrbracket$ :
- a.  $\llbracket \text{fewer than 4} \rrbracket$  takes wider scope over  $\exists$ :  $\leadsto$  Upper-bound reading  
 $\llbracket \text{fewer than 4} \rrbracket [\lambda n. [\exists [n \text{ boys lifted the piano together}]]]$   
 $\Leftrightarrow \max([\lambda n. [\exists x[|x| = n \wedge \text{BOYS}(x) \wedge \text{LIFT-THE-PIANO-TOGETHER}(x)]]] < 4$   
i.e., the max. value that is equal to the cardinality of piano-lifting boys is less than 4.
  - b.  $\exists$  takes wider scope over  $\llbracket \text{fewer than 4} \rrbracket$ :  $\leadsto$  Existential entailment  
 $\llbracket \exists [\lambda x. [\llbracket \text{fewer than 4} \rrbracket [\lambda n. |x| = n]] \text{boys} \rrbracket \text{lifted the piano together}$   
 $\Leftrightarrow \exists x [\max([\lambda n. |x| = n]) < 4 \wedge \text{BOYS}(x) \wedge \text{LIFT-THE-PIANO-TOGETHER}(x)]$   
 $\equiv \exists x [|x| < 4 \wedge \text{BOYS}(x) \wedge \text{LIFT-THE-PIANO-TOGETHER}(x)]$  (see (8b))  
 $\neq \exists x [\text{BOYS}(x) \wedge \text{LIFT-THE-PIANO-TOGETHER}(x)]$

In the account of SMax, the maximality operator  $\max$  is independent of the lexical semantics of modified numerals, and the use of  $\max$  is rather optional. Consequently, the scope of  $\max$  – depending on the landing site of *fewer than n* in quantifier raising – can be flexible. Thus, all the readings shown in (7) and (10) can be generated, and the pragmatic rule (9) is needed to block the unattested ‘existential entailment’ reading shown in (7b). Moreover, since  $\max$  is optional, when it is not applied, as shown in (12), the effect is equivalent to  $\exists$  taking wide scope over  $\max$ .

- (11) **SMax** –  $\max$  is not contained in the lexical semantics of *fewer than*: (cf. (6))  
 $\llbracket \text{fewer than} \rrbracket_{\langle d, \langle dt, t \rangle \rangle} \stackrel{\text{def}}{=} \lambda n_d. \lambda P_{\langle dt \rangle}. \exists m [m < n \wedge P(m)]$
- (12) **SMax**: when  $\max$  is not applied:
- a.  $\llbracket \text{fewer than 4 boys smiled} \rrbracket = \exists x [|x| < 4 \wedge \text{BOYS}(x) \wedge \text{SMILE}(x)]$  = (7b)
  - b.  $\llbracket \text{fewer than 4 boys lifted the piano together} \rrbracket$   
 $= \exists x [|x| < 4 \wedge \text{BOYS}(x) \wedge \text{LIFT-THE-PIANO-TOGETHER}(x)]$  = (10b)

Buccola (2016) points out that due to the extra flexibility in using  $\max$ , SMax is superior to LMax in analyzing the generic reading of the sentence *fewer than 4 boys can together lift that piano*. As shown in (13), under this **generic** reading, the sentence means that for a certain number  $n$ , in general,  $n$  boys can collectively lift that piano, and this number  $n$  is smaller than 4. Crucially, this reading can be naturally derived via SMax, with no use of  $\max$ . However, since  $\max$  is a necessary part in the semantics of *fewer than* in LMax, LMax fails to generate this reading.

- (13) The **generic** reading of *fewer than 4 boys can together lift that piano*:  
 $\exists n[n < 4 \wedge \forall_{\text{GEN}}x[|x| = n \wedge \text{BOYS}(x) \rightarrow \diamond \text{TOGETHER-LIFT-THAT-PIANO}(x)]]$   
 (Context: Al asks: ‘How many boys do we need to lift that piano?’ Then Bill answers: ‘Well, I’m not sure. But I believe fewer than 4 boys can together lift that piano.’)

To sum up, Buccola and Spector (2016) propose to use a maximality operator that is applied to sets of **numbers**, and the use of this maximality operator helps create ambiguity (via scope interaction and/or optionality). Their pragmatic rule helps to block some of the over-generated readings.

## 2.2. Challenges to the approach of Buccola and Spector (2016)

Here I present empirical and conceptual challenges to these two accounts LMax and SMax. First of all, as already mentioned, both LMax and SMax generate an unattested upper-bound reading for sentences containing collective predicates (see (10a)), and their pragmatic constraint (9) is not applicable in this case to rule out this reading. Similarly, the sentence shown in (13) has two other readings that can be generated in LMax and SMax: (i) any group of boys with a cardinality less than 4 can, in general, lift that piano together (see (14a)); (ii) the maximal number  $n$  such that in general,  $n$  boys can together lift that piano is less than 4 (see (14b)). While it is doubtful whether (14a) is an available reading of the sentence, the reading (14b) is certainly unavailable.

- (14) Two other readings of *fewer than 4 boys can together lift that piano*:  
 a.  $\forall_{\text{GEN}}x[|x| < 4 \wedge \text{BOYS}(x) \rightarrow \text{CAN-LIFT-THE-PIANO-TOGETHER}(x)]$   
 (Either max takes a narrow scope within *fewer than 4 boys* or it is not used at all.)  
 b.  $\max(\lambda n. \forall_{\text{GEN}}x[|x| = n \wedge \text{BOYS}(x) \rightarrow \text{CAN-LIFT-THE-PIANO-TOGETHER}(x)]) < 4$   
 (max takes a wide scope over the rest of the sentence.)

Second, since the accounts of LMax and SMax rely heavily on a pragmatic rule that targets specifically the use of numerals (see (9)), these accounts fail to relate the pattern shown in (3) with some other data discussed in the semantics literature. Solt (2007) has noticed that the use of *few* interacts with the type of predicates in affecting the grammaticality of sentences. As shown in (15) and (16), the DE quantifier *few* is compatible with distributive predicates, but incompatible with collective predicates. Moreover, Solt (2007) has pointed out that to express the notion of a small quantity in sentences containing collective predicates, *a few* should be used, instead of *few*, as illustrated by the contrast between (16) and (17). Intriguingly, when we compare (15) and (17), the attested readings show exactly the same pattern as in (3). Obviously, a unified account that can explain both the patterns with the use of **non-increasing modified numerals** and with the use of *few/a few* would be more favorable, and this kind of accounts cannot rely on rules constraining the interpretation of numerals, because no numeral is involved in (15) – (17).

- |                                                                            |                                                                                                                        |
|----------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <p>(15) <u>Few boys smiled.</u></p> <p>a. ✓ <b>Upper-bound reading</b></p> | <p style="text-align: right;"><i>few</i> + <b>distributive</b> predicate</p> <p>b. # <b>Existential entailment</b></p> |
|----------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|

- (16) \*Few boys lifted the piano together. Ungrammatical: *few* + **collective** predicate
- (17) A few boys lifted the piano together. *a few* + **collective** predicate  
 a. # **Upper-bound reading** b. ✓ **Existential entailment**

Third, as already discussed by Buccola and Spector (2016), the over-generation approach makes wrong predictions on NPI (negative polarity item) licensing. As shown in (18), NPI licensing is possible in (18a), suggesting that *fewer than 4 boys* is involved in creating a DE environment when combined with a distributive predicate; in contrast, NPI licensing is impossible in (18b), suggesting that no DE environment is created when *fewer than 4 boys* combines with a collective predicate. This kind of contrast should be unexpected if there were indeed an over-generation mechanism underlying the interpretation of modified numerals. Actually, these data on NPI licensing suggest that some part of the semantic contribution of *fewer than 4 boys* (e.g., in creating a DE environment) is initially unspecified, but later determined by the type of predicates it combines with.<sup>7</sup>

- (18) NPI licensing:  
 a. Fewer than 4 boys ate **any** soup. **Distributive** predicate  $\leadsto$  NPI licensing ✓  
 b. \*Fewer than 4 boys surrounded **any** table. **Collective** predicate  $\leadsto$  NPI licensing #  
 c. Fewer than 4 boys surrounded a table.

Fourth, there is an important factor overlooked by Buccola and Spector (2016): whether the noun that combines with a non-increasing modified numeral is a **group noun** (e.g., *army*, *team*, *committee*) or a **non-group noun** (e.g., *boy*, *dog*). Therefore, their accounts fail to fully characterize the exact mechanism that governs the semantic composition between distributive / collective predicates and the rest part of sentences. As (19) illustrates, even though here the predicate is collective, the sentence has an upper-bound reading (i.e., it is false if 4 or more than 4 groups of boys lifted the piano together), but no existential entailment (i.e., it is compatible with a situation in which no groups of boys lifted the piano together after all). Moreover, (20) shows that NPI licensing is possible here despite the use of a collective predicate (cf. (18b)). These data show that the interpretation of ‘[[DE modified numeral + **group** noun] + collective predicate]’ is parallel to that of ‘[[DE modified numeral + **non-group** noun] + distributive predicate]’, suggesting that the notion of group should also be taken into consideration.

- (19) Fewer than 4 groups of boys lifted the piano together. **collective** predicate  
 a. ✓ **Upper-bound reading** b. # **Existential entailment**

- (20) Fewer than 4 groups of soldiers surrounded any castle.  $\leadsto$  NPI licensing ✓

<sup>7</sup>This might be unsurprising if we reflect on the role the type of predicates plays in specifying actual interpretations in other cases. For example, (i) in *John and Mary left*, where the predicate is distributive,  $[[\text{John and Mary}]]$  is essentially  $\lambda P.[\text{John} \sqcap \text{Mary}(P)]$ , i.e., a set intersection, while in (ii) *John and Mary built a raft together*, where the predicate is collective,  $[[\text{John and Mary}]]$  essentially denotes  $[\text{John} \oplus \text{Mary}]_e$ , i.e., a sum (or a group). See Zhang (2015); Champollion (2016), etc., that deal with this issue and give the semantics of coordination a unified account.

(21) No fewer than 4 boys smiled. [[no fewer than 4]]  $\approx$  [[at least 4]]

### 3. A new account à la **Brasoveanu (2013)**

### 3.1. The framework of Brasoveanu (2013) and the semantics of *fewer than 4 boys smiled*

<sup>8</sup>Geurts and Nouwen (2007) have also argued that *more than n* should not be analyzed as a generalized quantifier.

- (22) Exactly 3 boys saw exactly 5 movies. **Cumulative reading**  
 $\leadsto$  The contextually maximal set of boys, the cardinality of which is exactly 3, saw the contextually maximal set of movies, the cardinality of which is exactly 5.
- (23) a. At least 4 boys smiled. (# Perhaps there were other boys smiling, but I forgot.)  
 b. Four boys smiled. (✓ Perhaps there were other boys smiling, but I forgot.)

The central idea of DPL is to analyze sentential meanings as **information change potential** (i.e., ways of changing (the representation of) the information of the interpreter), instead of truth conditions (Groenendijk and Stokhof 1991). Thus, the meaning of a sentence can be captured in terms of a relation between states. For our current purpose, it is analyzed as a pair of **assignment functions**.

Following Brasoveanu (2013), my DPL models have the structure  $\mathfrak{M} = \langle \mathfrak{D}, \mathfrak{I} \rangle$ , in which  $\mathfrak{D}$  is the domain of individuals, and  $\mathfrak{I}$  is the basic interpretation function such that  $\mathfrak{I}(R) \subseteq \mathfrak{D}^n$ , for any  $n$ -ary relation  $R$ . The domain  $\mathfrak{D}$  consists of **atomic** and **non-atomic individuals**. **Atomic individuals** are singleton sets, e.g., {JOHN}; **non-atomic individuals** are sets with a cardinality larger than 1, e.g., {JOHN, BILL}. I also include the empty set  $\emptyset$  in  $\mathfrak{D}$ . The **cardinality** of an individual  $x$ , written as  $|x|$ , means the count of its singleton subsets. The **sum** of two individuals  $x \oplus y$  is the union of the sets  $x$  and  $y$ , e.g., {JOHN}  $\oplus$  {BILL} = {JOHN, BILL}. The **part-of relation** over individuals  $x \leq y$  means that  $x$  is a part of  $y$ , and formally it means that  $x \subseteq y$ . For any property  $P$ , the **cumulative closure**  $*P$  is the smallest set such that  $P \subseteq *P$  and if individuals  $a, a' \in *P$ , then  $a \oplus a' \in *P$ .

An **assignment function**  $g$  is a total function from the set of variables  $\mathcal{V}$  to  $\mathfrak{D}$ . Sentence meanings are modeled as  $\langle g, h \rangle$ , i.e., a pair of assignment functions, in which  $g$  represents the current information state, and  $h$  the updated state.  $h[x]g$  means that for any variable  $v \in \mathcal{V}$ , if  $v \neq x$ , then  $h(v) = g(v)$ , i.e.,  $h$  differs from  $g$  at most with regard to the value it assigns to the variable  $x$ .

As shown in (24a), atomic formulas for lexical relations are **tests** (only unary relations, i.e., properties, are shown in this paper), i.e., the input and output assignment functions  $g$  and  $h$  are equal and the value of certain variables is checked. Cardinality constraints are tests as well, as illustrated in (24b) with the use of '='. Dynamic conjunction and random assignment are shown in (24c) and (24d). (25a) shows an example, in which the introduced discourse referent is marked in green, the restrictor in red and the nuclear scope in blue, and it can be decomposed in the way shown in (25b).

- (24) a.  $\llbracket P(x) \rrbracket^{(g,h)} = \mathbb{T}$  iff  $g = h$  and  $h(x) \in * \mathfrak{I}(P)$ . **Atomic formula**  
 b.  $\llbracket |x| = n \rrbracket^{(g,h)} = \mathbb{T}$  iff  $g = h$  and  $|h(x)| = n$ . **Cardinality constraint**  
 c.  $\llbracket \phi \wedge \psi \rrbracket^{(g,h)} = \mathbb{T}$  iff there is a  $k$  s.t.  $\llbracket \phi \rrbracket^{(g,k)} = \mathbb{T}$  and  $\llbracket \psi \rrbracket^{(k,h)} = \mathbb{T}$ . **Dynamic conjunction**  
 d.  $\llbracket [x] \rrbracket^{(g,h)} = \mathbb{T}$  iff  $h[x]g$ . **Random assignment**

- (25) a.  $\llbracket A^x \text{ wolf came in} \rrbracket \Leftrightarrow \exists x \llbracket |x| = 1 \wedge *WOLF(x) \rrbracket (*COME-IN(x))$   
 b.  $\exists x \llbracket |x| = n \wedge \phi \rrbracket (\psi) := [x] \wedge |x| = n \wedge \phi \wedge \psi \quad [x]: \text{storing a discourse referent (dref)}$

Brasoveanu (2013)'s maximization operator  $\sigma$  introduces a maximal referent (see (26)). As (27) illustrates, basically, here  $x$  stores **all** the atomic entities that satisfy the restrictor and nuclear scope.

- (26)  $\llbracket \sigma x(\phi) \rrbracket^{(g,h)} = \mathbb{T}$  iff **Maximization operator  $\sigma$**   
 (i)  $\llbracket [x] \wedge \phi \rrbracket^{(g,h)} = \mathbb{T}$  and (ii) there is no  $h'$  such that  $\llbracket [x] \wedge \phi \rrbracket^{(g,h')} = \mathbb{T}$  and  $h(x) < h'(x)$ .
- (27)  $\llbracket \text{Exactly three}^x \text{ wolves came in} \rrbracket \Leftrightarrow \exists |x| = 3 \llbracket *WOLF(x) \rrbracket (*COME-IN(x))$   
 $\Leftrightarrow \sigma x(*WOLF(x) \wedge *COME-IN(x)) \wedge |x| = 3$  (The post-supposition part is to be revised.)

In Brasoveanu (2013), post-suppositions are implemented as **tests on the output context**, i.e., they are introduced at certain points in meaning derivation, but checked after the at-issue meaning of a formula is evaluated. Thus, tests need to be added into our representation of input and output states, and the meaning of a sentence is written as  $\langle g[\zeta], h[\zeta'] \rangle$ , where  $g$  and  $h$  are assignment functions, and  $\zeta$  and  $\zeta'$  are (possibly empty) sets of tests such that  $\zeta \subseteq \zeta'$ . As (28) shows, a post-supposition  $\phi$  does not update the input assignment function  $g$ ; it is only added into the input set of tests  $\zeta$ . Based on this, some adjustments are made in defining DPL concepts, as shown in (29).

- (28)  $\llbracket \phi \rrbracket^{(g[\zeta], h[\zeta'])} = \mathbb{T}$  iff  $\phi$  is a test,  $g = h$  and  $\zeta' = \zeta \cup \{\phi\}$  **Post-supposition  $\phi$**
- (29) a.  $\phi$  is **true** relative to an input context  $g[\emptyset]$  ( $\emptyset$  is an empty set) iff there is an output assignment  $h$  and a (possibly empty) set of tests  $\{\psi_1, \dots, \psi_m\}$  such that  
 (i)  $\llbracket \phi \rrbracket^{(g[\emptyset], h[\{\psi_1, \dots, \psi_m\}])} = \mathbb{T}$  and (ii)  $\llbracket \psi_1 \wedge \dots \wedge \psi_m \rrbracket^{(h[\emptyset], h[\emptyset])} = \mathbb{T}$ . **Truth**  
 b.  $\llbracket P(x) \rrbracket^{(g[\zeta], h[\zeta'])} = \mathbb{T}$  iff  $g = h$ ,  $\zeta = \zeta'$  and  $h(x) \in *S(P)$ . **Atomic formula as test**  
 c.  $\llbracket \phi \wedge \psi \rrbracket^{(g[\zeta], h[\zeta'])} = \mathbb{T}$  **Dynamic conjunction**  
 iff there is a  $k$  and a  $\zeta''$  such that  $\llbracket \phi \rrbracket^{(g[\zeta], k[\zeta''])} = \mathbb{T}$  and  $\llbracket \psi \rrbracket^{(k[\zeta''], h[\zeta'])} = \mathbb{T}$ .  
 d.  $\llbracket [x] \rrbracket^{(g[\zeta], h[\zeta'])} = \mathbb{T}$  iff  $h[x]g$  and  $\zeta = \zeta'$ . **Random assignment**  
 e.  $\llbracket \sigma x(\phi) \rrbracket^{(g[\zeta], h[\zeta'])} = \mathbb{T}$  iff (i)  $\llbracket [x] \wedge \phi \rrbracket^{(g[\zeta], h[\zeta'])} = \mathbb{T}$  **Maximization operator  $\sigma$**   
 and (ii) there is no  $h'$  such that  $\llbracket [x] \wedge \phi \rrbracket^{(g[\zeta], h'[\zeta'])} = \mathbb{T}$  and  $h(x) < h'(x)$ .

Finally, to analyze the distributive reading of sentences, I also follow Brasoveanu (2013) and define a distributivity operator  $\delta$ . As shown in (30), when we distributively interpret a formula  $\phi$  relative to a plural individual  $g(x)$ , we check that  $\phi$  is satisfied by each atom  $a$  that is a part of  $g(x)$ .<sup>9</sup> The (ii) part of this definition means that the distributivity operator  $\delta$  discharges all the post-suppositions contributed by  $\phi$  within its scope. Thus distributivity is externally static.

<sup>9</sup>This is rather a simplified picture. Basically,  $\delta x(\phi)$  is treated as a test here, and I don't consider any quantificational dependencies introduced by or within the scope of  $\delta$ . Things become much more complicated for this kind of example: *Every year, John wrote a longer novel, which is about 50 pages longer than the previous one* (See Bumford 2015).

- (30)  $\llbracket \delta x(\phi) \rrbracket^{\langle g[\zeta], h[\zeta'] \rangle} = \mathbb{T}$  iff  $g = h$ ,  $\zeta = \zeta'$ , and for all atoms  $a \leq g(x)$ , if we let  $g'$  be such that  $g'[x]g$  and  $g'(x) = a$ , then there is a  $k$  and a (possibly empty) set of tests  $\{\psi_1, \dots, \psi_m\}$  such that (i)  $\llbracket \phi \rrbracket^{\langle g'[\zeta], k[\zeta \cup \{\psi_1, \dots, \psi_m\}] \rangle} = \mathbb{T}$  and (ii)  $\llbracket \psi_1 \wedge \dots \wedge \psi_m \rrbracket^{\langle k[\zeta], k[\zeta] \rangle} = \mathbb{T}$

On the base of this DPL framework developed by [Brasoveanu \(2013\)](#), the semantics of sentences of the pattern ‘DE modified numeral + distributive predicate’ can be accounted for straightforwardly.

- (31)  $\llbracket \text{Fewer than } 4^x \text{ boys smiled} \rrbracket \Leftrightarrow \exists^{|\mathbf{x}| < 4} [\text{*BOYS}(x)] \delta(\text{*SMILE}(x))$   
 $\Leftrightarrow \sigma x(\text{*BOY}(x) \wedge \delta x(\text{*SMILE}(x))) \wedge |\mathbf{x}| < 4$   
 $\Leftrightarrow \sigma x(\text{*BOY}(x) \wedge \delta x(\text{*SMILE}(x))) \wedge |\mathbf{x}| < 4$   
 i.e., the maximal set  $x$  such that (i) it consists of boys and (ii) each atomic part of  $x$  smiled has a cardinality smaller than 4.<sup>10</sup>

As shown in (31), both the predicates in the restrictor and nuclear scope are distributive, thus the at-issue meaning contributed by modified numerals, i.e., the maximization operator, takes scope over the whole sentence. On the base of this, the cardinality constraint is evaluated as a second dimension of meaning, and thus *fewer than 4* has the effect of taking a pseudo wide scope over the whole sentence, resulting in the upper-bound reading. Notice that I have also included the empty set  $\emptyset$  in the domain  $\mathfrak{D}$ , thus it is not guaranteed that the introduced maximal referent is a non-empty set, which accounts for our intuition that this sentence has no existential entailment.<sup>11</sup>

### 3.2. The notion of group and the semantics of *fewer than 4 boys lifted the piano together*

Following [Barker \(1992\)](#) (see also [Schwarzschild 1996](#); [Winter 2001](#); [Champollion 2010](#)), I consider **groups** a special kind of **atomic individuals**. E.g., *a certain committee constituted by John and Bill* means a singleton set, and I write it as  $\uparrow \{\text{JOHN}, \text{BILL}\}$  in the following. In fact, the atoms of an individual  $X$  (i.e., the singleton subsets of a non-empty set  $X$ ) can form many different groups, depending on context. E.g., the atoms of  $\{\text{JOHN}, \text{BILL}\}$  (i.e.,  $\{\text{JOHN}\}$  and  $\{\text{BILL}\}$ ) can form a beach volleyball team, a jazz duo, a job search committee, etc. Therefore,  $\uparrow$  can be considered an operator that is the function composition of (i) a context-dependent **choice function** and (ii) a **group-generating operator** that takes a non-empty set  $X$  as input and returns the set containing all the groups constituted by the atoms in  $X$ . As a consequence, for  $\uparrow X$  to be well-defined,  $X$  needs to be a non-empty set. Moreover, the operator  $\uparrow$  is externally static, i.e., any secondary-dimension meaning introduced within the scope of  $\uparrow$  needs to be discharged therein.

As (32) illustrates, there is an interaction between the type of nouns and predicates: group nouns are compatible with collective predicates, but incompatible with distributive predicates;

<sup>10</sup>Obviously, the maximal referent introduced by modified numerals can be an infinite set, and sentences such as *fewer than 5<sup>x</sup> prime numbers are odd* cause no problems (cf. [Buccola and Spector 2016](#), see also Footnote 4).

<sup>11</sup>However, in *Fewer than 4<sup>x</sup> boys smiled; they<sup>x</sup> solved all the problems*, the use of *they* – a refset anaphora (see [Charlow 2014](#)) referring to the boys who smiled – brings the presupposition that the maximal referent introduced previously has a cardinality above zero, and its interpretation fails if the accommodation of presupposition fails.

(32) The interaction between the type of nouns and predicates:

|                                     |                            |
|-------------------------------------|----------------------------|
| a. * Every soldier formed a circle. | b. ✓ Every soldier smiled. |
| c. ✓ Every army formed a circle.    | d. * Every army smiled.    |

(33) Meaning postulates for distributive and collective predicates:

- Smile* requires its agent be a **non-group atomic individual**.
- Form a circle* and *lift the piano together* require their agent be a **group**.

(34)  $[[\text{Fewer than } 4^x \text{ boys}^Y \text{ lifted the piano together}]] \rightsquigarrow a \text{ fewer-than-4-boy group}$

$$\Leftrightarrow \exists Y[Y = \uparrow [[\text{fewer than } 4^x \text{ boys}]]](\text{*LIFT-THE-PIANO-TOGETHER}(Y))$$

$$\Leftrightarrow [Y] \wedge Y = \uparrow \{i \in x | \sigma x(\text{*BOY}(x)) \wedge |x| < 4\} \wedge \text{*LIFT-THE-PIANO-TOGETHER}(Y) \quad (\text{see (25b)})$$

$$\Leftrightarrow [Y] \wedge Y = \uparrow \{i \in x | \sigma x(\text{*BOY}(x)) \wedge |x| < 4\} \wedge \text{*LIFT-THE-PIANO-TOGETHER}(Y)$$

i.e., a group of boys, the total number of which is smaller than 4, lifted the piano together.

To sum up, Sections 3.1 and 3.2 together account for the generalization shown in (3). The semantic contribution of *fewer than 4* remains constant, and there is no over-generation. In addition, each and every part of the proposed analysis here has been motivated independently in the literature.

**Between 4 and 8** The data in (4) show that sentences containing *between 4 and 8* pattern with those containing *fewer than 4* with regard to whether there is an upper-bound reading. This

<sup>13</sup>This ‘a fewer-than-4-boy group’ analysis is somehow reminiscent of the contrast between (15) and (17): *few boys* is used along with distributive predicates, while *a few boys* is used along with collective predicates.

can be accounted for straightforwardly: in (35b), the predicate is collective, and *between 4 and 8 boys* refers to a group. Crucially, there is no maximization operator to limit the number of groups.

- (35) a.  $[[\text{Between 4 and } 8^x \text{ boys smiled}]] \Leftrightarrow \sigma x(*\text{BOY}(x) \wedge \delta x(*\text{SMILE}(x))) \wedge |x| \in [4, 8]$   
 b.  $[[\text{Between 4 and } 8^x \text{ boys}^Y \text{ lifted the piano together}]]$   
 $\Leftrightarrow [Y] \wedge Y = \uparrow \{i \in x | \sigma x(*\text{BOY}(x)) \wedge |x| \in [4, 8]\} \wedge *LIFT\text{-THE-PIANO-TOGETHER}(Y)$

**The use of group nouns** As shown in the meaning postulates (33), both distributive and collective predicates require their agents be atomic individuals, but collective predicates specifically require their agents be groups. Obviously, this straightforwardly explains why the interpretation of ‘[[modified numeral + group noun] + collective predicate]’ is parallel to that of ‘[[modified numeral + non-group noun] + distributive predicate]’. As illustrated in (36), here the collective predicate *surround the castle* distributes over groups (here *armies*), leading to an upper-bound reading.

- (36)  $[[\text{Fewer than } 4^Y \text{ armies surrounded the castle}]]$   
 $\Leftrightarrow \sigma Y(*\text{ARMY}(Y) \wedge \delta Y(*\text{SURROUND-THE-CASTLE}(Y))) \wedge |Y| < 4$

**Few / a few** In the current account, nothing hinges on the numeral in modified numerals. Thus, sentences containing *few / a few* can be analyzed in the same way, simply by replacing the numeral in modified numerals with a context-sensitive threshold value of largeness, as illustrated in (37).

- (37) a.  $[[\text{Few}^x \text{ boys smiled}]] \Leftrightarrow \sigma x(*\text{BOY}(x) \wedge \delta x(*\text{SMILE}(x))) \wedge |x| < \text{THRESHOLD}^{\text{CONTEXT}}$   
 b.  $[[\text{A few}^x \text{ boys}^Y \text{ lifted the piano together}]]$   
 $\Leftrightarrow [Y] \wedge Y = \uparrow \{i \in x | \sigma x(*\text{BOY}(x)) \wedge |x| < \text{THRESHOLD}^{\text{CONTEXT}}\} \wedge *LIFT\text{-THE-PIANO-TOGETHER}(Y)$

**No fewer than 4** The current account can also be extended to give a compositional analysis for *no fewer than 4* (e.g., *no fewer than 4 boys smiled*). Similar to other modified numerals, *no fewer than 4* also (i) introduces a maximal referent and (ii) adds a cardinality constraint as a secondary dimension of meaning. Evidently, only this cardinality part needs to be slightly modified.

In the same spirit as Szabolcsi (1997); Geurts and Nouwen (2007), etc., which have pointed out that modified numerals provide quantity information and should not be analyzed as generalized quantifiers, here I follow Zhang and Ling (2015, 2017) and analyze this kind of quantity information in terms of intervals. Intervals are convex sets of degrees, and thus their type is  $\langle dt \rangle$ . We can write an interval –  $\lambda \delta_d. \{\delta | D_{\text{lower-bound}} \leq \delta \leq D_{\text{upper-bound}}\}$  – in terms of its upper- and lower-bounds:  $[D_{\text{lower-bound}}, D_{\text{upper-bound}}]$ . An interval represents a range of possible values on a scale. In a certain sense, we can consider (3,5) a vaguer value than [4,5] or a singleton set [4,4], because (3,5) contains more possibilities. The operations on intervals are defined on

the base of this idea (see Moore 1979). The compositional details of deriving the cardinality part of *(no) fewer than 4* are shown in (38). Notice that in (38e), I analyze the meaning of *no* as an operator on sets: it takes a set as input and returns its complement. As shown in (38f), the cardinality part of *no fewer than 4* is basically equivalent to what *at least 4* means, which is consistent with our intuition.

- (38) The cardinality part of *(no) fewer than 4* is analyzed as a set of degrees of type  $\langle dt \rangle$ :
- a.  $\llbracket 4 \rrbracket_{\langle dt \rangle} \stackrel{\text{def}}{=} [4, 4]$  I.e., a singleton set of degrees
  - b.  $\llbracket \text{fewer} \rrbracket_{\langle dt \rangle} \stackrel{\text{def}}{=} (-\infty, 0)$  I.e., a set denoting a differential of negative value
  - c.  $\llbracket \text{than} \rrbracket_{\langle dt, \langle dt, dt \rangle \rangle} \stackrel{\text{def}}{=} \lambda I_{\text{COMP.-STANDARD}}. \lambda I_{\text{DIFFERENTIAL}}. \lambda I_{\text{COMP.-SUBJ.}} [I_{\text{COMP.-SUBJ.}} - I_{\text{COMP.-STANDARD}}] = I_{\text{DIFFERENTIAL}}$
  - d.  $\llbracket \text{fewer than 4} \rrbracket_{\langle dt \rangle} = \lambda I. [I - [4, 4] = (-\infty, 0)] = (-\infty, 4)$   
(Interval subtraction:  $[x_1, x_2] - [y_1, y_2] = [x_1 - y_2, x_2 - y_1]$ ) (see Moore 1979)
  - e.  $\llbracket \text{no} \rrbracket_{\langle dt, dt \rangle} \stackrel{\text{def}}{=} \lambda I. \lambda I' [I' = (-\infty, +\infty) \setminus I]$
  - f.  $\llbracket \text{no fewer than 4} \rrbracket_{\langle dt \rangle} = \lambda I' [I' = (-\infty, +\infty) \setminus (-\infty, 4)] = [4, +\infty)$

***Fewer than 4 boys can together lift that piano*** The generic reading of this sentence (see also Section 2.1) is derived in (39), with the assumption of a silent genericity operator  $\forall_{\text{GEN}}$  binding  $Y$ .

- (39)  $\llbracket \text{Fewer than } 4^x \text{ boys}^Y \text{ can together lift that piano} \rrbracket$   
 $\Leftrightarrow \forall_{\text{GEN}} \llbracket \text{Fewer than } 4^x \text{ boys}^Y \rrbracket \llbracket \text{can together lift that piano} \rrbracket$   
 $\Leftrightarrow \forall_{\text{GEN}} Y [Y = \uparrow \{i \in x \mid \sigma x(*\text{BOY}(x)) \wedge |x| \in (-\infty, 4)\} \rightarrow \diamond * \text{TOGETHER-LIFT-THAT-PIANO}(Y)]$   
 I.e., in general, boy groups of a cardinality smaller than 4 can together lift that piano.

Crucially, the sentence meaning derived in (39) does not entail that boy groups of any cardinality smaller than 4 can together lift that piano. As I have mentioned above,  $(-\infty, 4)$  means a range of possible values, and thus it provides quantity information in a vague way. Therefore, the effect of using the information ‘*fewer than 4 boys*’ in describing a group is analogous to the effect of describing a dish as *meat stew*: *meat stew* contains some kind of meat, but not any kind of meat, and due to our world knowledge, the possibility of, say, dinosaur meat, is certainly very improbable.

In sum, the data discussed in Section 3.3 can all be easily accounted for, which provides more empirical support for the current proposed account for modified numerals.

#### 4. Sentences with a cumulative (or co-distributive) reading

Brasoveanu (2013) and Buccola and Spector (2016) approach cumulative-reading sentences differently. In Brasoveanu (2013)’s analysis of sentence (22) (repeated here as (40)), the same maximization operator globally binds both the variables  $x$  and  $y$ , introducing simultaneously two maximal sets. A consequence of this is that when there is a DE modified numeral, it is predicted that there is an upper-bound reading, but no existential entailment. The examples in (41) suggest that this prediction is borne out. On the other hand, according to Buccola and

Spector (2016)'s account for sentence (42), the predicate here is considered a collective one, and thus, the sentence has an existential entailment, but no upper-bound reading. Both cases can be handled by the current proposed analysis. However, there is a remaining issue for future research. For this kind of sentences containing multiple (modified) numerals, what factors determine their interpretation? Can there be examples showing a true ambiguity? Are animacy and agent/theme asymmetry involved here?

- (40) Exactly  $3^x$  boys saw exactly  $5^y$  movies. Cumulative reading  
 $\sigma xy(*BOY(x) \wedge *MOVIE(y) \wedge *SEE(x, y)) \wedge |y| = 5 \wedge |x| = 3$
- (41) These  $10^x$  chickens laid fewer than  $20^y$  eggs in total. ✓ Upper-bound; # Existential  
Fewer than  $20^y$  eggs were laid by these  $10^x$  chickens. ✓ Upper-bound; # Existential  
 $\sigma xy(*CHICKEN(x) \wedge *EGG(y) \wedge *LAY(x, y)) \wedge |y| < 20 \wedge |x| > 10$   
 (cf. Fewer than 10 chickens laid 20 eggs in total. # Upper-bound; ✓ Existential)
- (42) Fewer than  $4^x$  boys<sup>Y</sup> drank 20 beers between them. # Upper-bound; ✓ Existential  
 $[Y] \wedge Y = \uparrow \{i \in x | \sigma x(*BOY(x)) \wedge |x| < 4\} \wedge *DRINK-20-BEERS-BETWEEN-THEM(Y)$   
 (cf. 4 boys drank fewer than 20 beers between them. ✓ Upper-bound; # Existential)

## 5. Buccola and Spector (2016)'s 'informativity-based maximality' approach

Buccola and Spector (2016) has also proposed an approach of informativity-based maximality. The basic idea is that for a degree  $n$  to be  $P$ -maximal in  $w$ , it satisfies two requirements: (I) the proposition  $P(n)$  must be true in  $w$ , and (II) there is no degree  $m$  such that (i)  $P(m)$  is true in  $w$  and (ii)  $P(m)$  is more informative than  $P(n)$ . This idea is formally implemented as a  $\max_{\text{inf}}$  operator, and there are two specific analyses: **L**(exical)**Max**<sub>inf</sub> (see (43)) and **S**(eparate)**Max**<sub>inf</sub>.

- (43) a.  $\llbracket \text{fewer than} \rrbracket^w \stackrel{\text{def}}{=} \lambda n_d. \lambda P_{\langle s, \langle dt \rangle \rangle}. \exists m [m < n \wedge \max_{\text{inf}}(P)(w)(m)]$  LMax<sub>inf</sub>  
 b.  $\llbracket \text{fewer than 4} \rrbracket^w \stackrel{\text{def}}{=} \lambda P_{\langle s, \langle dt \rangle \rangle}. \exists m [m < 4 \wedge \max_{\text{inf}}(P)(w)(m)]$

This 'informativity-based maximality' approach has at least the following four problems, and the first two have already been mentioned and discussed in Buccola and Spector (2016). (I) First, scope interactions between a modified numeral and an existential closure still cause over-generation. Using a pragmatic rule like (9) can sometimes rule out some unattested readings, but, as I have discussed in Section 2.2, the use of this pragmatic rule has its own problems. (II) Second, although this approach naturally accounts for the (un)availability of upper-bound readings, there are non-trivial complications with regard to accounting for the (un)availability of existential entailment. Some stipulations are added in Buccola and Spector (2016) to deal with this issue. (III) Third, given semantic compositionality, a good account for the semantics of *fewer than 4* should be able to be extended to account for the semantics of *no fewer than 4*. However, LMax<sub>inf</sub> cannot achieve this. Roughly speaking, in combining *no* with *fewer than 4* to derive the semantics of *no fewer than 4*, since the part  $\max_{\text{inf}}(P)(w)(n)$  in (43) should intuitively remain constant for both *fewer than 4* and *no fewer than 4*, it is unclear how *no* targets only the part  $m < n$  or  $m < 4$ . (IV) Fourth, if SMax<sub>inf</sub> is adopted, i.e.,  $\max_{\text{inf}}$  is independent of the semantics of modified numerals, then it raises the question why  $\max_{\text{inf}}$  cannot be used in

sentences containing bare numerals. If it is used, then since informativity-based maximality is now part of the truth conditions of sentences, in a situation where I ate 4 apples, the sentence *I ate 3 apples* is simply false, not under-informative.

However, there are another set of relevant data that seem to motivate the approach of informativity-based maximality (see Buccola 2015a; Buccola and Spector 2016), namely sentences expressing different scalarity entailment. E.g., from *fewer than 10 eggs can feed these people*, it follows that *fewer than 11 eggs can feed these people*, but from *fewer than 10 people can fit into this elevator*, it follows that *fewer than 9 people can fit into this elevator*. Whether the current proposed analysis can be extended to account for this kind of inference pattern is left for future research.

## 6. Brasoveanu (2013)'s approach vs. Solt (2006)'s 'decomposition + split scope' analysis

Solt (2006) has proposed a 'decomposition + split scope' account for *few*: *few* is decomposed into (i) a positive cardinality and (ii) a negation operator that takes the widest possible scope (see (44)).

- (44)  $[[\text{few}]]_{\langle et \rangle} \stackrel{\text{def}}{=} \lambda x. [\text{LARGE-VALUE}^{\text{CONTEXT}}(|x|)];$  storing a negation operator
- a.  $[[\text{Few students passed the test}]]$   
 $\Leftrightarrow \neg \exists x [\text{LARGE-VALUE}^{\text{CONTEXT}}(|x|) \wedge * \text{STUDENT}(x) \wedge * \text{PASS-THE-TEST}(x)] \quad \neg > \exists$
- b.  $[[\text{A few students passed the test}]]$   
 $[[\text{A few students}]] = \lambda P_{\langle et \rangle}. \exists x [\neg \text{LARGE-VALUE}^{\text{CONTEXT}}(|x|) \wedge * \text{STUDENT}(x)] \quad \exists > \neg$

For sentences like *fewer than 4 boys lifted the piano together*, if we assume that there is also a silent existential closure within the subject DP (i.e., *A fewer-than-4-boy (group)*) and adopt a compositional analysis à la Solt (2006), presumably the existential entailment and the lack of an upper-bound reading of this sentence can also be accounted for. Compared with Brasoveanu (2013)'s approach, Solt (2006)'s seems to have some disadvantages and an advantage. First, Solt (2006) cannot address the maximal reference issue. Second, in terms of compositionality, *fewer than 4* cannot be derived from (i) negation and (ii) *larger than 4* – '*equal to 4*' needs to be ruled out (see Zhang and Ling 2017). However, it seems that within the current proposed analysis, modified numerals like *fewer than 4* and *no fewer than 4* are analyzed in the same way (see Section 3.3), which raises the question of how to account for NPI licensing. This is also left for future research.

## 7. Summary and outlook

In this paper, based on existing well-motivated components of natural language semantics, I explain the interplay between (i) the interpretation of sentences containing non-increasing modified numerals and (ii) the type of predicates therein. In addition to what has been discussed in Sections 4 – 6, there are two remaining issues: (i) Whether there are other ways of implementing the secondary dimension of meaning of modified numerals, and whether/how they differ in terms of dynamicity/staticity; (ii) Whether/how the semantics of modified numerals interacts with modals.
