# Foreword

The present volume contains a collection of papers presented at the 21st annual meeting “Sinn und Bedeutung” of the Gesellschaft für Semantik, which was held at the University of Edinburgh on September 4th–6th, 2016.

239 abstracts were submitted to SuB21; of the 72 talks and 30 posters on the program, 82 were elaborated into the papers in this collection.

The editors of the present volume would like to thank the authors for their contributions and all the anonymous reviewers for their collaboration. We also wish to thank Ede Zimmermann for patient and helpful advice; our fellow organizers Nikolas Gisborne and Marieke Schouwstra; our administrative team Julie Anderson, Steven McGauley, Sylvia Rennie, and Davy Wilkinson for invaluable help in the background; our student volunteers Michela Bonfieni, Kiera Davidson, Jim Donaldson, Sorchia Gilroy, E Jamieson, and Schuyler Laparle; the invited speakers Nicholas Asher, Sigrid Beck, and Peter Lasersohn; Sarah Meyer Truswell for designing the front cover; and everyone else who contributed to the success of the conference.

# Van Benthem's problem, exhaustification, and distributivity<sup>1</sup>

Sam ALXATIB — *CUNY GC*

Natasha IVLIEVA — *HSE Moscow*

**Abstract.** We discuss the problem of deriving upper-bounded meanings of **few**, **fewer than**, and related expressions, in treatments where they are taken to denote predicates of individuals. In such analyses, the determiner-like uses of these expressions are derived by existentially-closing their predicate denotations, but this is known to give rise to problems (van Benthem, 1986). We show that the needed upper bound can be derived by applying an exhaustification operator above existential closure. Crucially, this exhaustification operator is insensitive to the distributive properties of the predicates in the sentence, an assumption that we see as consistent with recent work supporting the blindness view of implicatures (Fox and Hackl, 2006; Magri, 2009). We also discuss some similarities and differences between our analysis and Buccola and Spector's (2016) maximality-based approach.

**Keywords:** Modified numerals, exhaustification, distributivity, maximality.

## 1. Introduction

It is known that the expressions **many** and **few**, along with morphosyntactic derivatives like **fewer than 3**, show adjectival as well as determiner-like uses. Examples are shown in (1).

- (1)    a.    The many/few people who smiled were smiling broadly  
       b.    (The) people who smiled were many/few  
       c.    Many/few people smiled

It is also known that, in the case of **many**, these multiple uses can be accommodated in a uniformly adjectival treatment, if it is complemented with an operation of Existential Closure (EC). The idea would be that **many** denotes a predicate of individuals, holding of those plural entities that reach a contextually-set cardinality, and in cases like (1c) where **many** behaves like a determiner, the truth conditions result from existentially closing the predicate.

But (as is also known), EC generates problematic results in the case of **few**. Suppose that, analogously to **many**, **few** denotes a predicate of (plural) individuals, holding of just those pluralities that fall below a certain cardinality threshold. If the determiner-like reading is to be derived from EC, the resulting truth conditions will require that some 'small' plurality exist that has whatever other properties appear in the given sentence. But these predicted conditions are inaccurate, because (i) they incorrectly require existence, and (ii) they fail to set a desired upper bound. The unwanted existence requirement comes from EC: under EC, and following standard ontological assumptions, sentences like (1c) where **few** behaves like a determiner cannot be true unless the given predicate(s) are verified by some *existing* plurality. But as is generally agreed in the literature, such sentences are intuitively true even if no individuals

---

<sup>1</sup>We are grateful to Brian Buccola, Danny Fox, Rick Nouwen, Benjamin Spector, Eytan Zweig, and the audience at the 21st *Sinn und Bedeutung* in the University of Edinburgh. All errors are our own.

verify the predicate(s).<sup>2</sup> The second problem, the upper bound problem, is that the existence of small pluralities is compatible with the existence of larger ones; any large plurality of e.g. smiling people will have a small sub-plurality that satisfies the condition of fewness, which means that scenarios where a great number of people smiled will be predicted (incorrectly) to verify the truth conditions of **few people smiled**.

In this paper we will have little to say about the existence problem (problem (i) above). Our focus will be on the upper bound problem, known in current literature as van Benthem's problem (van Benthem 1986). We propose an exhaustification mechanism that correctly sets the needed upper bound, thus circumventing van Benthem's problem. The key detail in the proposal is that exhaustification applies without any sensitivity to the distributive/collective properties of the predicates appearing in the given construction. This assumption builds on recent work promoting the 'blindness' view of implicatures. We explain the details of our proposal in Section 2, and discuss some of its consequences in Section 3. In Section 4 we turn our attention to Buccola and Spector's (2016) discussion of these issues, and provide a brief (and at the moment inconclusive) comparison between one of their proposals and ours. In the remaining parts of the current section, we elaborate on the details of van Benthem's problem, taking note in particular of how it interacts with distributive predicates, and with non-distributive ones.

### 1.1. Van Benthem's problem and distributive/non-distributive predicates

To keep things simple we will assume that EC is the product of an unpronounced existential determiner,  $\exists$ , defined in (2).

$$(2) \quad \llbracket \exists \rrbracket = [\lambda P_{\langle e,t \rangle} . \lambda Q_{\langle e,t \rangle} . \exists x (P(x) = Q(x) = 1)]$$

We will also focus our attention on comparative phrases like **more than 4** and **fewer than 4**, instead of **many** and **few**, in order to sidestep the vagueness of the latter's semantics. To keep the presentation simple we assume that **more than 4** and **fewer than 4** denote predicates of individuals:<sup>3</sup>

$$(3) \quad \begin{array}{ll} \text{a.} & \llbracket \text{more than 4} \rrbracket = [\lambda x_e . |x| > 4] \\ \text{b.} & \llbracket \text{fewer than 4} \rrbracket = [\lambda x_e . |x| < 4] \end{array}$$

If predicates of type  $\langle e, t \rangle$  can compose by Predicate Modification, then **more/fewer than 4 people** will denote another set/predicate of plural entities, namely entities of size greater (or less) than four that consist of people. Applying  $\exists$  to these predicates will produce an existential quantifier that maps a given predicate  $Q$  to True iff  $Q$  holds of some plurality of people that contains more than (or less than) four atoms. The LFs and truth conditions for the two sentences are shown below.

<sup>2</sup>Though sentences like **few students smiled** license existence inferences by default, the inference is thought to be extra-semantic, given its disappearance in DE contexts, and cancellability in **in fact** continuations.

<sup>3</sup>As far as we can see, this assumption can be replaced with a more complex syntax/semantics for comparatives without affecting the tenability of the overall proposal. See Alxatib (2013), Chapter 7.

- (4) a. **[[ $\exists$  more than 4 people] smiled]**  
 b.  $\exists x(\llbracket \text{people} \rrbracket(x)=1 \ \& \ |x|>4 \ \& \ \llbracket \text{smiled} \rrbracket(x)=1)$
- (5) a. **[[ $\exists$  fewer than 4 people] smiled]**  
 b.  $\exists x(\llbracket \text{people} \rrbracket(x)=1 \ \& \ |x|<4 \ \& \ \llbracket \text{smiled} \rrbracket(x)=1)$

As remarked above, the conditions in (5b) are less informative than desired: they hold even in situations where more than four people smiled, because if (say) five people smiled, there is guaranteed to be a smiling *sub*-group whose size is lower than four. In fact, if we look more closely we can see that the truth conditions of (5a) are identical to those that result when **4** is replaced with any other numeral. To see this, consider the minimally different **fewer than 5 people smiled**:

- (6) a. **[[ $\exists$  fewer than 5 people] smiled]**  
 b.  $\exists x(\llbracket \text{people} \rrbracket(x)=1 \ \& \ |x|<5 \ \& \ \llbracket \text{smiled} \rrbracket(x)=1)$

If the conditions in (5b) hold, then there is a smiling plurality of size less than four, and therefore less than five, which means that (5a) entails (6a). Conversely, if (6b) holds, i.e. if there is a plurality of smilers of size less than five, then by the distributivity of the predicate **smiled** it follows that there is a smiling sub-plurality of size less than four. Therefore, (6a) entails (5a). This makes (5a) and (6a) equivalent, and the numeral in them semantically irrelevant.

At this point it is crucial to highlight the role of distributivity, of the predicate **smiled** in this case, in making (6)/(5) equivalent. In the case of non-distributive predicates like **lifted the piano (together)**, only one of the two entailments noted above will hold. Consider the LFs and truth conditions in (7) and (8).

- (7) a. **[[ $\exists$  fewer than 4 people] lifted the piano]**  
 b.  $\exists x(\llbracket \text{people} \rrbracket(x)=1 \ \& \ |x|<4 \ \& \ \llbracket \text{lifted the piano} \rrbracket(x)=1)$
- (8) a. **[[ $\exists$  fewer than 5 people] lifted the piano]**  
 b.  $\exists x(\llbracket \text{people} \rrbracket(x)=1 \ \& \ |x|<5 \ \& \ \llbracket \text{lifted the piano} \rrbracket(x)=1)$

(7b) says that there is a person-plurality of size less than four that lifted the piano. When this holds, the conditions in (8b) must also hold; if there is a piano-lifting plurality of size less than four, then that same plurality makes it true that there is one of size less than five. (7a) therefore entails (8a), in parallel to the entailment from (5a) to (6a). But the reverse entailment does not hold here; if there is a piano-lifting group of size less than five ( $=$ (8b)), it does not follow that there is one of size less than four ( $=$ (7b)): Suppose exactly four people lifted the piano together. The size of this group falls below five, but not below four, and there is no guarantee that some sub-group of the four lifters also lifted the piano, because the lifting is true of them collectively, not individually.

We therefore see that van Benthem's problem (the problem of the upper bound) causes numerals to be semantically redundant in the case of distributive predicates, though as we pointed out,

this is not the case for non-distributive predicates. We will now explain what this redundancy means for attempts to derive the upper bound by pragmatic strengthening (or exhaustification): because (under distributivity) all alternatives of the form **fewer than n** are equivalent, there will be no way of selecting the right alternatives for exhaustification, and of using those alternatives to generate the desired upper bound at the correct **n**. We expand on this next. From this point on, we will write ' $\exists > \text{few}$  constructions' to refer to sentences where EC outscopes **few** and similar expressions. We also write 'distributive/non-distributive  $\exists > \text{few}$  constructions' to refer to  $\exists > \text{few}$  constructions that contain (or do not contain) distributive predicates.

## 1.2. Van Benthem's problem and pragmatic strengthening?

Our current truth conditions for distributive  $\exists > \text{few}$  constructions only require existence, and appear to make no use of the numeral modified by **fewer than**.<sup>4</sup> But what if the truth conditions were complemented with the negation of other, more informative alternatives? In (Neo-) Gricean pragmatics, a sentence *S* that is uttered in a certain context licenses not only the inferences that result from its literal meaning, but also the inference that alternative sentences which (i) were not uttered, (ii) would have been as relevant in that context, and (iii) are stronger than *S*, are false. It may seem that pragmatic principles along these lines can be used to derive the upper bound of  $\exists > \text{few}$  sentences, but as we now explain, pragmatic strengthening of distributive  $\exists > \text{few}$  LFs is either vacuous, or excessive.

The first of these two outcomes results if the only relevant alternatives to an  $\exists > \text{few}$  sentence are those where the numeral/degree is substituted for another. In the case of our example (5a), repeated below as (9a), this assumption limits the alternatives to those in (9b).

- (9) a.  $[[\exists \text{ fewer than } 4 \text{ people}] \text{ smiled}]$   
       b.  $\{[[\exists \text{ fewer than } 3 \text{ people}] \text{ smiled}],$   
            $[[\exists \text{ fewer than } 5 \text{ people}] \text{ smiled}],$   
            $[[\exists \text{ fewer than } 6 \text{ people}] \text{ smiled}], \dots \}$

The problem is that none of the alternatives in (9b) are stronger than (9a); they are all equivalent. This gives the strengthening mechanism nothing to negate (or 'exclude') in strengthening (9a), and leaves it vacuous.

Now, suppose we enrich our set of alternatives and add constructions of the form  $[[n \text{ people}] \text{ smiled}]$ , i.e. where **fewer than** is removed:

---

<sup>4</sup>We will return to the existence requirement in Section 4.

- (10) a.  $[[\exists \text{ fewer than 4 people}] \text{ smiled}]$   
 b.  $\{[[\exists \text{ fewer than 3 people}] \text{ smiled}],$   
 $[[\exists \text{ fewer than 5 people}] \text{ smiled}],$   
 $[[\exists \text{ fewer than 6 people}] \text{ smiled}],$   
 c.  $[[\exists \text{ 2 people}] \text{ smiled}],$   
 $[[\exists \text{ 3 people}] \text{ smiled}],$   
 $[[\exists \text{ 4 people}] \text{ smiled}],$   
 $[[\exists \text{ 5 people}] \text{ smiled}], \dots \}$

Each alternative in (10c) requires that there be an  $n$ -sized plurality of smiling people, and hence they each asymmetrically entail the weak existence truth conditions of (10a). It follows, by the simple pragmatic recipe described above, that an utterance of (10a) will semantically require existence, and via pragmatic strengthening will imply that no group of four or five smilers exists—so far correctly—but also that no group of three smilers exists, and no group of two smilers exists. By nullfying the semantic contribution of the numeral in the original utterance, the strengthening mechanism described above will not help recover the correct upper bound, because there will be no way to correctly identify its location.

In the next section, we will present a modified strengthening mechanism that bypasses van Benthem's problem. We will first introduce the mechanism's two key components, Innocent Exclusion and blindness, and show how they interact to produce the correct upper bound for distributive  $\exists > \text{few}$  constructions. We will then discuss our predictions for non-distributive cases, and finally, compare our analysis to the analysis offered in Buccola and Spector (2016).

## 2. Reconsidering Pragmatic Strengthening

### 2.1. Innocent Excludability, Blindness, and Implicature Calculation

We will assume that the strengthened meaning of a sentence  $S$  is derived by applying an exhaustification operator  $\text{Exh}$  to the denotation of  $S$  (along the lines of Fox 2007a, following proposals by Groenendijk and Stokhof 1984; Krifka 1995; Landman 1998; van Rooy 2002).  $\text{Exh}$  may be viewed as a covert variant of **only**. Its semantics is defined below:

$$(11) \quad \llbracket \text{Exh} \rrbracket^w(A_{\langle st, t \rangle})(p_{\langle s, t \rangle}) = 1 \text{ iff } p(w) = 1 \ \& \ \forall q(q \in \text{EXCL}(p, A) \rightarrow q(w) = 0)$$

The exhaustification operator takes a proposition  $p$ , its 'prejacent', and a set of alternatives  $A$ , and asserts that  $p$  is true and that all its excludable alternatives (from  $A$ ) are false. The set of excludable alternatives  $\text{EXCL}(p, A)$  is a subset of  $A$ . Different versions of  $\text{Exh}$  proposed in the literature differ with respect to how this set of excludable alternatives is defined. One possibility is to define  $\text{EXCL}(p, A)$  as that subset of  $A$  that contains all (and only) propositions that are not entailed by  $p$ :

$$(12) \quad \text{EXCL}(p, A) = \{q : q \in A \ \& \ p \not\models q\}$$

But we will now show why (12) is problematic, and why (following Fox and others) we adopt

the notion of 'Innocent Excludability' instead of it.

## 2.2. Innocent Excludability

It was argued in Sauerland (2004) that disjunctive constructions should have not only their conjunctive counterparts as alternatives, but also the disjuncts. This is based on cases like (13).

(13) John needs to talk to Mary or Sue.

(13) naturally implies that John does not need to talk to Mary specifically, nor to Sue. If this is to be derived as an implicature, then the mechanism that generates implicatures must have access to the alternatives seen in (14), where the disjunction is replaced with its disjuncts. The alternatives are shown together with the *conjunctive* alternative to (13), but in this example the conjunctive alternative will not play an important role.

- (14)
- a. John needs to talk to Mary
  - b. John needs to talk to Sue
  - c. John needs to talk to Mary and Sue

Note that each of (14a) and (14b) is logically stronger than the original (13), which means that, if they are included in the set of alternatives, they will count as excludable by the definition in (12) and consequently be negated by the strengthening mechanism. Here, this seems to be a good result.<sup>5</sup> But in the case of unembedded disjunctions like (15), the same ingredients make strengthening contradictory.

(15) John saw Mary or Sue.

- (16)
- a. John saw Mary.
  - b. John saw Sue.
  - c. John saw Mary and Sue.

Under the assumption that disjunction has its disjuncts among its alternatives, the application of Exh to (15) is predicted to assert (15) and negate both of (16a) and (16b) (in addition to negating (16c)). But this leads to the contradiction in (17):

(17) John saw Mary or Sue and he didn't see Mary and he didn't see Sue.

The conclusion from this result is that (12), our current definition of excludable alternatives, must be revised in a way that allows the alternatives in (14) to participate in strengthening (13), but blocks (16a–b) from participating in strengthening (15). The revision we adopt is Fox's (2007a), who defines excludability as 'innocent' excludability.

---

<sup>5</sup>Negating the conjunctive alternative in (14c) is vacuous here, since it follows from negating either of the disjuncts.

Our formulation of Innocent Excludability (IE) is the following: given a proposition  $p$  and a set of propositions  $A$ , the IE-alternatives ( $\text{EXCL}(p, A)$ ) are those that remain in  $A$  after the *non-innocent* subsets of  $A$  are removed from  $A$ . The non-innocent sets, in turn, are those whose 'set-negation' contradicts  $p$ , and that have no proper subsets whose set-negation contradicts  $p$ . The set negation of a set  $A$  is the conjunction of the negations of  $A$ 's elements. These definitions are summarized below:

$$(18) \quad \begin{aligned} \text{EXCL}(p, A) &= A - \bigcup \{B : B \subseteq A \text{ and } B \text{ is non-innocent w.r.t. } p\} \\ \text{a. } B \text{ is non-innocent w.r.t. } p &\text{ iff (i) } B^\neg \models \neg p, \text{ and} \\ &\text{(ii) } \neg \exists B' (B' \subset B \text{ \& } B'^\neg \models \neg p). \\ \text{b. } B^\neg &= \bigwedge \{\neg q : q \in B\} \end{aligned}$$

This revised definition of EXCL in (18) successfully distinguishes the case of (13) from (15). Let us represent the disjunction in (15) as  $p \vee q$ , and its alternatives as  $p$ ,  $q$ , and  $p \wedge q$ :

$$(19) \quad A = \{p, q, p \wedge q\}$$

Now, given the definition in (18), what subsets of  $A$  are non-innocent with respect to  $p \vee q$ ? It is clear that negating all of the propositions in  $A$  will jointly contradict the disjunctive  $p \vee q$ , so  $A$  itself satisfies condition (i) in (18a). But  $A$  fails condition (ii) in (18b) because there is a proper subset of  $A$  whose set negation also contradicts  $p \vee q$ . This is the set  $\{p, q\}$ . And because  $\{p, q\}$  does *not* have proper subsets whose set negations contradict  $p \vee q$ , it follows that  $\{p, q\}$  is non-innocent with respect to  $p \vee q$ . So, the set of IE-alternatives in  $A$ , given  $p \vee q$ , is the result of subtracting the non-innocent set  $\{p, q\}$  from  $A$ :

$$(20) \quad \text{EXCL}(p \vee q, A) = A - \{p, q\} = \{p \wedge q\}$$

It follows that strengthening  $p \vee q$  given the set of alternatives  $A$  will not be contradictory, and will generate the inference that the conjunctive  $p \wedge q$  is false.

Consider now the case of (13), where disjunction is embedded under a universal modal. Here we may represent (13) itself as  $\Box(p \vee q)$ , and its alternatives as  $\Box p$ ,  $\Box q$ , and  $\Box(p \wedge q)$ :

$$(21) \quad A' = \{\Box p, \Box q, \Box(p \wedge q)\}$$

It should be clear that negating all of the alternatives in  $A'$  does not contradict  $\Box(p \vee q)$ ; the negation will merely require that not all accessible worlds be  $p$ -worlds, and not all accessible worlds be  $q$ -worlds. This is consistent with  $\Box(p \vee q)$ , because the modal base may consist of a mix of worlds, some being  $p$ -worlds and others being  $q$ -worlds. There are therefore no non-innocent sets within  $A'$  given  $\Box(p \vee q)$ ,

$$(22) \quad \text{EXCL}(\Box(p \vee q), A') = A' - \{\} = A'$$

and from this it follows that exhaustifying (13), given the set of alternatives in  $A'$ , will generate the inference that each element in  $A'$  is false:

$$(23) \quad \text{Exh}(A', \Box(p \vee q)) = \Box(p \vee q) \ \& \ \neg\Box p \ \& \ \neg\Box q \ \& \ \neg\Box(p \wedge q)$$

This concludes our introduction of Innocent Excludability. We now turn to the second of our two key ingredients, blindness.

### 2.3. Blindness

We take ‘blindness’ to be a property of semantic operators or mechanisms. When we say that an operator *O* is blind to some informational content, we mean that *O* applies without any sensitivity to that content, that is, that *O* applies to representations (e.g. syntactic ones) where that information is absent. Though our discussion of blindness will remain somewhat vague in this paper, we see Gajewski (2002) as an important reference for how the notion may be made more precise (see specifically Gajewski’s definition of ‘logical skeleton’).

We know of two proposals in the literature on implicatures that appeal to blindness. In one, Fox and Hackl (2006), it is argued that implicature calculation (and calculation of focus semantics) is blind to whether the predicates appearing in the given sentence utilize a discrete or dense scale of measurement. The claim is that implicatures are derived from representations where all measurement scales are assumed to be dense (we will explain the argument briefly below). If right, this means that implicature calculation (and calculation of focus semantics) is insensitive to content that on the surface appears to be *lexical*. As we will see later, our own proposal is similar to Fox and Hackl’s in this respect. In another proposal, Magri (2009), implicature calculation is argued to be blind to contextual/world knowledge. We will review Magri’s argument after we summarize Fox and Hackl’s, but we want to make it clear that we will not talk in detail about how either of these two accounts might interact with our own. Our intention is to use the two proposals as precedent for the hypothesis that exhaustification is blind.<sup>6</sup>

#### 2.3.1. Fox and Hackl (2006)

A central question in Fox and Hackl (F&H) is why sentences like (24) do not give rise to ‘exact’ implicatures.

$$(24) \quad \text{John read more than 3 books} \\ \not\Rightarrow \neg(\text{John read more than 4 books})$$

Assuming that (24) has an alternative where the numeral **3** is replaced with **4**, we expect the latter to participate in exhaustifying the meaning of (24), since **John read more than 4 books** is stronger than (24). But then we expect (24) to imply that John read more than three but not more than four books, i.e. exactly four books.<sup>7</sup> In their discussion of the problem, Fox and Hackl point out that this prediction is specific to cases where the relevant scale is *discrete*; if

<sup>6</sup>Readers familiar with Fox and Hackl in particular will no doubt wonder how the density hypothesis interacts with our own exhaustification mechanism. This is by no means a trivial question, but we leave it for later work.

<sup>7</sup>Note that this predictions hinges on the assumption that comparatives have other comparatives as alternatives. One could add constructions of the form **exactly n ...**, and we would no longer predict comparatives to give rise to these exact inferences. This possibility was in fact proposed in Spector (2005), but argued against in Fox (2007b).

the scale of degrees were dense, then there will be some alternative whose negation contradicts the utterance itself. Take (25) as an example.

(25) John is taller than 6 ft.

Let us assume that (25) requires that John reach a degree of height  $d$  above six feet. Unlike the integer scale, the scale of height is intuitively dense, meaning that for any two degrees of height  $d_1$  and  $d_2$  there is a degree of height  $d_3$  in between them. If (25) requires that John reach some height  $d$  above six feet, then by the density of the height scale there must exist some degree of height  $d'$  above six feet and below John's actual height  $d$ . Consider now the alternative in (26).

(26) John is taller than  $d'$

Since  $d'$  is above 6 feet, it follows that (26) is stronger than (25), which means that in strengthening (25) the algorithm should negate (26). But negating (26) means that John is at most  $d'$ -tall, which makes him shorter than  $d$ , i.e. shorter than his assumed actual height. The consequence is that, no matter how tall John is assumed to be, there is always a degree of height just below his own (and above six feet) that can form a stronger comparative sentence than (25), and whose negation will contradict the semantic content of (25).<sup>8</sup> The broader consequence of this is that implicatures of comparatives are predicted to generate contradictions if the relevant scale of degrees is dense. Yet the absence of implicatures in comparatives appears to hold regardless of whether the scale is discrete, as in the case of (24), or dense, as in the case of (25). Given this, Fox and Hackl propose that the level of representation at which implicatures are calculated (as well as focus etc.) is one where all scales are dense. This is their Universal Density of Measurement hypothesis.

The proposal we borrow from Fox and Hackl is that implicature calculation is in some sense blind to information provided by neighboring lexical material. That is, implicature calculation seems to proceed as if some abstract representations replaced the elements that make up the given sentence. By masking the properties of the elements they stand in for, e.g. the discreteness of the counting scale in (24), the abstraction renders implicature calculation insensitive to information that would otherwise change its outcome.

### 2.3.2. Magri (2009)

Another empirical argument in favor of the blindness view was presented in Magri (2009).<sup>9</sup> Magri claims that the notion of entailment relevant for implicature calculation is *logical*, rather than contextual. His argument is based on the oddness of sentences like (27):

(27) Some Italians come from a warm country.

The argument is this. (27) is odd because the use of **some** triggers a scalar implicature that the alternative with the universal quantifier, **all Italians come from a warm country**, is false.

<sup>8</sup>See Gajewski (2009) for a discussion of how this interacts with innocent excludability.

<sup>9</sup>See also Magri (2011); Schlenker (2012); and Magri (to appear) for discussion.

This leads to the strengthened proposition that *some but not all* Italians come from a warm country, which contradicts our knowledge that all Italians come from the same country. But as Magri points out, this explanation works only if we assume that this piece of world knowledge is unavailable to implicature calculation. While the alternative **all Italians come from a warm country** is logically stronger than (27), the two sentences are *contextually* equivalent; knowing that all Italians come from the same country, if some Italians come from a warm country, then it must be the case that all of them do (and vice versa). If this information is factored into the implicature-calculating mechanism, the **all**-alternative would not be negated, because it is equivalent to (27), and the oddness would no longer be predicted. If, on the other hand, the mechanism was blind to world-knowledge, and was sensitive only to logical information, then exhaustification would apply, and produce the detected oddness of (27).<sup>10</sup>

In what follows, we will attempt to exhaustify our  $\exists > \text{few}$  structure again, but with the blindness hypothesis and Innocent Excludability in mind. We will show that if the distributivity of the given predicate is hidden from the exhaustification mechanism—in parallel to how scale discreteness is hidden, in Fox and Hackl's proposal—we predict that the upper bound be placed correctly, thus overcoming the challenge of van Benthem's problem.

#### 2.4. Exhaustification revisited

Consider once again the  $\exists > \text{few}$  LF in (28),

(28)    **[[ $\exists$  fewer than 4 people] smiled]**

And consider the alternatives below:

- (29)    a.    {  $\exists$  fewer than 2 people smiled,  
                   $\exists$  fewer than 3 people smiled,  
          b.     $\exists$  fewer than 5 people smiled,  
                   $\exists$  fewer than 6 people smiled, ...  
          c.     $\exists$  2 people smiled,  
                   $\exists$  3 people smiled,  
          d.     $\exists$  4 people smiled,  
                   $\exists$  5 people smiled,  
                   $\exists$  6 people smiled, ... }

As we saw in Section 1.2, the distributivity of the verb **smiled** makes each of the alternatives in (29a–b) equivalent to (28), so negating any of them individually will contradict (28). This means that each alternative in (29a–b) makes its own *singleton* non-innocent set, since by definition, a set is non-innocent if its set-negation contradicts the utterance, and if it has no proper subset whose set-negation contradicts the utterance. The alternatives in (29a–b) are therefore not innocently excludable.

<sup>10</sup>As Magri himself notes, the success of his analysis requires that (27) be *obligatorily* exhaustified, since the oddness of the sentence would otherwise not be predicted. The reader is referred to the original paper for details.

What about the alternatives in (29c–d)? As we showed in Section 1.2, negating these together does not contradict the truth conditions of (28), so they are all predicted to be innocently excludable. It follows that exhaustifying (28) with respect to the alternatives in (29) will produce an excessively low upper bound:

$$(30) \quad \text{Exh}((29), (28)) = 1 \text{ iff } \exists x(\llbracket \text{people} \rrbracket(x) = 1 \ \& \ |x| < 4 \ \& \ \llbracket \text{smiled} \rrbracket(x) = 1) \ \& \\ \neg \exists x(\llbracket \text{people} \rrbracket(x) = 1 \ \& \ |x| \geq 2 \ \& \ \llbracket \text{smiled} \rrbracket(x) = 1) \ \& \\ \neg \exists x(\llbracket \text{people} \rrbracket(x) = 1 \ \& \ |x| \geq 3 \ \& \ \llbracket \text{smiled} \rrbracket(x) = 1) \ \& \dots$$

But recall also that the equivalence of (29a–b) and (28) does not hold when **smiled** is replaced with a collective predicate. In those cases, the alternatives with the lower numeral asymmetrically entail those with the higher numeral. If there exists a piano-lifting group of size less than four, then there exists a piano-lifting group of size less than five, namely the same one, but the reverse does not hold: if there is a lifting group of size less than five, it does not follow that there is one of size less than four.

Now suppose that, by blindness, the exhaustification mechanism were insensitive to the lexical properties of the verb. Then the grouping of alternatives into non-innocent sets will change, and consequently change the contents of the (innocently) excludable set. Let us repeat (29) and (30), but abstract away from the NP/VP:

$$(31) \quad \llbracket [\exists \text{ fewer than } 4 \text{ NP}] \text{ VP} \rrbracket$$

$$(32) \quad \begin{array}{ll} \text{a.} & \{ \exists \text{ fewer than } 2 \text{ NP VP}, \\ & \exists \text{ fewer than } 3 \text{ NP VP}, \\ \text{b.} & \exists \text{ fewer than } 5 \text{ NP VP}, \\ & \exists \text{ fewer than } 6 \text{ NP VP}, \dots \\ \text{c.} & \exists 2 \text{ NP VP}, \\ & \exists 3 \text{ NP VP}, \\ \text{d.} & \exists 4 \text{ NP VP}, \\ & \exists 5 \text{ NP VP}, \\ & \exists 6 \text{ NP VP}, \dots \} \end{array}$$

We can immediately see that the alternatives in (32b) are non-innocent, because each of them is individually weaker than (31), and therefore comprises a singleton non-innocent set of its own. The alternatives in (32a) are stronger than (31), but they are not innocently excludable because they form non-innocent sets with alternatives in (32c). As an example, take the first alternative in (32a) and the first alternative in (32c). Negating the former amounts to saying that there are no groups (of NPs that VP) of size less than 2, which means that the size of VPing NP groups is 2 or greater. This contradicts the negation of the first alternative in (32c), which says that there are no groups of VPing NPs of size 2 or more. Note that, by themselves, each of these alternatives can be negated consistently with (31), so on their own, they do not form non-innocent sets with respect to (31).

More generally, then, for any numeral (or degree)  $d$  lower than 4, there is a non-innocent set that contains the alternatives  $[\mathfrak{A} \text{ fewer than } d \text{ NP VP}]$  together with the alternative  $[\mathfrak{A} d \text{ NP VP}]$ . Any set containing just these two sentence is non-innocent, because its set negation is contradictory and therefore inconsistent with (31).

What about the alternatives in (32d)? It may appear that each of these can be paired with an alternative from (32b) into a non-innocent set. But in fact, these sets have non-innocent proper subsets: remember that each alternative in (32b) individually forms a singleton non-innocent set, so pairing it with an alternative from (32d) will not produce a non-innocent set.

It follows, then, that the excludable alternatives from (32) are the ones in (32d), and negating these produces the desired upper bound.

$$(33) \quad \text{Exh}((32), (31)) = 1 \text{ iff } \exists x(\llbracket \text{NP} \rrbracket(x) = 1 \ \& \ |x| < 4 \ \& \ \llbracket \text{VP} \rrbracket(x) = 1) \ \& \\
\neg \exists x(\llbracket \text{NP} \rrbracket(x) = 1 \ \& \ |x| \geq 4 \ \& \ \llbracket \text{VP} \rrbracket(x) = 1) \ \& \\
\neg \exists x(\llbracket \text{NP} \rrbracket(x) = 1 \ \& \ |x| \geq 5 \ \& \ \llbracket \text{VP} \rrbracket(x) = 1) \ \& \dots$$

### 3. Discussion and consequences

In a nutshell, our proposal derives the upper bound of  $\mathfrak{A} > \text{few}$  constructions not from their literal semantics, but from an exhaustification mechanism that negates whatever is excludable from the set of alternatives. In Section 2 we showed that, in order for the exhaustification mechanism to produce the correct upper bound, the entailment relations it 'sees' between the alternatives must be independent of whether the predicates in those alternatives are distributive or collective. We pointed to findings in the literature on implicatures, notably Fox and Hackl (2006) and Magri (2009), that suggest that exhaustification is blind to lexical/contextual information.

But the proposal brings many questions with it. First, it is known that implicatures are often cancellable, so if an implicature-generating mechanism is responsible for the upper bound in the sentences that concern us, why is it that the upper bound is intuitively obligatory?

Our answer to this is that, in the case of distributive predicates, lack of exhaustification produces underinformative truth conditions. We make this precise and borrow Buccola and Spector's Pragmatic Economy Constraint:

$$(34) \quad \textbf{Pragmatic economy constraint (Buccola and Spector, 2016):}$$

An LF  $\phi$  containing a numeral  $n$  is infelicitous if, for some  $m$  distinct from  $n$ ,  $\phi$  is truth-conditionally equivalent to  $\phi[n \rightarrow m]$  (the result of substituting  $m$  for  $n$  in  $\phi$ ).

We will look more closely at Buccola and Spector's proposal in the next section. At the moment we can simply point out that (34) is used by them to get around a similar problem to ours: why is exhaustification (or, on their account, maximality) obligatory? The effect of (34) is to require that numerals make a truth conditional difference. As we saw in Section 1.2, unexhaustified  $\mathfrak{A} > \text{few}$  constructions have the same truth conditions regardless of the numeral that appears in them, and because of this, they are ruled out by the economy constraint in (34). On the

other hand, exhaustifying  $\exists > \text{few}$  constructions (blindly) retrieves the semantic import of the numeral, and thus satisfies (34).

But now we face a second question. If exhaustification is made obligatory because of a filter against uninformative numerals, we predict that exhaustification be *optional* in *non-distributive*  $\exists > \text{few}$  sentences. The reason is simply that, as we saw in Section 1.2, changing the numeral in non-distributive  $\exists > \text{few}$  constructions *does* change the truth conditions, so there is no reason yet to favor either of the exhaustified or unexhaustified parses of (35):

(35) Fewer than 4 people lifted the piano (together).

Interestingly, sentences like (35) do not intuitively place an upper bound in the same way as distributive  $\exists > \text{few}$  examples. As Buccola and Spector point out, (35) requires only that *some* group of lifters reach a size below four; the sentence is still true if the piano was lifted by some other group of size five, six, etc. This reported judgment fits the prediction of the current proposal, which permits unexhaustified parses of (35) given that the numeral in it is non-trivial. But importantly, the proposal as it stands also allows exhaustified parses of non-distributive  $\exists > \text{few}$  structures. So we currently predict (35) to also have upper-bounded readings. We leave this issue to future work.

Another important problem that we have set aside so far is the existence prediction of EC. The predicted truth conditions of  $\exists > \text{few}$  constructions, whether exhaustified or not, require that some *existing* plurality verify the predicates appearing in the sentence. We do not have a solution to this problem yet, but we will say more about it after we discuss Buccola and Spector's account, to which we now turn.

#### 4. Maximality: Buccola and Spector (2016)

We must make it clear that our review of Buccola and Spector (B&S) is by no means representative of the many ideas they discuss. Our attention will be restricted to their syntactic maximality account (SMax) of modified numerals. Once we go over the basics of the account, we offer a brief comparison between it and our own proposal. As announced in the introduction, the comparison will be inconclusive, but it will highlight an advantage of B&S that has to do with the existence inference discussed earlier.

##### 4.1. Syntactic Maximality (SMax)

The ingredients of B&S's SMax account are the following. First, expressions like **fewer than 4** denote generalized quantifiers (GQs) over degrees (type  $\langle dt, t \rangle$ ) rather than predicates of individuals. Second, nodes that denote degrees (type  $d$ ) can undergo two type-shifting operations, which we represent syntactically. One, ISCARD, takes a degree  $d$  and returns a predicate of (plural) individuals. The predicate holds of individuals whose size equals  $d$ . The other, ISMAX, takes a degree  $d$  and returns a GQ over degrees. The GQ holds of a set of degrees provided that its maximal element is  $d$ . The definitions are shown below:

- (36) a.  $\llbracket \text{fewer than 4} \rrbracket = [\lambda D_{\langle d,t \rangle} . \exists d(d < 4 \ \& \ D(d) = 1)]$   
 b.  $\llbracket \text{ISCARD} \rrbracket(d) = [\lambda x_e . |x| = d]$   
 c.  $\llbracket \text{ISMAX} \rrbracket(d) = [\lambda D_{\langle d,t \rangle} . \max(D) = d]$

On B&S's account, a sentence like (37) can have two possible LFs. In one LF, the phrase **fewer than 4** undergoes QR and binds a trace of type  $d$  in its base position. The trace is shifted by ISCARD into a predicate of individuals, and the result is composed with other predicates ultimately closed by an EC operation.

- (37) **Fewer than 4 people smiled**

- (38)  $\llbracket \text{fewer than 4} \rrbracket [\lambda d [\llbracket \exists [\text{ISCARD}(d) \text{ people}] \text{ smiled} \rrbracket]]$

With the dislocated modified numeral scoping above EC, the resulting truth conditions require that some degree  $d$  below 4 exist, and that some smiling plurality be of size  $d$ . These are the same (uninformative) truth conditions as those predicted on our account (without exhaustification):

- (39)  $\llbracket (38) \rrbracket = 1$  iff  $\exists d(d < 4 \ \& \ \exists x(|x| = d \ \& \ \llbracket \text{people} \rrbracket(x) = 1 \ \& \ \llbracket \text{smiled} \rrbracket(x) = 1))$   
 $= 1$  iff  $\exists x(|x| < 4 \ \& \ \llbracket \text{people} \rrbracket(x) = 1 \ \& \ \llbracket \text{smiled} \rrbracket(x) = 1)$

In another LF of (37) the phrase **fewer than 4** is moved further, and binds a trace that undergoes shifting by ISMAX.

- (40)  $\llbracket \text{fewer than 4} \rrbracket [\lambda d' [\llbracket \text{ISMAX}(d') \rrbracket] \lambda d [\llbracket \exists [\text{ISCARD}(d) \text{ people}] \text{ smiled} \rrbracket]]$

The truth conditions of this LF require that, for some degree  $d$  below 4, the maximal size of existing smiling groups equal  $d$ . This is the same as saying that the maximal size of existing smiling groups fall below 4, which matches the intuited upper-bounded reading of the sentence.

- (41)  $\llbracket (40) \rrbracket = 1$  iff  $\exists d(d < 4 \ \& \ \max\{d' : \exists x(|x| = d' \ \& \ \llbracket \text{ppl} \rrbracket(x) = 1 \ \& \ \llbracket \text{smiled} \rrbracket(x) = 1)\} = d)$   
 $= 1$  iff  $\max\{d : \exists x(|x| = d \ \& \ \llbracket \text{ppl} \rrbracket(x) = 1 \ \& \ \llbracket \text{smiled} \rrbracket(x) = 1)\} < 4$

The choice between LFs (38) and (40), for sentence (37), is based on the Pragmatic Economy Constraint (PEC) that we cited earlier. Recall that the constraint blocks LFs that contain uninformative numerals. In (38), the numeral is uninformative because of the distributivity of **smiled** (see discussion in Section 1.2), but in (40), changing the numeral clearly changes the truth conditions. By the PEC, then, only the latter LF can be associated with (37), which means that upper-bounded readings are obligatory when distributive predicates are used. In the case of non-distributive predicates, however, 'non-maximal' LFs incur no violation of the PEC, because their truth conditions depend crucially on the numeral. It follows that sentences like (42) can be interpreted without an upper bound—LF (43)—or with an upper bound—LF (45).

- (42) **Fewer than 4 people lifted the piano (together)**

(43) **[fewer than 4]**  $\lambda d$   $[[\exists [\text{ISCARD}(d) \text{ people}]] \text{ lifted the piano}]]$

(44)  $[[ (43) ]] = 1$  iff  $\exists d(d < 4 \ \& \ \exists x(|x| = d \ \& \ [\text{people}](x) = 1 \ \& \ [\text{smiled}](x) = 1))$   
 $= 1$  iff  $\exists x(|x| < 4 \ \& \ [\text{people}](x) = 1 \ \& \ [\text{lifted...}](x) = 1)$

(45) **[fewer than 4]**  $\lambda d'$   $[\text{ISMAX}(d')] \lambda d$   $[[\exists [\text{ISCARD}(d) \text{ people}]] \text{ lifted...}]]$

(46)  $[[ (45) ]] = 1$  iff  $\exists d(d < 4 \ \& \ \max\{d' : \exists x(|x| = d' \ \& \ [\text{ppl}](x) = 1 \ \& \ [\text{lifted...}](x) = 1)\} = d)$   
 $= 1$  iff  $\max\{d : \exists x(|x| = d \ \& \ [\text{ppl}](x) = 1 \ \& \ [\text{lifted...}](x) = 1)\} < 4$

#### 4.2. A comparison: Exhaustification or maximality?

As we said earlier, we cannot comprehensively compare our proposal to that of B&S. Nevertheless, we can take note of some features that the two accounts have in common, and other features that distinguish them. We leave a more detailed assessment to future investigation.

One common ingredient to B&S and the current proposal is the reliance on the PEC, and the resulting prediction that, with non-distributive predicates, upper-bounded readings are *permitted but not obligatory*. In our account, this is because unexhaustified parses are not blocked by the PEC in non-distributive  $\exists > \text{few}$  LFs; in B&S, it is because the PEC permits both maximal as well as non-maximal LFs. Whether or not this prediction fits the facts remains to be seen, but it appears that in this respect the two accounts are similar.<sup>11</sup> The proposals are also alike in deriving the upper bound from sources that are external to the modified numeral itself. In our account, the source of the upper bound is the (blind) exhaustification operator, while in B&S it is the ISMAX shift operation.

But there are differences. Consider first the existence inference mentioned in Section 3. On our proposal the inference results from existentially closing the predicate **fewer than 4**, but importantly, the inference remains even when the LF is (blindly) exhaustified. We therefore predict that upper-bounded readings still require existence, and that sentences like (37) be *false* in situations where no one smiled. We see this as a disadvantage of our account, and an advantage of B&S's, where applying ISMAX above ISCARD effectively removes the requirement of existence.<sup>12</sup>

There is, however, a possible amendment to exhaustification that deserves further research, which involves adding null individuals to the domain of entities. At the moment we cannot present a concrete version of this idea, and leave it to future development (see Landman 2004, and also B&S's maximal-informativity proposals in their Section 8). If such an analysis can be formulated, it may come with different predictions from B&S's SMax proposal, which es-

<sup>11</sup>B&S discuss cases where collective predicates take upper-bounded readings, citing personal communication with Philippe Schlenker. See their Section 7.

<sup>12</sup>It must be noted that removing the existence inference in B&S depends on defining max so that it returns the degree 0 when its input is the empty set. In situations where no one smiled, there are no degrees in the set  $\{d : \exists x(|x| = d \ \& \ [\text{ppl}](x) = 1 \ \& \ [\text{smiled}](x) = 1)\}$ , and hence no maximal degree that can inform the semantics of ISMAX. To get around this, it must be explicitly stated that  $\max\{\} = 0$ .

sententially correlates non-existence with upper-boundedness, since the two come together from applying ISMAX.

## 5. Conclusions

We discussed a problem that arises with the interpretation of expressions **few** and **fewer than 3** in certain environments. The problem can be described as follows. When combined with distributive predicates, those expressions intuitively impose an upper bound. However, assuming the adjectival semantics for **few** and deriving its quantificational meaning through EC, sentences with **few** are predicted to have uninformative truth conditions. We showed also that the needed upper bound cannot result from standard pragmatic strengthening mechanisms.

We proposed a modified strengthening mechanism that can derive the correct upper bound. The key properties of the proposed mechanism are (i) its insensitivity to information about distributivity, and (ii) innocent exclusion (Fox, 2007a). Our proposal was compared to Buccola and Spector's maximality-based account. As we pointed out, the comparison is incomplete and requires further investigation.

<sup>2</sup>In addition to these, there are headline, futurate, and performative uses of the present. These all violate Stativity, while the first two also violate Utterance Indexicality. We return to this issue in the conclusion.

We propose a unified semantics for the present tense in English that accounts for the properties of these two uses and the canonical present. There have been some previous attempts to derive one or the other of the noncanonical uses with customized solutions (Smith 1997: 185; Schlenker 2004; Eckardt 2015). We aim for a general theory that takes advantage of two pieces of off-the-shelf technology: i) a bicontextual semantics for tense (Sharvit, 2004, 2008), and ii) a version of Kamp and Reyle's (1993) semantics for the past perfect.

Our invocation of the past perfect comes from an apparently hitherto unnoticed contrast between the play-by-play and historical uses. The play-by-play present cannot “anchor” the past perfect—that is, it cannot describe an event which the past perfect locates another event anterior to, as shown in (4a). But the historical present can, as shown in (5a).

- (4) *Play-by-play present*  
 Commentator: Federer serves. It's long. He looks at the line. He yells in protest.  
 a. # The judge **had called** a fault.  
 b. The judge **has called** a fault.  
 c. The judge **called** a fault.
- (5) *Historical present*  
 Rumors of Berlusconi's crimes swirl. His advisors confront him. He scoffs.  
 a. He **had paid** off the prostitute for her silence already.  
 b. He **has paid** off the prostitute for her silence already.  
 c. He **paid** off the prostitute for her silence already.

In either of these uses, the present tense can, by contrast, be used to anchor the present perfect (4b, 5b) or simple past (4c, 5c).

Specifically, we propose that the present tense is indexical to the time of a *context of assessment* (Sharvit, 2004, 2008), which can be pragmatically distinct from the speech time, a coordinate of the *context of utterance* (cf. Schlenker 2004). When the present tense is unmoored from the speech time, Utterance Indexicality and Stativity are simultaneously lifted. In turn, we argue that the contrast in (4) and (5) reflects an additional restriction of the past perfect, namely that it is indexical to both the context of assessment and the context of utterance, cf. Kamp and Reyle (1993: 598). Together, these two ingredients correctly predict that, under the pragmatic norms governing the play-by-play present, the past perfect is inadmissible.

## 1. The canonical present

Both properties of the canonical present follow from standard treatments, where the present tense is sensitive to the time of the utterance context (*u*). A familiar encoding of this is given in (6) within a referential theory of tense.

- (6) *A standard treatment of the present tense*  
 $\llbracket \text{PRES}_i \rrbracket^{u,g}$  is defined iff  $g(i) \subseteq \text{TIME}(u)$ . When defined,  $\llbracket \text{PRES}_i \rrbracket^{u,g} = g(i)$

Utterance Indexicality follows straightforwardly. Stativity also follows with three assumptions:

- The utterance time,  $\text{TIME}(u)$ , contains the reference time,  $g(i)$ , as opposed to being contained in it (Kratzer, 1998: 101) or simply overlapping it (von Stechow, 1995: 365).
- Without progressive morphology, the present tense in English conveys perfective aspect (the eventuality is contained in the reference time) (Smith 1997: 110, Giorgi and Piansi 1997: 163).
- Utterances are conceived of as instantaneous (Kamp and Reyle 1993: 536–537, Giorgi and Piansi 1997: 160, Smith 1997: 110–112, 2003: 103–104, a.o.), a constraint we formulate concretely as follows:

- (7) *Utterance Time Width (UTW)*  
 $|\text{TIME}(u)| < \epsilon$ , where  $\epsilon$  is the minimum size for an event

With Utterance Time Width,  $\text{TIME}(u)$  — and hence  $g(i)$  contained inside it — is too narrow to contain the event described by an activity or accomplishment. Only statives, which have the subinterval property (Dowty, 1979), describe an eventuality that is small enough. There is always some subpart of a state, satisfying the eventuality description, which can fit inside  $\text{TIME}(u)$ .

Even achievements and semelfactives are incompatible with the canonical present, unless they have an habitual interpretation.

- (9)
- |    |  |                     |
|----|--|---------------------|
| a. | # Bill <b>wins</b> the race.                   |                     |
|    | Intended: 'Bill is winning/wins the race now.' | <i>achievement</i>  |
| b. | # Sue <b>coughs</b> .                          |                     |
|    | Intended: 'Sue is coughing/coughs (once) now.' | <i>semelfactive</i> |
- (Smith, 1997: 111)

We take this to mean that the utterance time must, in fact, be so narrow that punctual events cannot be contained within it.

### 1.1. Extension to the play-by-play use

The play-by-play present, by our definition, is used in the direct reporting of circumstances as they unfold. It can be found in sportscasting (10a) and in demonstrations (10b) (Palmer 1965: 58, Leech 1971: 2–3).

- (10) a. (USA vs. New Zealand, 2015 Women's Soccer Friendlies)  
 Commentator: Wambach **leads** it back and now Krieger **has** it. Tobin Heath **goes** far. (<https://www.youtube.com/watch?v=Kqe9n7zvnnw>, 1:40:55)
- b. Demonstrator: Look, I **take** this card from the pack and **place** it under the handkerchief so. (Leech, 1971: 2)

Such play-by-play discourses do not require the perfective (a.k.a. simple present). There is a choice of aspect, depending on the nature of the events being described (Ferguson, 1983: 164). The perfective is used to describe a sequence of rapid, completed actions, as in a soccer game (10a), while the progressive is used to report longer, more continuous events, like those in a boat race (11).

- (11) (Men's 8 Rowing Final, 2008 Olympics)  
 Commentator: Now the job for the Canadian crew is to hang on to the lead they had at the halfway mark. They **are breathing** hard. They really **are gulping** in the air there. But they know that they've got a good lead there. They know they can finish, but Great Britain **are moving** very well[...]  
 (<http://www.youtube.com/watch?v=KkP3P5ucR4U>, 5:37)

The play-by-play present always describes events that occur roughly at the time of utterance, so it exhibits Utterance Indexicality. Smith (1997: 111) offers one intuitive solution for why play-by-play sentences do not exhibit Stativity: they “telescope time. We understand them punctually, suspending our knowledge of their normal duration.” In other words, durative predicates are coerced into describing an event small enough to fit inside the utterance time. Presumably, since the play-by-play present describes a completed interpretation in the perfective, this would include at least its end point.

There are several arguments that coercion cannot be what allows the play-by-play use to avoid Stativity. First, even punctual events are too large to be contained within the utterance time, as shown in (9) above, since achievements and semelfactives do not have a nonhabitual interpretation in the canonical present. The coercion operation that Smith implicates in the play-by-play present might, in principle, output an event small enough to fit within the utterance time. But this runs counter to conventional wisdom, which takes coercion to operate within a certain fixed inventory of eventuality predicates (Moens and Steedman, 1988; de Swart, 1998).

Second, if the play-by-play present involved coercion, then accomplishments should not exhibit the same ambiguity with *almost* that they do elsewhere (Dowty, 1979: 58).

- (13) John almost painted a picture.  
 ‘John didn’t start painting a picture.’  
 ‘John started to paint a picture, but did not finish it.’ (Dowty, 1979: 58)

But in fact, accomplishment predicates do exhibit this ambiguity in the play-by-play present.

- (14) Commentator: Federer almost crosses the entire court.  
 ‘Federer doesn’t start to cross the court.’  
 ‘Federer starts to cross the court, but does not get to finish.’

Finally, coercion cannot offer an explanation for why a play-by-play sentence cannot anchor the past perfect. In (4a) above, by the time the past perfect sentence describing the calling event is uttered, the yelling event is already in the past and should be able to anchor it.

That is, to account for the play-by-play use, it is not enough simply to manipulate the event structure of the predicate. Something must be said about how the eventuality described relates to other times in the context.

## 1.2. Extension to the historical use

What we call the historical present is used to describe situations that have already taken place or are simply imagined. It makes them more “dramatic” as if “someone actually witness[es] the events as they are described” (Palmer 1965: 39, Leech 1971: 6–7, Close 1981: 106). This historical use is frequently found in ordinary narratives (16a) and stage directions (16b).

- (16) a. I couldn’t believe it! Just as we arrived, up **comes** Ben and **slaps** me on the back as if we’re life-long friends. “Come on, old pal,” he **says**, “Let me buy you a drink!” I’m telling you, I nearly fainted on the spot.  
 (Quirk et al., 1985: 181)
- b. From the right, Willy Loman, the Salesman, **enters**, carrying two large sample cases. The flute **plays on**. He **hears**, but is not aware of it. He is past sixty years of age, dressed quietly. Even as he **crosses** the stage to the doorway of the house, his exhaustion is apparent. He **unlocks** the door, **comes** into the kitchen, and thankfully **lets** his burden down...  
 (Miller, *Death of a Salesman*)

Assuming a typical utterance context, it is clear that a standard treatment of the present tense is incompatible with the historical use, since it does not exhibit Utterance Indexicality. However, the historical present could arise when the utterance context is *improper*, when one or more coordinates (e.g., speaker and addressee) does not coincide with the time coordinate (Predelli, 2005). For instance, in an answering machine message — *I am not here now, so please leave a message* — the time coordinate of the context might pick out the time of listening (decoding), even though the speaker does not utter (encode) the message at that time.

Eckardt (2015: 221–223) proposes that the historical present makes use of an improper context

(see also Bary 2016). At the risk of oversimplifying, we might represent this as an operator that shifts just the time coordinate of the context.

$$(17) \quad \llbracket \text{HP}(\phi) \rrbracket^{\langle \text{TIME}(u), \text{SPEAKER}(u), \dots \rangle, g} = \llbracket \phi \rrbracket^{\langle t_i, \text{SPEAKER}(u), \dots \rangle, g}$$

In these discourses, then, the time coordinate of the context identifies a past time  $t_i$ . A standard semantics for present tense will consequently locate the reference time at this time, rather than the actual time of utterance. This correctly predicts that the speaker coordinate can pick out an individual who does not even exist at the shifted time, as in (18).

- (18) Fifty eight years ago to this day, on January 22, 1944, just as the Americans **are** about to invade Europe, the Germans **attack** Vercors. **My grandfather** tries to escape. . .  
(Schlenker, 2004: 298)

Under this account, however, it is mysterious why the historical present *can* anchor the past perfect, as in (5a) above. The past perfect describes a paying-off event that precedes the time of the scoffing event. With a standard semantics for the past perfect (e.g., Reichenbach 1947), this time must itself be located anterior to the time of the context. But the time of the context still *overlaps* the time of the scoffing event when the past perfect sentence is uttered.

It is not enough simply to shift the time of the context to account for the historical present. Other tense-aspect categories, like the past perfect, are also sensitive to it.

### 1.3. The historical present in free indirect discourse

Before moving on, we should address a potential worry. One might think that the historical present is simply an instance of *free indirect discourse*, a literary style used to directly represent the perspective of a character (Banfield 1982; Doron 1991; a.o.). Indeed, many cases of the historical use feel as if they are filtered through the lens of a protagonist.

- (20) a. **Creeping Christ? he thinks. What does he mean? His head turns sideways, his hair rests in his own vomit, the dog barks, Walter roars, and bells peal out across the water. He feels a sensation of movement, as if the filthy ground has become the Thames. It gives and sways beneath him; he lets out his breath, one great final gasp. You've done it this time, a voice tells Walter. But he closes his ears, or God closes them for him. He is pulled downstream, on a deep black tide.** (Mantel, *Wolf Hall*)
- b. She rejected one brush; she chose another. **When would those children come? When would they all be off?** she fidgeted. **That man**, she thought, her anger rising in her, **never gave; that man took. She, on the other hand, would be forced to give.** (Woolf, *To the Lighthouse*)

It is not possible to reduce the historical present to free indirect discourse. The latter *necessarily* reports the perspective of a character (Banfield, 1982; Doron, 1991).

- (21) Context: Figaro sees Coutess Almaviva, who is wearing his wife's clothes.  
 Figaro froze in place. He couldn't believe his eyes. **His wife** had swooned into the  
 Count's arms and was now kissing him passionately. (Doron, 1991: 54)

By contrast, there are uses of the historical present that do not force reporting of a character's perspective (i.e., definite descriptions that are not valid with respect to the protagonist).

- (22) Oedipus is very happy. He is going to see **his mother** again tomorrow.

While the historical present can occur in free indirect discourse, they cannot simply be equated. As it will turn out, we will adopt the semantics for the present tense that Sharvit (2004, 2008) proposes to account for free indirect discourse, and so we return briefly to this interaction later.

## 2. A proposal

We take natural language expressions to be interpreted relative to two contexts: a *context of utterance* ( $u$ ) and a *context of assessment* ( $a$ ). Such bicontextualism has been deployed in several empirical domains, including for free indirect discourse (Doron, 1991; Schlenker, 2004; Sharvit, 2004, 2008; Eckardt, 2015) and future tense (MacFarlane, 2003), as well as predicates of personal taste and epistemic modals (MacFarlane, 2014).

Individual expression can be sensitive to one, the other, or both of these contexts. Adopting the division that Sharvit (2004, 2008) proposes, local pronouns are sensitive to the utterance context, while tense is sensitive to the assessment context.

- (23) a.  $\llbracket I \rrbracket^{u,a,g} = \text{SPEAKER}(u)$   
 b.  $\llbracket \text{you} \rrbracket^{u,a,g} = \text{ADDRESSEE}(u)$   
 (24) a.  $\llbracket \text{PRES}_i \rrbracket^{u,a,g}$  is defined iff  $g(i) \subseteq \text{TIME}(a)$ . When defined,  $\llbracket \text{PRES}_i \rrbracket^{u,a,g} = g(i)$   
 b.  $\llbracket \text{PAST}_i \rrbracket^{u,a,g}$  is defined iff  $g(i) < \text{TIME}(a)$ . When defined,  $\llbracket \text{PAST}_i \rrbracket^{u,a,g} = g(i)$

Sharvit takes temporal and locative adverbials, such as *tonight* (25a) and *here* (25b), to be sensitive to the context of assessment.

- (25) a.  $\llbracket \text{tonight} \rrbracket^{u,a,g} = \text{the night of the day surrounding } \text{TIME}(a)$   
 b.  $\llbracket \text{here} \rrbracket^{u,a,g} = \text{LOCATION}(a)$

But we do not think that this is true of all temporal adverbials. In particular, those with *ago* seem sensitive to the context of utterance. The discourse below describes a series of past events. The continuation in (26a) is infelicitous because *two years ago* cannot receive a back-shifted interpretation: it picks out a time interval two years before the actual time of utterance.

- (26) I couldn't believe it! Just as we arrived, up comes Ben and slaps me on the back as if we're life-long friends.
- a. # **Two years ago** he stole twenty dollars from me. . .
  - b. **Two years before** he stole twenty dollars from me. . .

While Sharvit assumes that the two contexts are always identical in root contexts, we propose that the assessment context can be *freely chosen*, subject to pragmatic considerations. In this, we are adapting an idea of Schlenker (2004), who also makes use of two contexts in his account of the historical present. For him, there is a context of thought, where “a thought originates,” and a context of utterance, where “a thought is expressed.” In spite of a superficial similarity, these do not line up with the two contexts we appeal to, as Schlenker divides up context-sensitive expressions differently. Simplifying somewhat, local pronouns and tenses are sensitive to the context of utterance, while temporal and locative adverbials are sensitive to the context of thought.

In the historical present, Schlenker proposes that the context of thought is set to the actual context, while the context of utterance is located elsewhere (in the past, in the thinker's imagination, etc.) This leads to several complications. First, temporal adverbials — such as, *tonight* in (27) — can shift in historical present discourses, and hence must be fixed by his context of utterance.

- (27) Forty years ago today John Lennon is about to take to the stage at the Cavern.  
**Tonight** his life will change forever. (Schlenker, 2004: 296)

Second, the context of utterance must be improper, since the speaker need not exist at the time of the events described in the historical present, as shown in (18) above. Consequently, Schlenker's account cannot explain its ability to anchor the past perfect (§1.2).

Most importantly, Schlenker does not offer a unified account of canonical and noncanonical uses of the present, which is our goal. While we adopt a different version of bicontextualism — in particular, a different division of context-sensitive expressions — we will crucially allow the context of assessment to diverge pragmatically from the context of utterance.

### 3. Deriving the noncanonical uses

In the canonical present, the assessment time does not diverge from the utterance time. Stativity and Utterance Indexicality thus arise for the same reasons that we described earlier.

- (28) *Canonical present*  
 $\text{TIME}(a) = \text{TIME}(u)$

The noncanonical uses of the present tense arise when the assessment context stands in a different relation to the utterance context.

### 3.1. The historical present

Intuitively, the historical present can make something in the past “the present.” For us, this involves pragmatically setting the time of assessment to some time before the utterance time. (For imagined events, the assessment time may not precede the utterance time, but it is similarly unmoored.)

- (29) *Historical present*  
 $\text{TIME}(a) < \text{TIME}(u)$

Stativity for the canonical use arises from linking the assessment time to the utterance time, which must be very small. But if the assessment time is anterior, it can be wide enough for the reference time to contain a non-state.

The historical present thus does not exhibit Stativity.<sup>3</sup>

<sup>3</sup> Free indirect discourse can occur quite freely inside a narrative in the historical present.

- (i) Louise places the parcel on the kitchen table. She can't wait to open it. **Who could have sent it? What does it contain? How shiny the wrapping paper is! The sender certainly must be rich. Today seems to be her lucky day.** (Eckardt, 2015: 221)

This is easy to derive under Sharvit's (2004, 2008) account of free indirect discourse (*pace* Eckardt 2015: 221–224 and Bary 2016). For the simplified version of this discourse in (ii), a FID operator in the present tense quantifies over contexts that are compatible with what Louise believes at the time of the *assessment* context, yielding the truth conditions in (iii).

- (ii) Louise places the parcel on the kitchen table. **Today is her lucky day.**  
 (iii) When defined,  $\llbracket \text{FID-Louise-PRES}_2\text{-}w_0 \text{ Today PRES}_3 \text{ be her lucky day} \rrbracket^{u,a,g} = 1$  iff for every context-assignment pair  $\langle a', g' \rangle$  such that  $a'$  is compatible with what Louise believes at  $g(2)$  (where  $g(2) \subseteq \text{TIME}(a)$ ) in  $\text{WORLD}(a)$ , the day surrounding  $\text{TIME}(a')$  is her lucky day at  $g'(3)$  (where  $g'(3) \subseteq \text{TIME}(a')$ ) in  $\text{WORLD}(a')$

Is it possible to shift into the historical present inside an FID context? This is not easy to show, but perhaps not.

- (iv) Mary ran, stumbling, down the steps of the station. She was going to miss her train, she thought. How had she gotten here? She had been responsible and thought of everything.  
 a. # That morning, she **wakes** up bright and early, heading straight out the door. She **rushes** to the DMV and **gets** in line right when they open.  
 b. That morning, she **woke** up bright and early, heading straight out the door. She **rushed** to the DMV and **got** in line right when they opened.

Under Sharvit's account, a (non-double-access) present tense should *in principle* be possible when the FID operator is past, yielding a simultaneous reading like that available for a bound past tense. She argues that in such cases a preference for the bound past (based on a preference for *de se* pronouns) trumps the present tense (Sharvit, 2008: 388). The same should apply to the historical present as well.

It remains an open question how the assessment time is chosen in the historical present, if  $\text{TIME}(a)$  must simply precede  $\text{TIME}(u)$ . We do not yet completely understand when or how this happens. On the one hand, speakers seem able to move the context of assessment at will, as shown by their ability to alternate freely between the past and the historical use of the present.

- (31) Then all of a sudden everybody **gets** involved and they **made** a mess. So uh... this lady **says**... uh this uh Bert, “Oh, my son’ll make them. He’s an electrician.” So he **makes** them, and he **charges** all the neighbors twenty dollars a set, and there I **paid** three dollars. So I **called** her a crook. And I **called** her son a crook. So, they **were** really mad at me. (Schiffrin, 1981: 46)

But on the other hand, there do seem to be constraints on what the context of assessment can be: it is hard to push it backwards.

- (32) He looks at the ceiling.  
 a. # Yesterday, a spider **is** climbing there.  
 b. Yesterday, a spider **was** climbing there.

Perhaps, these two cases might be unified by a principle that only allows the assessment context to move forward in time. We leave this issue for the future.

### 3.2. The play-by-play present

Intuitively, the play-by-play use describes an event that ends “at” the utterance time. There is some evidence that speakers wait until an event has terminated to report it (Mathon and Boulaki, 2011). This can arise if the assessment time is pragmatically set so that it properly contains the utterance time.

- (33) *Play-by-play present*  
 $\text{TIME}(a) \supsetneq \text{TIME}(u)$

The play-by-play use does not exhibit Stativity, then, because  $\text{TIME}(a)$  can again be wide enough for the reference time to contain a non-state.

A caveat: The relation in (33) allows, in principle, for the assessment time to continue after the utterance time. This would permit an event to be *ongoing* during the utterance time. But this is not how people use the play-by-play present. As we showed in (10–11) above, there is a contrast between the simple present (for culminated events) and the present progressive (for ongoing ones). This suggests that there is an additional constraint at work: the Upper Limit Constraint (Abusch, 1997), which bans reference to times after the local “now.” In our formulation, this amounts to a condition on the times of the two contexts:

- (35) *Bicontextual Upper Limit Constraint (ULC)*  
 $\max(\{t : t \in \text{TIME}(a)\}) = \max(\{t : t \in \text{TIME}(u)\})$

If no part of the assessment time can follow the utterance time, then events will always have terminated by the utterance time in the play-by-play use of the present.

### 3.3. What other relations are possible?

One salient question is what other temporal relations between the utterance and assessment contexts are possible. There are eight relations one might imagine:  $<$ ,  $>$ ,  $=$ ,  $\subseteq$ ,  $\subsetneq$ ,  $\supseteq$ ,  $\supsetneq$ ,  $\circ$ . However, as the following shows, our constraints on the width of the utterance interval and upper limits on  $\text{TIME}(a)$  collapse several of these together.

- (36) a.  $\text{TIME}(a) < \text{TIME}(u)$ : *historical present*  
 b.  $\text{TIME}(a) > \text{TIME}(u)$ : forbidden by the Bicontextual ULC (35)  
 c.  $\text{TIME}(a) = \text{TIME}(u)$ : *canonical present*  
 $\text{TIME}(a) \subsetneq \text{TIME}(u)$ : difficult to distinguish from  $\text{TIME}(a) = \text{TIME}(u)$ , given UTW (7)  
 $\text{TIME}(a) \subseteq \text{TIME}(u)$ : difficult to distinguish from  $\text{TIME}(a) = \text{TIME}(u)$ , given UTW (7)  
 d.  $\text{TIME}(a) \supsetneq \text{TIME}(u)$ : *play-by-play*  
 $\text{TIME}(a) \supseteq \text{TIME}(u)$ : difficult to distinguish from  $\text{TIME}(a) \supsetneq \text{TIME}(u)$   
 $\text{TIME}(a) \circ \text{TIME}(u)$ : identical to  $\text{TIME}(a) \supsetneq \text{TIME}(u)$ , given the bicontextual ULC (35)

In the end, all possible relations between the utterance and assessment times reduce to just the three that are attested.

## 4. Accounting for the past perfect contrast

The ingredients are now in place to return to our initial empirical question: Why is the past perfect fine with the historical present, but not the play-by-play present?

- (37) *Historical present*  
 Rumors of Berlusconi's crimes swirl. His advisors confront him. He scoffs.  
 a. He **had paid** off the prostitute for her silence already.  
 b. He **has paid** off the prostitute for her silence already.  
 c. He **paid** off the prostitute for her silence already.
- (38) *Play-by-play present*  
 Commentator: Federer serves. It's long. He looks at the line. He yells in protest.  
 a. # The judge **had called** a fault.  
 b. The judge **has called** a fault.  
 c. The judge **called** a fault.

It should be noted that the play-by-play use is not alone. The past perfect is also incompatible with the canonical use of the present.

- (39) *Canonical present*  
 Trump isn't listening to his new campaign manager.  
 a. # She **had let** him down.  
 b. She **has let** him down.  
 c. She **let** him down.

We suggest that this commonality is not accidental: both the canonical and play-by-play uses involve an assessment time that overlaps the utterance time. In the following we exploit this. We show how a perspectival treatment of the past perfect, like that of Kamp and Reyle (1993), can lead to temporal inconsistencies in these uses, though not in the historical present, where the assessment time is unmoored from the utterance time.

#### 4.1. Perspective in the past perfect

Kamp and Reyle (1993) propose that the past perfect can encode a Reichenbachian pluperfect, locating the reference time anterior to a salient past “perspective point.”<sup>4</sup>

- (40) Fred arrived at 10. He **had got up** at 5; he **had taken** a long shower, **had got** dressed and **had eaten** a leisurely breakfast. He **had left** the house at 6:30.  
 (Kamp and Reyle, 1993: 594)

In narrative flashbacks, a sequence of past perfect sentences is interpreted as forward moving. Each sentence's reference time advances, though they are all anterior to the same perspective point.

For Kamp and Reyle, past perfect morphology is compatible with a combination of two semantic features, which require the reference time to precede a perspective point that precedes the utterance time.

- (42) a. +PAST:  $p < \text{TIME}(u)$   
 b. *past*:  $g(i) < p$   
 (Kamp and Reyle, 1993: 601)

#### 4.2. Incorporating the perspective point

We translate Kamp and Reyle's framework into our own by equating  $p$  and  $\text{TIME}(a)$ :

<sup>4</sup>For Reichenbach (1947), the perspective point is the *reference time*. He does not aim to account for narrative flashbacks.

(43) *Past perfect in a bicontextual framework*

- a.  $\text{TIME}(a) < \text{TIME}(u)$
- b.  $g(i) < \text{TIME}(a)$

It is clear, then, why the past perfect is not compatible with the canonical and play-by-play presents. Its requirement that the assessment time precede the utterance time contradicts their pragmatic setting of the assessment time to (at least) contain the utterance time.

(44) *Canonical present*

$$\text{TIME}(a) = \text{TIME}(u)$$

(45) *Play-by-play present*

$$\text{TIME}(a) \supsetneq \text{TIME}(u)$$

Thus, only the historical present, which locates  $\text{TIME}(a)$  before  $\text{TIME}(u)$ , allows the past perfect.

## 4.3. Equivalence with the simple past and present perfect

After a sentence in the historical present, the simple past and present perfect are able, intuitively, to describe the same event as the past perfect, as in (46), repeated from above.

## (46) Rumors of Berlusconi's crimes swirl. His advisors confront him. He scoffs.

- a. He **had paid** off the prostitute for her silence already.
- b. He **has paid** off the prostitute for her silence already.
- c. He **paid** off the prostitute for her silence already.

The paying off event is anterior to the assessment time, satisfying the requirements of the past perfect. Those of the past tense are also met, which similarly requires that the reference time precede the assessment time.

$$(47) \quad \llbracket \text{PAST}_i \rrbracket^{u,a,g} \text{ is defined iff } g(i) < \text{TIME}(a). \text{ When defined, } \llbracket \text{PAST}_i \rrbracket^{u,a,g} = g(i)$$

The present perfect, too, locates the paying off event before the assessment time. We assume that it encodes the combination of present tense and a (roughly Parsonian) perfect aspect, which describes the poststate of some eventuality.

$$(48) \quad \begin{array}{ll} \text{a.} & \llbracket \text{PRES}_i \rrbracket^{u,a,g} \text{ is defined iff } g(i) \subseteq \text{TIME}(a). \text{ When defined, } \llbracket \text{PRES}_i \rrbracket^{u,a,g} = g(i) \\ \text{b.} & \llbracket \text{PERF VP} \rrbracket^{u,a,g}(t) = 1 \text{ iff } \exists e_1 \exists e_2 (\llbracket \text{VP} \rrbracket^{u,a,g}(e_1) = 1 \wedge \text{POST-STATE}(e_2, e_1) \wedge t \subseteq \tau(e_2)) \end{array}$$

The conditions in (48a–b) together ensure that there is a poststate of Berlusconi's paying off that overlaps the assessment time (e.g., the time of the scoffing in (46)).

The temporal differences between the past perfect, present perfect, and simple past are leveled, then, when the assessment time and utterance time are decoupled, as in discourses with the historical present.

## 5. Conclusion and future directions

We have combined three existing ideas in the literature: i) a bicontextual semantics for tense, proposed originally for free indirect discourse (Sharvit, 2004, 2008); ii) a bicontextual treatment of the past perfect, cf. Kamp and Reyle (1993); and, iii) pragmatic setting of the assessment context, cf. Schlenker (2004). Combining these approaches allows us to directly predict: the felicity of the present tense in its canonical, play-by-play, and historical uses; why the play-by-play and historical present do not exhibit Stativity, but the canonical present does; and, why the historical use is compatible with past perfect, but the other two uses are not.

Importantly, we do not have to appeal to any special mechanisms beyond the idea that pragmatics controls when the time of assessment diverges from the time of utterance. More generally, we have proposed that three diverse cases of temporal perspectival shift — free indirect discourse, past perfect anchoring, and the historical present — can be given a unified account as a shift in the same indexical coordinate,  $\text{TIME}(a)$ .

In closing, we would like to consider the prospects of extending this theory to other noncanonical uses of the present tense. In most cases, we believe, scrutiny will fall on our ancillary assumptions, not the bicontextual semantics itself. For performative uses, the question ultimately is how Stativity is obviated — is the assessment time unmoored, as in the play-by-play and historical present, or do such uses speak against the restriction on utterance width? For the futurate and future-like uses in (49a–b), the issues concern the ULC, which we appealed to for preventing the assessment time from following the utterance time.

- (49) a. The Yankees **play** the Red Sox tomorrow. (Lakoff, 1971: 339)  
 b. Es *bezieht* sich. Wir **kriegen** Regen.  
     it cover.PRES.3SG self. we **get.PRES.1PL** rain  
     ‘It’s getting cloudy. We’ll get some rain.’ (Hilpert, 2008: 170)

While the English case is a futurate (with a scheduled interpretation), the German just expresses probability. It thus may be that the present tense can impose different restrictions on  $\text{TIME}(a)$  and  $\text{TIME}(u)$  across languages.

In addition, a broader theory of the present tense should account for how its various uses are deployed in the construction of larger discourses. One concrete case is narrative progression, which the historical present licenses in the same way that the simple past does.

- (50) a. John **gets up**, **goes** to the window, and **raises** the blind. It is light out. He **pulls** the blind down and **goes** back to bed.  
 b. John **got up**, **went** to the window, and **raised** the blind. It was light out. He **pulled** the blind down and **went** back to bed. (Partee, 1984: 253)

Early accounts of narrative progression linked it to specific properties of temporal and aspectual morphemes (Kamp and Rohrer, 1983; Partee, 1984; Hinrichs, 1986; Kamp and Reyle, 1993). The fact that the historical present also exhibits narrative progression suggests that it may, in fact, be more about the pragmatics of descriptions of event sequences (Kehler, 2002; Smith, 2003; Asher and Lascarides, 2003; Klein, 2009; Altshuler, 2010). What these pragmatic principles are, and how they should be integrated with tense, is a subject for future research.

## Kinds, epistemic indefinites, and *some*-exclamatives<sup>1</sup>

Curt ANDERSON — *Heinrich-Heine-Universität Düsseldorf*

**Abstract.** Although exclamative sentences have garnered much attention over the years, most work has focused on understanding what have been called *wh*-exclamatives and nominal exclamatives, to the exclusion of other types of exclamative constructions. I focus on what I call *some*-exclamatives, clausal exclamatives where the predicate uses the determiner *some*. I provide an analysis of these exclamatives, showing how their existence is motivated by independent properties of exclamative constructions and *some*.

**Keywords:** exclamatives, exclamation, genericity, kinds, indefinites

### 1. Introduction

In discussion of exclamatives in English, the vast majority of attention has been focused on analyzing and explaining the properties of *wh*-exclamatives (such as those in (1)), nominal exclamatives (as in (2)), and what Taniguchi (this volume) calls negative inversion exclamatives (like in (3)). These tend to form the canonical cases of exclamative sentences discussed in English.

- (1)    a.    What a large watermelon!  
      b.    How beautiful the birds sing!

- (2)    The peppers he eats!

- (3)    Aren't you happy!

However, other exclamative and exclamative-like structures exist in English that have received much less attention compared to the aforementioned ones. One example of such an exclamative (and the topic of this paper) is a construction making use of a DP headed by the determiner *some*, what I call *some*-exclamatives. Although *some*-exclamatives have been discussed before (Israel, 1996, 2011), they remain relatively understudied compared to the better-understood *wh*-exclamatives and nominal exclamatives.

Some examples of these exclamatives are given in (4) through (7), with a paraphrase underneath each example. These exclamatives express a belief on the part of the speaker that the subject of the exclamative is of the type denoted by the noun phrase complement to *some* (such as *dancer* in (4)), but that their instantiation of this property is unexpected in some way.

---

<sup>1</sup>I thank Marcin Morzycki, Cristina Schmitt, Alan Munn, Sebastian Löbner, Willi Geuder, Kyle Rawlins, Ezra Keshet, Stephanie Solt, Ai Taniguchi, Ekaterina (Katja) Gabrovska, the semantics group at Michigan State University, and the audience at SuB 21 in Edinburgh for their comments and suggestions. This paper represents work done in part at Collaborative Research Center 991 at Heinrich-Heine-Universität, funded by the German Science Foundation. All errors are my own, of course.

- (4) Boy, was she (ever) *some* dancer!  
 “She was a dancer and she was an exceptional dancer.”
- (5) That was *some* wine she brought to the party!  
 “She brought wine to the party and it was very good wine.”
- (6) *Some* friend she turned out to be!  
 “She was a friend and she was a particularly poor friend.”
- (7) It’s going to be *some* party!  
 “We’re having a party and it’s going to be a great party.”

Israel suggests that the exclamative meaning in these is likely to be related to the hedging (epistemic indefinite) use of *some*. I will argue that the exclamative use arises from an interaction of two components. First, like Israel, I suppose that the epistemic indefinite use of *some* plays a role by creating a set of alternatives, and furthermore propose the existence of an exclamative operator that structures this set of alternatives and asserts an attitude towards a particular alternative from the set.

In looking at this particular type of exclamative structure, several questions arise. First, how does this type of exclamative structure relate to other types of exclamatives in English? Namely, what do *some*-exclamatives have in common with other exclamatives in English, such as *wh*-exclamatives, nominal exclamatives, and negative inversion exclamatives? To answer this question, it’s necessary to ask a second question: what are the properties of *some* that allow for it to be involved in generating this exclamative meaning? This paper concentrates on this second question, in particular looking at the lexical semantics of *some* and how its indefinite meaning allows for an exclamative meaning to arise. Additionally, this paper looks at not only how the exclamative meaning arises, but also what is exclaimed about. I claim that *some*-exclamatives exclaim about a kind, in the sense of Carlson (1977).

This paper is structured as follows. Section 2 provides additional discussion of *some*-exclamatives; I distinguish *some* from the singular indefinite *a*, motivate *some*-exclamatives as exclamatives, and suggest that certain types of theories of exclamatives are not a very good fit for analyzing *some*-exclamatives. Then, in section 3, I argue that *some*-exclamatives are sensitive to kinds. In sections 4 and 5 I provide my analysis, with section 6 discussing additional data outside the purview of this paper. I wrap up my discussion in section 7.

## 2. Background

### 2.1. The data

*Some*-exclamatives come in two variants, what I call the in-situ variant and the preposed variation. In the in-situ variant, as in (8), the DP headed by *some* appears after the copula. In the preposed variant, illustrated with (9), the DP appears before the subject. In this paper, I focus on the

in-situ variant, with the assumption that it's the underlying variant, while the preposed version is derived through movement of the *some*-headed DP.

- (8) a. John is some lawyer! (in-situ)  
 b. This is going to be some party! (in-situ)
- (9) a. Some lawyer John is! (preposed)  
 b. Some party this is going to be! (preposed)

*Some* generally doesn't give rise to exclamatives. One condition that must be met in order for the exclamative interpretation to be available is that there must be a particular intonational contour on the *some* indefinite. When this intonational contour is removed (marked with *I* in the examples below), the exclamative meaning is unavailable, and the ordinary indefinite meaning arises.

- (10) a. That was some<sub>I</sub> wine she brought to the party!  
 b. #That was some wine she brought to the party.
- (11) a. It's going to be some<sub>I</sub> party!  
 b. #It's going to be some party.

I propose that the intonation plays a role in creating the exclamative, in marking the presence of a morpheme carrying an exclamative operator. This operator, as I develop later, structures the set of alternatives denoted by the sentential core of the exclamative, and assert an attitude towards one of the alternatives.

Although *some*-exclamatives make use of *some*, which is used in constructing indefinite DPs in English, it is not simply being an indefinite that allows for *some* to have an exclamative use; English lacks a corresponding *a*-exclamative (as would be intended with the examples in (12)).

- (12) a. #John is a lawyer!  
 b. #It's going to be a party!

This lack of an *a*-exclamative suggests that there are additional properties of *some* that make it well-suited for being used in an exclamative. The next section briefly discusses how *some* and *a* differ.

## 2.2. *Some* is an epistemic indefinite

How does *some* differ from the singular indefinite *a*? The primary way that they differ is that *some* is an epistemic indefinite. Epistemic indefinites are indefinites that impose restrictions on the speaker regarding their knowledge of who the indefinite refers to. Unreduced *some* is the canonical case of this type of indefinite in English, although epistemic indefinites are well-attested cross-linguistically as well (Haspelmath, 1997).

In English, *some* contrasts with *a* in committing the speaker to uncertainty regarding the referent of the indefinite. The speaker may know some description of the individual, but the particular individual who satisfies the description cannot be known.<sup>2</sup> The short exchange in (13) illustrates this, where A's use of *some* commits A to not being able to identify the individual who was shot. B's question regarding the identity of the individual is odd because of speaker A's commitments due to using *some*.

- (13) A: Some cabinet minister has been shot!  
B: #Who?

In contrast, although *a* is compatible with a lack of knowledge, it doesn't require it in the way that *some* does. The exchange in (14) is acceptable, since although the use of the indefinite may signal that the speaker does not know who was shot, it doesn't commit the speaker to ignorance.

- (14) A: A cabinet minister has been shot!  
B: Who?

This contrast shows that there must be additional constraints on the use of *some* in order to capture a difference between *some* and the singular indefinite *a*. In my analysis, I will make a proposal for this difference that builds on work by Kratzer and Shimoyama (2002).

### 2.3. Is this really an exclamative?

Michaelis and Lambrecht (1996) note a collection of properties that exclamative constructions prototypically have. These are listed in (15). I argue that *some*-exclamatives should be considered as a type of exclamative based on the observation that *some*-exclamatives exhibit many of these properties.

- (15) Semantico-pragmatic properties of exclamatives (Michaelis and Lambrecht, 1996)
- a. presupposed open proposition
  - b. scalar extent
  - c. assertion of affective stance: expectation contravention
  - d. identifiability of described referent
  - e. deixis

First, *some*-exclamatives exhibit the (a) property in the above list. What Michaelis and Lambrecht mean by presupposed open proposition is that exclamatives are factive. *Some*-exclamatives are also factive, as can be shown by using the 'Hey, wait a minute!' test for presuppositions (Shanon, 1976; von Stechow, 2004).

<sup>2</sup>With some caveats, of course. *Some* can also express indifference with respect to the identity of the individual as well, which is plausibly related to its ignorance use. *Some* is also sensitive to different types of knowledge regarding an individual, such as naming them versus pointing them out in a crowd. See Maher 2013 for some discussion of this latter point.

- (16) A: John is *some* lawyer! He always loses his cases!  
 B: Hey, wait a minute! I didn't know John was a lawyer.

As already noted, *some*-exclamatives seem to exclaim about some high scalar property as well, exhibiting the (b) property above. That exclamatives also express an attitude can be considered similar to the (c) property in the list. Finally, by deixis (property (e)) Michaelis and Lambrecht mean that the attitude in an exclamative is generally anchored both personally (with respect to an individual—the speaker) and temporally (to the speech time). This seems to hold in part for *some*-exclamatives as well, where the attitude is anchored to the speaker by default.

These properties also match in some ways with Zanuttini and Portner (2003)'s claim that exclamative constructions are factive, express a sense of noteworthiness, and cannot function in question/answer pairs. Given the similarities between *some*-exclamatives and other exclamatives in terms of their meanings, then, I will consider *some*-exclamatives to be a type of exclamative construction.

#### 2.4. Theories of exclamatives

As exclamative constructions have been an important area for research for some time, there have been many different proposals for exclamatives in general as well as for constructions in particular languages. Although I cannot hope to do a thorough review of all of them, I'll note (following Castroviejo Miró (2008)) that the field has in some ways coalesced around three main types of theories regarding exclamatives: theories that assimilate root exclamatives to embedded exclamatives, theories that treat exclamatives as degree constructions, and theories that derive exclamatives from question semantics.

One style of theory of exclamatives attempts to understand exclamatives by assimilating root *wh*-exclamatives, such as those in (17), to embedded exclamatives like those in (18) (D'Avis, 2002; Abels, 2005).

- (17) a. How tall John is! (root exclamative)  
 b. What a success the party was! (root exclamative)
- (18) a. It's amazing how tall John is! (embedded exclamative)  
 b. I'm surprised what a success the party was! (embedded exclamative)

Embedded exclamatives clearly inherit much of their semantic force from the predicate they are embedded under (such as *amazing*). The hope for this style of theory is that root exclamatives can be represented by assuming that they too are embedded under an *amazing*-predicate, at some level of representation.

The difficulty with extending this approach to *some*-exclamatives is that *some*-exclamatives do not embed under *amazing*, *disappointing*, or other predicates we might have reasonably expected

would be candidate predicates for this type of theory. This is shown in (19). It would seem then that, whatever the merits of this analysis, it is difficult to naively extend it to *some*-exclamatives.

- (19) \*It's amazing/disappointing/unexpected (that) John is some friend!

I turn now to a different type of analysis of exclamative constructions. In contrast with question theories of exclamatives, which treat exclamatives as being underlyingly questions, degree theories of exclamatives treat exclamative constructions as being on par with other degree constructions, such as measure phrase modification or comparatives. In other words, rather than accounting for the semantics of exclamatives by saying that they are sets of propositions, the semantics of exclamatives is accounted for by assuming that exclamatives make use of sets of degrees.

Some accounts in this type of theory are those of Castroviejo Miró (2006) and Rett (2008, 2011). Castroviejo Miró argues for a degree analysis of *wh*-exclamatives in Catalan based on the observation that the degree word *tan* in Catalan occurs in both exclamative environments and in canonical degree constructions. What makes exclamatives different from other sentence types is how they update the common ground. Assertions update the common ground to exclude worlds incompatible with the assertion, while exclamatives in this analysis background the information contributed by the degree construction, and implicate a speaker-oriented attitude towards a degree.

Rett (2011) also argues that exclamatives are degree constructions. She observes that exclamatives often make use of overt gradable expressions, such as in (20). When no gradable predicate is overt, however, a covert gradable predicate M-OP is used, where M-OP measures over a contextually salient dimension (in the cases in (21) below, the dimensions corresponding to *delicious* and *exotic* might be licit in context).

- (20) a. What delicious desserts John baked!  
b. The exotic places John visited!

- (21) a. What M-OP desserts John baked!  
b. The M-OP places John visited!

The core of the exclamative, for Rett, is a set of degrees (rather than a set of propositions). A process of default existential closure over degrees converts this into a proposition. A covert illocutionary operator expresses surprise towards that degree.

But, it's not obvious that this is the correct path to go down in order to analyze *some*-exclamatives as well. The reason for this is the nature of M-OP; M-OP is used to coerce gradability where none existed before, using some contextual salient scale. The difficulty lies in the fact that *some* seems to already be involved with scalar meaning, namely quantity. For instance, the question-answer pair in (22) shows that *some* can be used to provide an answer expressing a quantity. Moreover, *some* is well-known to be part of a scale with the quantifier *all*.

- (22) A: Was any of the wine spilled?  
 B: Some (of it).

Since *some* participates in a scale denoting quantity already, it seems reasonable to think that *some*-exclamatives should have an interpretation where they express surprise at a quantity. This type of reading is available with nominal exclamatives as in (23), showing that in principle an exclamative could have this type of reading. However, *some*-exclamatives do not seem to be compatible with a quantity reading, as (23) demonstrates.

- (23) The wine we drank! It would've filled buckets!

- (24) \*That was some wine we drank! It would've filled buckets!

Finally, it's not clear that *some* is involved with degree constructions in general. For instance, generally expressions of the style in (25) aren't allowed in many varieties of English, including mine, further weakening a case for *some* having a degree component to it.

- (25) a. \*some tall!  
 b. \*some sweet!

With these facts in mind, I set aside the possibility that *some*-exclamatives should be analyzed as degree constructions (but this of course doesn't rule out other exclamative constructions as being degree constructions).

Moving on, another sort of theory of exclamatives treats exclamatives as being semantically related to questions. Specifically, the propositional content of an exclamative is equivalent to that of a question, but the difference between a question and an exclamative lies in their sentential force. These kinds of theories adopt a semantics for questions in the style of Hamblin (1973), Karttunen (1977), and Groenendijk and Stokhof (1984).

Hamblin (1973) proposed that the denotations of questions were sets of propositions corresponding to answers to that question. A question of the form *Who came to the party?* could be considered as having the set of alternatives in (26), for instance, with *who* signaling the syntactic position where the alternative propositions should have their content varied. This set raises an issue as to which particular proposition is true.

$$(26) \quad \llbracket \textit{Who came to the party?} \rrbracket = \left\{ \begin{array}{l} \text{Mary came to the party,} \\ \text{Bill came to the party,} \\ \text{Bob came to the party,} \\ \dots \end{array} \right\}$$

This view of questions has come to be quite influential, and, with modifications later by Karttunen (1977) and Groenendijk and Stokhof (1984), the view that questions denote sets of propositions has become a dominant view in their analysis.

Under normal assumptions, declarative sentences denote propositions, functions from worlds to truth values, type  $\langle s, t \rangle$ . However, if this is so, what do sentences that aren't declarative denote? Hamblin proposes that questions are sets of propositions, a view further developed by Karttunen (1977) and Groenendijk and Stokhof (1984). The question *Who is coming?* might be represented as in (27).

$$(27) \quad \llbracket \textit{Who is coming?} \rrbracket = \lambda p \exists x [p(w) \wedge p = \lambda w' [\textbf{come}(w')(x)]]$$

Gutiérrez-Rexach (1996) adopts this view of questions and proposes that both questions and exclamatives have, at their core, essentially the same denotations. What sets exclamatives apart from questions is the use of an illocutionary operator *EXC* which operates on a variable indexed to the speaker, the world, and a set of propositions. Gutiérrez-Rexach's definition for this is as in (28), where *EMOT* is a set of emotive properties that speakers can have towards propositions, such as surprise and amazement.

$$(28) \quad \text{Let } a \text{ be the speaker, } w \text{ a world (typically the actual world), } p \text{ a proposition, and } P \in \textit{EMOT} \text{ (the set of emotive properties). Then,}$$

$$\textit{EXC} \stackrel{\text{def}}{=} \lambda a \lambda w \lambda p_{\langle s, t \rangle} \exists P_{\langle s, \langle st, et \rangle \rangle} [P(w)(p)(a)]$$

A somewhat different theory of exclamatives is that of Zanuttini and Portner (2003). In their analysis, Zanuttini and Portner follow Gutiérrez-Rexach in analyzing the core of a *wh*-exclamative sentence as being a question. Where Zanuttini and Portner's analysis differs is in the source of the exclamative reading itself. They argue that exclamatives have at their core a notion of domain widening.

The concept of domain widening here is related to the analysis of *any* in Kadmon and Landman (1993), where *any* is a simple indefinite determiner, but shifts the domain of quantification to a stronger domain when embedded under negation. In Zanuttini and Portner, domain widening applies at the level of propositions. Domain widening applies to the set of propositions denoted by the sentential core of the exclamative, and widens this set to include propositions not previously under consideration. Their definition of widening is provided in (29).

$$(29) \quad \text{Widening} \quad \quad \quad (\text{Zanuttini and Portner, 2003})$$

For any clause  $S$  containing  $R_{\text{widening}}$ , widen the initial domain of quantification for  $R_{\text{widening}}$ ,  $D1$ , to a new domain,  $D2$ , such that

- i.  $\llbracket S \rrbracket^{w, D2} - \llbracket S \rrbracket^{w, D1} \neq 0$  and
- ii.  $\forall x \forall y [(x \in D1 \ \& \ y \in (D2 - D1)) \rightarrow x < y]$

To illustrate how this works, let's consider the exclamative in (30). Zanuttini and Portner follow Karttunen (1977) in treating questions as denoting sets of true answers, so the set of alternatives for this exclamative is as in (31).

$$(30) \quad \text{What peppers he eats!}$$

- (31)  $\llbracket \text{What peppers he eats!} \rrbracket$   
 $= \{p : p \text{ is true in } w \text{ and } \exists a \text{ such that } p = [\text{'he eats } a']\}$   
 $= \{\text{'he eats poblanos'}, \text{'he eats serranos'}, \text{'he eats jalapeños'}\}$

To build the exclamative interpretation, the domain of this set of alternatives is expanded to include propositions that weren't under consideration before. In the set in (32), which has undergone widening, the proposition *he eats habaneros* is now included. In essence, what the widening operation does is build the interpretation that this person eats a variety of peppers, and he even eats these extremely spicy peppers, habaneros. If there are any other peppers he eats, they're not worth our consideration, since they've fallen outside of the widened domain.

- (32)  $\{\text{'he eats poblanos'}, \text{'he eats serranos'}, \text{'he eats jalapeños'}, \textbf{'he eats habaneros'}\}$

The difficulty in extending a question theory of exclamatives to *some*-exclamatives, however, is that *some*-exclamatives share little with questions in their surface structure. However, under some recent analyses (such as Kratzer and Shimoyama (2002)) indefinites do share semantic and pragmatic properties with questions, in that both interrogative sentences and declarative sentences with indefinites can be modeled as denoting sets of propositional alternatives. In the next sections, I develop a theory of *some*-exclamatives that builds on this kind of representation.

### 3. Kinds and *some*-exclamatives

I argue that, at their core, *some*-exclamatives are ultimately kind-related. That is to say, *some*-exclamatives make assertions involving kinds, as opposed to (say) degrees. There are two important pieces of evidence that kinds are involved in *some*-exclamatives. First, NPs that do not have clear, well-established kinds are odd in *some*-exclamatives. Going back to Carlson (1977), it's been argued that reference to kinds depends on the accessibility of an established kind. Since green bottles (in (33a)) are not an established kind, they also do not allow for subkinds, and hence are illicit in *some*-exclamatives. A similar line of reasoning holds for (33b), as people that are in the next room do not form a kind.

- (33) a. ??This is some green bottle!  
 b. #John is some person from the next room!

As noted by Constantinescu (2011), some nouns do not have readily accessible stereotypical properties associated with them, such as *building* or *room*. Since kinds correspond to general properties that characterize groups of individuals, we might suppose that the lack of stereotypical properties for *building* and *room* would make subkinds for them difficult to construe in many contexts. This predicts that *building* and *room* would be difficult to use in *some*-exclamatives, which seems to be the case (34). Other nouns that lack stereotypical properties, such as *non-Methodist*, are also difficult to use. The difficulty in using these nouns that do not denote kinds is another piece of evidence that *some*-exclamatives are kind-related.

- (34) a. ??This is some building!  
 b. ??This is some room!

(35) ??He is some non-Methodist!

Finally, an additional piece of evidence suggesting that there is reference to kinds in *some*-exclamatives can be found by looking at post-nominal adjectives like *navigable* and *visible*. As noted by Bolinger (1967), these adjectives obligatorily get temporary, episodic interpretations when used post-nominally, as in (36). However, when these adjectives are used in the canonical pre-nominal position, like in (37), these adjectives either get the episodic interpretation, or an interpretation where they are commenting on inherent, stable properties.

Larson and Marušič (2004) go a step further and claim that this is a reflection of a stage-level/individual-level distinction, in the sense of Carlson (1977), where stage-level properties are temporary properties applying to spatio-temporally located stages of individuals, while individual-level properties are permanent properties applying to the whole individuals themselves. This idea is closely related to kinds, in that instantiations of kinds (but not kinds themselves) are the sorts of objects that stage-level predications can be made of.

(36) a. the stars visible (stage-level only)  
b. the rivers navigable (stage-level only)

(37) a. the visible stars (stage-level or individual-level)  
b. the navigable rivers (stage-level or individual-level)

In *some*-exclamatives, pre-nominal adjectives are allowed, as shown in (38), while the same adjective is barred post-nominally. If Larson and Marušič (2004) are correct in identifying the post-nominal position as being related to stage-level interpretation, then this is further support for a kind-level interpretation being used in *some*-exclamatives. As episodic stage-level interpretations must be predicated of individuals, the fact that these post-nominal adjectives are allergic to the noun phrase in *some*-exclamatives suggests that the NP is also not a predicate of individuals.

(38) a. This is some navigable river! (We barely made it to the river mouth alive!)  
b. These are some visible stars! (I can barely see them, and I know where to look!)

Finally, it should also be noted that Weir (2012) has proposed that, in certain cases, the determiner *some* (in its more familiar use) is sensitive to kinds. He notices examples such as (39), where what the speaker is expressing ignorance about is which kind of object is being referred to. These examples cannot be paraphrased with the form 'I saw a contraption in the copy room and I don't know which contraption it was,' but must be paraphrased with something more like 'I saw a contraption in the copy room and I don't know what kind of contraption it was.'

(39) a. I saw some contraption in the copy room this morning.  
b. I came home to find some plant growing through a hole in my wall.  
c. Doctor, some growth appeared on my arm. Should I be worried?

To conclude this, I will assume that kinds play a role in the interpretation of *some*-exclamatives. In particular, I'll suggest that *some*-exclamatives make reference to subkinds of the kind denoted by the NP that the determiner *some* combines with.

#### 4. Kinds within the DP

In the previous section, I argue that *some*-exclamatives involve reference to kinds, at some level. The locus for reference to kinds in *some*-exclamatives, I'll assume, is within the DP. I mention a few proposals that form the background to my analysis in this section, where I will ultimately assume a model that is similar in spirit to that of Zamparelli (1995)'s idea of a layered DP.

There are many proposals that put reference to kinds with the DP. One proposal is Zamparelli (1995). Zamparelli suggests that the DP be expanded into a number of functional projections (as in (40)). This creates a division of labor between the various projects in the structure; different types of semantic information are available at different levels in the DP structure, creating a close connection between the semantic derivation and the syntactic derivation.

Gehrke and McNally (2013) argue for a system similar to that of Zamparelli (1995), with kinds represented low within the DP. However, rather than treating the noun as directly denoting a kind, as Zamparelli does, they suggest that common nouns denote properties of kinds (see also McNally and Boleda 2004).

$$(40) \quad \llbracket car \rrbracket = \lambda x_k [\mathbf{car}(x)]$$

In order to make this property something that can be predicated of ordinary objects, it must be transformed into a property of token entities and not kinds. They suggest, following related proposals by Déprez (2005) and Müller-Reichau (2011), that NumP is the locus for this operation. This is illustrated in (41), where *R* is a variant of Carlson (1977)'s realization relation, which relates kinds to individuals that instantiate them.

$$(42) \quad \llbracket [\text{NumP} [\text{NP } car]] \rrbracket = \lambda y \exists x_k [\mathbf{car}(x_k) \wedge R(y, x_k)]$$

This has the benefit of providing a transparent mapping between syntax and semantics. I will assume a version of this in my analysis, where *some* plays the role of a Num head and realizes kinds.

## 5. Analysis

### 5.1. Structure of the exclamative

The basic core of a *some*-exclamative such as *John is some lawyer!* would be represented as in (43). I assume that these exclamatives are built essentially from a standard sentential core, with the crucial difference being the use of an exclamative operator EX-OP merged in C. The intonational contour of *some*-exclamatives is assumed to mark the presence of this otherwise covert operator.

(43)

### 5.2. The representation of *some* sentences

As discussed earlier, *some* is an epistemic indefinite, requiring that the speaker not have precise knowledge as to the identity of some individual. Although the particular way that this gets cashed out in different theoretical analyses varies, there are several that are especially worth attention here. The first that of Farkas (2002). Farkas analyzes *some* as requiring that the variable it contributes be unidentified—that is, that the value that variable is assigned not necessarily be the same across all possibilities. In essence, this is a way of ensuring that the speaker can never commit to a particular valuation for that variable.

A second is that of Alonso-Ovalle and Menéndez-Benito (2010). They propose that the ignorance implicature of Spanish *algún*, which is similar to *some* in some respects, can be modeled through competition with *un*. They analyze *algún* as in (44), where *algún* combines first with a subset selection function  $f$ , a function from sets to sets. The use of the subset selection function models contextual domain restriction.  $f$  in this analysis is restricted via the presupposition **anti-singleton**( $f$ ) so that its range must be a non-singleton set. When  $f$  combines with the

restrictor of *algún*, the NP, the effect is to make it so that there must be at least two individuals that could possibly satisfy the existential claim. *Un* is analyzed as not having the anti-singleton presupposition, and the ignorance component of *algún* surfaces as an implicature through competition with *un*.

$$(44) \quad \llbracket \text{algún} \rrbracket = \lambda f \lambda P \lambda Q : \text{anti-singleton}(f). \exists x [f(P)(x) \wedge Q(x)]$$

Finally, there is von Fintel (2000). This analysis is not about *some* per se, but about *whatever*, which also includes a sense of uncertainty about it.<sup>3</sup> Von Fintel builds on Dayal (1997)'s analysis of *whatever* in assuming that *whatever* includes a presupposition of ignorance. The presupposition is most relevant for my purposes here, in that it forces the speaker to not be able to identify which particular individual across worlds satisfies the predicate *P*, just that there are at least two.

$$(45) \quad \text{whatever}(w)(F)(P)(Q) \\ \text{a. Presupposes: } \exists w', w'' \in F : \iota x.P(w')(x) \neq \iota x.P(w'')(x) \\ \text{b. Asserts: } \forall w' \in F : Q(w')(\iota x.P(w')(x))$$

What these proposals have in common is a general analytical intuition that epistemic indefinites and other morphemes that express ignorance impose a requirement that the speaker cannot commit to a particular individual. Rather, what these must do is leave as an open possibility that there are multiple individuals who could satisfy the descriptive claim that is being made. I borrow this intuition for my analysis of *some*.

For my purposes here, I adopt Kratzer and Shimoyama (2002)'s practice of analyzing all sentences—not only question sentences—as denoting sets of propositional alternatives. In particular, sentences making use of indefinites will have as their denotation a set of propositions that vary with respect to an individual (this will be developed in the next section). However, this formalization in and of itself does not build in a difference between the singular indefinite and *some*. To cash out the difference between the singular indefinite *a* and *some* in this sort of system, I give the principle in (46), the anti-singleton condition, which can be thought of as a use-condition associated with *some* but not *a*. What this principle serves to do is ensure that the speaker cannot narrow the set of alternatives to make an assertion about a single particular individual across worlds. This condition will be active in both normal sentences using *some*, and also exclamative sentences using *some*.

$$(46) \quad \text{Anti-singleton condition on } \textit{some}: \text{ A sentence containing } \textit{some} \text{ must denote a set containing at least two alternatives.}$$

In the following sections, I show how the alternatives at the core of the exclamative vary with respect to a kind, and how an exclamative operator applies to this set.

<sup>3</sup>In class notes, von Fintel has an analysis of *some* that is similar, according to Alonso-Ovalle and Menéndez-Benito (2010). See von Fintel (1999).

### 5.3. The sentential core of *some*-exclamatives

Following the discussion the previously, I'll assume that NPs denote properties of kinds. The denotation for the NP *lawyer* will be the property corresponding to the lawyer-kind. This predicate will be true of any sub-kinds of the lawyer kind (or the kind LAWYER itself).

$$(47) \quad \llbracket \text{lawyer} \rrbracket = \lambda k. \mathbf{lawyer}(k)$$

Based on proposals from Müller-Reichau (2011), Gehrke and McNally (2013) and others, Num will be the locus for shifting properties of kinds to properties of individuals. What shifts kinds to individuals in my analysis is *some*. Accordingly, *some* will be merged low, as a Num head, taking the NP as an argument, and yielding a property of individuals, as other indefinites do by assumption. The sentential core for a *some*-exclamative would be represented as in (48), where  $R$  is a realization relation.  $R(x, y_k)$  is true just in case  $x$  is a realization of kind  $y_k$ .

$$(48) \quad \llbracket \text{John is some lawyer} \rrbracket = \{p' : \exists x_k \text{ s.t. } p' = [R(\mathbf{j}, x_k) \wedge \mathbf{lawyer}(x_k)]\}$$

This representation of the sentence, though, still does not adequately model an exclamative meaning. In the next section, I propose an exclamative operator that is the final step in transforming the sentence into an exclamative.

### 5.4. The exclamative operator

A set of propositions isn't the right kind of semantic object to add to the discourse, as it is not a single truth value. In a non-exclamative sentence, a covert assertoric operator maps the set of alternatives corresponding to the sentence to a truth value (see Alonso-Ovalle and Menéndez-Benito 2010 and Kratzer and Shimoyama 2002 for discussion on what this kind of operator would look like). In the case of an exclamative sentence, a different operator applies. This operator, EX-OP, differs from an assertion operator in that it expresses a speaker-oriented attitude towards a proposition, rather than asserting a proposition itself. This attitude towards a proposition is what is added to the discourse. The special exclamative intonation that is attached to the *some*-exclamative marks the presence of this covert exclamative operator.

The exclamative operator EX-OP I define as in (49). This operator applies to a set of propositions  $P$ , asserts that there is an ordering to  $P$  (e.g., an ordering based on a property such as unexpectedness or surprisal), and then asserts an attitude towards the maximal proposition on this scale of propositions ( $\text{MAX}(P)$ ). This attitude is indexed to the speaker.

$$(49) \quad \llbracket \text{Ex-Op} \rrbracket = \lambda P \left[ \begin{array}{l} \text{there is a salient ordering for } P \text{ and} \\ \text{ATTITUDE}(\mathbf{speaker})(\text{MAX}(P)) \end{array} \right]$$

This building of a scale goes some way towards explaining why *some* and not *a* can be involved in generating an exclamative; as EX-OP imposes an ordering over the set of propositions, it will require a set for which there can be a non-trivial ordering. By entailing that there are at least two members, *some* will be suitable for this, while *a* will not be.

Applying EX-OP to the set of alternatives denoted by the sentence (e.g., a logical form such as in (48)) will yield a proposition such as in (50).

$$(50) \quad \llbracket \text{Ex-Op}(\text{John is some lawyer}) \rrbracket \\ = \text{there is a salient ordering for } \{p' : \exists x_k \text{ s.t. } p' = [R(\mathbf{j}, x_k) \wedge \text{lawyer}(x_k)]\} \text{ and} \\ \text{ATTITUDE}(\text{speaker})(\text{MAX}(\{p' : \exists x_k \text{ s.t. } p' = [R(\mathbf{j}, x_k) \wedge \text{lawyer}(x_k)]\}))$$

To summarize, *some* generates a set of alternatives that vary by subkinds instantiated by the subject. This set of alternatives is further constrained by a presupposition that says that this set must contain at least two alternatives in it. This constraint is what models the epistemic indefinite nature of *some* in other contexts. In the next section, I use this fact about *some* in conjunction with an exclamative operator to build the full meaning of *some*-exclamatives.

## 6. Addendum: Pejorativity and genericity in *some*-exclamatives

The majority of this paper has concentrated on what I've called the in-situ variant of the *some*-exclamative, where the DP containing *some* is in the position after the copula. In this section, I turn very briefly to the preposed variant.

The preposed variant is similar to the in-situ variant, in that both exclaim about some extreme property and the speaker asserts an attitude towards this. However, the preposed variant differs from the in-situ variant in that it requires a negative or pejorative evaluation on the part of the speaker; although the in-situ variant is compatible with this attitude, it does not require it. In other words, the preposed *some*-exclamative rules out any positive or neutral evaluation on the part of the speaker.

To illustrate this, consider the sentence in (51) with the (a) and (b) follow-ups. Both the (a) and (b) follow-ups are licit here, showing that the exclamative doesn't necessarily commit the speaker to either a positive or a negative evaluation of the subject; the speaker can use the exclamative to exclaim about John being both a good lawyer, and also a not very good lawyer.

- (51) John is some lawyer!
- a. He always wins his cases and does lots of pro bono work.
  - b. He loses every case and still charges a lot.

However, the preposed variant is different, as shown in (52), in that the (a) follow-up is incompatible with the exclamative while the (b) follow-up is still compatible. This shows that the exclamative in this case commits the speaker to a negative evaluation of John's abilities as a lawyer. This commitment to a negative evaluation rules out the follow-up in (a) that implicates a positive evaluation.

- (52) Some lawyer John is!
- a. #He always wins his cases and does lots of pro bono work.
  - b. He loses every case and still charges a lot.

One possibility is that the raising of the *some*-DP signals the presence of a syntactic projection encoding a pejorative attitude at the left edge of the clause. Similar proposals have been made for other phenomena, such as *shm*-reduplication in English (Grohmann and Nevins, 2004). But, a full analysis of the syntactic and semantic consequences of positing such a projection is beyond this paper.

Turning back to the role of genericity in *some*-exclamatives, one rub in the analysis in this paper is that perhaps *some*-exclamatives don't track the standard notion of kind very well, in that expressing surprise with respect to the subkind instantiated is marked. For instance, in (53), although knives with wooden handles and ceramic knives are subkinds of knives, the follow-ups in the (b) and (c) sentences suggest that the exclamation doesn't allow one to exclaim about these properties. Rather, the licitness of the (a) follow-up in (53) suggests that what the *some*-exclamative is exclaiming about is how the knife relates to the commonly associated event with knives, cutting. Similarly, the (b) follow-up in (54) is illicit, even though foot specialists are a kind of doctor. The (a) follow-up, which is licit, relates to the doctor's performance in doing his or her duties.

- (53) Some knife this is!
- a. It couldn't even cut this banana!
  - b. #It has a wooden handle!
  - c. #It's made of ceramic!
- (54) Some doctor he is!
- a. He couldn't diagnose my athlete's foot!
  - b. #He's a foot specialist!

Although these examples do not (necessarily) weaken the claim I make that *some*-exclamatives involve kinds and genericity in some sense, it does raise questions about how to further define these notions with respect to *some*-exclamatives.

## 7. Conclusion

In this paper I've laid out an analysis of *some*-exclamatives, which have remained understudied in the broader literature on exclamatives. *Some*-exclamatives are interesting in that they show another example of an exclamative construction where the exclamation is not derived from morphology related to the formation of questions. The analysis I propose suggests a refinement of our understanding of exclamative sentences. Proposals such as those of Gutiérrez-Rexach (1996) and Zanuttini and Portner (2003) analyze exclamatives as having a question semantics. Recent work in the semantics of indefinites has argued that indefinites also have an alternative semantics associated with them, making them quite closely related semantically to questions. This connection allows us to very easily make sense of *some*-exclamatives and exclamatives as a whole; exclamative constructions are not about questionhood, as proposed by Gutiérrez-Rexach (1996) and Zanuttini and Portner (2003), but are rather about manipulating sets of alternatives.

**Abstract.** In this paper we set out three consequences of a game-theoretic model for conversation, Message Exchange (ME) Games (Asher et al., 2016), which we think are of linguistic interest. We develop a notion of conversational success, explain subjectivity and bias in interpretation using concepts from epistemic game theory, and characterize the strategic usefulness of using so called expressions of “not at issue” content using ME games.

**Keywords:** epistemic games, conversation, discourse, conversational success, at-issue content, subjectivity

## 1. Introduction

The philosopher Grice long ago popularized the idea that conversation is a rational activity (Grice, 1975), yet curiously, efforts to apply philosophical and economic analyses of rationality and rational strategizing to linguistic phenomena have been sporadic and very restricted in their aims. Much of this work, including van Rooij (2004); Franke et al. (2012); Franke (2008) and Asher and Lascarides (2013), has been directed to the justification of Gricean maxims of conversation, often with the further aim of computing scalar implicatures. As argued in Asher and Lascarides (2013), the focus on Gricean maxims is largely misplaced: they are not in and of themselves an interesting *linguistic phenomenon*; they are an informal, and somewhat inchoate, description of what more formal models of rational interaction predict. Such formal models, when coupled with a well-developed theory of discourse structure and interpretation, have a much broader range of application to linguistic phenomena. In this paper, we argue that they play a crucial role in the analysis of three particular phenomena: evaluations of conversational success, not-at-issue/at-issue notions of content, and the subjectivity of interpretation. As we will make clear in our analysis of the subjectivity of interpretation, our formal model of rational strategizing affects how we structure and interpret a conversation. As some of us have argued at length that discourse structure affects many dynamic semantic phenomena (temporal structure, the interpretation of anaphora and ellipsis) as well as discourse content as a whole, these models thus have a general importance for understanding content in all its manifestations.

Mathematics, theoretical computer science and economics have produced a rich and pertinent body of work on which to draw in building a model of rational behavior. Conversations, for example, have a natural analysis as games. They typically involve at least two agents, each with their own interests and goals. These goals may be compatible or they may be in conflict, but in either case, one agent’s successfully achieving her conversational goals will typically depend upon her taking her interlocutors’ goals and interests into account. In cooperative conversations, in which agents’ goals are completely aligned, conversational partners typically still need to coordinate actions, even linguistic actions. In strategic or non-cooperative conversations, in

---

<sup>1</sup>We thank ERC grant 269427 for research support.

which participants have opposing interests concerning the outcome of the conversation, the necessity to consider the opponents' aims and actions is almost always even more important. A debate between two political candidates is an instance: each candidate has a certain number of points to convey to the audience, and each wants to promote her own position and damage her opponent's or opponents'. To achieve these goals, each participant typically needs to plan for anticipated responses from the other.

Our paper is organized into three main parts. First, we look at an application of a game theoretic model to the notion of conversational success and provide an abbreviated description of the technical details of the model, which we call *epistemic message exchange games*. We then show how the model sheds insight on the subjectivity of interpretation. In the third section, we apply the game theoretic model to an analysis of different types of content, in particular the distinction between what linguists call "at-issue" and "not-at-issue" content.

## 2. Conversational success

While linguists are accustomed to semantic evaluations in terms of truth and satisfaction alone, ordinary people evaluate their conversational contributions and those of others more generally in terms of what we call *success*. Did the agent achieve her conversational goals with her contributions or not? Conversational success thus has to do with the goals a conversationalist has. What, then, are conversational goals? One possibility is to identify a conversational goal extensionally as the set of conversations that are successful from the point of view of the speaker. Conversational goals are then defined as subsets of the set of all possible conversations that exclude those conversations that do not go well. Sometimes a conversation will count as successful in virtue of containing a particular verbal string, as illustrated in (1).

- (1) a. EPA administrator : May I look inside the containment structure?
- b. Ghostbuster (Bill Murray): You didn't say the magic word.
- c. EPA administrator: Please, may I look inside the containment structure?
- d. Ghostbuster (Murray): No. (from *Ghostbusters*)

At least one of the goals of Murray's character is simply to have the EPA administrator prefix his request with the word *please*. If we define this goal extensionally, we end up with the set of all conversations in which that string follows (1a) and (1b). Most conversational goals, however, are not defined by particular strings. What matters are the commitments to conversational contents that the interlocutors ultimately adopt. An evaluation of conversational success therefore typically has ties to a conversation's content or its ordinary semantic evaluation. Importantly, this does not mean that the content of a conversation must be *true* or accurate; a conversational contribution may be successful in persuading an interlocutor to do something, for example, even if the contribution is inaccurate or false. Certain 2016 US Presidential campaigns provide ample evidence of this possibility.

Content related goals can be tied to particular discourse moves. Following Asher and Lascarides (2003), asking a non-rhetorical question, for instance, indicates that the speaker has the conversational goal of obtaining an answer from her interlocutor or interlocutors. A simple

conversational goal for an assertion is typically to have one's interlocutors agree or at least not openly object to it. Asher and Lascarides (2003) call such goals *speech act related goals*.

Conversational goals, however, can also global, general properties of a conversation that guide a large stretch of discourse or even the conversation as a whole. Consider, for instance, a prosecutor who either wants a witness to commit to some issue or wants to demonstrate before a jury that the interlocutor is evading or refuses to answer the question. Success may require several discourse moves (and may never be achieved at all). As a real life example, consider the following exchange between CNN's Jake Tapper and Mike Pence, who was the US Vice-President elect at the time.<sup>2</sup> Tapper asks Pence if he was aware that the transition team for Trump's presidency had put in for a security clearance for Michael Flynn Jr., the highly controversial son of Trump's choice for National Security Advisor. Pence repeatedly dodges the direct yes or no question, forcing Tapper to point out why all of Pence's attempts to deflect the question were not answers. While Tapper never succeeds in getting a direct answer from Pence, his eventual success in extracting at least a strong implicature that Pence was aware of the demand for clearance required a series of arguments pointing out why each attempt at diversion by Pence was just that.

More often than not, the goal of a particular conversation such as an interview or a debate will be a combination of simpler conversational goals in some temporal logic like Linear Temporal Logic (LTL) (Lamport, 1980), which includes the temporal operators  $\Diamond$  for *eventually* and  $\Box$  for *always*, as well as operators for the temporal relations *since* and *until*. A reporter, for example, might have the complex goal of eventually getting a satisfactory answer to each of her individual questions to her interlocutor, and the goal of getting an answer to a question  $Q$ , as we have seen, typically has the general form: until an answer to  $Q$  is produced, show that no answer to  $Q$  has been given and then repeat  $Q$ . A more complex goal, which might be adopted by a participant in a political debate, is to reply to every attack on her and to land more attacks on her opponent than he lands on her. This goal is not expressible in LTL, but is in the framework we develop below.<sup>3</sup> Asher et al. (2016) provide many examples of such goals and show how these goals may differ in complexity. They also show how to link goals to strategies for achieving them.

Games provide natural structures within which to investigate the success of sequences of linguistic actions. Game theory evaluates actions in terms of utility, and the simple Boolean case of winning conditions we have alluded to above is an instance of a utility function. Signalling games (Lewis, 1969; Spence, 1973), which have been very popular in linguistics, are not appropriate for the task, however. Signalling games are designed to tackle a different aspect of language, namely, the coordination on linguistic content in reflective equilibrium (see Lewis's account of the emergence of linguistic conventions). By contrast, we are interested in evaluations of conversational success, even—and especially—in cases where interests of the conversationalists are opposed. In such cases the meanings of messages in the context of sig-

<sup>2</sup>'Pence pressed on clearance for Flynn's son,' *The Lead*. The full exchange can be viewed here: <http://edition.cnn.com/videos/politics/2016/12/06/mike-pence-trump-flynn-jr-transition-lead-bts.cnn>

<sup>3</sup>See Asher et al. (2016) for details.

nalling games is problematic to say the least; Crawford and Sobel (1982) show that in cases of opposing interests messages cease to have content in reflective equilibrium.

Our game theoretic model is different from signalling games in several respects. For one, we will take messages to have an exogenously given meaning that determines how one conversationalist responds to the messages of another. This allows us to avoid the problems of message interpretation in signaling games where the interests of the players are opposed. Another way in which our model differs from signaling games is that while signaling games are typically “one shot”, a good model of conversational goals, as suggested in the examples above and argued in detail in Asher et al. (2016), should require agents to strategize about conversations as open-ended sequences of moves with no set end. In the exchange between Jake Tapper and Mike Pence, described above, Tapper had the goal of eventually getting an answer to his question about Michael Flynn Jr., and he didn’t stop his line of questioning until he got at least an implied answer; he had to be prepared for an open-ended set of moves by Pence designed to avoid the question. In general, conversational agents must plan for any number of moves by their opponents to try to frustrate or to prevent them from achieving their goals. In fact, we can put no *a priori* upper bound on the number of moves that accomplishing this goal might require, and thus a game theoretic framework for conversation must countenance a potentially infinite sequence of exchanges of messages between conversational participants.

To model these aspects of strategic conversations, Asher et al. (2016) developed a game theoretic framework of *Message Exchange* or ME games. The intuitive idea behind an ME game is that a conversation is a sequence, either finite or infinite, of turns. In each turn, one of the players ‘speaks’ or plays a sequence of moves, and each sequence of moves itself describes a discourse structure in the sense of SDRT (*Segmented Discourse Representation Theory*; Asher and Lascarides, 2003) that extends the discourse structure built up from previous turns. More precisely, the vocabulary  $V$  of an ME game contains a set of discourse unit labels  $DU = \{\pi, \pi_0, \pi_1, \dots\}$ , a set of formulas from a language for dynamic semantics that serve to describe the contents of the basic units (where ‘ $\pi: \phi$ ’ means that the formula  $\phi$  describes the contents of the discourse unit  $\pi$ ), and a set of discourse relation symbols  $\mathcal{R}$  relating discourse constituents from the different moves made so far in the game.

Turns in ME games are relativized to players. In the case of conversations, it is essential to keep track of “who says what”; Tapper saying that Pence had knowledge of Flynn Jr.’s past is not the same as Pence himself admitting to having had this knowledge. To model this, each player  $i$  is assigned a copy  $V_i$  of the vocabulary  $V$  of SDRT moves, which is simply given as  $V_i = V \times \{i\}$ . Thus when Player  $i$  plays  $u \in V$ , it is noted as  $(u, i)$ . Conversations correspond to plays of ME games which are finite or infinite sequences over  $(V_0 \cup V_1)$ , noted as  $(V_0 \cup V_1)^\infty$ , for a game with two players, 0 and 1 (for details see Asher et al., 2016; Asher and Paul, 2017).

Given that we have defined a conversation as a sequence or element of  $(V_0 \cup V_1)^\infty$ , a conversational goal will be a subset of  $(V_0 \cup V_1)^\infty$ . But who determines what the goals are in a given conversation? That is, who determines which subsets of  $(V_0 \cup V_1)^\infty$  represent success? Speakers presumably have their internal goals, but it is not necessarily those that determine

conversational success. Each person who is involved in or who witnesses a conversation has her own ideas about what the winning conditions of the participants are or should be.

To this end, Asher et al. (2016) introduced a crucial component for analyzing conversations that they called the *Jury*. The Jury determines the conversational goals of the participants. The Jury is itself an abstract decision rule determining winning conditions, but it can be instantiated with the conversationalists themselves, or with a third party that evaluates the conversation. In strategic settings, taking conversational partners as evaluators can lead to trouble, as each will be tempted to declare him- or herself the winner. In many settings such as political debates, the natural Jury to consider is the actual audience, some segment of the population who witnessed the debate or the whole set of participants, or yet some other body like the editorial board of a newspaper.

Asher et al. (2016) consider only an impartial Jury, who also enforces constraints like the consistency of a player's contributions or the constraint that a player respond to questions or other moves of the other players. For most conversations, however, there will be many Juries. These Juries may disagree with each other about winning conditions, and some may have a very biased take on a conversation. Nevertheless, given what we have said so far, we will need to evaluate conversational success relative to a particular Jury. Accordingly, ME games pair the space of possible conversations  $(V_0 \cup V_1)^\infty$  with a Jury  $\mathcal{J}$ .

Evaluating conversational success is to a certain extent a subjective or relative matter, since it depends on the conversational goals assigned to players by the Jury. Different juries may disagree as to what the conversational goals should be, and a group of people or even a single person may be undecided as to what sort of Jury she is. Still, once a goal is set as a subset of  $(V_0 \cup V_1)^\infty$ , it is an objective matter as to whether the conversation meets this goal or does not; either the conversational play is an element of the subset designating a conversationalist's winning condition or it is not.

A final point concerns the evaluation of conversational success. When does a Jury decide a conversationalist has met the winning condition assigned to her? While for Asher et al. (2016) a Jury must survey an entire conversational string and all its continuations, which may be infinite, Asher and Paul (2016) argue that this misses the fact that an actual Jury evaluates in a dynamic fashion, after each turn by one of the conversational participants. The idea is to represent a winning condition by a scoring function over players' conversational turns. A turn can be rated more or less good with respect to the winning conditions the Jury has in mind, or more or less disastrous. If the Jury has a scoring function with a discounting parameter that lowers the score for turns later in the conversation, it will always being able to confidently pick a winner in a 0 sum game within a finite amount of time. Asher and Paul (2016) illustrate how such a scoring function works on a snippet from one of the debates between candidates for the Republican Presidential candidate of 2016.

So what is the import of ME games for linguistics? The field of pragmatics has always been concerned with the use of language, and ME games yield a formal pragmatic framework that provides principled reasons for why and how we use language to attain conversational goals.

Harkening back to the concerns of traditional rhetoricians, our account answers the question: what is a reasonable scoring function and how should a conversationalist attempt to maximize her score? To answer this question, the framework of ME games replaces semantic evaluation in terms of truth at a world with pragmatic evaluation in terms of conversational success relative to a Jury. The underlying structure of game theory also generates a notion of logical consequence for conversational success, a very rough approximation of which would be LTL's notion of consequence, which works for simple goals, though the nature of the full consequence relation is as far we know unexplored. Finally, the framework predicts whether there is a winning conversational strategy for a given goal and what it would look like in linguistic terms.

### 3. The subjectivity of interpretation

In this section, we explore the nature of a Jury's scoring functions, and in particular how subjectivity and bias naturally influence them. One of the astounding facts about conversations is that people who participate in or merely observe them can come away with dramatically different interpretations of what was said, even though not everything goes. Different Juries can disagree about what was said, what was implied, and about who was successful. Consider, for instance, the one-line retort by Presidential candidate Trump to Presidential candidate Clinton during the third US Presidential debate in 2016:

- (2) Such a nasty woman.

The literal meaning and the conventional implicatures of this remark in context are clear; with (2), Trump committed himself to a negative assessment of Clinton. However, people perceived the role of (2) in achieving an agent's conversational goals very differently. One Jury, an appreciable segment of the American population, found this remark totally out of place in a Presidential debate. Another one, Trump's base, found the comment appropriate and would have assigned it a high score. Each of these interpretations depends on how the Jury assigns winning conditions to the players, which includes constraints under which, the Jury judges, conversations should be conducted.

Bias and subjective beliefs will also influence the way that a Jury interprets the very structure of a discourse. Consider the following excerpt, discussed at length in Asher et al. (2016), from a press conference by Senator Coleman's spokesman Sheehan. Senator Coleman was running for re-election as a US senator from Minnesota in the 2008 election.

- (3) a. **Reporter:** On a different subject is there a reason that the Senator won't say whether or not someone else bought some suits for him?  
 b. **Sheehan:** Rachel, the Senator has reported every gift he has ever received.  
 c. **Reporter:** That wasn't my question, Cullen.  
 d. **Sheehan:** (i) The Senator has reported every gift he has ever received. (ii) We are not going to respond to unnamed sources on a blog.  
 e. **Reporter:** (i) So Senator Coleman's friend has not bought these suits for him? (ii) Is that correct?  
 f. **Sheehan:** The Senator has reported every gift he has ever received.

Sheehan continues to repeat, *The Senator has reported every gift he has ever received* seven more times in two minutes to every follow up question by the reporter corps.<sup>4</sup>

While many of the contributions by Sheehan and the reporter corps have a clear and uncontroversial meaning and discourse function, some contributions are open to interpretation. For instance, how are we to interpret the response  $\alpha$  by Sheehan in (3b), (3d.i), and (3f)? ME games provide an insightful answer. To formulate the above exchange as an ME game, we first fix the players and the Jury. We can assume that there are two active players: the reporter corps (R) and spokesman Sheehan (S). We will also consider two Juries, each of which interprets the exchange differently. The first, Jury 1, starts out with a presumption of full disclosure and honesty from S; Jury 2 is a biased Jury that is disposed to believe whatever the spokesman says, because, for example, Jury 2 and S are from the same political party. We'll see below that Juries 1 and 2 will arrive at different interpretations of the structure and content of (3), and in particular, of S's repeated response.

To model the subjectivity of conversational interpretation, we must clarify what elements of a discourse structure are influenced by subjective interpretation. Asher et al. (2016) and Asher and Paul (2016) assume no ambiguity in the discourse moves made by players in an ME game (though for a look at a prior treatment of ambiguity in the ME setting, see Venant and Asher, 2015). However, at least at a first pass and assuming a perfect communication channel, it is the ambiguous moves that are up for interpretation, so we will need to countenance some ambiguity. At the same time, not everything is up for interpretation—an emphatic *no* to a polar question doesn't mean *yes*.

We will assume that the grammar, including syntax and lexical and compositional semantics, delivers an unambiguous core or, following Asher and Lascarides (2003), an *underspecified logical form* (ULF) for a discourse. We will also distinguish between *plays*, the objective components of discourse moves that are uncontroversially part of the speakers' public commitments, and *histories*. A play in our ME games is a ULF, and given our assumption about exogenously given meaning, we will assume this ULF and its interpretation are common knowledge of the players and the Jury. Of course, a ULF typically involves underspecified elements (whose semantics we can specify via existential quantifications over variables standing for the elements that require specification) that are specified via reasoning that depends on a variety of subjective sources. For (3), the observed play, call it play  $\rho$ , is a representation for (a-f), in which each contribution has its normal compositional semantics and some of the uncontroversial discourse connections, like the fact that (c) corrects the discourse connection between (a) and (b), are made explicit. Other relations are left underspecified, including the relation between (a) and (b), (c) and (d.i), and (e) and (f).

(4) provides the ULF for (3), where each  $\pi_n$  labels an SDRT formula,  $Sel_{\mathbb{R}}$  is a selection function over discourse relations that signals the presence of underspecified relations, and  $Sel_{\Pi}$  is a selection function over discourse units that marks the presence of underspecified arguments.

<sup>4</sup>See <http://www.youtube.com/watch?v=VySnpLoaUrI>.

- (4)  $\pi_2 : (\pi_0 : 3a \wedge \pi_1 : 3b \wedge \text{Sel}_{\mathbb{R}}(\pi_0, \pi_1)) \wedge \pi_3 : 3c \wedge \text{Correction}(\pi_2, \pi_3) \wedge$   
 $\pi_7 : (\pi_6 : (\pi_4 : 3d.i \wedge \pi_5 : 3d.ii \wedge \text{Explanation}(\pi_4, \pi_5)) \wedge \text{Sel}_{\mathbb{R}}(\text{Sel}_{\Pi}, \pi_6)) \wedge$   
 $\pi_{10} : (\pi_8 : 3e.i \wedge \pi_9 : 3e.ii \wedge \text{Confirm-Question}(\pi_8, \pi_9)) \wedge \text{Result}(\text{Sel}_{\Pi}, \pi_{10}) \wedge$   
 $\pi_{11} : 3f \wedge \text{Sel}_{\mathbb{R}}(\text{Sel}_{\Pi}, \pi_{11})$

Here is a gloss of the ULF (4).  $\pi_1$  is a *complex* discourse unit (CDU) that groups together  $\pi_0$  and  $\pi_1$ , which are related via some underspecified relation,  $\mathcal{R}_1$ , which is the target of the correction in  $\pi_3$ . In SDRT, when a correction targets a relation instance, the Correction must take scope over a CDU containing that relation instance. It is also uncontroversial that Explanation holds between  $\pi_4$  and  $\pi_5$  and that a Confirmation-Question relation holds between  $\pi_8$  and  $\pi_9$ . On the other hand it is unclear how to connect the CDU  $\pi_6$  or the unit  $\pi_{11}$  to the preceding context.<sup>5</sup> The explicit discourse connector *So* signals a result between  $\pi_6$ ,  $\pi_{10}$  or some other discourse unit and the CDU  $\pi_{10}$ . However, the left argument of this relation and those of the two underspecified relations are themselves underspecified which we note using the function  $\text{Sel}_{\Pi}$ .

But (4) only represents one possible play in an ME game tree. There could be many more branches. Figure 1 below depicts how (4) and alternative plays branching out from it would form an ME game tree. The relation instances with underspecified arguments are drawn in red.

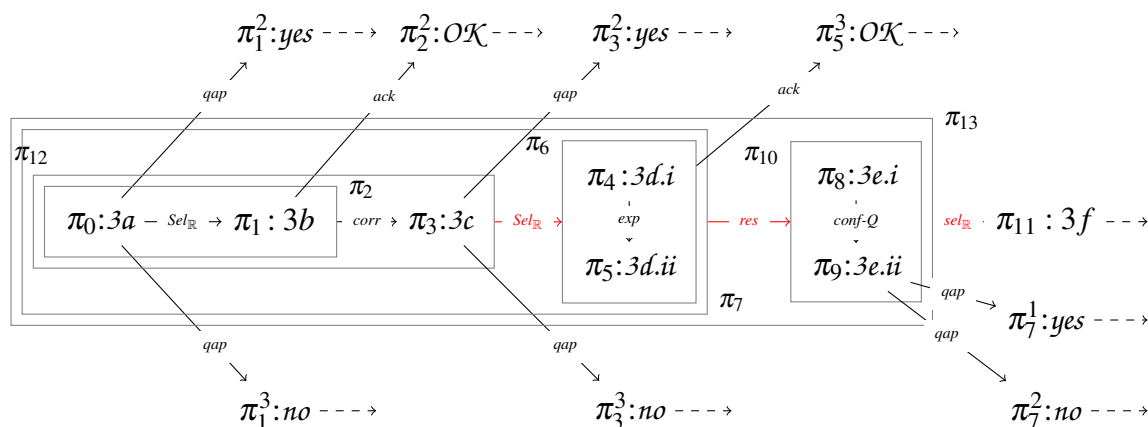

Figure 1: A game tree of plays for (3)

A *history* is a completed SDRS that fills in the underspecified elements of a ULF and thereby serves as an interpretation of a given play. (5) and (6) fill out two histories,  $h_1$  and  $h_2$ , for the observed play  $\rho$  and ULF of (4). IQAP stands for Indirect Question-Answer-Pair.

- (5)  $\pi_{12} : (\pi_2 : (\pi_0 : 3a \wedge \pi_1 : 3b \wedge \text{Background}(\pi_0, \pi_1)) \wedge \pi_3 : 3c \wedge \text{Correction}(\pi_2, \pi_3)) \wedge$   
 $\pi_{13} : (\pi_7 : (\pi_6 : (\pi_4 : 3d.i \wedge \pi_5 : 3d.ii \wedge \text{Explanation}(\pi_4, \pi_5)) \wedge \text{Correction}(\pi_{12}, \pi_6)) \wedge$   
 $\pi_{10} : (\pi_8 : 3e.i \wedge \pi_9 : 3e.ii \wedge \text{Conf-Q}(\pi_8, \pi_9)) \wedge \text{Res}(\pi_7, \pi_{10})) \wedge \pi_{11} : 3f \wedge \text{Backgr}(\pi_{13}, \pi_{11})$

<sup>5</sup>In fact, it is unclear whether the CDU  $\pi_6$  even exists or whether  $\pi_4$  alone will relate to the preceding context. We have assumed a CDU for simplicity.

- (6)  $\pi_{12} : (\pi_2 : (\pi_0 : 3a \wedge \pi_1 : 3b \wedge IQAP(\pi_0, \pi_1)) \wedge \pi_3 : 3c \wedge Correction(\pi_2, \pi_3)) \wedge$   
 $\pi_{13} : (\pi_7 : (\pi_6 : (\pi_4 : 3d.i \wedge \pi_5 : 3d.ii \wedge Explanation(\pi_4, \pi_5)) \wedge Correction(\pi_{12}, \pi_6)) \wedge$   
 $\pi_{10} : (\pi_8 : 3e.i \wedge \pi_9 : 3e.ii \wedge Conf-Q(\pi_8, \pi_9)) \wedge Res(\pi_7, \pi_{10})) \wedge \pi_{11} : 3f \wedge Correct(\pi_{13}, \pi_{11})$

To analyze how histories develop from plays, we use the tools of epistemic game theory. We present a detailed, formal development in Asher and Paul (2017), but sketch the essentials and the linguistic consequences here. In moving from ME games to *epistemic* ME games, we exploit the notion of a *type*, a fundamental tool in epistemic game theory that Harsanyi (1967) used to represent information that players have about each other. In particular, we add to an ME game  $\mathcal{G} = ((V_0 \cup V_1)^\infty, \mathcal{J})$ , a set of types for the players 0 and 1 and for the Jury  $\mathcal{J}$ . To model the beliefs of an individual  $i$ , which may be a player or the Jury, we also add a function  $\beta$  from a pair of a play  $\rho$ , where  $\rho \in (V_0 \cup V_1)^\infty$ , and type  $t$  for  $i$  to a probability distribution over types for the other players, types for the Jury, and possible histories (complete SDRSs) given  $\rho$ . As the conversation evolves, players will update their beliefs about the history of the conversation and the type of the other players using Bayesian conditionalization over new conversational events they observe (Stalnaker, 2009).

Returning to Example (3), there are two types relevant for interpreting S: the *dishonest* type,  $t_D$ , according to which S is trying to cover up the fact that Coleman received the suits but did not declare them, and the *honest* type,  $t_H$ , according to which S truly implicates that the Senator did not receive the suits and simply does not want to respond to this charge based on an uncertain source (see (d.ii)). To illustrate how types affect interpretation, we will take the Jury to assign victory conditions in terms of two types: R wins if S's conversational contributions confirm he is of type  $t_D$ ; S wins if his contributions confirm he is of type  $t_H$ . The Jury updates its beliefs about the types of the players as the players make new moves. We now break down the two cases,  $t_D$  and  $t_H$ , in more detail.

**Case 1:** Before the start of the press-conference, in the absence of other information, Jury 1's type  $t$  is indifferent with respect to S's honesty. That is, the Jury starts with a prior assigning equal probability to  $t_H$  and  $t_D$ .

Let  $\alpha$  be the ULF for (3b). When the Jury updates with the unexpected  $\alpha$  as a response to (3a), they are genuinely puzzled by the response. While it's natural to assume that an honest senator has reported every gift he has received, the inference from  $\alpha$  to an answer to (3a) (why won't the Senator say who bought the suits?) is complicated and indirect. A Jury must consider the interpretation of (3a) and (3b) conditional on both  $t_D$  and  $t_H$ . Conditionalizing on  $\alpha$  and the assumption that S is of type  $t_D$ , the Jury, like R, assigns a high probability to the interpretation illustrated in  $h_1$ , that (3b) does not answer (3a) and is rather related to it via Background. Conditionalizing on  $\alpha$  and the assumption  $t_H$  confers only a slightly higher probability to an IQAP relation than a Background relation between (3a) and (3b). When we combine the probabilities over  $t_D$  and  $t_H$ —because Jury 1 is considering both—we therefore get a higher probability for  $\neg IQAP$  than for IQAP, leading to higher probability of  $h_1$ . Conditionalizing in turn on these relative values, the Jury naturally interprets R's response in (3c) as a Correction of S's move in (3b) under the interpretation of (3b) as implicating an answer and therefore satisfying R's request for a direct answer in (3a). In (3d.i), however, S corrects R's Correction, reiterating

his original response, and explains why he does so in (3d.ii): the Senator and his staff do not want to comment on unnamed sources on some blog. This would seem to follow whether we conditionalize on  $t_H$  or  $t_D$ .

The upshot of Sheehan's correction should be that (3b) *is* in fact related to (3a) via IQAP. R then picks up on this conclusion and asks a Confirmation Question to confirm that this is indeed the case. We show this by linking (3e) to the graph built up from (3a)-(3d) with Result in both  $h_1$  and  $h_2$ . At this point we could imagine that for our Jury  $\mathcal{J}$ ,  $\text{prob}_{\mathcal{J}}(t_H)$  is once again equal to  $\text{prob}_{\mathcal{J}}(t_D)$  and  $h_1$  and  $h_2$  are equally likely. But now things go downhill for Sheehan in the eyes of Jury 1. Sheehan in effect refuses to engage with R or confirm the implied result in (3e) by repeating  $\alpha$  to every follow up question, Q, on the topic.

Call the exchange in (3a) and (3b) 'round 1' and that in (3c) and (3d) 'round 2'. We now examine how S's responses after round 2 affect the Jury's estimate of his type and its interpretation of what he says. Although S repeats  $\alpha$  10 more times in the press conference from which our excerpt (3) is drawn, for simplicity of this analysis, we shall consider only rounds 3 through 5, for which S has three possible responses to each Q: *yes*, which is short for *Yes, the Senator has received gifts from his friend*; *no* which is short for *No, the Senator has never received gifts from his friend*; and  $\alpha$ . The possible continuations for Sheehan that are relevant for the three rounds where R repeatedly poses different forms of Q are presented below in tabular form:

	round 3	round 4	round 5
$\sigma_1$	<i>yes</i>	—	—
$\sigma_2$	<i>no</i>	—	—
$\sigma_3$	$\alpha$	<i>yes</i>	—
$\sigma_4$	$\alpha$	<i>no</i>	—
$\sigma_5$	$\alpha$	$\alpha$	<i>yes</i>
$\sigma_6$	$\alpha$	$\alpha$	<i>no</i>
$\sigma_7$	$\alpha$	$\alpha$	$\alpha$

Let  $\mathbb{S} = \{\sigma_1, \sigma_2, \dots, \sigma_7\}$ .  $\mathbb{S}$  represents the relevant possible set of plays, over which the Jury has a probability distribution.  $\sigma_7$  is the actual case in which S responds with  $\alpha$  to all instances of Q. An honest senator would have his spokesperson Sheehan respond with a *no* to the reporter's question eventually. To give a precise model for what happens following Asher and Paul (2017), we need some numbers. The belief function for Jury 1 assigns the following probabilities to the sequences of moves  $\sigma_n$  relative to the types  $t_H$  and  $t_D$ .

	$\sigma_1$	$\sigma_2$	$\sigma_3$	$\sigma_4$	$\sigma_5$	$\sigma_6$	$\sigma_7$
$t_H$	0	0.167	0	0.167	0	0.166	0
$t_D$	0.125	0	0.125	0	0.125	0	0.125

Notice that at the outset, the Jury accords an equal probability to  $t_H$  and  $t_D$ ; the values on the rows above each sum up to .5.

We can now calculate how conversational moves can affect the Jury's assessment of S's type. In particular, we want to look at two "events",  $E_H$  and  $E_D$ , representing an honest senator vs. a dishonest senator and defined as follows:

$$E_H = \{t_H\} \times \mathbb{S}, \quad E_D = \{t_D\} \times \mathbb{S}$$

Now let's take a belief function  $\beta$  over the empty play or ULF  $\varepsilon$  as our starting point to model the beliefs of the Jury 1, which is of some type  $t_1$ , at the start of the press-conference.

$$\beta[\varepsilon](t_1)(E_H) = \beta[\varepsilon](t_1)(E_D) = 0.5$$

The Jury is thus equally unsure as to whether S is honest or dishonest. Recall that the Jury reverts to this distribution after round 2.

Let  $\rho_1 = \langle Q \rangle \langle \alpha \rangle$  be the play after round 2, i.e., after (3d). The strategies that are compatible with  $\rho_1$  are  $\mathbb{S}_1 = \{\sigma_3, \sigma_4, \sigma_5, \sigma_6, \sigma_7\}$ . Hence, we can define the events

$$E_H(\rho_1) = \{t_H\} \times \mathbb{S}_1, \quad E_D(\rho_1) = \{t_D\} \times \mathbb{S}_1, \quad E(\rho_1) = E_H(\rho_1) \cup E_D(\rho_1)$$

Now,

$$\beta[\varepsilon](t_1)(E(\rho_1)) = 0.708$$

Let  $j \in \{4, 6\}$ . Then we have, conditionalizing on the new event  $E(\rho_1)$ :

$$\beta[\rho_1](t_1)(\langle t_H, \sigma_j \rangle) = \beta[\varepsilon](t_1)(\langle t_H, \sigma_j \rangle \mid E(\rho_1)) = 0.167/0.708 = 0.238$$

and for  $k \in \{3, 5, 7\}$

$$\beta[\rho_1](t_1)(\langle t_D, \sigma_k \rangle) = \beta[\varepsilon](t_1)(\langle t_D, \sigma_k \rangle \mid E(\rho_1)) = 0.125/0.708 = 0.175$$

Thus after round 3, the belief function of the Jury in Case 1, after Bayesian updates, can be represented in the following tabular form.

	$\sigma_3$	$\sigma_4$	$\sigma_5$	$\sigma_6$	$\sigma_7$
$t_H$	0	0.238	0	0.238	0
$t_D$	0.175	0	0.175	0	0.175

and we have  $\beta[\rho_1](t_1)(E_H(\rho_1)) = 0.476$  and  $\beta[\rho_1](t_1)(E_D(\rho_1)) = 0.525$

Next, let  $\rho_2 = \langle Q \rangle \langle \alpha \rangle \langle Q \rangle \langle \alpha \rangle$  be the play after round 3, i.e., after (3f). The strategies that are compatible with  $\rho_2$  are  $\mathbb{S}_2 = \{\sigma_5, \sigma_6, \sigma_7\}$ . As before, we can define the events

$$E_H(\rho_2) = \{t_H\} \times \mathbb{S}_2, \quad E_D(\rho_2) = \{t_D\} \times \mathbb{S}_2, \quad E(\rho_2) = E_H(\rho_2) \cup E_D(\rho_2)$$

and hence

$$\beta[\varepsilon](t_1)(E(\rho_2)) = 0.587$$

We have, as before

$$\beta[\rho_2](t_1)(\langle t_H, \sigma_6 \rangle) = \beta[\varepsilon](t_1)(\langle t_H, \sigma_6 \rangle \mid E(\rho_2)) = 0.238/0.587 = 0.404$$

and for  $j \in \{5, 7\}$

$$\beta[\rho_2](t_1)(\langle t_D, \sigma_k \rangle) = \beta[\varepsilon](t_1)(\langle t_D, \sigma_j \rangle \mid E(\rho_2)) = 0.175/0.587 = 0.298$$

Thus,  $\beta[\rho_2](t_1)(E_H(\rho_2)) = 0.404$  and  $\beta[\rho_2](t_1)(E_D(\rho_2)) = 0.596$ . So after round 2, after Bayesian updates, the Jury believes even more that S has type  $t_D$

The beliefs of the Jury about the type of S (and of the Senator) after each round of the conversation can be represented pictorially as follows.

Figure 3

Given these calculations, we can imagine that such a Jury might then stop the conversation once the probability of  $t_D$  becomes high enough. For such a Jury, Sheehan's repetitions doom his play to be losing.

A key feature of our analysis is that the Jury's estimation of S's type also affects its *interpretation* of the conversation. The Jury's beliefs about the interpretation of what S says evolve as the Jury conditionalizes on events that are a combination of a new element of play as given in  $S$  and an assignment of types. The *yes* and *no* responses in the continuations to (3) would have an unambiguous interpretation as answers to the preceding occurrence of  $Q$ . The response  $\alpha$ , however, is more problematic; what exactly is the role of  $\alpha$  as a response to (3a)? And while  $\alpha$  has a natural interpretation in (3d.i) as a Correction, subsequent repetitions of  $\alpha$  are even less clear than its use in (3b). Consider, for instance, S's assertion of  $\alpha$  as a response to R's question (3e), an affirmative answer to which should be a consequence, were  $\alpha$  an indirect answer to (3a). While this and further instances of  $\alpha$  could be attached with Background or Correction or with no specified relation at all, the probabilities of these histories given a play are vastly different depending on the type assignments.

To make things more concrete, let's focus just on the two histories we've considered in (5) and (6). Given Jury 1's belief function, repeating  $\alpha$  to each variant of  $Q$  lowers the probability of  $t_H$ . But what does conditionalization do to the probabilities of  $h_1$  and  $h_2$ ? One plausible hypothesis is that the probability of  $h_1$  covaries with the probability of  $t_H$ . Conditionalizing on events of the form  $E_D(\rho_i)$  and  $E_H(\rho_i)$  thus lowers the probability that repetitions of  $\alpha$  after

(3d.i) are Correction moves that provide answers to Q and raises the possibility that they are uncooperative moves unconnected with R's questions. An honest Sheehan for this Jury would not have continued to make the  $\alpha$  move as a Correction without further explanation. Once S continues to play  $\alpha$ , the probability mass shifts more and more to the interpretation of  $\alpha$  as a non-cooperative move.

In turn, conditionalization on the event of the interpretation  $h_1$  entrenches the Jury's belief that Sheehan is of type  $t_D$ . Thus, histories and types have an important co-dependence. A person's interpretation of a conversation can reinforce or change her beliefs about the players and or the Jury, which in turn may confirm or change how she shapes the history of the conversation.

**Case 2:** An alternative Jury, which is strongly predisposed to assign Sheehan  $t_H$  would have seen matters differently. Consider the following belief function for this Jury, in which the Jury already has a prior probability of .7 in  $t_H$ .

	$\sigma_1$	$\sigma_2$	$\sigma_3$	$\sigma_4$	$\sigma_5$	$\sigma_6$	$\sigma_7$
$t_H$	0	0	0	0.05	0	0.15	0.5
$t_D$	0.10	0	0.10	0	0.10	0	0

Such a Jury would have already accepted  $\alpha$  as a perfectly acceptable indirect answer to (3a) and so opted for the history  $h_2$  for (3). It would also have constructed a different history for the rest of the conversation after (e). It would see each repetition of  $\alpha$  as another correction of R's attempts to reopen a topic that Sheehan has already settled. Since S is of type  $t_H$ , he need not continue the discussion of a matter that has already been labelled as one that Sheehan will not comment on. Given this interpretation of the repetitions of  $\alpha$ , the probability of  $t_H$  on the belief function for this Jury would remain high when the Jury conditionalizes upon that interpretation, and S has a winning strategy. See Figure 4 below.

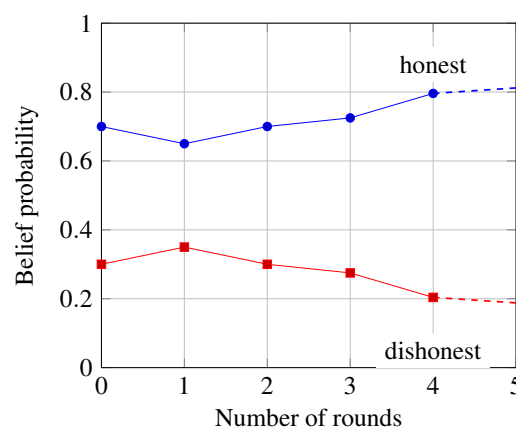

Figure 4

Given the continued high probability of  $t_H$ , conditionalizing on events of the form  $\{t_H\} \times \mathbb{S}$  in turn assigns a high probability and confirms the continuation of history  $h_2$  in which S continues to correct R. Jury 2 conditionalizes on events like those defined in our analysis of Jury 1 but

arrives at a very different conclusion;  $\alpha$  is not interpreted as a non-cooperative move but as a Correction, and the updating of probabilities on types and on histories confirm each other.

The co-dependence between an interpreter's assessment of a speaker's type and his interpretation of what she says has several interesting consequences. The first is that *a priori* biases are easy in general to strengthen through interpretation. Furthermore, we have seen that bias is dependent on context. Hence, the model predicts that the more biased talk to which the Jury is exposed, the more it will carry this bias into the interpretation of future conversations. The moral is that interpretation is subject to manipulation. Although we have assumed that few components of discourse moves are ambiguous, our example illustrates that discourse connections, which are often ambiguous, can lead different Juries to very different conclusions.

This subjectivity goes even beyond language to the interpretation of "facts." Hunter et al. (2017) argue that interpreting non-linguistic events has significant parallels to interpreting conversation and that the two interact to produce a complete picture of a situation. If we couple this view with what we have developed here, our model implies that the interpretation of facts also naturally gives rise to a subjective bias. Figuring out the truth from a collection of facts described to suit someone's purposes is difficult.

The counterpart to this is that being a fair or impartial Jury, being open to other interpretations is not a natural outcome of conversational interaction. The model predicts that constraints exogenous to the natural way speakers interpret conversation and interpretation are needed to lead to an impartial assessment of conversational moves. So how do we ensure fair or unbiased interpretation for the Jury, or anyone else for that matter? This question links our question of assessment of conversational success with the present concern about the subjectivity of interpretation. One important parameter to fix are the types evoked to drive interpretation, as well as the probability distribution over them. In the model of Asher and Paul (2017), the types are simply abstract objects, devices for encoding probabilities about discourse histories and, indirectly, strategies. As such, the set of types is vast and uncountable. Yet typically, only certain types are relevant to interpretation. How do we determine an appropriate restricted set? Doing this also involves bias. To take an extreme case, if we only picked one type in our interpretation of (3), all the probability mass would align on that one type; conditionalization on new evidence would yield nothing new. A Jury considering just the one type would perforce be biased in the extreme and its views impervious to change.

A balanced or fair interpretation would thus need at least two types that are in an intuitive sense contraries of each other, as we have done in our treatment of (3). Moreover, one would need to start out with a balanced distribution over these types or at least be aware of the problems of bias coming from prior interactions. Nevertheless, we strongly suspect that having only two types is in general far from sufficient to arrive at the correct interpretations of conversational moves, and indeed, of the world around us.

#### 4. Analyzing different types of content

A final illustration of the relevance of epistemic games to linguistics comes from the way speakers use *not at-issue* (NAI) information (Potts, 2005). Consider the following dialogue excerpt from the movie *The Princess Bride*, in which Wesley (W) has kidnapped Buttercup (B) and is questioning her about her fiancée Prince Humperdink (H). Buttercup and Wesley were once in love, but Wesley has disguised himself as a pirate, so Buttercup does not recognize him. They have just noticed their pursuers: Humperdink and his men.

- (7) a. **B:** He (Humperdink) can find a falcon on a cloudy day, he can find you!  
 b. **W:** So you think your dearest love will save you?  
 c. **B:** I never said he was my dearest love and yes, he will save me. That I know.  
 d. **W:** You admit to me that you do not love your fiancé?  
 e. **B:** He knows I do not love him.

As a background to (7), it is clear from the context that Wesley's goal is to determine Buttercup's feelings for Humperdink while concealing his identity. Concealing his identity is important because Buttercup would have good reason to hide her love for Humperdink from Wesley.

Wesley uses a presupposition in (7b), a form that conveys NAI content, to try to discern whether Buttercup loves Humperdink. As many linguists have noted, NAI constructions do not admit of simple rejoinders; Buttercup cannot take issue with the presupposition that Humperdink is her dearest love with a simple 'no', 'I disagree', or 'that's not true'. Getting Buttercup to reveal her type in this situation involves a more complicated strategy than simply asking directly if she loves Humperdink. Why does Wesley choose such a strategy? Why does he pretend to play along with Buttercup's apparent conversational goal—to convince Wesley that he should let her go because he is going to be caught—when he isn't actually interested in it?

We believe epistemic ME games can help clarify matters, but first, we need some background assumptions. We follow Hunter and Asher (2016)'s discursive, SDRT analysis of NAI content according to which NAI content results from the way that an utterance contributes to a hierarchical discourse structure. At any given point in a discourse, certain discourse moves will be more salient and easier to build off of than others. The set of salient discourse units, referred to as *The Right Frontier* in various discourse theories, will evolve as a discourse proceeds in a way that is subject to general discursive principles. Hunter and Asher's central claim is that utterances that involve multiple discourse units, which they argue must be the case when an utterance contains both NAI and AI content, have their own internal discursive structure, and the same general discursive principles that determine whether other discourse units are on the Right Frontier or not also determine which parts of a multi-part utterance are on the Right Frontier and therefore salient. Speakers exploit these principles to make certain parts of their utterances easier to build off of than others. Those parts that are on the Right Frontier will be at-issue (so long as they are on the RF); those that are not will be NAI. In SDRT, presupposed content is attached to a position off the Right Frontier (Asher and Lascarides, 1998); the presupposition of (7b) is therefore NAI, as desired. With Buttercup's correction in (7c) and Wesley's subsequent

follow-up in (7d), however, the discourse shifts seamlessly to one in which the presupposed content is placed back on the Right Frontier and thereby made at-issue.

With this background in place, let's look more closely at the discourse structure of (7) and its interaction with conversational goals. Suppose that Buttercup is of one of two types: either she loves H and is of type  $t_l$ , or she does not and is of type  $t_n$ . We will suppose that in either case, she is not interested in dissembling her type. Wesley's conversational goal can be formulated as getting Buttercup to reveal whether she is of type  $t_n$  or type  $t_l$  while concealing his type. We assume further that after (7a), Wesley has the option of using (7b) with the NAI device or asking the direct question DQ: *Do you love Humperdink?* In the context of (7a) and the more general pursuit by Humperdink and his men, DQ would blatantly shift the topic and naturally arouse suspicions: why would an unknown pirate care about Buttercup's affections for Humperdink? There is a high probability that Buttercup would fashion a conversational continuation—e.g., *why should YOU care about that?*—that would endanger Wesley's goal of concealing his identity. By opting for an NAI construction, Wesley makes *Buttercup* responsible for the shift in discourse topic, which is less likely to arouse suspicion.

The expected utility of DQ is thus lower than that of (7b) when it comes to achieving Wesley's goal of concealing his identity. This goal in turn serves the larger goal of determining Buttercup's type. Buttercup would have no obvious reason to hide her love for Humperdink from a total stranger, especially a stranger who knows that she is engaged to Humperdink. On the other hand, her old feelings for Wesley, whom she believes at this point to be dead, might give her reason to be less than forthcoming with him. Buttercup's rejection of the NAI content in (7b) is more significant, and therefore more useful for determining Buttercup's type, if she does not realize she is talking to Wesley. Thus the NAI device in (7b) has a higher expected utility for Wesley's primary goal as well.

Now suppose that Buttercup had been of type  $t_l$  and had not questioned the NAI content, responding only to the AI content with something like, *Yes, he will save me* (Sv). By conditionalizing on Sv, which entails Buttercup's acceptance and public commitment to the NAI content<sup>6</sup>, the probability that Buttercup is of type  $t_l$  is plausibly high. The NAI construction would be helpful in this case as well, because it would allow Wesley to cut his losses and infer that Buttercup's romantic allegiances had shifted, another way of obtaining his winning condition.

We have illustrated one example of a strategic use of NAI content, but there are many others (see Hunter and Asher, 2016). In each of these cases, NAI constructions are strategically useful when a speaker  $s_0$  has a conversational goal that he wishes to conceal. Our model predicts this strategic use of NAI devices if we make the reasonable assumption that a move by  $s_0$  to place a bit of content  $\phi$  on the Right Frontier as a topic for discussion raises the probability that  $s_0$  has a conversational goal of getting a commitment from his interlocutor,  $s_1$ , to  $\phi$  or  $\neg\phi$ . Someone wanting to conceal his desire to extract such a commitment will be better off placing  $\phi$  in an NAI position. In this case, he can still get the commitment he seeks: if  $s_1$  continues

<sup>6</sup>Wesley's use of a presupposition should not entail that Buttercup commits to its content, but once she opts to build on Wesley's structured discourse contribution, she commits herself to the whole of both its content and its structure. See Hunter and Asher (2016) for more details.

the conversation without disputing  $\phi$ ,  $s_1$  commits to the content of  $\phi$ . Conversely, if  $s_1$  does dispute  $\phi$ ,<sup>7</sup> then she may reveal information to  $s_0$  without  $s_0$  making  $\phi$  discourse salient.

We formalize the strategic use of NAI content in Proposition 1. Recall that  $\Diamond\phi$  is true on a conversational string just in case  $\phi$  is true at some stage in the conversation; let  $C_1\phi$  stand for ‘ $s_1$  commits to  $\phi$ ,’ and let ‘ $\models$ ’ stand for the satisfaction relation defined over the basic exogenous semantics for plays in  $(V_0 \cup V_1)^\infty$  (for details, see Asher et al., 2016). Let  $\rho_n$  for  $\rho \in (V_0 \cup V_1)^\infty$  be a prefix of length  $n$  of  $\rho$  and let  $\beta_1$  be the belief function for a fixed type of  $s_1$ . Let  $t_\phi$  be a type of  $s_0$  whose winning condition includes a move that commits  $s_1$  to  $\phi$ . Let  $\varepsilon$  be the empty play in  $(V_0 \cup V_1)^\infty$ .

**Proposition 1.** *Let  $G$  be an ME game with  $\text{Win}_0 \subseteq \{\rho \in (V_0 \cup V_1)^\infty : \rho \models \Diamond C_1\phi\} \cap \{\rho \in (V_0 \cup V_1)^\infty : \neg \exists n \beta_1[\rho_n](t_\phi) > \beta_1[\varepsilon](t_\phi)\}$ . Then if 0 has a winning strategy  $\sigma$  in  $G$ ,  $\sigma$  will include a use of an NAI device for conveying a question about  $\phi$  instead of an AI device for conveying  $\phi$ .*

Hunter and Asher (2016) argued that the NAI status of a bit of content  $\phi$  cannot be attributed to syntactic and semantic features of  $\phi$  alone; its status is ultimately determined by how  $\phi$  attaches to a larger discourse structure. Our discussion here makes a similar point about conversational goals: the nature of a goal cannot be recovered directly by considering the at-issue status of content in the discourse; its nature is ultimately determined by the larger discourse structure or history. In particular, we cannot assume that the difference between AI and NAI content is that AI content directly addresses a conversational goal while NAI content plays some secondary, supporting role relative to conversational goals, contra claims made in by Roberts (2012) and Simons et al. (2010) *inter alia*. If we consider only (7a)–(7c), then it is true that Wesley’s apparent conversational goal aligns with the AI content of his utterance in (7b); that is, it seems that he shares Buttercup’s goal to determine whether Humperdink will catch him. However, once we consider the longer string including not only (7d) and (7e), but also Wesley’s subsequent questioning of Buttercup, then we understand that his actual goal is more accurately reflected by his NAI moves. Even if Buttercup is not immediately aware of this actual conversational goal, the audience of the film, acting as a Jury, can see this clearly.

## 5. Conclusions and future work

We have elaborated some consequences of using ME games for linguistic analysis, consequences that we think touch on important issues in pragmatics and semantics. We have shown how a notion of conversational success and a precise definition of conversational goals can affect the discourse structure of a dialogue. We have also shown how to add epistemic considerations to discourse interpretation, which has allowed us to formulate an analysis of the power and the limits of subjectivity in interpretation. We have further shown how the framework of epistemic ME games yields an analysis of bias, its ubiquity and its effects on interpretation. At the same time, we have argued that there are limits to bias; one cannot arbitrarily reinterpret unambiguous messages to mean something different from what they normally mean.

Another very important issue that we leave for future work concerns the notion of a fair or “unbiased” interpretation, something of interest not only to linguists but the general public at

<sup>7</sup>For an account of corrections, see Asher and Lascarides (2003).

large. While such a notion has an intuitive meaning, working out a precise analysis within a framework like epistemic ME games requires an analysis of the types relevant to such an interpretation. We also feel that fair interpretations are hard. Given that a fair interpretation is a conversational goal, our framework can actually tell us precisely how hard it is, but we do not know at present the complexity of such a goal nor even how to formulate it precisely.

Another application of epistemic ME games that we find linguistically interesting is their use in analyzing the strategic uses of vehicles of content that affect discourse salience or that introduce content without affecting salience. To this end, we have given a preliminary analysis of the strategic usefulness of not at-issue expressions of content. Future work will aim to improve this analysis with more case studies and a more careful taxonomy of expressions that affect discourse salience.

# Obligatory Additives in the Antecedent of Conditionals

Nadine BADE — *University of Tübingen*

**Abstract.** The paper investigates the obligatory insertion of additive particles in the antecedent of conditionals. Two theories are compared with regard to their different predictions regarding this insertion. One theory works with the principle *Maximize Presupposition* (Heim, 1991), the other postulates a relation between mandatory exhaustivity inferences and insertion of additive particles (Bade, 2016). The first theory predicts additives to be obligatory under downward entailing (DE) operators which are holes for presuppositions. The second theory predicts the insertion of additives to not be obligatory under DE-operators due to the fact that exhaustivity inferences are usually blocked in these environments for independent reasons (Chierchia et al., 2012). Previous studies already suggest that additives (and iteratives) are not obligatory under negation, contrary to the predictions of *Maximize Presupposition* (Bade and Tiemann, 2016). In the present paper, an experimental study on the insertion of German “auch” in antecedent of conditionals is reported which tests the predictions of both theories and further confirms an account of obligatory additivity working with *Obligatory Implicatures*.

**Keywords:** presuppositions, conditionals, implicatures.

## 1. Introduction

The paper investigates the obligatory insertion of additive particles in the antecedent of conditionals. Previous studies on obligatory presupposition triggers suggest that additive particles do not fall in the class of triggers whose obligatory insertion follows from the principle *Maximize Presupposition* (Bade, 2016). Rather, the data suggest that additives are inserted to block or cancel exhaustivity implicatures. One important prediction of *Maximize Presupposition* is that presupposition triggers are obligatory in contexts which are holes for presuppositions, such as under negation and in the antecedent of conditionals. It has been shown that additives are not obligatory under negation (Bade and Tiemann, 2016). This is straightforwardly explained under an account working with *Obligatory Implicatures*. Since exhaustification is blocked under negation for independent reasons, insertion of the trigger is unnecessary. The study presented here tested the predictions of *Maximize Presupposition* and the competing theory *Obligatory Implicatures* for the insertion of additives in antecedents of conditionals. The results show that additives are generally not obligatory in this environment. Moreover, the data suggest that the insertion of additives interacts with the interpretation of the conditional as a whole. The study is thus also revealing with regard to the ongoing question under which circumstances exhaustivity implicatures occur locally.

Section 1 gives the theoretical background, specifically it discusses the two theories *Obligatory Implicatures* and *Maximize Presupposition*. In section 2 an acceptability rating study on German “auch” in antecedent of conditionals is presented which tested the predictions of the two theories.

## 2. Theoretical Background

Presupposition triggers are obligatory when their presupposition is fulfilled in the context, see examples in (1) (Heim, 1991; Sauerland, 2008; Percus, 2006; Chemla, 2008).

- (1)
- a. The / # A father of the victim arrived.
  - b. Bob came to the store. Bill came, #(too).
  - c. Peter went to Norway this year. He went to Norway #(again) last year.
  - d. John # believes / knows Paris is in France.

There are two approaches to the phenomenon of obligatory presuppositions, one is working with the principle *Maximize Presupposition*, the other makes use of *Obligatory Implicatures*. Previous experimental findings suggest that presupposition triggers fall into two classes with regard to their obligatory insertion. The insertion of one set of triggers is better captured using *Maximize Presupposition*, the insertion of the other group seems to follow from *Obligatory Implicatures*. Both theories predict the insertion of the triggers in (1) to be obligatory. Theories working with *Maximize Presupposition* assume that there is lexical competition between the trigger and its non-presuppositional counterpart, which are ordered on a scale, see examples in (2).

- (2) Scales: {the, a}, {both, every}, {believe, know}, {again,  $\emptyset$  }, {SG, PL}, {too,  $\emptyset$  }, {PRES, PAST}

Using the weaker item on this scale of presuppositional strength will lead to an “anti-presupposition” or “implicated presupposition”, i.e. the inference saying that the presupposition of the stronger competitor is false. The inference arising from using (3a) instead of (3b), for example, is that it is not certain that there is a unique 6ft long catfish, see (3c).

- (3)
- a. Robert caught a 6ft long catfish.
  - b. Robert caught the 6ft long catfish.
  - c.  $\neg \exists x. \forall y. 6\text{ft-catfish}(y) \leftrightarrow x = y$

Parallely, (4a) has an inference that it is not certain that the victim has one unique father, which contradicts common knowledge. As a result, the definite determiner is obligatorily inserted. “Antipresuppositions” (Percus, 2006) are argued to have a special status. First, these inferences are said to be projective content, a property they share with presuppositions. Since the negated (4a) has the presuppositional stronger competitor in (4b) the same undesired inference arises that the presupposition of (4b) is false, see (4c). As a result the definite must be inserted under negation.

- (4)
- a. #A father of the victim did not arrive.
  - b. The father of the victim did not arrive.
  - c.  $\sim \neg \exists x. \forall y. \text{father-of-victim}(y) \leftrightarrow x = y$

Another property is that these inferences usually resist strengthening. That is, the inference in (3a) cannot be strengthened to “It is certain that there is more than one 6ft long catfish”, as would be expected if they were implicatures.

However, it has been observed that not all presupposition triggers behave alike when it comes to their obligatory insertion. Specifically, it has been shown that the inferences from not using presupposition triggers other than the definite determiner do not necessarily come with the features just discussed. First, it has been argued that some of the “antipresuppositions” can be strengthened in the same way as implicatures (Chemla, 2008). The sentence with “believe” in (5), for example, has a strong inference that it is certain that the speaker does not have a brother. This is because speakers are usually opinionated when it comes to them having siblings or not.

- (5) Jane believes I have a brother.

Second, the presupposition triggers “too” and “again” (German “auch” and “wieder”) are not obligatory under negation, which shows that their “antipresuppositions” do not project, see examples in (6) below (Bade and Tiemann, 2016).

- (6) a. Yesterday Jenna went ice-skating. Today she did not go (again).  
b. Bob came to the party. It is not true that John came, (too).

Moreover, the circumstances under which the trigger “too” is inserted seems to align with the circumstances under which exhaustivity implicatures arise. The more pressure to derive an exhaustivity implicature, the more pressure to insert the trigger (Bade, 2014, 2016). These facts are more compatible with a theory that assumes that obligatory insertion of the presupposition trigger follows from *Obligatory Implicatures*.

The theory assumes that the (b) sentences in (7)-(9) have implicatures, given in (c) respectively, which are contradictory to the contexts in (a).

- (7) a. Paris is in France.  
b. Mary believes<sub>F</sub> that Paris is in France.  
c. It is not certain that Paris is in France.
- (8) a. John has visited Rome.  
b. Peter<sub>F</sub> has visited Rome.  
c. Peter is the only one who has visited Rome.
- (9) a. Mary came to John’s party last year.  
b. She came to John’s party this year<sub>F</sub>.  
c. This year is the only time Mary came to John’s party.

These implicatures are derived by a covert exhaustivity operator, see definition in (10) (Fox, 2007), which evaluates the focus, for example on “Peter” in (8b). One further assumption is that, in the absence of other overt alternatives, the Question Under Discussion (QUD, Roberts

(1996)) which matches the focus provides the set of alternatives (Bade, 2016). The derivation of the exhaustivity implicature is given in (11).

- (10) a.  $\llbracket \text{EXH} \rrbracket (A_{\langle \langle s, t \rangle, t \rangle} (p_{\langle s, t \rangle})(w) \Leftrightarrow p(w) \ \& \ \forall q \in \text{NW}(p, A): \neg q(w)$   
 b.  $\text{NW}(p, A) = \{q \in A: p \text{ does not entail } q\}$
- (11)  $\llbracket [ [ \text{EXH } Q ] [ \text{Peter}_F \text{ has visited Rome } ] ] \rrbracket = \text{Peter was in Rome in } w \ \& \ \forall q [q \in [\lambda p. \exists x. p = \lambda w. x \text{ was in Rome in } w] \ \& \ p \not\Rightarrow q \rightarrow q(w) = 0]$

This theory does not predict triggers to be obligatory under negation since exhaustivity is blocked here for independent reasons (Bade and Tiemann, 2016). Moreover, the inferences arising from not using the trigger are supposed to be implicatures, which explains that they are dependent on context and can be strengthened (Sauerland, 2004).

The empirical picture arising so far is that presupposition triggers fall into two classes with regard to obligatory insertion (Bade, 2016). One set of triggers, including the definite, is better captured by *Maximize Presupposition* since inserting it is obligatory below DE-operators and its insertion does not depend on the context, especially the QUD. Another set of triggers, including “know”, “again” and “too”, follow from *Obligatory Implicatures*. Leaving them out creates implicatures which can be contradictory to the context and do not arise under DE-operators.

### 3. Experimental Study

#### 3.1. Idea: presupposition triggers in antecedents of conditionals

*Maximize Presupposition* predicts presupposition triggers to be obligatory in antecedents of conditionals since they are holes for presuppositions. That is, the presupposition of “again” in (12a) that Peter was in Norway before projects out of the if-clause in (12b).

- (12) a. Peter was in Norway again this year.  
 b. If Peter was in Norway again this year, he was fishing.

As a result, if (13a) is used instead of (12b), which is the presuppositionally stronger competitor, the “anti-presupposition” in (13b) arises that the presupposition of the competitor is false.

- (13) C: Peter was in Norway last year.  
 a. If Peter was in Norway this year, he was fishing.  
 b.  $\neg \rightarrow$  It is not true that Peter was in Norway before.

Due to this inference, (13a) is predicted to be degraded in the context given in (13) which establishes that Peter was in Norway before by *Maximize Presupposition*.

According to *Obligatory Implicatures* the insertion of the presupposition trigger should only be forced if an exhaustivity implicature arises which is contradictory to the context. The question thus is: what exactly are the exhaustivity implicatures that arise with if-clauses? There is

evidence from scalar implicatures that exhaustivity implicatures arise below the if-clause. The sentence in (14) is ambiguous between the reading in (14a) and the one in (14b).

- (14) If you have salad or dessert, you pay \$20.  
 a. If EXH you have salad or dessert, you pay \$20.  
     ‘If you have salad or dessert but not both you pay \$20.’  
 b. If you have salad or dessert, you pay \$20.  
     ‘If you have salad or dessert or both, you pay \$20.’

Since the scale ordering the items {or, and} (Horn, 1984) is reversed under downward-entailing operators the sentence in (14b) is already the strongest competitor. Adding an exhaustivity operator below “if” usually would not lead to strengthening and thus is ruled out on the basis of the economy condition (Chierchia et al., 2012). Readings such as the one in (14a) are available, but are argued to require special circumstances and usually pitch accent on the scalar item (Fox and Spector, to appear).

For sentences with particularized conversational implicatures yielded by focus, such as the one in (15), the picture looks very similar. There are two exhaustification strategies, given in (15a) and (15b) and both seem available.

- (15) If Peter<sub>F</sub> came, there were discussions.  
 a. If EXH Peter came, there were discussions.  
 b. EXH If Peter came, there were discussions.

The LF for (15a) is given below in (16), the one for (15b) is given in (17).

(17)

Let us assume that the context in which (16) is uttered is the one in (18).

(18) Mary came.

- a. If EXH Peter<sub>F</sub> came, there were discussions.
- b. EXH If Peter<sub>F</sub> came, there were discussions.

The relevant alternatives for (18a) are propositions of the form given in (19).

(19) Alt = {Peter came, Mary came, Peter and Mary came, ...}

If the exhaustification strategy in (18a) is chosen, both alternatives “Mary came” and “Mary and Peter came” are excluded since they are non-weaker and the reading in (20) is yielded. Assuming that a epistemic (realistic) modal base is chosen for the covert modal which is restricted by the if-clause this reading yields a contradiction (Kratzer, 1991).

(20)  $\forall w \in \{w' : w' \text{ is compatible with the evidence available in the utterance situation in } w_{@} \} \& \text{ Peter came in } w \& \text{ Mary did not come in } w \rightarrow \text{there were discussions in } w$

‘If Peter and not Mary came, there were discussions.’

Since it is already established in the context that Mary came the indicative conditional with a low EXH operator must be perceived as contradictory. There is no possible world in accordance with the facts of  $w_{@}$ , the actual world, where Mary did not come. With the exhaustification strategy in (18b) the relevant alternatives are the one in (21).

(21) Alt = {If Peter came, there were discussions; If Mary came, there were discussions; If Peter and Mary came, there were discussions ...}

The sentence in (18b) entails that if Peter and Mary came there were discussions. The only alternative which is non-weaker and thus excluded is that if Mary came there discussions, see the interpretation of (18b) in (22).

(22)  $\forall w \in \{w' : w' \text{ is compatible with evidence available in the utterance situation in } w_{@} \} \& \text{ Peter came in } w \rightarrow \text{there were discussions in } w \& \neg \forall w \in \{w' : w' \text{ is compatible}$

with the evidence available in the utterance situation in  $w_{@}$  } & Mary came in  $w \rightarrow$   
 there were discussions in  $w$   
 ‘If Peter came there were discussions and not if Mary came there were discussions.’

This reading says that Peter’s coming is the condition for there being discussions and not Mary’s coming. This is not contradictory to the fact that Mary came. There is, of course, a third option where no exhaustivity operator is inserted into the structure. This reading is also predicted to not yield any inferences which could be contradictory to the the discourse. Only if the first option with  $EXH < If$  is chosen, the trigger should be obligatory according *Obligatory Implicatures*. Since this reading is predicted to be marginally available, leaving out the trigger should be fine in most cases.

To sum up, the theories make different predictions with regard to the insertion of presupposition triggers in antecedents of conditionals. For *Maximize Presupposition* the trigger should be obligatory as long as its presupposition is fulfilled. According to *Obligatory Implicatures*, the trigger is only obligatory if exhaustification leads to a contradiction with the context. This can only happen when an exhaustivity operator is inserted below “if”. A correlation between interpretation and pressure to insert the trigger is thus predicted. The purpose of the study presented was to test these predictions.

### 3.2. Material and Design

The idea behind the study was to test the predictions of the two theories *Maximize Presupposition* and *Obligatory Implicatures* regarding the obligatory insertion of the German additive particle “auch” in the antecedent of conditionals. The design of the study was simple. There was a context establishing that the presupposition of the additive was fulfilled, see the example in (23).

- (23) Teresa, Sabrina und Isa gehen in die selbe Klasse und haben gerade eine Klausur zurück bekommen. Sabrina sagt zu Teresa: Ich bin durch die Klausur gefallen. Theresa antwortet:  
*Teresa, Sabrina and Ida are students in the same class and just got back an exam. Sabrina says to Theresa: I failed the test. Theresa replies:*

The target sentence was following the context and appeared in two conditions with and without the additive (+ADD/-ADD).

- (24) a. Wenn Ida auch durchgefallen ist, muss der Test schwer gewesen sein.  
*If Ida also failed the test, the test must have been hard. +ADD*  
 b. Wenn Ida durchgefallen ist, muss der Test schwer gewesen sein.  
*If Ida failed the test, the test must have been hard. -ADD*

Participants were asked to read context and target sentences carefully and then judge the acceptability of the target in a given context on a scale from 1 to 5 (where 5 stands for totally

acceptable). To test the prediction of *Obligatory Implicatures* that the insertion of the trigger is only obligatory under a certain interpretation participants were moreover asked two comprehension questions. The first question addressed the interpretation of the antecedent, an example is given in (25). Participants could choose between three answer options given in (25a-c).

- (25) **Q1: According to Teresa, under which conditions must the test have been hard?**
- a. Sabrina failing (IF A)
  - b. Ida failing (IF B)
  - c. Both Ida and Sabrina failing (IF A and B)

The second question people were asked aimed at finding out whether there are inferences resulting from using the conditional which could yield contradictions, an example is given in (26). They had three options for answering, given in (26a-c).

- (26) **Q2: Does Theresa believe that Sabrina failed?**
- a. Yes (Y)
  - b. Unclear (U)
  - c. No (N)

The answers to these two questions together were supposed to tell which interpretation people had in mind when judging the acceptability of the sentences. Especially interpretation question number two was supposed to give insights into whether the sentence without the additive was perceived as contradictory to the previous discourse, i.e. whether there was an inference (antipresupposition or implicature) that created a contradiction. With the additive, the sentence should make clear that the speaker (Teresa in the example given) believes that Sabrina failed, the answer to Q2 should thus clearly be “Yes”. However, it is not clear from the sentence with the additive that the speaker considers both Sabrina’s and Ida’s failing conditions for the test being hard, i.e. the sentence with “auch” is ambiguous between the two readings in (27).

- (27) If Ida failed too, the test must have been hard.
- a.  $\forall w \in \{w' : w' \text{ is compatible with the evidence available in the utterance situation in } w_{@}\} \& \text{Ida failed in } w \& \text{Sabrina failed in } w \rightarrow \text{the test was hard in } w$   
If both Ida and Sabrina failed, the test must have been hard.
  - b.  $\forall w \in \{w' : w' \text{ is compatible with the evidence available in the utterance situation in } w_{@}\} \& \text{Ida failed in } w \rightarrow \text{the test was hard in } w$   
If Ida failed, the test must have been hard.

The reading in (27b) is considered to be less prominent but available. It said that only Ida’s failing is a necessary condition for the test being hard (but presupposes that Sabrina failed). The contexts were set-up in a way that principally allowed for both readings. No matter which one of the two was chosen, however, the acceptability of the sentence should not be affected by since they both do not lead to a contradiction. The more interesting question was which readings arose for the sentence without the trigger. If a reading was yielded which was contradictory to the previous discourse the difference in acceptability between the sentence with and without the trigger was assumed to be significant according to *Obligatory Implicatures*. Compared to

that, the differences between acceptability of the sentence with and without the trigger should not reach significance if the sentence without the trigger was not considered being contradictory. The reading which yields a contradiction is one where the exhaustivity is inserted below “if” (IF > EXH). This reading requires the participants to answer that only Ida’s failing is a condition for the test being hard (Q1= If B). In addition, the sentence should imply that Teresa is unsure that Sabrina passed (Q2= No). One reading which is not contradictory to the previous sentence is one where the exhaustivity operator is inserted above “if” (EXH > IF). This reading is supposed to be reflected by participants saying that only Ida’s failing is a condition for the test being hard (Q1 = IF B), but in addition the speaker has no doubt that Sabrina failed too (Q2 = Yes). This reading is thus the same as the one in (27b) and available with and without “too”. The last reading does not involve any exhaustivity operator and is also not contradictory to the discourse; it is one where both Ida’s and Sabrina’s failing are considered conditions for the test being hard (Q1= If A and B) and the sentence is not perceived as a contradiction to the fact that Sabrina passed (Q2 = Yes). This reading is the one in (27a) and should hardly be available without the additive. The interpretations corresponding to the combination of answers given to Q1 and Q2 are summarized in figure 1 below.

Answer(s)	Interpretation
Q1= IF B and Q2 =No	If only B then C (IF > EXH)
Q1= IF B and Q2 =Yes	Only if B then C (EXH > IF)
Q1 = IF A and B and Q2=Yes	If A and B then C (#EXH)

Figure 1: Interpretations corresponding to answers

### 3.3. Predictions

*Maximize Presupposition* predicts sentences with the additive to overall be judged more acceptable than sentences without the additive in contexts which verify its presuppositions. This is because the sentence in (28a) in the context of (28) has the competitor in (28b). Not using this competitor should, through pragmatic reasoning, lead to hearer to calculate the “antipresupposition” in (28c), saying that the presupposition of (28b) is false.

- (28) Sabrina failed.
- If Ida failed the test was hard.
  - If Ida failed too, the test was hard.
  - $\neg \exists p \in C \ \& \ p \neq \text{Ida failed} \ \& \ p(w) = 1$

The inference in (28c) is contradictory to the fact that Sabrina failed. The sentence without the additive should thus be unacceptable in the context. Calculating this inference is supposed to be the default interpretation in the given context since the competition with “too” is made prominent by the overt alternative “Sabrina failed”. The prediction would thus be that sentences

without the additive are most often interpreted as denying the truth of (28), which would result in a high percentage of “no” answers to Q2. If, however, no such inference (“antipresuppositions”) arises the sentence should be judged acceptable without the trigger.

According to *Obligatory Implicatures* the sentence without the trigger should be less acceptable than the sentence with the trigger only if an exhaustification strategy is chosen which yields a contradiction. This is only the case if the exhaustivity operator is inserted below “if” (IF > EXH). The question under which circumstances exhaustification is mandatory versus optional is still open. However, some preferences for which exhaustivity implicatures arise in conditionals can be determined based on the research on scalar implicatures (Chierchia et al., 2012; Fox and Spector, to appear). Under the assumption that exhaustification below downward-entailing operators usually requires contextual pressure and pitch accent on the relevant alternative trigger, the exhaustification strategy which yields the contradiction (IF > EXH) should be the least likely interpretation. If one adopts the view that inserting EXH is the default if it leads to strengthening, the interpretation with EXH above “if” should be the most frequent one (EXH > IF). As a result, the insertion of the trigger in antecedents of conditional is considered not obligatory since the interpretation which triggers the insertion is a very marginal one (at least in the contexts used in the experiment). As *Maximize Presupposition*, *Obligatory Implicatures* predicts no decrease of acceptability for sentences without the trigger which do not yield a contradictory inference. The predictions of both theories are summarized in figure 2 below.

Interpretation	Predictions ObligImp	Predictions MaxPres
If only B then C (IF > EXH)	FREQUENCY LOW, ACCEPT +ADD > ACCEPT -ADD	FREQUENCY HIGH, ACCEPT +ADD > ACCEPT -ADD
Only if B then C (EXH > IF)	FREQUENCY HIGH, ACCEPT +ADD = ACCEPT -ADD	FREQUENCY LOW, ACCEPT +ADD = ACCEPT -ADD
If A and B then C (#EXH)	FREQUENCY LOW, ACCEPT +ADD = ACCEPT -ADD	FREQUENCY LOW, ACCEPT +ADD = ACCEPT -ADD

Figure 2: Interpretations corresponding to answers

### 3.4. Analysis and Results

One factor was manipulated for the study creating two conditions: the target items were conditionals which either were presented with or without the German additive “auch” in a context which satisfied its presupposition (+/-ADD). There were three dependent variables: the acceptability of the sentence on a Likert scale (1-5), and the answers to two comprehension questions. Six experimental items were created per condition, which made for 12 experimental items in total. 24 filler items were used. 24 German native speakers, students or former students of the university of Tübingen participated in the experiment, they received 5 Euros for their participation.

Results were analyzed with linear mixed effect models using the lmer function in R (Bates,

2005). The fixed factor was ADDITIVE, random factors were subject and items. The analysis revealed a significant effect of ADDITIVITY on acceptability. The insertion of the additive decreased acceptability of the conditional, see figure 3.

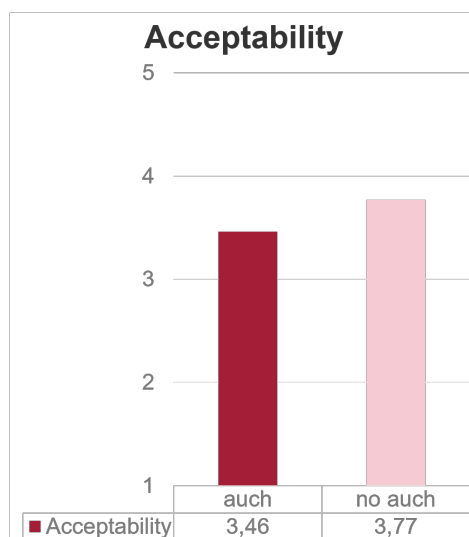

Figure 3: Acceptability of sentences with and without additive

Moreover, the additive had a marginally significant influence on which interpretation was chosen in response to Q1 (“What are the conditions for the event described by the consequent? IF A, IF B, IF A and B?”) ( $p < .08$ ): with “auch” more “both” (IF A and B) responses were chosen. “Auch” also had a significant influence on choice of interpretation for Q2 (Does the speaker believe the previously mentioned fact that A occurred? YES, NO, UNSURE) ( $p < .01$ ), more “no” answers were given with the presence of the additive. Since the analysis revealed that pooling “yes” answers with “unsure” answers or pooling “no” answers with “unsure” answer did not affect the analysis, the interpretations “yes”/“uncertain” were pooled together as suggesting no contrast to previous discourse, whereas “no” responses were considered as suggesting a contrast/contradiction to previous discourse. Overall, using the additive increased percentage of interpretations without any exhaustivity operator (#EXH, no contrast + IF A and B response), it decreased percentage of interpretations with high EXH (EXH > IF, no contrast + If B response) and increased interpretations with low EXH (IF > EXH, contrast and IF B response) see figures 4 and 5.

Figure 4: Proportion of interpretations chosen with and without additive

	#EXH	EXH>IF	IF>EXH
-ADD	35,7%	62,3%	2%
+ADD	44,2%	47,4%	8%

Figure 5: Proportions of interpretations chosen with and without additive

The responses to Q1 and Q2 both have a significant influence on acceptability (Q1  $p < .05$ , Q2  $p < .01$ ). Comparing different models using a chi-square test revealed that the best model for predicting acceptability included both the factor ADDITIVITY as well as responses to Q1 and Q2. A causal mediation analysis furthermore showed that both responses had an influence on acceptability which was not influenced by the presence of the additive.

The interpretation without any exhaustivity operator (#EXH) is significantly more acceptable overall ( $M = 4.15$ ) than the interpretation involving high or low exhaustivity operators (IF>EXH,  $M = 3.25$ ; EXH>IF,  $M = 2.8$ ). The interpretation with no EXH got even more acceptable with the presence of the additive, however the difference was not significant. The interpretations where there was either a low or high EXH got less acceptable with the presence of the additive, see proportions of interpretations in figures 6 and 7. This difference was only significant for the interpretation with EXH > IF.

Figure 6: Acceptability by interpretation chosen with and without additive

	#EXH	EXH>IF	IF>EXH
-ADD	4,42	3	3,4
+ADD	4,07	2,6	2,9

Figure 7: Acceptability by interpretation chosen with and without additive

### 3.5. Discussion

As predicted by *Obligatory Implicatures* the percentage of interpretations which were perceived as contradictory to the discourse was low (<5%). This is in line with the assumption that the inference arising when the trigger is not inserted is an exhaustivity implicature, which only occurs below DE-entailing operators under special circumstances. This is because under normal circumstances it yields to weakening of the statement. The inference resulting from the LF in (29) leads to the weaker statement in (29a) which is entailed by the stronger LF without EXH, see (29b).

- (29) If EXH Peter came, there were discussions.  
 Alt = {Peter came, Mary came, Peter & Mary came}  
 a. If Peter and not Mary came, there were discussions.  
 b. If Peter came there were discussions.  
     ⇒ If Peter and Mary came, there were discussions.  
     ⇒ If Peter and not Mary came, there were discussions.

Usually these circumstances where EXH is inserted below DE-operators involve pitch accent on the scalar item and are analyzed using stacked exhaustivity operators (Fox and Spector, to appear). Since the implicatures discussed in this paper are particularized conversational implicatures, not generalized ones, their occurrence might be even more restricted under DE operators. Since the sentences were only read by participants and there were no contextual cues for strong pitch accent, the low availability of these interpretations is expected from the viewpoint of a grammatical approach to implicatures. More research is needed on this issue to specify the circumstances under which local particularized conversational implicatures can occur at all. The results presented suggest that obligatorily inserting additives might be a good indicator.

Theories working with *Maximize Presupposition* would have to explain why competition with the stronger version with the additive is not activated and the resulting anti-presupposition did not arise, since otherwise the sentence without “too” should have been perceived as contradictory to the previous discourse more often. Of course making *Maximize Presupposition* sensitive to discourse is not impossible. However, there seems to be a clear contrast to the anti-presupposition resulting from using the indefinite. This inference, sometimes referred to as an anti-uniqueness inference (Heim, 1991), seems to arise as a default and seems to be insensitive to DE-operators and the broader discourse, see the (obligatory) oddness of (30) (cf. Bade, 2016).

(30) A man entered the bar. # If a man is thirsty, he will order a beer.

The results thus speak in favor of an analyses which distinguishes these cases from one another and postulates two groups of presupposition triggers when it comes to obligatory insertion: one, including additives, is inserted to avoid an implicature. The other, involving definites, follows from *Maximize Presupposition* (Bade, 2016; Bade and Tiemann, 2016).

The results further show that insertion of “auch” decreases acceptability of conditionals when its presupposition is fulfilled in the context. As predicted by *Obligatory Implicatures* the trigger is not obligatory per se but must be inserted only if an exhaustivity implicature must be blocked. The results suggest that the interpretation without any exhaustivity operators is the most acceptable one ( $M = 4,25$ ). Its acceptability is not significantly affected by the presence of the trigger. However, it is significantly more available with the presence of the additive (35% versus 44%). That is, the additive must be considered optional for the acceptability of sentences with this interpretation (#EXH).

For the rare cases in which the conditional was interpreted as contradicting the context, the additive did not affect the overall low acceptability either ( $M=3,15$ ). What is puzzling is that the availability of these interpretations seemed to increase with the presence of the additive. One possible explanation is that the presence of an overt focus sensitive particle increased the pressure to put focus on the noun it associated with. This focus was then understood as contrastive to the previous discourse. However, that means that, to make the presupposition of “auch” true, participants must have accommodated another antecedent/true proposition in the discourse. More research is needed to understand why this option was available at all

since additives are usually considered very hard to accommodate (Heim, 1992). Since the interpretation was rarely chosen and only by few participants individual differences might be at play here as well.

The interpretation which was most often chosen (55% on average) and received the overall lowest acceptability is one which is in line with an analysis where an exhaustivity operator is present in the structure, but above the “if”-clause, see (31).

- (31) EXH If Peter came (too), there were discussions.  
 ‘Only if Peter came (too), there were discussions.’  
 a.  $\forall w \in \{w' : w' \text{ is compatible with the evidence available in the utterance situation in } w_{@} \} \& \text{ Peter came in } w \rightarrow \text{there were discussions in } w$

This interpretation is available with and without the additive. However, its availability significantly decreased with the presence of “too” (62,3% versus 47,4%) and so did its acceptability (M=3 versus M=2,6). This interpretation must thus be considered the crucial one for explaining the overall decrease in acceptability with the presence of the additive. Whereas additional stipulations have to be made to explain this using *Maximize Presupposition* the results can straightforwardly be explained using *Obligatory Implicatures*. The relevant QUD (Question Under Discussion, Roberts (1996)) at play for this reading seems to be the one in (32), providing the set of alternatives in (32a). EXH above “if” excludes one alternative, see (32b).

- (32) If who came, there were discussions?  
 a. {If Peter came,...; If Mary came...; If Peter and Mary came ... }  
 b.  $\neg \forall w \in \{w' : w' \text{ is compatible with the evidence available in the utterance situation in } w_{@} \} \& \text{ Mary came in } w \rightarrow \text{there were discussion in } w$

What “too” marks in this case is not that the question in (32) has been previously answered but rather that the “local” question “Who came?” has already been answered (by the previously asserted “Mary came”). As was mentioned before, exhaustifying (31) with respect to the QUD in (32) will not be contradictory to the fact that Mary came. As a result, the additive is not considered obligatory. The fact that it is even perceived as disturbing in this case can be explained by assuming that making reference to an already answered QUD which is not relevant to the current QUD anymore is a dispreferred pragmatic move.

The answer to the question whether additives are obligatory in antecedents of conditionals thus seems to depend on what interpretation is chosen for the conditional. If the context allows for an interpretation without any exhaustivity operators, the additive is optional. It does not change acceptability but can make this interpretation clearer. With an interpretation where an exhaustivity operator is inserted high, above the “if”-clause, the insertion of the additive is perceived as the dispreferred option. The results further supports *Obligatory Implicatures* and the view that additive particles can function as a window into local exhaustivity implicatures.

# Two indefinite pronouns in Catalan Sign Language (LSC)<sup>1</sup>

Gemma BARBERÀ — *Universitat Pompeu Fabra*

Patricia CABREDO HOFHERR — *UMR 7023, CNRS / Paris 8*

**Abstract.** This paper analyses two pronouns in Catalan Sign Language (LSC) that refer to unidentified human referents: WHO^SOME<sub>up</sub> and ONE<sub>up</sub>. We first show that in contexts that discriminate between indefinite pronouns and existential readings of human impersonal pronouns, both pronouns pattern with indefinite pronouns. We then examine the semantic properties of the two pronouns. WHO^SOME<sub>up</sub> and ONE<sub>up</sub> contrast with respect to their number, compatibility with collective predicates, scope with respect to event iteration and domain restriction requirements. In terms of specificity, both pronouns are epistemically non-specific, but ONE<sub>up</sub> is interpreted as scopally and partitively specific while WHO^SOME<sub>up</sub> is neutral with respect to scopal and partitive specificity.

**Keywords:** Catalan Sign Language (LSC), semantics, indefinite pronouns, specificity distinctions

## 1. Introduction

This paper examines two expressions that refer to unidentified human referents in Catalan Sign Language (LSC, *llengua de signes catalana*): the pronouns WHO^SOME<sub>up</sub> and ONE<sub>up</sub>.<sup>2</sup>

- (1) ONE<sub>up</sub> HOUSE ENTER STEAL.  
'Someone broke into the house.'
- (2) WHO^SOME<sub>up</sub> GO INDIA VACCINATE MUST.  
'When one goes to India one must get vaccinated/  
When someone goes to India he must get vaccinated.'

The goals of this paper are two-fold. First, we will show that these expressions correspond to indefinite pronouns comparable to (3), rather than existential uses of impersonal pronouns as exemplified by German *man* or French *on* in (4).

<sup>1</sup>The research reported in this paper is part of the Franco-German ANR-DFG project *Towards a typology of human impersonal pronouns* (ANR-11-FRAL-0011, 2012–15). The work of G. Barberà was partly supported by the project GramRefLSC, Ministerio de Economía y Competitividad, FFI2015-68594-P. For their useful comments and interesting discussions on previous versions of this work, we would like to thank the audiences at the *Workshop on the Semantic Contribution of Det and Num* (UAB, May 2016), *Formal and Experimental Advances in Sign Language Theory* (FEAST) (Venice, September 2016), *Sinn und Bedeutung 21* (Edinburgh, September 2016), and *New Ideas in Semantics and Modelling* (Paris, September 2016). We are grateful to Delfina Aliaga and Santiago Frigola for the elicitation sessions and for the discussions on LSC. Thank you to Rob Truswell and the editors for their careful comments and suggestions on this paper. All remaining mistakes are our responsibility.

<sup>2</sup>This article follows the usual glossing conventions in the sign language literature. Manual signs are represented by the capitalized word corresponding to the translation of the sign. The abbreviations used in the glosses are the following (# is a placeholder for the loci in signing space corresponding to 1st, 2nd and 3rd person referents): IX# (index pointing sign); #-VERB-# (verb agreeing with subject and object). Sub-indices mark localizations in signing space: *lo* (low), *up* (up); lower indexed letters (*a*, *b*) mark lateral loci and coreference relations. Reduplication of signs is indicated by +++.

- (3) **Someone** stole my bike.
- (4) **On** a volé mon vélo. (Fr)  
 Man hat mein Fahrrad gestohlen. (Ge)  
 ON/MAN has (stolen) my bike (stolen)  
 ‘They stole my bike.’

Secondly, we examine the profile of the two pronouns regarding epistemic, scopal and partitive specificity (see Farkas, 2002; von Heusinger, 2002). We will show that both pronouns are epistemically non-specific. WHO^SOME<sub>up</sub> is neutral with respect to scopal and partitive specificity, while ONE<sub>up</sub> is interpreted as scopally and partitively specific.

We proceed as follows. Section 2 provides some background on the referential use of space in sign languages in general and in LSC more specifically. In Section 3 we discuss the morphological composition of WHO^SOME<sub>up</sub> and ONE<sub>up</sub>. In Section 4 we examine the two pronouns in contexts that are characteristic for human impersonal pronouns and we show that both expressions pattern with indefinite pronouns, not with existential readings of impersonal pronouns. In Section 5 we present an array of semantic contrasts between the two pronouns. Section 6 concludes.

## 2. Background: The use of space in sign languages

In sign languages, space is used for grammatical purposes (see Perniss, 2012, for a detailed overview). In Western sign languages, signing space is considered to be constrained to the space in front of the signer's torso. The signing space can be divided into the horizontal plane and the frontal plane. The horizontal plane is perpendicular to the body of the signer and is the default plane where the majority of signs are localized (Figure 1). The frontal plane runs parallel to the body of the signer from the waist up (Figure 2).

Figure 1: Sign localized on the horizontal plane

Figure 2: Sign localized high on the frontal plane

The figures above illustrate signs associated with a lateral area in the horizontal plane (Figure 1) and in the high part of the frontal plane (Figure 2). The spatial area associated with a Noun Phrase (NP) in sign language is called R-LOCUS (Klima and Bellugi, 1979). Canonically, NPs are associated with a locus on the horizontal plane of signing space, for example by a pointing index sign glossed IX3 (as in Figure 3) or by signing the lexical sign in the area of the locus (as in Figure 4 below).

Figure 3: Sign IX3<sub>a</sub> pointing to R-locus *a*

In a sentence like (5) below, the two arguments are associated with two distinctive R-loci, indicated in the glosses by the subscripts *a* and *b* and shown in the pictures in Figure 4. The R-loci play a role for agreement and for anaphoric reference. As illustrated in Figure 5, the agreeing verb GIVE moves from the R-locus of the subject MARTÍ to the R-locus of the object JOANA. As shown by the continuation (6), R-loci may be used in coreferential contexts to refer to a previously introduced argument, for example by using a pronominal index sign IX3<sub>a</sub> as in Figure 3.

- (5) MARTÍ<sub>a</sub> IX3<sub>a</sub> JOANA<sub>b</sub> IX3<sub>b</sub> BOOK 3<sub>a</sub>-GIVE-3<sub>b</sub>.  
 ‘Martí gave Joana a book.’

Figure 4: Sign MARTÍ at R-locus *a*

Sign JOANA at R-locus *b*

Figure 5: Verb GIVE articulated from R-locus *a* to R-locus *b*

(6) **IX3a BOOK INTEREST.**

‘He (Martí) found the book interesting.’

In example (5) the R-loci for the NPs are on the horizontal plane in front of the torso, as illustrated by Figure 4. It has been shown that the height of localization in the frontal plane is also relevant for the expression of reference. In American Sign Language (ASL) high R-loci trigger an indefinite interpretation (Bahan, 1996; MacLaughlin, 1997). In LSC, the frontal plane is used to express specificity distinctions (Barberà, 2012): NPs localized at a low R-locus are interpreted as epistemically specific (they are identifiable by the signer and belong to a restricted set), whereas NPs localized at a high R-locus are interpreted as epistemically non-specific (they are unidentifiable by the signer and do not belong to a restricted set).

The following examples provide a minimal pair for the interpretation of high vs. low R-locus for an NP in LSC.<sup>3</sup> In (7a) the determiner *SOME* is localized at a low R-locus (indicated in the glosses with *lo*, Figure 6) and corresponds to a reading where the signer is talking about a specific group of students, which he can identify. In (7b), in contrast, the determiner *SOME* is localized at a high R-locus (indicated in the glosses with *up*, Figure 7) and a non-specific reading arises: the signer cannot identify the set of students.

- (7) a. STUDENT *SOME<sub>lo</sub>* DEMONSTRATION GO. (LSC)  
       ‘Some students (that I can identify) went to the demonstration.’  
       b. STUDENT *SOME<sub>up</sub>* DEMONSTRATION GO.  
       ‘Some students (that I cannot identify) went to the demonstration.’

Figure 6: Sign *SOME* at a low R-locusFigure 7: Sign *SOME* at a high R-locus

The two pronouns analysed in this paper are articulated in a high R-locus and trigger an epistemically non-specific interpretation, resembling the behaviour of NPs in this respect. However, in some contexts, pronominal elements in LSC articulated in high R-loci may have a scopally and partitively specific interpretation, unlike lexical NPs (see Section 5 below).

<sup>3</sup>In sign languages, signing space may be also used topographically. In topographical uses of space the spatial location of the sign provides information about the actual locations of entities, for example when referring to a book located on a high shelf (see Perniss, 2012, for discussion of different uses of signing space). In this article we leave the topographical use aside.

### 3. Morphological properties of the two pronouns

The pronoun  $\text{WHO}^{\text{SOME}}_{\text{up}}$  is the concatenation of the sign for the interrogative pronoun **WHO** with the sign for the determiner **SOME**. The manual component of both uses of **WHO** is an arc-shaped movement of the wrist with the thumb pointing upwards, localized on the chin of the signer and with final contact.

The interrogative use of **WHO** (8) and the **WHO** forming part of the indefinite pronoun (9) differ in their non-manual components. While the interrogative particle co-occurs with furrowed eyebrows (Figure 8), the indefinite pronoun co-occurs with particular non-manuals that include sucking the cheeks in and pulling the mouth ends down, sometimes combined with a shrug (Figure 9).

- (8) **COME WHO?**  
'Who came?'

- (9) **IX3 WHO<sup>SOME</sup><sub>up</sub> SEE.**  
'She saw someone.'

Figure 8: The sign for the interrogative **WHO**

Figure 9: Sign for the pronoun  $\text{WHO}^{\text{SOME}}_{\text{up}}$

The indefinite pronoun  $\text{ONE}_{\text{up}}$  is signed in a high locus (see Figure 10) with the handshape of the numeral **ONE** (see Figure 11). The non-manuals for the indefinite pronoun  $\text{ONE}_{\text{up}}$  resemble those for the indefinite pronoun  $\text{WHO}^{\text{SOME}}_{\text{up}}$  (Figure 9): they also consist in sucking the cheeks in and pulling the mouth ends down (Figure 10).

- (10) **ONE<sub>up</sub>** HOUSE ENTER STEAL.  
 ‘Someone broke into the house.’ (= (1))

- (11) **ONE** GIRL HOUSE ENTER.  
 ‘A/one girl broke into the house.’

Figure 10: The pronoun ONE<sub>up</sub> at a high locus, ex. (10)

Figure 11: The numeral ONE at a low locus, ex. (11)

Both pronouns are articulated in a high location of signing space (as indicated by the subscript *up* in the glosses), rather than in the default lower area. Both receive an epistemically non-specific interpretation, as is generally the case for elements associated with R-loci in the higher plane in LSC (see Barberà, 2012, and discussion of the example (7) above).

#### 4. Indefinite or Impersonal Pronouns?

In LSC non-specific human pronouns are a common strategy to encode an unspecified human referent (Barberà and Quer, 2013). Reference to an unspecified human referent is also part of the semantic domain of dedicated human impersonal pronouns that allow existential readings such as German *man* or French *on*.

We have shown above that morphologically WHO^SOME<sub>up</sub> looks like a wh-indefinite. The pronoun ONE<sub>up</sub>, however, could potentially be an impersonal pronoun derived from the numeral *one*, as English *one* or Spanish *uno*.

To establish that WHO^SOME<sub>up</sub> and ONE<sub>up</sub> are indeed indefinite pronouns, we examined their behaviour in contexts that distinguish indefinites from existential uses of impersonal pronouns cross-linguistically (see Cabredo Hofherr, 2008, and references cited there). Indefinite pronouns (i) are incompatible with a generalizing reading in simplex sentences, (ii) are incompatible with corporate readings, (iii) trigger disjoint reference when the pronoun is repeated in anaphoric chains, and (iv) have narrow and wide scope interpretations with respect to adverbs like *twice*. Impersonal pronouns, in contrast, (i) are compatible with a generalizing reading, (ii) are compatible with corporate readings, (iii) typically allow joint and disjoint reference when the pronoun is repeated in anaphoric chains, and (iv) have a narrowest scope interpretation in their existential uses. We consider each of the four contexts in turn.

#### 4.1. Generalizing vs. episodic readings

Episodic contexts are contexts in which an individual or an event is anchored to a particular spatio-temporal context (*Yesterday John had breakfast at 10am*). In contrast, in generalizing contexts either the individuals or the events are not anchored to a spatio-temporal context and express either recurring properties of an individual (*John has breakfast at 7am*) or general properties not tied to particular individuals (*Pandas are big/eat bamboo*).

The French pronoun *on* has generalizing and episodic readings. The generalizing reading of *on* is exemplified in (12a). This reading is comparable to the English *people* or to non-anaphoric *they*, as in the translation of (12a). As (12b) shows, indefinite pronouns like *someone* do not allow generalizing readings over people in general.

- (12) a. Au Mexique, **on** mange des grillons. (Fr)  
           in Mexico ON eats indef.pl grasshoppers  
           ‘In Mexico, they / people eat grasshoppers.’  
           (generalizing over people associated with Mexico)  
       b. In Mexico, **someone** eats/ate grasshoppers.  
           (not generalizing over people associated with Mexico, ≠ (12a))

The two LSC pronouns typically appear in episodic contexts (13). When inserted in generalizing contexts, the pronouns are interpreted on a par with (12b): (14) is understood as a habitual reading for an unspecified individual, but not as a generalization over individuals in Lleida in general.

- (13) a. YESTERDAY **ONE**<sub>up</sub> BIKE STEAL-3<sub>up</sub>.  
       b. YESTERDAY **WHO^SOME**<sub>up</sub> BIKE STEAL-3<sub>up</sub>.  
           ‘Yesterday someone stole a/the bike.’
- (14) a. LLEIDA **ONE**<sub>up</sub> SNAIL EAT.  
       b. LLEIDA **WHO^SOME**<sub>up</sub> SNAIL EAT.  
           ‘In Lleida, there is someone who eats snails.’  
           (not generalizing over people associated with Lleida)

In locative universal contexts as in (15) the null subject triggers a generic reading in LSC, meaning something paraphrasable with *people associated with location X in general*. When **WHO^SOME**<sub>up</sub> is used in this context the episodic reading arises (16). The insertion of **ONE**<sub>up</sub> in the context triggers either an episodic reading (17a) or a habitual reading of the predicate, with an existential interpretation of the individual (17b).

- (15) CHINA AREA EAT CAT. (null subject)  
       ‘In China they eat cats.’
- (16) CHINA AREA **WHO^SOME**<sub>up</sub> EAT CAT.  
       ‘In China someone ate a cat/some cats.’

- (17) CHINA AREA **ONE**<sub>up</sub> EAT CAT.  
 a. 'In China someone ate a cat/cats.'  
 b. 'In China, there is someone who eats cats.'

#### 4.2. Corporate readings: predicates with designated subjects

Corporate readings arise with predicates that have a designated subject such as *deliver the mail*, *raise taxes* (Kärde, 1943; Pesetsky, 1995). In French, the corporate reading is compatible with an existential reading of the impersonal human pronoun *on*. The impersonal *on/they* in (18) is interpreted as referring to the people charged with raising taxes. Indefinite pronouns like *quelqu'un / someone*, in contrast, do not receive an interpretation corresponding to the group prototypically associated with the predicate in (19).

- (18) **On** a augmenté les impôts.  
 'ON raised the taxes.' > 'They raised taxes.'  
 (corporate reading: the people in charge of raising taxes)
- (19) **Quelqu'un** a augmenté les impôts.  
 'Someone raised the taxes.'  
 (no corporate reading: agent not part of the designated subject of the predicate).

In LSC, neither **WHO^SOME**<sub>up</sub> nor **ONE**<sub>up</sub> trigger the corporate interpretation in the parallel examples. Like (19), the examples in (20) are interpreted as saying that there was an unknown individual who raised the taxes but the examples do not imply that this individual belongs to a designated group of people in charge of raising taxes.

- (20) a. **WHO^SOME**<sub>up</sub> RAISE TAXES.  
 b. **ONE**<sub>up</sub> RAISE TAXES.  
 'Someone raised the taxes.' (~ (19))

#### 4.3. Scope with respect to adverbials

Existential uses of impersonal pronouns, like French *on* and German *man*, have obligatory narrow scope with respect to frequency adverbs like *twice* or *always* (Zifonun, 2000 for German; Cabredo Hofherr, 2008 for French).

- (21) On a volé mon vélo deux fois. (Fr)  
 ON has stolen my bike two times  
 'ON stole my bike twice.' (2 times > someone)

Neither of the two LSC pronouns takes obligatory narrow scope. **WHO^SOME**<sub>up</sub> allows wide and narrow scope readings with respect to the adverb, with wide scope for the pronoun preferred in examples like (22a). **ONE**<sub>up</sub> differs from **WHO^SOME**<sub>up</sub> with respect to scope: the use of **ONE**<sub>up</sub> only allows a wide scope reading (23).

- (22) WHO<sup>up</sup>SOME<sup>up</sup> IX1 BIKE 1-STEAL-3<sup>up++</sup> TWO TIMES.  
 ‘Someone stole my bike two times. / Two times, someone stole my bike.’  
 a. someone > 2 times (preferred)  
 b. 2 times > someone
- (23) ONE<sup>up</sup> BICYCLE 1-STEAL-3<sup>up++</sup> TWO TIMES.  
 ‘Someone stole my bicycle two times.’ (someone > 2 times)

However, the use of signing space introduces a complicating factor: The localization of the R-loci in signing space can disambiguate in favour of a reading with co-varying subjects for the different events. In LSC the establishment of two different R-loci for the subject explicitly marks distribution over the subject, resulting in a reading where the indefinite subject co-varies with the stealing event (narrow scope reading). In example (22), the iterated movement of the verb STEAL is twice to an unspecified R-locus, marked ++ in the gloss. In example (24) below, in contrast, the agreeing verb STEAL is inflected with two distinct lateral R-loci (R-locus *a* and R-locus *b*) and this yields an interpretation according to which on two occasions my bike was stolen, by two different individuals.

- (24) WHO<sup>up</sup>SOME<sup>up</sup> IX1 POSS BIKE 1-STEAL-3<sup>up.a</sup> 1-STEAL-3<sup>up.b</sup> TWO TIMES.  
 ‘They stole my bike two times.’ (2 times > someone)

The availability of this explicitly distributing inflection for the verb may contribute to the preference for example (22) to be interpreted as not distributed.

We further tested the effect of adverb placement on interpretation. In order to avoid explicit distribution over different R-loci, we used the adverb ALWAYS in these examples. With the pronoun ONE<sup>up</sup>, the interpretation of the subject is a constant individual (~ specific indefinite) independently of the position of the adverb ALWAYS (see (25a)/(26a)/(27a)). For WHO<sup>up</sup>SOME<sup>up</sup> the position of the adverb ALWAYS makes a difference to interpretation. With an initial or final position of ALWAYS, the pronoun WHO<sup>up</sup>SOME<sup>up</sup> is interpreted as (potentially) co-varying with the iterated events (25b)/(26b). A reading as a constant individual is forced when ALWAYS appears between WHO<sup>up</sup>SOME<sup>up</sup> and the verb as in (27b).

We analyse the contrast with respect to WHO<sup>up</sup>SOME<sup>up</sup> as indicating that WHO<sup>up</sup>SOME<sup>up</sup> is interpreted inside the VP by default and only takes wide scope if it is overtly separated from the VP by the adverb ALWAYS.

- (25) a. IX NEIGHBOURHOOD ONE<sup>up</sup> BIKE STEAL-3<sup>up</sup> ALWAYS.  
 ‘In this neighbourhood there is someone who always steals bikes.’  
 (constant agent of the stealing events)  
 b. IX NEIGHBOURHOOD WHO<sup>up</sup>SOME<sup>up</sup> BIKE STEAL-3<sup>up</sup> ALWAYS.  
 ‘In this neighbourhood they always steal bikes.’  
 (agent of stealing events need not be identical, can co-vary with the events)

- (26) a. **ALWAYS** IX NEIGHBOURHOOD ONE<sub>up</sub> BIKE STEAL-3<sub>up</sub>.  
 ‘In this neighbourhood there is someone who always steals bikes.’  
 (constant agent of the stealing events)
- b. **ALWAYS** IX NEIGHBOURHOOD WHO^SOME<sub>up</sub> BIKE STEAL-3<sub>up</sub>.  
 ‘In this neighbourhood they always steal bikes.’  
 (agent of stealing events need not be identical, can co-vary with the events)
- (27) a. IX NEIGHBOURHOOD ONE<sub>up</sub> **ALWAYS** BIKE STEAL-3<sub>up</sub>.  
 b. IX NEIGHBOURHOOD WHO^SOME<sub>up</sub> **ALWAYS** BIKE STEAL-3<sub>up</sub>.  
 ‘In this neighbourhood there is someone who always steals bikes.’

The data show that neither WHO^SOME<sub>up</sub> nor ONE<sub>up</sub> has the scope behaviour with respect to adverbs observed for existential readings of impersonal pronouns. We will come back to this contrast in scope behaviour between the two pronouns in Section 5 below.

#### 4.4. Anaphora

In coreferential chains, impersonal pronouns (such as English *man*, French *on*, German *man*) allow co-referent interpretation of repeated pronouns as in (28), while indefinite pronouns do not (29).

- (28) a. When **one**<sub>i</sub> goes to hospital, **one**<sub>i</sub> / he<sub>\*i/k</sub> always fears the worst.  
 b. **One**<sub>i</sub> goes to hospital, and **one**<sub>i</sub> / he<sub>\*i/k</sub> worries.
- (29) a. When **someone**<sub>i</sub> goes to hospital, **someone**<sub>\*i/j</sub> / he<sub>i/\*k</sub> always fears the worst.  
 b. **Someone**<sub>i</sub> goes to hospital, and **someone**<sub>\*i/k</sub> / he<sub>i/k</sub> worries.

With respect to this diagnostic, the two LSC pronouns again pattern with indefinite pronouns: the repetition of ONE<sub>up</sub> and WHO^SOME<sub>up</sub> triggers disjoint interpretation in (30)/(31). In LSC the equivalent of *when*-clauses is marked by the sign MOMENT as in example (30). Without MOMENT, the example corresponds to a paratactic coordination of two main clauses.

- (30) **ONE**<sub>up</sub> MOMENT HOSPITAL GO, **ONE**<sub>up</sub> ALWAYS THINK RESULT WORST.  
 ‘When one<sub>k</sub> is admitted to the hospital, one<sub>j</sub> always fears the worst results.’  
 (= different people in hospital and worrying)
- (31) **WHO^SOME**<sub>up</sub> HOSPITAL GO, **WHO^SOME**<sub>up</sub> ALWAYS THINK RESULT WORST.  
 ‘Someone<sub>i</sub> is admitted to the hospital; and someone<sub>k</sub> always fears the worst results.’  
 (= different people in hospital and worrying)

#### 4.5. Summary

The diagnostics examined here show that neither  $\text{WHO}^{\text{SOME}}_{\text{up}}$  nor  $\text{ONE}_{\text{up}}$  behave like episodic readings of impersonal human pronouns available for French *on* or German *man*.

Furthermore, there is evidence that  $\text{WHO}^{\text{SOME}}_{\text{up}}$  is not a relative pronoun introducing free relatives either. In LSC, relative clauses are marked with squinted eyes and, optionally, with the particle *MATEIX* (Mosella, 2012). The examples with  $\text{WHO}^{\text{SOME}}_{\text{up}}$  do not show either of these markings. The comparison of  $\text{WHO}^{\text{SOME}}_{\text{up}}$  with free relatives with a *wh*-pronoun as in (33) shows that the free relative is articulated with brow-raise with scope over the relative clause.

- (32)  $\text{WHO}^{\text{SOME}}_{\text{up}}$  EXAM DONE LEAVE CAN.  
‘When someone finishes the exam he can leave.’

- (33) [EXAM DONE WHO] <sub>brow raise</sub> LEAVE CAN.  
‘Whoever has finished the exam may leave.’

We therefore conclude that both  $\text{WHO}^{\text{SOME}}_{\text{up}}$  and  $\text{ONE}_{\text{up}}$  are indefinite pronouns in LSC that pattern with pronouns like *someone* in English. As we have seen in Section 4.3 above, however, the two indefinite pronouns differ in their interpretation with respect to frequency adverbs. In the next section we examine the semantic contrasts between the two pronouns in more detail.

### 5. Contrasts between $\text{WHO}^{\text{SOME}}_{\text{up}}$ and $\text{ONE}_{\text{up}}$

In what follows, we show that  $\text{WHO}^{\text{SOME}}_{\text{up}}$  and  $\text{ONE}_{\text{up}}$  differ with respect to a number of semantic properties: number specification, compatibility with collective predicates, co-variation of the referent with event pluralities and a requirement for domain restriction for the referent.

#### 5.1. Plural vs. singular interpretation

$\text{WHO}^{\text{SOME}}_{\text{up}}$  and  $\text{ONE}_{\text{up}}$  differ with respect to their number specification. When  $\text{WHO}^{\text{SOME}}_{\text{up}}$  is used, the subject need not be singular (34a). With  $\text{ONE}_{\text{up}}$  the subject has to be singular (34b).

- (34) a. CHINA AREA  $\text{WHO}^{\text{SOME}}_{\text{up}}$  EAT CAT.  
In China someone/some people ate a cat/cats.’  
(can be more than one person)  
b. CHINA AREA  $\text{ONE}_{\text{up}}$  EAT CAT.  
‘In China there is someone who eats cats.’  
(one person only)

The contrast between the pronouns with respect to number interpretation is further confirmed in contexts in which the plurality of the unknown agent is explicitly denied. In the context we

tested, an office has been broken into and after the event, the footprints belonging to a single person were found outside the office. The singular interpretation of  $\text{ONE}_{\text{up}}$  coincides with the information about the number of the unknown agent from the context, and our informant added a confirmation headnod corresponding to an expression like *as expected* to the example in (35). In contrast, as  $\text{WHO}^{\wedge}\text{SOME}_{\text{up}}$  is interpreted as ‘more than one’ by default, a context in which the footprints belong to the same person cancels the implicature that there is more than one agent of the event, leading to an expression of surprise by the informant (*How weird!?*) in (36).

- (35) YESTERDAY HERE OFFICE  $\text{ONE}_{\text{up}}$  c-STEAL-3<sub>up</sub>. AFTERWARDS CHECK  
 FOOTPRINT UNIQUE SINGLE SAME IX3<sub>up</sub> <sup>headnod</sup>  
 ‘Yesterday someone broke into the office. We checked the footprints afterwards and they belong to the same person, as expected.’
- (36) YESTERDAY HERE OFFICE  $\text{WHO}^{\wedge}\text{SOME}_{\text{up}}$  c-STEAL-3<sub>up</sub>. AFTERWARDS CHECK  
 FOOTPRINT UNIQUE SINGLE SAME IX3<sub>up</sub>. WEIRD.  
 ‘Yesterday some people broke into the office. We checked the footprints afterwards and they belong to the same person. How weird!?’

## 5.2. Collective and distributive readings

The analysis proposed of between  $\text{WHO}^{\wedge}\text{SOME}_{\text{up}}$  as preferentially plural and  $\text{ONE}_{\text{up}}$  as singular is further confirmed by the fact that  $\text{WHO}^{\wedge}\text{SOME}_{\text{up}}$  is compatible with collective predicates (37), while  $\text{ONE}_{\text{up}}$  is not (38).

- (37) WAR CITY  $\text{WHO}^{\wedge}\text{SOME}_{\text{up}}$  SURROUND.  
 ‘They surrounded the city during the war.’
- (38) \*WAR CITY  $\text{ONE}_{\text{up}}$  SURROUND.

$\text{ONE}_{\text{up}}$  has a plural distributive form, consisting of a reduplication of the pronoun, which is grammatical with collective and distributive predicates. When this reduplicated form of the pronoun is used, reduplication of the verb is also obligatory; otherwise the sentence is ungrammatical. The reduplicated verb further triggers a distributive reading of the object.

- (39) WAR CITY  $\text{ONE}_{\text{up}}+++$  SURROUND+++.  
 ‘They each surrounded a different city during the war.’
- (40) NEIGHBOURHOOD  $\text{ONE}_{\text{up}}+++$  BIKE STEAL-3<sub>up</sub>+++.  
 ‘In this neighbourhood, there is a number of (unidentified) people that each stole a bike/bikes.’

However, an exception is found with body-anchored verbs (like EAT), that do not admit reduplication. Because of this phonological restriction, the verb is not reduplicated when combined

with the plural distributive form of  $\text{ONE}_{\text{up}}$  but the sentence is still grammatical and we get the distributive reading.

- (41) **CAKE  $\text{ONE}_{\text{up}+++}$  EAT.**  
 ‘Some people had a piece of cake each.’

### 5.3. Co-variation with the event

As we have already seen in Section 4.3 above, the two pronouns differ in their scoping properties with respect to adverbs.  $\text{WHO}^{\wedge}\text{SOME}_{\text{up}}$  triggers undetermined reference of subject and allows subjects to co-vary with the events.

In contrast,  $\text{ONE}_{\text{up}}$  does not co-vary with respect to the events, yielding a scopally specific interpretation. The referent of  $\text{WHO}^{\wedge}\text{SOME}_{\text{up}}$  can co-vary with quantification over the event (here with the adverb **ALWAYS**): a scenario with a plurality of stealing events with different subjects for each event is possible. In contrast, with the pronoun  $\text{ONE}_{\text{up}}$  there is not co-variation of the subject with respect to the events. Therefore the iterated thefts are perpetrated by the same unknown person.

- (42) a. **BUILDING IX POSS OFFICE DANGER. ALWAYS  $\text{WHO}^{\wedge}\text{SOME}_{\text{up}}$  STEAL-3<sub>up</sub> MONEY**  
 ‘The building of my office is very dangerous. They always steal money.’
- b. **BUILDING IX DANGER. IX1 POSS OFFICE ALWAYS  $\text{ONE}_{\text{up}}$  STEAL-3<sub>up</sub> MONEY**  
 ‘The building (of my office) is very dangerous. There is someone who always steals money in/from my office.’

### 5.4. Domain restriction

A restricted domain is compatible with both pronouns. However, while  $\text{ONE}_{\text{up}}$  strongly favours a reading in which there is a salient set that the referent belongs to, such a set is not required with  $\text{WHO}^{\wedge}\text{SOME}_{\text{up}}$ .

In the examples (43a) and (44a) with  $\text{WHO}^{\wedge}\text{SOME}_{\text{up}}$ , the unidentified human referent can but need not belong to a contextually salient set. With  $\text{ONE}_{\text{up}}$ , however, the referent is interpreted as belonging to a particular set, as shown in examples (43b) and (44b).

- (43) a. **BUILDING IX FIRE FIREMEN ARRIVED.  $\text{WHO}^{\wedge}\text{SOME}_{\text{up}}$  CL:GO-UP-ROOF**  
 ‘The building was on fire and the firemen arrived. One (fireman or normal person) went up to the roof.’

- b. BUILDING IX FIRE FIREMEN ARRIVED. **ONE<sub>up</sub>** CL:GO-UP-ROOF  
 ‘The building was on fire and the firemen arrived. One (of the firemen) went up to the roof.’
- (44) a. LIBRARY WOMAN PERSON RETIRE. **WHO^SOME<sub>up</sub>** SUBSTITUTE  
 ‘The librarian is getting retired. Someone (from a non-restricted set) will substitute her.’
- b. LIBRARY WOMAN PERSON RETIRE. **ONE<sub>up</sub>** SUBSTITUTE  
 ‘The librarian is getting retired. One (of her team) will substitute her.’

Further evidence that **ONE<sub>up</sub>** explicitly favours a reading with a salient set is provided by continuations with the sign **DE** (meaning ‘belong’). In this context a continuation with a typical group inferred is more felicitous (45a) than a continuation with unexpected information (45b).

- (45) **ONE<sub>up</sub>** DEAN INFORM  
 ‘Someone informed the dean.’
- a. **PERSON<sub>up</sub>** DE FACULTY.  
 ‘He is someone from the faculty.’
- b. # **PERSON<sub>up</sub>** DE GYMNASIUM.  
 ‘He is someone from the gym.’

### 5.5. Interpretation of object and telicity

We found some evidence that the two pronouns seemed to correlate with a difference in telicity. With a telic predicate like **EAT**, **WHO^SOME<sub>up</sub>** triggers a specific interpretation of the object, an episodic context and the event is interpreted as punctual (perfective) (46a). With **ONE<sub>up</sub>** as a subject, the interpretation of the object was non-specific, with either habitual interpretation (imperfective) or an episodic interpretation that did not have a salient individual as an object (46b).

- (46) a. **WHO^SOME<sub>up</sub>** CAT EAT.  
 ‘Someone ate a/the cat.’  
 Informants added: **IX SEE DISAPPEAR** ‘I see it disappeared.’  
 (the (relevant) cat is no longer there)
- b. **ONE<sub>up</sub>** CAT EAT.  
 ‘There is one who eats cats.’  
 Informants intuition: a/the salient cat has not disappeared

In future work we will explore the hypothesis that the effect of the pronoun on the object is indirect. According to our working hypothesis, **WHO^SOME<sub>up</sub>** is not interpreted as a topic, and the interpretation of the object as specific is triggered by the fact that it is interpreted as the most plausible topic. **ONE<sub>up</sub>**, on the other hand, corresponds to a constant, if unidentified, individual and as such can be interpreted as a topic itself, favouring an interpretation in which the object is semantically incorporated comparable to *eat cats*.

## 5.6. Summary

Using the specificity distinctions discussed by Farkas (2002); von Heusinger (2002), the properties discussed in this section can be summarized as follows.

Both WHO^SOME<sub>up</sub> and ONE<sub>up</sub> are epistemically non-specific: the referent of the pronoun is unknown to the signer and to the addressee.

The two pronouns differ with respect to their scopal properties: WHO^SOME<sub>up</sub> is preferentially interpreted as having a narrow scope reading and co-varies with iterated events, while ONE<sub>up</sub> is interpreted as having wide scope with respect to event iteration. ONE<sub>up</sub> is scopally specific while WHO^SOME<sub>up</sub> allows both wide and narrow scope interpretations.

Finally, the two pronouns differ with respect to partitivity. WHO^SOME<sub>up</sub> can, but need not, be part of a salient group while ONE<sub>up</sub> is interpreted as belonging to a contextually salient group: ONE<sub>up</sub> is partitively specific while WHO^SOME<sub>up</sub> is compatible with partitive or non-partitive interpretations.

The following table summarizes the contrasts between the two indefinite pronouns:

<i>Types of specificity</i>	WHO^SOME <sub>up</sub>	ONE <sub>up</sub>
<b>Epistemic</b> unknown to signer	+ (16)	+ (17)
<b>Scopal</b> wide scope with TWICE	+/-	+
wide scope (sentence final/initial ALWAYS)	– (25a) & (26a)	+ (25b) & (26b)
wide scope (pre-verbal ALWAYS)	+ (27a)	+ (27b)
scope over event plurality ( <b>co-variation with events</b> )	+ (42a)	– (42b)
<b>Partitive</b> interpreted as part of a salient group	–	+ (45)
<i>Other properties</i>		
<b>Cardinality</b>	1 or more (34a)	singular (34b)
<b>Telicity</b> punctual event vs. habitual	+ (46a) punctual	– (46b) habitual

## 6. Conclusions

We have shown that the expressions WHO<sup>^</sup>SOME<sub>up</sub> and ONE<sub>up</sub> pattern with indefinite pronouns like *someone*, not with existential readings of impersonal human pronouns like *on* in French. Both pronouns are epistemically non-specific since the referent of the pronoun has to be unknown to the speaker. Future work has to establish how WHO<sup>^</sup>SOME<sub>up</sub> and ONE<sub>up</sub> fit into the typology of epistemic indefinites discussed in the recent literature (Aloni and Port, 2011; Alonso-Ovalle and Menéndez-Benito, 2013).

The data presented further show that the two pronouns differ with respect to a range of semantic properties. First, while WHO<sup>^</sup>SOME<sub>up</sub> is number neutral, ONE<sub>up</sub> is interpreted as referring to a singular referent. For reference to a multiplicity, the sign ONE<sub>up</sub> needs to be reduplicated yielding a form ONE<sub>up</sub>+++ that forces a distributive reading. Secondly, WHO<sup>^</sup>SOME<sub>up</sub> is preferentially interpreted as having a narrow scope reading with respect to unbounded event iteration, i.e. a reading in which the agent co-varies with the event, while ONE<sub>up</sub> is interpreted as having wide scope. We found that WHO<sup>^</sup>SOME<sub>up</sub> only gets a wide scope reading if it is overtly separated from the VP by the adverb ALWAYS. With respect to a bounded adverb like TWICE, WHO<sup>^</sup>SOME<sub>up</sub> takes wide scope. Finally, WHO<sup>^</sup>SOME<sub>up</sub> need not have a partitive interpretation, while ONE<sub>up</sub> has a partitive interpretation as belonging to a salient set. These observations suggest that ONE<sub>up</sub> is a strong indefinite, whereas WHO<sup>^</sup>SOME<sub>up</sub> is a weak indefinite.

In future work we will explore the hypothesis that WHO<sup>^</sup>SOME<sub>up</sub> and ONE<sub>up</sub> contrast with respect to their information structure status. Unless it is moved out of the VP, WHO<sup>^</sup>SOME<sub>up</sub> does not function as a topic making it similar to the implicit agent of passives: a sentence containing it will be interpreted asthetic unless an alternative topic is available. We will explore the hypothesis that ONE<sub>up</sub> on the other hand is scopally specific and interpreted as part of a group that is contextually salient. If this hypothesis is correct, the contrast between the two pronouns would resemble the contrast in English between the following two examples:

- (47) a. They repaired the lift.  
b. There is someone who repaired the lift.

Finally, the data discussed here show that in LSC the role of high loci in signing space is different for pronouns and for lexical NPs, suggesting that the structured use of signing space can be modulated depending on the grammatical category of the NP. Lexical NPs associated with a high locus are associated with an epistemically and partitively non-specific interpretation. In contrast, the pronoun ONE<sub>up</sub> is partitively specific despite the fact that it is associated with a high locus.

# HAVE as a relation between individuals and properties<sup>1</sup>

Toni BASSAGANYAS-BARS — *Universitat Pompeu Fabra - Barcelona*

**Abstract.** This paper argues that the role of HAVE-predicates is to introduce relations into the discourse, one of whose arguments is the individual denoted by the sentence subject. This is the only token-level argument in the relation: the other is modeled as a nominalized property (Chierchia, 1984; Chierchia and Turner, 1988). A number of peculiarities of HAVE are argued to follow from this account, including its connection with existential predicates (McNally, 1992, 2009).

**Keywords:** have, possession, properties, kinds, nominalized functions.

## 1. Introduction

Ever since Keenan (1987), a significant share of the semantic literature on HAVE<sup>2</sup> has focused on the compositional challenges posed by relational nouns in object position of this verb, i.e. the phenomenon dubbed ‘existential-HAVE’. The goal is to account for the putative contrast between (1a) and (1b):

- (1) a. John has a/many/the/every/both car(s)
- b. John has a/many/#the/#every/#both sister(s)

From this perspective, what needs to be explained is: (i) why relational nouns trigger a definiteness effect, largely parallel to that found in the pivot of existential sentences, while sortal nouns do not; (ii) how the subject ends up saturating/being identified with the internal argument of the object; (iii) how to factor in the contribution of the determiner within the object; and (iv) what exactly HAVE contributes to the meaning of the whole.

Several analyses of existential-HAVE have been suggested, all of which account for (at least some of) the data but make HAVE –or a small subset of its uses– look like a very peculiar creature full of idiosyncrasies. One of the consequences of such views is that they cast no light on the persistent intuition in the literature on possession that there is a some connection between HAVE, existential predicates and copular sentences.

This paper presents a compositional account of HAVE as a predicate that introduces a 2-place relation into the discourse by linking it to one of its participants, the sentence subject. As a result of introducing a HAVE-sentence into a context, the individual that the subject is in a relation to is also introduced. This result is achieved in an indirect way: HAVE relates its subject not with a token-level entity, but with a description of an individual; this description is modeled as a nominalized property (Chierchia, 1984; Chierchia and Turner, 1988). The nature of the

---

<sup>1</sup>I would like to thank Louise McNally, Josep M. Fontana, Bert LeBruyn, Henriette de Swart, Kjell Johan Sæbø, Joost Zwarts, and the audience of *Sinn und Bedeutung* 21 for discussion, and to Obra Social la Caixa, MINECO (grants FFI2013-41301-P and FFI2016-76045-P) and AGAUR (grant 2014SGR698) for financial support.

<sup>2</sup>HAVE refers to an abstract, language-independent predicate of which English *have*, French *avoir* or Catalan *tenir* are concrete manifestations.

relation introduced into the discourse as a result of uttering an—affirmative—HAVE-sentence depends on the relationality of the noun heading the object-NP.<sup>3</sup>

The analysis builds on the account of English existentials in McNally (1992, 2009), which was designed to account for the similarities between existentials and some copular predicates. It thus intends to capture both the observation that existentials and HAVE-sentences share a number of traits and the fact that if a language has a HAVE-verb, it is going to be an obvious candidate for the role of existential predicate.

The paper is organized as follows: section 2 goes over some of the existing semantic accounts of existential-HAVE; section 3 presents a range of data that challenge the existing views in one way or another; in section 4 I introduce the view of relational nouns that I will assume; section 5 lays out the assumptions I make about the notion of nominalized property and its relation to kinds and tokens; section 6 is devoted to the formal analysis; section 7 concludes.

## 2. The received view(s)

Space precludes an exhaustive summary of the analyses that have been put forward for existential HAVE in the last decades. I will limit myself to reviewing the assumptions and main elements that some of the existing accounts are built on (see e.g. Myler (2014) and LeBruyn and Schoorlemmer (2016) for up-to-date introductions to possession and HAVE-verbs).

Partee (1999) is the first compositional account of the observation (made in Keenan (1987)) that HAVE takes a 2-place predicate as its object, the internal argument of which seems to be saturated by the sentence subject. She assigns the determiner a relational type, which results in an NP denoting an ‘unsaturated generalized quantifier’. HAVE is assigned a denotation that takes this special type, contributes an ‘exist’ predicate à la Barwise and Cooper (1981) (which explains the definiteness restriction), and makes sure the subject falls into the right place—the internal argument of the relational noun.

Landman (2004) offers a different view that is reminiscent both of Milsark’s (1974) account of the English existential predicate and of analyses relying on the notion of semantic incorporation (Van Geenhoven, 1998), whereby HAVE combines with relations and provides existential quantification of one of their arguments—thus explaining the definiteness effect. Bassaganyas-Bars (2015) applies a similar view both to existential-HAVE and to the existential predicate in Old Catalan, a language in which the two constructions differ only in the oblique marking of one of the arguments in the latter.

LeBruyn et al. (2016) is another analysis that relies on the notion of incorporation (formalized in Dynamic Montague Grammar). On their view, HAVE takes properties (with implicit arguments) and ‘relationalizes’ them. The range of interpretations available is contributed by the lexical item in the case of relational nouns, and by the noun’s Qualia Structure (Pustejovsky, 1995) in the case of sortal nouns. This analysis provides an insight I will make use of: it suggests that there is no difference in type between relational and sortal nouns; the distinction

<sup>3</sup>For the purposes of this paper, I am not making use of the NP/DP distinction.

between them, however, is crucial for determining the relation the HAVE-sentence eventually expresses. This implies that there is no difference between the two types of nouns regarding the definiteness restriction, a point I will also argue for.

This family of accounts shares the assumption that the analysis of ‘John has a sister’ needs to get us to the denotation logically represented in (2):

$$(2) \quad \exists x.\textbf{sister}(\mathbf{j})(x)$$

In different ways, they all succeed. However, they encounter problems when the full range of determiners (indefinite and definite) that are possible in existential-HAVE contexts is considered, as we will see below. Two of them (Landman and LeBruyn et al.), in fact, are designed for cases where the determiner is *a*, but they leave unclear how to treat other determiners.

Sæbø (2009) tackles the problem from a different angle. His account scopes beyond existential-HAVE to cover all the uses of HAVE. He suggests that HAVE always embeds small clauses (the predicate of which can be overt or implicit) and turns them into predicates, and the lambda-abstracted variable (which can come from a relational noun, an anaphoric element or an implicit relation of possession) is co-indexed with the sentence subject. The role of HAVE is, as in the other analyses, to connect the subject with the material in object position, but the options for accomplishing this go well beyond the binding of the internal argument of the relational noun. As in Partee (1999), the definiteness effect is ultimately attributed to an ‘exist’ predicate associated with relational nouns. Myler (2014) proposes a related analysis in the Distributed Morphology framework.

Sæbø’s analysis is technically complex and requires some non-standard assumptions, but it is able to subsume practically all uses of HAVE under an appealing single account. However, it relies heavily on covert material to yield the right interpretation for HAVE-sentences. In addition, by providing HAVE with a very special sort of semantics, it does not capture any similarities between HAVE and existential and copular contexts in an obvious way.

Although there are important differences among these analyses, in the next section we will see that they all run into complications once we consider all the data we naturally find with HAVE and the kinds of interpretation for HAVE-sentences they give rise to.

### 3. Bringing more data into the picture

The literature on existential constructions has converged on the idea that the definiteness effect requires a more fine-grained explanation than a simple opposition between ‘strong’ and ‘weak’ NPs. Most literature on HAVE, however, still relies on this type of account. There are essentially two kinds of cases where we find HAVE embedding a relational noun with a definite or obligatorily quantificational determiner. The first is not problematic for any of the accounts above. The second, however, is harder to accommodate.

The first case comprises those examples where the DP is not discourse-new and saturation of

the internal argument of the relational noun does not depend on the sentence subject. This class of cases requires heavy contextual support. An example of such a context is provided by LeBruyn et al. (2016: 58). While playing a card-game based on the Simpson family, a player could utter (3a) if she had the card corresponding to Abraham J. Simpson, or (3b) if she were holding Bart, Lisa and Maggie's cards in her hands.

- (3) a. I have the grandfather.  
b. I have every child.

Following Abbott (1993), I will call these readings *contextualized*. They contrast with the normal interpretation of sentences with relational nouns, where the relation expressed by the noun holds between the subject and the object; these are the *non-contextualized* readings. Partee (1999) and LeBruyn et al. (2016) associate contextualized interpretations with another version of HAVE, that works like a regular transitive verb.

The more problematic set of cases are those with definite NPs that clearly correspond to a non-contextualized reading. In some of them we get a kind or amount reading, as these examples from the Corpus of Contemporary American English (Davies, 2008) illustrate:

- (4) a. The guy looks good for his age and has the body of an athlete (COCA)  
b. Stafford has the arm and the intelligence to be a good NFL QB (COCA)  
c. Pigs have the intelligence of a three year old child (COCA)

These sentences express non-contextualized relations between a person/animal and their body, arm, or intelligence, not context-dependent ones. Similar cases have the object of HAVE extracted from a restrictive relative clause. A cursory corpus search suggests that the main verb in the restrictive clause tends to be intensional (5a), but examples with extensional verbs can also be found (5b):

- (5) a. I'd like to tell ten-year old Sarwat that at last he has the friends he was looking for (COCA)  
b. At twenty you have the face nature gave you (COCA)

Finally, NPs with overt classifiers like 'kind' or 'type' get a non-contextualized interpretation with definite articles and even obligatorily quantificational determiners. In a context where three kinds of sisters are being discussed (e.g. nice sisters, indifferent sisters and bully sisters), (6a) is perfectly possible with a non-contextualized reading; in a context where we assume that sisters come in different, recognizable kinds, (6b) is perfectly felicitous as well.

- (6) a. Mary has the three kinds of sisters.  
b. Mary has every kind of sister.

The picture that starts revealing itself looks similar to the one we get with existential constructions. Definite or obligatorily quantificational NPs which preserve a non-contextualized reading with relational nouns are parallel to those that preserve a non-contextualized reading in

English existentials (Lumsden, 1988; McNally, 1992; Abbott, 1993, 1997):

- (7) a. There was every \*(kind of) biologist at that conference.  
b. John has been every \*(kind of) biologist.

The analyses we have gone over in the previous section do not account in an obvious way for this pattern of data. One can however envisage ways to accommodate the definites, e.g. by invoking type-shifting mechanisms or some operation akin to Chierchia's Derived Kind Predication (Chierchia, 1998).<sup>4</sup> In contrast, the behavior of quantificational NPs if they quantify over kinds is harder to fit into any of the analyses.

Other data point to the fact that HAVE does not behave like a regular, extensional transitive verb that relates two token-level entities. One such case is the resistance of the object of HAVE to be pronominalized with *wh*-relative pronouns. This feature is also shared with existential constructions, and contrasts with a common transitive like 'date':

- (8) a. I like some of the friends/qualities \*which/that/∅ John has.  
b. I talked to some of the people \*which/that/∅ there are in this class.  
c. I know some of the people which/that/∅ you've been dating.

More evidence comes from dialects of English which allow for *that*-less subject relative clauses. They are permitted in intensional contexts, some copular constructions, existentials and HAVE-sentences (examples from McNally (2009)):

- (9) a. I have an idea might work.  
b. There's a man here can't speak English.

Finally, there is the fact that the most natural interpretation of an anaphoric pronoun in the object position of HAVE is a kind-level one (Myler, 2014). In a context where someone expresses admiration for a car parked on the street (say it is a Porsche 911), *it* or *one* in (10a) can be interpreted as referring to the car in question, whereas in (10b) they refer naturally to the kind of car, not the specific car-token.

- (10) a. Did you know Mary owns it/that's the one Mary owns?  
b. Did you know Mary has it/that's the one Mary has?

Data of this kind involving the English existential construction led McNally (1992) to analyze the pivot not as a token-level individual, but a higher-level one—a nominalized property. The introduction of an actual individual into the discourse (satisfying the descriptive content of the property) results from an entailment of the use of a HAVE-sentence.

The behavior of HAVE-sentences illustrated in (8), (9) and (10) looks mysterious under any of the accounts reviewed in the previous section, which in all cases consider HAVE a relation

<sup>4</sup>Derived Kind Predication is type-shifting operation that applies to predicates of objects so that they can combine with kind-denoting NPs. See Chierchia (1998: 364) for details.

between token-level individuals. In contrast, it gets a natural account if we consider that the object of HAVE denotes precisely a nominalized property. *Wh*-relative pronouns can be argued to be restricted to token-level entities; *that*-less relative clauses seem to be possible when the antecedent of the omitted pronoun refers to a non-token-level entity, and the kind-level interpretation of the anaphora in the object of HAVE follows if kinds are understood as higher-order individuals as well (as most literature making use of both nominalized properties and kinds assumes—see e.g. Chierchia (1998) and McNally (2009)).

If we consider in addition that, as mentioned above, HAVE is one of the main sources of existential predicates cross-linguistically (Creissels, 2014), which is expected if the object of HAVE and the pivot in existential predicates are ontologically similar, an account that treats HAVE as a relation between a token-level individual and a nominalized property starts looking like a serious candidate for explaining what is it that makes HAVE look like such a strange, slithery creature. Before turning to the formal analysis, I will lay out the assumptions I will make about relational nouns and nominalized properties.

#### 4. A non-transitive view of relational nouns

Most of the accounts of existential-HAVE reviewed above rest on the view of relational nouns which conceives of them as transitive nouns.<sup>5</sup> Making logical representations like (11) fit into the composition of HAVE-sentences is the thread that unifies this line of research.

$$(11) \quad \llbracket \text{mother} \rrbracket = \lambda x \lambda y. \text{mother}(x)(y)$$

This view of relational nouns is not, however, without problems. One of them is that it groups together classes like body-parts, kinship terms, parts and wholes and deverbal and deadjectival nominalizations (Barker, 1995), which on the one hand are treated in disparate ways in different languages, and on the other tend to behave differently with respect to tests within each individual language (Heine, 1997).

A second (related) problem is that tests that select for the class of relational nouns as a whole are scarce. The most used one is compatibility with *of*-PPs in possessive NPs in English. This test is not free of problems either, as the felicity of (12a) (from LeBruyn et al. 2016), and the existence of contrasts like the one in (12b) shows.<sup>6</sup> (See LeBruyn et al. (2016) and references therein for more issues on the conception of relational nouns as transitive nouns.)

- (12)    a.    The blog of Doctor Watson  
           b.    The hammer of Thor/#my uncle

<sup>5</sup>LeBruyn et al. (2016) treat them as being of type  $\langle e, t \rangle$ , but they ultimately rely on providing them with another argument to explain their interaction with HAVE.

<sup>6</sup>This particular example may point to a contrast between necessary and contingent relations, which some languages mark overtly (Heine, 1997). The relation between Thor and a hammer can be conceived as a necessary one; having a hammer is one of the features that defines Thor. In contrast, it does not define normal people's normal uncles. The fact that relational nouns normally sound felicitous in the *of*-PP construction could stem from the fact that they express necessary relations, but the class of necessary relations is bigger than the ones expressed by relational nouns. Whether this hypothesis is worth pursuing remains for future research.

Although these arguments against treating relational nouns as having argument structure are not absolutely conclusive, there might be room for an alternative treatment that avoids these problems, simplifies composition, and makes additional correct predictions. I will therefore treat relational nouns as one-place predicates with an associated meaning postulate whereby they entail the existence of another entity they are in a particular relation to:

- (13) a.  $\llbracket mother \rrbracket = \lambda x. \mathbf{mother}(x)$   
 b.  $\forall x \forall w [\mathbf{mother}_w(x) \rightarrow \exists y [\mathbf{motherhood}_w(y)(x)]]$
- (14) a.  $\llbracket friend \rrbracket = \lambda x. \mathbf{friend}(x)$   
 b.  $\forall x \forall w [\mathbf{friend}_w(x) \rightarrow \exists y [\mathbf{friendship}_w(y)(x)]]$
- (15) a.  $\llbracket top \rrbracket = \lambda x. \mathbf{top}(x)$   
 b.  $\forall x \forall w [\mathbf{top}_w(x) \rightarrow \exists y [\mathbf{part-whole}_w(y)(x)]]$

On this view, relational nouns are relation-entailing predicates of individuals. Let us hypothesize that their use in discourse is governed by the condition in (16):

- (16) The introduction of a token discourse referent for a relation-entailing individual  $x$  needs to be anchored to a discourse referent corresponding to the other argument in the relation they entail.

To see how this works, let us consider the following example, which illustrates how the relational noun ‘girlfriend’ can be used in discourse:

- (17) After a woman found out via Facebook that a man who’d ‘poked’ her in real life had a long term girlfriend, she turned to digital manners advice givers Farhad Manjoo and Emily Yoffe of Slate to ask whether she should tell the girlfriend. (COCA)

The entity corresponding to the description ‘girlfriend’ is first introduced into this piece of discourse by a HAVE-sentence. The condition above is respected: the HAVE-sentence anchors it to the other entity in the relation. Once this is done, an entity satisfying the description has entered the discourse and can be referred to freely, as in the last sentence of (17).<sup>7</sup>

(17) illustrates that the most straightforward way English offers to introduce a relational noun into the discourse is a HAVE-sentence.<sup>8</sup> The relation between HAVE and relational nouns seems to be a symbiotic one. These (individual-denoting) nouns need a predicate to introduce them

<sup>7</sup>This view explains another putative test for relational nouns, viz. incompatibility with predicatively used genitives (Partee, 1997):

- (i) a. That computer is John’s  
 b. ??That girlfriend is John’s

The infelicity of (ib) can be attributed to a violation of (16). Making the relational noun the sentence topic strongly implies that the individual it describes is already part of the discourse model. This entails that the entity it is in a relation to has also been introduced. The only possibility to interpret (ib) is to look for an alternative relation between this ‘girlfriend’ and John. Lacking any context, we cannot find one.

<sup>8</sup>Another possibility is the use of a possessive NP (either with ‘s or an *of*-PP), in which case the existence of the relation is presupposed and needs to be accommodated by the hearer.

into the discourse by linking them to an individual, to which they are in the relationship they entail. The job of HAVE, in turn, is precisely to introduce into the discourse relations linked to an individual—and eventually resulting in the addition of an individual describable with the relational noun into the discourse model. HAVE cannot supply a value for the relation, but the meaning postulate associated with the relational noun is there to contribute one.

The treatment of relational nouns presented here is parallel to the one for deverbal nouns in Grimm and McNally (2013), a class of nouns which is usually analyzed as relational (Barker, 1995: 60-62). Grimm and McNally treat them as one-place, relation-entailing nouns. They denote properties of events and are subject to a discourse condition very similar to (16): when they are introduced into the discourse, they need to be anchored to one of the participants they entail (see Grimm and McNally (2013) for details).

The account presented so far explains the relations conveyed by HAVE-sentences with discourse-new relational nouns. Turning to discourse-new sortal nouns, I will argue that they are used to convey non-ambiguous relations as well. Their value does not come from entailments of the noun, but from a combination of the semantics of the object and the subject, and world-knowledge. This is illustrated by the following sentences:

- (18)    a.    My neighbor has many dogs  
           b.    Have you visited John's pet shop? He has many dogs!  
           c.    If you want to buy a dog, go to the dog pound first: they have many dogs

Sentence (18a), uttered in a context where no specific information about the neighbor in question is part of the conversational background, expresses the standard relation that holds between human beings and dogs, the one we could call a 'person-dog relation'. This relation, provided by world knowledge, entails things like having the dog at home, feeding it, walking it, petting it, etc. This contrasts with the relations between dogs and pet-shop owners (18b) and dog-pounds (18c), for which different sets of entailments hold.

The upshot of that is that, when we hear a HAVE sentence with a non-relational noun like *dog* in object position, in a certain context, and after we have identified what kind of entity the subject is, world knowledge gives us a default relation between the two entities; this is how the nature of the relation introduced by HAVE is determined with non-relational nouns.<sup>9</sup>

It follows from the present account (as it does from LeBruyn et al. 2016) that the contrast between (1a) and (2) is an illusory one, and that something much like the definiteness effect should also hold for sortal nouns. That is, the way the full interpretation of (19a) and (19b) is determined differs.

<sup>9</sup>This view thus goes against accounts that rely entirely on free 'pragmatic determination' to settle the actual relation holding between the subject of the sentence and a noun like 'dog'. In contrast, it could in principle be compatible with the most elaborate account of how the meaning of these sentences is determined (LeBruyn et al., 2016), although how to factor in the contribution of the subject in this account is not immediately obvious. It is also compatible with a 'co-composition' account along the lines of Spalek (2014). Further details concerning this aspect of the analysis must be left for future research.

- (19) a. John has a/two/many beautiful car(s)  
 b. John has the/every/both beautiful car(s)

Tham (2006) defends this view. She argues that (19a) is an instance of ‘presentational *have*’, which requires the NP to be discourse-new; the definiteness effect is given a pragmatic explanation à la Abbott (1993). (19b), in contrast, is a special use where HAVE can take definite NPs, which is only possible when previous context supplies a relation between the two entities (Tham, 2006: 143). LeBruyn et al. (2016) reach a similar conclusion. Tham argues that there are languages (e.g. Mandarin Chinese) with a HAVE-verb that forbids definite objects. In the same vein, Heine (1997) points out that ‘there exists a strong correlation between have-constructions and the presence of indefinite possessors, to the effect that, in many languages, have-constructions assume meanings other than possessive ones unless associated with indefinite possessors’ (Heine, 1997: 35).

Therefore, there seems to be some evidence for an account that teases apart how we determine the meaning in (19a) and (19b), so that (19b) is grouped with (20) instead.

- (20) John has the/every/both child(ren)

This sentence is possible in a context where a child (or some children) are already part of the discourse model. According to (16), this requires that the entity they are in a parent-child relation to has been introduced into the discourse as well. Therefore, the relation between John and the child(ren) in question that (20) refers to has to be determined in some other way. Tham and LeBruyn et al. argue that in at least some of these cases it is up to discourse context to provide a salient interpretation. For instance, (20) could be uttered in a context where a group of paparazzi are following a celebrity family and they are assigned family members as specific targets. Partee (1999) and Sæbø (2009) seem to rely on vague interpretations of ‘possessive’ relations such as control, part-whole, etc. The issue cannot be settled here—although see Tham (2006) for some examples that do not imply ‘control’ in any intuitive way.

Equipped with these assumptions about relational and sortal nouns and the way they interact with HAVE, we can now tackle the next piece of the analysis: nominalized properties.

## 5. Nominalized properties, kinds and tokens

Nominalized properties, also called ‘nominalized functions’ and ‘entity correlates of properties’ in the literature, are a sort in the domain of entities corresponding to the reification of the description of a standard  $\langle e, t \rangle$  property. They were introduced by Gennaro Chierchia (Chierchia, 1984) as part of his Property Theoretic analysis of nominalization. Chierchia’s motivation was to give a compositional account for sentences like (21):

- (21) {Being nice/Goodness/That John is here/Red} is nice.

The operators  $\cup_n$  are used to type-shift back and forth from properties as predicates to properties as individuals. Entity correlates of properties (generally adapted to a model-theoretic

framework) have since been used for the analysis of existential sentences (McNally, 1992; McCloskey, 2014), kinds (Chierchia, 1998) and possessives (Koontz-Garboden and Francez, 2010), and have been argued to offer an alternative to semantic incorporation of  $\langle e, t \rangle$ -type objects (McNally, 2009) with different empirical consequences.

Nominalized properties are similar to kinds (Carlson, 1977); both are higher-order entities in  $D_e$  that are reified by token-level (possibly plural), particular individuals. How to tease the two notions apart has not been definitely established in the literature. It is generally agreed that kinds are a subset of nominalized properties; differences that have been suggested are the requirement that kinds have some degree of well-establishedness and a domain structured as a taxonomic hierarchy, whereas this does not necessarily hold for nominalized properties (Krifka, 1995; Chierchia, 1998; McNally, 2009; Müller-Reichau, 2011). In this section I will make a concrete proposal regarding the structure of the domain of entities, the relation between the different sorts inside this domain, and about NP-semantics. Full justification of each step would be beyond the scope of this article; see Bassaganyas-Bars (forthcoming).

I will assume a subdivision within  $D_e$  into token-level entities ( $e_o$ ), kind-level entities ( $e_k$ ) and nominalized properties ( $e_p$ ). The latter two form the sub-domain of higher-order entities. Variants of the realization relation **R** (Carlson, 1977) connect higher-order individuals to token-level individuals, but also nominalized properties to kinds.

The relation **R**<sub>ko</sub> is the Carlsonian **R**, the one that holds between an entity  $x_o$  and the kind  $y_k$  that it is an instance of. Unlike kinds, entities of sort  $e_p$  can include information on degree and number.<sup>10</sup> **R**<sub>po</sub> is the relation that holds between e.g. a (complex) individual  $x_o$  which is the sum of two object cars, and the (nominalized) property of being two cars (**two cars**<sub>p</sub>).

Introducing the role of **R**<sub>pk</sub> requires first outlining how the sub-domain of kinds is organized. This sub-domain is structured by a (transitive, asymmetric) taxonomic relation **T** (Krifka et al., 1995): **T**( $x, y$ ) holds if  $x$  is a subkind of  $y$ . Turning away from artificially constructed Linnaean taxonomies, what counts as a subkind of what is context-dependent. If we take the kind **car**<sub>k</sub>, either of these taxonomies –and many others– can be operative depending on context:

**R**<sub>pk</sub>( $x, y$ ) holds if  $x$  is an individual or a sum consisting of a number  $n$  of individuals of sort  $e_k$ , which are in the **T** relation with a kind  $z_k$ , and  $y$  is the property of being  $n$  sub-kinds of  $z_k$ .

<sup>10</sup>For the present purposes, I will focus on count nouns, so I will consider only information on number.

In the taxonomies above,  $\mathbf{A1}_k$  or  $\mathbf{Ford}_k$  are in the  $\mathbf{R}_{pk}$  relation to **one kind of car<sub>p</sub>**. Likewise,  $\mathbf{R}_{pk}(\mathbf{A1}_k \oplus \mathbf{A4}_k, \text{two kinds of Audi}_p)$  and  $\mathbf{R}_{pk}(\text{small car}_k \oplus \text{family car}_k, \text{two kinds of car}_p)$  also hold.

I will not consider well-establishedness as a prerequisite for kind-level denotation.<sup>11</sup> This implies that most instances of noun modification can be treated as kind-level modification. In addition, I will consider, following Müller-Reichau (2011: 51), that a set of sub-kinds (e.g.  $\lambda x_k[\mathbf{dog}(x_k)]$ ) and the corresponding kind-qua-entity ( $\mathbf{dog}_k$ ) are informationally equivalent. A variant of the  $\cap$  operators allows us to type-shift between the two kinds of denotation.

This view draws heavily from the NP-semantics posited in Krifka (1995) which he terms ‘concept-level’, and which I will consider analogous to the view of nominalized properties I am defending. Combining Krifka’s insights and the assumptions made so far, I will adopt the following logical representation of the denotation of ‘two cars’:

$$(22) \quad \llbracket \text{two cars} \rrbracket = \lambda y_p \forall x [(\mathbf{R}_{ko} \mathbf{T}(x, \mathbf{car}_k) \wedge \mathbf{two}(x)) \leftrightarrow \mathbf{R}_{po/pk}(x, y_p)]$$

This representation means that, in a classifier-less language like English, ‘two cars’ denotes the set of higher-order entities  $y_p$  such that either (i) any complex entity  $x$  which realizes the kind  $\mathbf{car}_k$ , and is the sum of two atoms, is in the  $\mathbf{R}_{po}$  relation to  $y_p$ , or (ii) any complex entity  $x$  comprised by sub-kinds of the kind  $\mathbf{car}_k$  is in the  $\mathbf{R}_{pk}$  relation to  $y_p$ .<sup>12</sup>

Whether (i) or (ii) is the right interpretation will depend on context. If a conversation is about a new neighbor, ‘two cars’ in ‘she only has two cars’ will most likely refer to the property of being two object cars; if it is about where to buy a new car, the same NP in ‘this dealer only has two cars’ can very plausibly refer to the property of being two sub-kinds of  $\mathbf{car}_k$ .

<sup>11</sup>Well-establishedness might be a prerequisite for some constructions (e.g. kind-denoting definite singular NPs), but not for kind-level denotation in general. That is, ‘blue shoe with pink dots’ can be as much of a kind as ‘mountain shoe’.

(i) Blue shoes with pink dots are rare/common/trendy this year.

<sup>12</sup>What this amounts to is that ‘two cars’ in English can denote the set of individuals in the second row of either of these lattices (corresponding to the domain of kinds and the domain of objects):

The atomic individuals in the object domain are the members of the set of objects resulting from applying  $\mathbf{R}_{ko}$  to one of the individuals in the kind-domain (in that case,  $\lambda x. \mathbf{R}_{ko}(x, \mathbf{Fiesta}_k)$ ).

How do we get to the logical representation in (22)? I will follow the literature on so-called ‘layered’ approaches to the semantics of noun phrases in considering that the innermost layer of the NP denotes in the kind-domain. Common nouns denote predicates of kinds, adjectives can be treated as predicates of kinds as well, and composition with modifiers can be treated as predicate modification. As already mentioned, I follow Müller-Reichau’s (2011) claim that a set of subkinds and its corresponding kind-qua-entity are informationally equivalent. A variant of Chierchia’s  $\cap$  type-shifter applies to yield an output of type  $e_k$ .

Following Krifka (1995), and deviating somewhat from the usual layered-DP accounts, I suggest that the layer that contributes information on number does not involve turning the kind-level denotation inherited from the innermost layer into the set of objects realizing it. Instead, at this point we create the nominalized property  $y_p$  of being a number  $n$  of realizations or subkinds of a certain kind  $z_k$ . I will call this layer ClassP (Borer, 2005). Its head is a—covert or overt—classifier taking two arguments, a kind-level entity and a cardinality word (with  $N$  being a variable over cardinality predicates).<sup>13</sup>

$$(23) \quad \llbracket \text{Class} \rrbracket = \lambda z_k \lambda N \lambda y_p \forall x [((\mathbf{R}_{ko} \mathbf{T}(x, z_k) \wedge N(x)) \leftrightarrow \mathbf{R}_{po/pk}(x, y_p))]$$

After combination with the two arguments, we reach (22), repeated here as (24).

$$(24) \quad \llbracket \text{two cars} \rrbracket = \lambda y_p \forall x [(\mathbf{R}_{ko} \mathbf{T}(x, \text{car}_k) \wedge \text{two}(x)) \leftrightarrow \mathbf{R}_{po/pk}(x, y_p)]$$

(24) denotes a set. At this point, two things can happen: this set can either be the input to a definite or obligatorily quantificational determiner, or we can pragmatically bind the variable corresponding to the nominalized property with the iota-operator, reflecting the fact that the nominalized property introduced into the discourse is presupposed to be unique, thus yielding (25). As we will see in the next subsection, this is of the type HAVE looks for.

$$(25) \quad \llbracket \text{two cars} \rrbracket = \iota y \forall x [(\mathbf{R}_{ko} \mathbf{T}(x, \text{car}_k) \wedge \text{two}(x)) \leftrightarrow \mathbf{R}_{po/pk}(x, y_p)]$$

English has some overt classifiers; one of them is ‘kind/sort/type of’. This classifier restricts the interpretation of the NP to the property of being  $n$  sub-kinds of a certain kind.

<sup>13</sup>By making the cardinality word obligatory, the fact that overt classifiers in English need some kind of determiner is captured. That is, it rules out bare plurals with classifiers like ‘kind’, which are ungrammatical.

- (i) a. \*Kinds of whales are extinct.
- b. \*John sells kinds of cars.

$$(26) \quad \llbracket \text{kind of} \rrbracket = \lambda z_k \lambda N \lambda y \forall x [(\mathbf{T}(x, z_k) \wedge \mathbf{N}(x)) \leftrightarrow \mathbf{R}_{pk}(x, y)]$$

At this point I have finally introduced the necessary pieces to undertake the compositional analysis of HAVE-sentences.

## 6. Analysis

This is the logical representation I propose for HAVE, where  $\pi$  is an unspecified relation:

$$(27) \quad \llbracket \text{HAVE} \rrbracket = \lambda x_p \lambda y \lambda s [\pi(s) \wedge \text{PROTO-WHOLE}(s)(y) \wedge \text{PROTO-PART}(s)(x_p)]$$

This denotation assumes the view on argument structure in Dowty (1991). However, the proto-roles used here are the ones proposed in Barker and Dowty (1993) for possessive NPs. Although it is not crucial, this move has two welcome consequences. First, it captures the fact that the relations expressible with a HAVE-sentence overlap with those that can be conveyed by possessive NPs (for which the PROTO-WHOLE and PROTO-PART proto-roles were designed).<sup>14</sup> Second, it naturally filters out odd sentences like (28a)–(28c):

- (28) a. #Three windows have a house.  
 b. #A problem has John.  
 c. #The tail has a cat.

With all the assumptions in place, let us begin with HAVE-sentences with a discourse-new object-NP containing a relational noun, as in (29). Relational nouns are treated as are one-place predicates with an associated meaning postulate, as (30) illustrates:

(29) John has two smart sisters.

- (30) a.  $\llbracket \text{sister} \rrbracket = \lambda x. \mathbf{sister}(x)$   
 b.  $\forall x \forall w [\mathbf{sister}_w(x) \leftrightarrow \exists y [\mathbf{siblinghood}_w(y)(x)]]$

Applying the NP-semantics outlined in the previous section, we start from ‘sister’ as a set of (sub-)kinds and combine it with ‘smart’ (modeled as a predicate of kinds as well) by predicate modification, yielding (31). Following the assumptions above,<sup>1</sup> steps in, returning (32):

$$(31) \quad \llbracket \text{smart sister} \rrbracket = \lambda x_k. \mathbf{sister}(x_k) \wedge \mathbf{smart}(x_k)$$

$$(32) \quad \llbracket \text{smart sister} \rrbracket = \mathbf{smart sister}_k$$

*Class*, defined in (23) above, takes (32) as an argument, and the result combines with the

<sup>14</sup>Note that ‘John has two houses’ denotes different relations if we refer to John as a regular guy, a realtor, a kid with divorced parents, etc., and that all of these relations can be expressed by a possessive NP like ‘John’s two houses’. However, the opposite might not be true, as Heine (1997) points out, because the NP can also mean in context ‘the two houses that John likes’, but it is not clear whether this relation can be expressed by the HAVE sentence ‘John has two houses’. The relevant point is that the same roles hypothesized for nominal possession could be used for HAVE-sentences.

cardinality predicate, eventually yielding (34):

$$(33) \quad \lambda z_k \lambda N \lambda y_p \forall x [((\mathbf{R}_{ko} \mathbf{T}(x, z_k) \wedge N(x)) \leftrightarrow \mathbf{R}_{po/pk}(x, y_p)) (\mathbf{smart\ sister}_k) = \\ \lambda N \lambda y_p \forall x [((\mathbf{R}_{ko} \mathbf{T}(x, \mathbf{smart\ sister}_k) \wedge N(x)) \leftrightarrow \mathbf{R}_{po/pk}(x, y_p))]$$

$$(34) \quad \lambda N \lambda y_p \forall x [((\mathbf{R}_{ko} \mathbf{T}(x, \mathbf{smart\ sister}_k) \wedge N(x)) \leftrightarrow \mathbf{R}_{po/pk}(x, y_p)) (\lambda z. \mathbf{two}(z)) = \\ \lambda y_p \forall x [((\mathbf{R}_{ko} \mathbf{T}(x, \mathbf{smart\ sister}_k) \wedge \mathbf{two}(x)) \rightarrow \mathbf{R}_{po/pk}(x, y_p))]$$

The contextually triggered iota-operator applies at this point, yielding (35):

$$(35) \quad \iota y_p \forall x [((\mathbf{R}_{ko} \mathbf{T}(x, \mathbf{smart\ sister}_k) \wedge \mathbf{two}(x)) \rightarrow \mathbf{R}_{po/pk}(x, y_p)) = \\ \mathbf{two\ smart\ sister}_p]$$

This is the input that HAVE can take, giving us (37) after combination with the subject:

$$(36) \quad \lambda x_p \lambda y \lambda s [\pi(s) \wedge \text{PROTO-WHOLE}(s)(y) \wedge \text{PROTO-PART}(s)(x_p)] (\mathbf{two\ smart\ sister}_p) = \\ \lambda y \lambda s [\pi(s) \wedge \text{PROTO-WHOLE}(s)(y) \wedge \text{PROTO-PART}(s)(\mathbf{two\ smart\ sister}_p)]$$

$$(37) \quad \lambda s [\pi(s) \wedge \text{PROTO-WHOLE}(s)(\mathbf{john}) \wedge \text{PROTO-PART}(s)(\mathbf{two\ smart\ sister}_p)]$$

After this set of states is existentially closed at some point further in the derivation, (37) introduces an entity of sort  $e_p$  into the discourse and an unspecified relation  $\pi$  linking it to John. Following McNally (1992), I suggest that adding a HAVE-sentence into the discourse entails the introduction of a discourse referent satisfying the description. A token-level individual in the  $\mathbf{R}_{po}$  relation to **two smart sisters**<sub>p</sub> thus enters the discourse model.

This is the point where the value of  $\pi$  is determined. ‘Sister’ is a relational noun. Condition (16) above established that entities describable by such predicates can only be introduced into the discourse by anchoring them to the other argument in the relation they entail. This is what the HAVE-sentence does. Therefore, as a result of updating the discourse with (37), a relation ( $\pi$ ) between John and two token-level individuals satisfying the descriptive content of **two smart sisters**<sub>p</sub> is asserted. Then, by virtue of the entailments on the introduction of a relational noun into the discourse, this relation is set to ‘siblinghood’:  $\pi$  gets its value. We reach the desired interpretation in an indirect way which allows us to account for the fact that the object of HAVE does not behave as a token-level individual, as shown in section 3.

The derivation of a sentence with a discourse-new sortal noun, like (38), is only minimally different. Following the same steps as for (29) above, we reach the representation in (39).

$$(38) \quad \text{John has three bicycles.}$$

$$(39) \quad \lambda s [\pi(s) \wedge \text{PROTO-WHOLE}(s)(\mathbf{john}) \wedge \text{PROTO-PART}(s)(\mathbf{three\ bicycles}_p)]$$

As a result, the nominalized property **three bicycles**<sub>p</sub>, and an unspecified relation  $\pi$  between this property and John, are added into the discourse model; by the entailments of the use of

HAVE-sentences, three object bicycles are introduced as well. ‘Bicycle’ is a sortal noun, so there is no meaning postulate to fall back on to retrieve a value for  $\pi$ . The object is discourse-new, so no context-dependent relations involving bicycles are being discussed. In such cases, world-knowledge is resorted to. Assuming that John is an individual with no particular relation to bicycles (he is not a professional cyclist, bicycle repairer or seller, etc.), the value of  $\pi$  will be set to the ‘person-bicycle-relation’, the one most of us have with our bikes (entailing exclusive right of use, responsibility for taking care of it, etc.). If John had been a cyclist,  $\pi$  would have been set to ‘cyclist-bicycle-relation’, with different entailments, and so forth.

So far we have considered the most straightforward cases among the ones discussed in section 3. It will be useful to consider how this analysis treats other cases where HAVE-sentences get a non-contextualized reading. One of them involves sentences like (40).

(40) John has three kinds of brothers.

Note that condition (16) does not apply to kind-level NPs with relational nouns. (41) relies on a discourse context containing individuals of sort  $e_k$  corresponding to sub-kinds of brothers. Whether it contains token-level individuals realizing them is immaterial. ‘Kinds of brothers’ can be introduced without having to anchor them to any other individual.

(41) Some kinds of brothers are harder to put up with than others.

Still, the natural interpretation of (40) is the one where John is one of the arguments of a siblinghood relation. How does this come about? Adding (40) to a context introduces the nominalized property **three kinds of brother**<sub>*p*</sub> and a relation  $\pi$  linking it to John. By entailment, a token-level discourse referent has to be added. The only way to satisfy this is by adding a complex individual whose atoms are (an unspecified number of) realizations of three different sub-kinds of brothers, with at least one token-level individual per sub-kind (e.g. two nice brothers, one bully brother, and two nerdy brothers). This means that token-level entities that satisfy the description ‘brother’ enter the discourse, and at this point, by virtue of the meaning postulate associated with token-level relational nouns,  $\pi$  is interpreted as ‘siblinghood’ and John is interpreted as the other member of the relation for each of the token-level entities eventually introduced into the discourse model.

Sentence (42) differs from (40) in the presence of the definite article, which nonetheless does not block a non-contextualized interpretation.

(42) John has the three kinds of brothers.

The interpretation is derived similarly: the definite article implies that previous context contains entities corresponding to three sub-kinds of brother, but not necessarily entities realizing them. The nominalized property **the three kinds of brother**<sub>*p*</sub>, which refers to the property of being the specific three kinds of brother being discussed, is made the object of a HAVE-sentence, and this entails the introduction of an unspecified number of object-level entities such that there is at least one for each of the three sub-kinds. Again by virtue of the meaning postulate associated

with relational nouns, the relation between the entities and the subject of the sentence will be ‘siblinghood’. What (42) illustrates is that, in its role of introducing relations into the discourse with a non-contextualized interpretation, HAVE cares more about the sort of its object-NP (it needs to be higher-order) than about its being discourse-new.

Let us now consider HAVE-sentences with obligatorily quantificational determiners which nonetheless yield non-contextualized interpretations, such as (43).

(43) John has every kind of brother.

The result of combining the overt classifier ‘kind of’ to a kind-denoting NP, as defined in section 5, yields the following representation:

$$(44) \quad \llbracket \text{kind of brother} \rrbracket = \lambda N \lambda y_p \forall x [(\mathbf{T}(x, \mathbf{brother}_k) \wedge N(x)) \rightarrow \mathbf{R}_{pk}(x, y_p)]$$

‘Every’ requires arguments of type  $\langle e, t \rangle$ , so there will be a type-mismatch. I will assume that, in cases where phrases headed by overt classifiers combine with quantificational determiners, there is a covert cardinality predicate (**At**) predicating atomicity, which saturates the N in the derivation.<sup>15</sup> As a result, we get the desired type:

$$(45) \quad \llbracket \text{kind of brother} \rrbracket = \lambda y_p \forall x [(\mathbf{T}(x, \mathbf{brother}_k) \wedge \mathbf{At}(x)) \rightarrow \mathbf{R}_{pk}(x, y_p)]$$

Since (45) denotes a set of entity correlates of properties, ‘every’ will quantify over higher-order entities, as illustrated by the simplified representation in (46). Sentences like (43) are thus licensed. The non-contextualized interpretation comes about as in (40) and (42) above.

$$(46) \quad \text{Every } x_p [\lambda y_p \forall x [(\mathbf{T}(x, \mathbf{brother}_k) \wedge \mathbf{At}(x)) \rightarrow \mathbf{R}_{pk}(x, y)] (\pi(x_p)(\mathbf{John}))]$$

Derivation of sentences like (47a)–(47c) rely on the existence of covert kind classifiers. With all the assumptions about the interpretation of HAVE-sentences with kind-denoting NPs discussed in this section, their interpretation should be straightforward.

- (47) a. John has the hair of a metal star from the 80’s.  
 b. John has the hair of Joey Tempest/Joey Tempest’s hair.  
 c. John has the hair he always dreamed of.

Space only allows for a brief remark on contextualized readings, cases like (3a), (3b), (19b) or (20) above. It was mentioned in section 3 that only some languages have a version of HAVE that supports these readings. On this analysis, it will be a version of HAVE that preserves its function of introducing relations linked to an entity in the discourse, but in this case the other entity in the relation will be of sort  $e_o$  instead of  $e_p$ , as in (48).

$$(48) \quad \llbracket \text{HAVE}_{\text{context.}} \rrbracket = \lambda x_o \lambda y \lambda s [\pi(s) \wedge \text{PROTO-WHOLE}(s)(y) \wedge \text{PROTO-PART}(s)(x_o)]$$

<sup>15</sup>This covert atomicity predicate has an overt expression in ‘every single kind of’. Note as well that there are cases of ‘every’ taking NPs with overt cardinality predicates (e.g. ‘every two days’).

The main difference lies in the value  $\pi$  can take: the strategies used above with discourse-new NPs are not available, so previous context, or an all-encompassing notion of ‘control’, has to be called on. There are languages that distinguish these two uses of HAVE overtly: Spanish, for instance, does it through the presence or absence of Differential Object Marking.<sup>16</sup>

## 7. Conclusions

The syntactic and semantic peculiarities of HAVE can be explained by analyzing it as a relation between token-level individuals and nominalized properties, and by considering that the way this relation is specified depends on the noun being sortal or relational. I have focused on cases where HAVE embeds NPs. Whether this approach can be extended to other uses of HAVE remains for future research (see Bassaganyas-Bars (forthcoming)).

# A unified existential semantics for bare conditionals<sup>1</sup>

Itai BASSI — *Massachusetts Institute of Technology*

Moshe E. BAR-LEV — *Hebrew University of Jerusalem*

**Abstract.** Bare conditionals show an unexpected quantificational variability contingent on whether they are embedded in an Upward Entailing context (universal import) or a Downward Entailing context (existential import). Contra Herburger (2015a, b)’s ambiguity theory, we argue in favor of a unified semantics for bare conditionals based on their behavior in VP ellipsis constructions and in non-monotonic contexts. We show that a similar pattern exists with Free Choice phenomena, and consequently suggest a parallel analysis to Fox (2007)’s treatment of such phenomena. We propose that bare conditionals have a basic existential semantics which is obligatorily strengthened into a universal meaning in UE contexts, while being preserved in DE contexts. Our claim that bare conditionals are underlyingly existential is further supported by Conditional Perfection data with bare and non-bare conditionals.

**Keywords:** conditionals, homogeneity, exhaustivity, alternatives, conditional perfection, quantification, free choice

## 1. Higginbotham’s puzzle and existing solutions

A bare conditional as in (1a) involves *universal* (or universal-like) generalization over cases (or worlds).<sup>2</sup> As first observed by Higginbotham (1986), this meaning is preserved when the conditional is embedded in the scope of *every*, as in (1b), but when embedded in the scope of *no* as in (1c) it seems as though the conditional contributes an *existential* force.<sup>3</sup> Having a universal meaning for the conditional in (1c), as in (1cii), will result in a too-weak meaning which is compatible with someone having a case where they goof off and succeed.

- (1) a. If you work hard you succeed.  
      ≈ In **all** cases where you work hard, you succeed.
- b. Everyone will succeed if they work hard.  
      ≈ For every x, in **all** cases where x works hard, x succeeds.
- c. No one will succeed if they goof off.
  - (i) ≈ There is no x s.t. **there is** a case where x goofs off and x succeeds.
  - (ii) ≠ There is no x s.t. in **all** cases where x goofs off, x succeeds.

Higginbotham (1986) presents the paradigm in (1) as a problem for compositionality, and this surprising behavior has troubled semanticists ever since (see Kratzer 2015; Leslie 2008; Herburger 2015a, b, a.o.).

<sup>1</sup>We would like to thank Sam Alxatib, Luka Crnič, Kai von Fintel, Danny Fox, Andreas Haida, Elena Herburger, Roni Katzir, Angelika Kratzer, Daniel Margulis, and the audiences in Sinn und Bedeutung 21 and NELS 46. All mistakes and shortcomings are our own.

<sup>2</sup>We limit ourselves here to conditionals that have some intensional import, and ignore quantified conditionals of the kind discussed in Kratzer (2015) which seem to only care about the actual world.

<sup>3</sup>Higginbotham’s own description is in terms of material implication vs. conjunction, but the puzzle persists in a more standard framework where conditionals aren’t truth-functional but involve quantification over worlds.

It has been argued by von Fintel and Iatridou (2002) (and more recently by Herburger 2015a) that the behavior of the embedded conditional in (1c) is not unique to conditionals in the scope of *no*, but extends to other Downward Entailing (DE) environments, for example when a bare conditional is embedded under *doubt*:

- (2) I doubt that Mary will come if John comes.  
 a.  $\approx$  I doubt that **there is** a case where John comes and Mary comes.  
 b.  $\not\approx$  I doubt that in **all** cases where John comes Mary comes.

The generalization that emerges is that systematically, bare conditionals contribute universal quantification in UE environments and existential quantification in DE environments. To conclude, we are left with a puzzle, which we'll call Higginbotham's puzzle:

- (3) **Higginbotham's puzzle:** How can bare conditionals contribute universal quantification in UE environments and existential quantification in DE environments compositionally?

Two main lines of compositional analyses with a unified semantics for conditionals have been proposed: (i) Analyses in which conditionals obey Conditional Excluded Middle (CEM) (Stalnaker 1968, von Fintel 1997, von Fintel and Iatridou 2002, Klinedinst 2011); (ii) proposals along the lines of the restrictor analysis of conditionals, according to which the quantificational force in question is supplied by a surrounding quantifier, with the *if*-clause serving as a domain restrictor (Leslie 2008; Kratzer 2015).

For reasons of space, we cannot discuss at length the advantages and shortcomings of those analyses.<sup>4</sup> Instead, our discussion in this paper will mainly relate to an alternative analysis which was recently advanced by Herburger (2015a, b). Herburger's solution to Higginbotham's puzzle is that conditionals are simply ambiguous:

- (4) **Herburger's hypothesis:** Bare conditionals are lexically ambiguous.  
 a. In UE environments they contribute universal quantification.  
 b. In DE environments they contribute existential quantification.<sup>5</sup>

In this paper we argue against Herburger's ambiguity hypothesis and provide a novel unified semantics that deals with Higginbotham's puzzle. Our empirical motivation for rejecting the ambiguity hypothesis comes from the observation that bare conditionals don't behave like classical ambiguities in VP ellipsis constructions and in non-monotonic contexts (section 2). We adopt Herburger's idea (which is already entertained in von Fintel 1997) that existential bare conditionals exist, and contend that *only* they exist: bare conditionals are *existential across the board*. We present an analogy between bare conditionals and Free Choice disjunction in different contexts as a motivation for this assumption (section 3). To derive the universal im-

<sup>4</sup>See Leslie (2008); Herburger (2015a, b) for arguments against CEM analyses, and von Fintel and Iatridou (2002); Huitink (2010) for a problematization of the restrictor analysis. We hope to conduct a more thorough comparison between these approaches and ours in future work.

<sup>5</sup>One might wonder about the principle that governs the distribution of the two possible meanings as characterized in (4). Even though Herburger herself doesn't explicitly suggest this, it seems natural to think of the Strongest Meaning Hypothesis (Dalrymple et al., 1994)) as a relevant principle. See also footnote 13.

port of bare conditionals in UE contexts from their basic existential meaning, we utilize the grammatical strengthening mechanism proposed by Fox (2007) for the analysis of Free Choice inferences, using exhaustification over sub-domain alternatives (as in Chierchia 2013) (section 4). We further show that Conditional Perfection data, which pose a difficulty for Herburger's ambiguity approach (as well as for standard universal semantics approaches), are naturally explained by our proposal, and that comparing Conditional Perfection in bare and non-bare conditionals provides another evidence for the existentiality of bare conditionals (section 5).

## 2. Shortcomings of an ambiguity theory

Herburger's hypothesis in (4) straightforwardly accounts for Higginbotham's puzzle. However, in this paper we argue that it cannot be maintained and that a unified analysis is called for. The basis on which we make this claim consists of the considerations in (5):

- (5) a. Bare conditionals do not behave like ambiguities in ellipsis constructions where the antecedent and the elided material are in environments of different monotonicity.
- b. When embedded in non-monotonic contexts, bare conditionals give rise to a universal interpretation in the UE component of the meaning and an existential interpretation in the DE component of the meaning, which is an unexpected behavior for ambiguities.
- c. To derive the phenomenon known as Conditional Perfection, an ambiguity approach is forced to assume that the meaning of a bare conditional is resolved universally in computing the assertion and existentially in computing its implicature.

In this section we elaborate on (5a) and (5b), deferring the discussion of (5c) to section 5. The common core of all of these arguments is that in cases where one occurrence of a bare conditional is involved in some way in both UE and DE parts of the interpretation, the meaning it contributes splits: universality for the UE part, and existentiality for the DE part. This is not the way ambiguities usually behave, and an ambiguity analysis clearly misses a generalization here. This pattern is above all reminiscent of Higginbotham's (1986) characterization of *if*'s behavior as "chameleon-like".

Let us discuss (5a) first. A familiar test for ambiguity is ellipsis: when an ambiguous phrase is elided, the ambiguity is resolved uniformly in the antecedent VP and the elided VP (Sag 1976; Heim 1996). However, bare conditionals fail this test: when bare conditionals are elided and the antecedent VP and the elided VP are in contexts with different monotonicity (namely when one of them is in a UE context and the other in a DE context), as in (6), they give rise to different quantificational forces. The conditional in the antecedent VP, which is in a UE context, is interpreted universally (6a), while the elided one, which is in a DE context, is interpreted existentially (6b).

- (6) Every boy calls his mother if he gets an A, and no girl does.  $\approx$ 
  - a. For every boy  $x$ , in **all** cases where  $x$  gets an A,  $x$  calls  $x$ 's mother, and
  - b. there is no girl  $x$  s.t. **there is** a case where  $x$  gets an A and  $x$  calls  $x$ 's mother.

An ambiguity analysis would predict either a universal meaning for both VPs, or an existential meaning for both. However, neither of these meanings is in fact attested, while the attested meaning is not predicted.

Turning to (5b), when a bare conditional is embedded in a non-monotonic context as in (7), the salient reading is one where the conditional seems to contribute a universal meaning for the UE component of the meaning and an existential meaning for the DE component.

- (7) Exactly two students call their mother if they get an A.  $\approx$
- a. **UE component:** There are two students  $x$ , s.t. in **all** cases where  $x$  gets an A,  $x$  calls  $x$ 's mother.
  - b. **DE component:** There are no more than two students  $x$  s.t. **there is** a case where  $x$  gets an A and  $x$  calls  $x$ 's mother.

Here too, an ambiguity analysis would presumably predict either a universal meaning for both components or an existential meaning for both, but not the attested reading where each component draws a different quantificational force from the bare conditional.

This is the puzzling situation in which we find ourselves now: In UE contexts bare conditionals behave like universal quantifiers, and in DE contexts they behave like existential quantifiers. An ambiguity analysis then seems appealing, but their behavior in VP ellipsis constructions and in non-monotonic contexts suggests that it is not on the right track.<sup>6</sup> A more promising direction is to assume one basic meaning and derive the other one from it. But which one should we choose as the basic meaning, the universal or the existential one, and how to derive the one from the other?

It might seem intuitive to choose the universal meaning as the starting point. However, we see no empirical or theoretical reason to assume that the basic semantics of bare conditionals surfaces in UE contexts rather than DE contexts. Our proposal will in fact follow the less intuitive strategy, and take the weak existential meaning to be the basic one. To prepare the ground, in the next section we provide a preliminary reason for this choice, based on the similar behavior of bare conditionals and Free Choice disjunction which is standardly assumed to involve a basic weak semantics. In section 5.4 we provide evidence supporting an existential semantics from comparing Conditional Perfection with bare and non-bare conditionals.

### 3. Towards a unified account: Analogy with Free Choice disjunction

Embedding the disjunctive marker *or* under an existential modal gives a stronger-than-expected conjunctive inference. This phenomenon is known as Free Choice (FC) and is illustrated in (8a). Since at least Kratzer and Shimoyama (2002), it has been argued that the FC inference of

<sup>6</sup>Note, however, that to account for (6) and (7) one can salvage the ambiguity analysis with a more involved story such as the supervaluationist one suggested in Spector (2013) for homogeneity in definite plurals. Very roughly, the idea would be that for a sentence containing a bare conditional to be super-true, it should be true under both possible meanings. Even though we have no argument to show against this kind of analysis, our proposal in section 4 avoids assuming an unwarranted ambiguity, and instead utilizes mechanisms that are independently argued for. We leave a thorough comparison between the two approaches to further research.

(8a) has the status of a scalar implicature, since it tends to disappear under DE operators, (8c):

- (8) a. John is allowed to eat ice-cream or cake  $\Diamond(A \vee B)$   
 $\approx$  John is both allowed to eat ice-cream **and** allowed to eat cake  $\Diamond A \wedge \Diamond B$   
 b. Everyone is allowed to eat ice-cream or cake  $\forall x[\Diamond(A(x) \vee B(x))]$   
 $\approx$  Everyone is both allowed ice-cream **and** allowed cake  $\forall x[\Diamond A(x) \wedge \Diamond B(x)]$   
 c. No one is allowed to eat ice-cream or cake  $\neg \exists x[\Diamond(A(x) \vee B(x))]$   
 $\approx$  No one is both allowed ice-cream **and** allowed cake  $\neg \exists x[\Diamond A(x) \wedge \Diamond B(x)]$

The pattern in (8) parallels the data from bare conditionals in (1). In both, a universal/conjunctive meaning appears in UE contexts and disappears in DE contexts. Moreover, consider the ellipsis example in (9) and the non-monotonic example in (10) in comparison to (6) and (7).

- (9) Every boy is allowed to eat ice cream or cake, and no girl is.  $\approx$   
 a. For every boy  $x$ ,  $x$  is both allowed to eat ice cream **and** allowed to eat cake, and  
 b. there is no girl  $x$  s.t.  $x$  is allowed to eat ice cream **or** cake.  
 (10) Exactly two children are allowed to eat ice cream or cake.  $\approx$   
 a. **UE component:** There are two children  $x$ , s.t.  $x$  is both allowed to eat ice cream **and** allowed to eat cake.  
 b. **DE component:** There are no more than two children  $x$  s.t.  $x$  is allowed to eat ice cream **or** cake.

In both FC and bare conditionals, then, whenever one occurrence is involved in providing meaning to both UE and DE components of the meaning, we get a conjunctive/universal meaning for the UE component and a disjunctive/existential meaning for the DE component. This similarity points towards a unified treatment of both phenomena. We follow Fox (2007) and others in assuming that FC disjunction involves the regular weak semantics of disjunction, and consequently assume a weak existential semantics for bare conditionals in analogy to it (for a more direct motivation see section 5.4). In the next section we propose an account of the quantificational split in bare conditionals using the same mechanism that derives FC inferences in Fox (2007), namely grammatical strengthening via recursive exhaustification. For reasons of space, we cannot spell out a full derivation of FC, rather we refer the reader to Fox (2007) for details and move on to present our analysis of bare conditionals.<sup>7</sup>

## 4. Proposal

### 4.1. The plot

We propose that bare conditionals not only *can* have existential semantics as Herburger (2015a) has it, but rather this is the *only* semantics they have. The universal interpretation of bare conditionals in UE contexts is arrived at by grammatical strengthening, via recursive exhaustification over alternatives. Our answer to Higginbotham's puzzle is summarized in (11).

<sup>7</sup>Embedded FC data as in (8b) (and also (9) and (10)) don't follow from Fox's analysis without additional assumptions (see, e.g., Chemla 2009). We will return to this issue later (see footnote 15).

(11) **Proposal in a nutshell:**

- a. Bare conditionals are underlyingly existential across the board.
- b. In UE contexts they undergo grammatical strengthening and become universal.
- c. In DE contexts their basic existential meaning is preserved.

In section 4.2 we lay out the details of the proposal. We do so in steps: we first introduce our assumptions about the core existential meaning of a bare conditional and the alternatives it triggers. Then we proceed to show how, with the help of recursive exhaustification, we can get from the basic existential meaning to the stronger universal meaning in UE environments, while preserving the basic existential meaning in DE environments. In section 4.3 we show how the analysis deals with the challenges from section 2. In section 4.4 we discuss the structure of alternatives we're assuming and its implications on the difference between bare and non-bare conditionals.

## 4.2. A unified existential semantics

We assume a semantics in which bare conditionals quantify existentially over antecedent worlds, restricted by a domain of quantification  $D_s$ . As can be seen in (12), we assume that  $D_s$  is syntactically realized and serves to restrict the domain of quantification for *if*:<sup>8</sup>

$$(12) \quad \llbracket \text{if}_{D_s} p, q \rrbracket = 1 \text{ iff } \exists w \in \llbracket p \rrbracket \cap D_s [\llbracket q \rrbracket(w) = 1]$$

(12) straightforwardly accounts for the cases where existential quantification was needed, such as (2). To derive the universal meaning in UE contexts, we hypothesize that bare conditionals trigger Sub-Domain Alternatives (SDAs) of the conditional, in the spirit of Chierchia (2013)'s analysis of Polarity Sensitive Items (see also Bar-Lev and Margulis 2014).

(13) **Hypothesis:** *if* <sub>$D_s$</sub>  gives rise to Sub-Domain Alternatives (SDAs).

The SDAs we assume are derived by replacing the original domain variable  $D_s$  with its subsets:

$$(14) \quad \textbf{Sub-Domain Alternatives: } \text{Alt}(\text{if}_{D_s} p, q) \supseteq \{\text{if}_{D'_s} p, q \mid D'_s \subseteq D_s\}$$

By way of illustration, take (1a) (repeated in (15)) as an example and assume a toy model with a set  $\{h_1, h_2\}$  of two working hard worlds, in (16a), and a set  $\{nh_1, nh_2\}$  of two non-working hard worlds, in (16b). Then the basic meaning of (15) is in (17a), and its domain alternatives, generated by replacing the  $D_s$  with its subsets (as prescribed by (14)), are in (17b):

$$(15) \quad \text{If you work hard you succeed.} \quad \quad \quad [= (1a)]$$

$$(16) \quad D_s = \{h_1, h_2, nh_1, nh_2\}$$

<sup>8</sup>We will have nothing to say here about how the domain of quantification  $D_s$  is determined. We also don't commit to what exactly is quantified over: it could be worlds, situations, events, etc. For concreteness we stick to worlds throughout our discussion.

- a.  $\llbracket \text{You work hard} \rrbracket = \{h_1, h_2\}$   
 b.  $\llbracket \text{You don't work hard} \rrbracket = \{nh_1, nh_2\}$
- (17) a. **Basic meaning of (15)**  
 $\exists w \in \llbracket \text{You work hard} \rrbracket \cap D_s[\text{you succeed in } w]$   
 $= \exists w \in \{h_1, h_2\}[\text{you succeed in } w]$   
 $= \text{You succeed in } h_1 \vee \text{You succeed in } h_2$  (in short: **a**  $\vee$  **b**)
- b. **Sub-Domain Alternatives of (15)**  
 $\{\text{if}_{D'_s} \text{ you work hard you succeed} \mid D'_s \subseteq \{h_1, h_2, nh_1, nh_2\}\}$

Looking at the denotations of the elements in (17b), we can translate (17b) to (18).<sup>9</sup> Note that the relationship between the basic meaning (17a) and the SDAs (18b-c) can be rendered in terms of the relationship between a disjunction and its disjuncts. For this reason, we shorten the former to **a**  $\vee$  **b** and the latter to **a** and **b**.

- (18) **Sub-Domain Alternatives of (15)**
- a.  $\exists w \in \{h_1, h_2\}[\text{you succeed in } w]$  (= (17a))<sup>10</sup> **a**  $\vee$  **b**  
 b.  $\exists w \in \{h_1\}[\text{you succeed in } w] = \text{You succeed in } h_1$  **a**  
 c.  $\exists w \in \{h_2\}[\text{you succeed in } w] = \text{You succeed in } h_2$  **b**

The domain alternatives have to be used up by an alternative sensitive operator, i.e., they are *obligatorily exhaustified* (as in Chierchia 2013).<sup>11</sup> Following Fox (2007), we assume a covert EXH operator as defined in (19). EXH takes the prejacent and a set of alternatives and returns the prejacent conjoined with the negation of all INNOCENTLY EXCLUDABLE (IE) alternatives. Informally, the restriction to IE alternatives amounts to the requirement that exclusion of alternatives does not contradict the prejacent and that the choice of alternatives to exclude is not arbitrary.

- (19)  $\llbracket \text{EXH} \rrbracket(\text{Alt}(p))(p)(w) \Leftrightarrow p(w) \wedge \forall q \in \text{IE}(p, \text{Alt}(p))[\neg q(w)]$   
 (Where  $\text{Alt}(p)$  is the set of alternatives of the prejacent  $p$ )

- (20)  $\text{IE}(p, \text{Alt}(p)) = \cap \{\text{Alt}(p)' \subseteq \text{Alt}(p) : \text{Alt}(p)' \text{ is a maximal set in } \text{Alt}(p), \text{ s.t. } \neg q : q \in \text{Alt}(p)' \cup \{p\} \text{ is consistent}\}$

The parse we propose for bare conditionals that yields universal interpretation contains two EXH operators:

<sup>9</sup>Here and throughout we neglect SDAs in which the sub-domain  $D'_s$  is such that  $\llbracket p \rrbracket \cap D'_s = \emptyset$ . These alternatives are not represented because they are contradictory, and therefore don't affect the alternative computation mechanism (to be discussed shortly).

<sup>10</sup>This is technically a SDA because by definition, the prejacent is a SDA of itself. But when talking about SDAs, we will sometime mean only "proper" sub-DAs, i.e. excluding the prejacent.

<sup>11</sup>It is crucial that exhaustification here would be obligatory and that the SDAs cannot be ignored ('pruned'), since otherwise we would wrongly predict that the universality of bare conditionals could be cancelled:

(i) #If you work hard you succeed, and if you work hard you might fail.

We leave open the important issue of how to motivate and implement this obligatoriness, and refer the reader to the discussion in Chierchia (2013). See also footnote 23.

- (21)  $\text{EXH}_{C'} [\alpha \text{ EXH}_C [\text{if}_{D_s} \text{ you work hard you succeed }]]$   
 (Where  $C$  in  $\text{EXH}_C [\phi]$  is the set of alternatives of  $\phi$ , namely  $\text{Alt}(\phi)$ )

The semantic computation of (21) is given in (22), using the toy model and the abbreviations introduced above. The final step of (22) reveals that the basic existential meaning of the conditional was strengthened via double exhaustification to a universal meaning.

- (22) a.  $\llbracket \text{If}_{D_s} \text{ you work hard you succeed} \rrbracket = 1 \text{ iff } \exists w \in \{h_1, h_2\} [\text{You succeed in } w] =$   
            $\text{You succeed in } h_1 \vee \text{You succeed in } h_2 = \mathbf{a} \vee \mathbf{b}$  (cf. (17a))  
 b.  $C = \text{Alt}(\mathbf{a} \vee \mathbf{b}) = \{\mathbf{a} \vee \mathbf{b}, \mathbf{a}, \mathbf{b}\}$  (cf. (18))  
 c.  $\llbracket \alpha \rrbracket = \text{EXH}_C[\mathbf{a} \vee \mathbf{b}] = \mathbf{a} \vee \mathbf{b}$  (EXH is vacuous because the SDAs are not IE)  
 d.  $C' = \text{Alt}(\text{EXH}_C[\mathbf{a} \vee \mathbf{b}])$   
        $= \{\text{EXH}_C[\mathbf{a} \vee \mathbf{b}], \text{EXH}_C[\mathbf{a}], \text{EXH}_C[\mathbf{b}]\}$   
        $= \{\mathbf{a} \vee \mathbf{b}, \mathbf{a} \wedge \neg \mathbf{b}, \mathbf{b} \wedge \neg \mathbf{a}\}$   
 e.  $\llbracket (21) \rrbracket = \text{EXH}_{C'}[\text{EXH}_C[\mathbf{a} \vee \mathbf{b}]] = (\mathbf{a} \vee \mathbf{b}) \wedge \neg(\mathbf{a} \wedge \neg \mathbf{b}) \wedge \neg(\mathbf{b} \wedge \neg \mathbf{a})$   
           (All the alternatives in  $C'$  except  $\mathbf{a} \vee \mathbf{b}$  are IE)  
            $= (\mathbf{a} \vee \mathbf{b}) \wedge (\mathbf{a} \leftrightarrow \mathbf{b}) = \mathbf{a} \wedge \mathbf{b}$   
 f.  $= \forall w \in \{h_1, h_2\} [\text{you succeed in } w]$ <sup>12</sup>

Let us go through the steps in (22). Applying EXH once with respect to the set of alternatives in (22b) is in (22c), which corresponds to the phrase we named “ $\alpha$ ” in (21). Since no alternative is Innocently Excludable (cf. (20)), the result equals to the input—the prejacent. However, the set of alternatives of  $\alpha$  is different from the one in (22b); this set is provided in (22d). The set in (22d) turns out to contain the original sentence ( $\mathbf{a} \vee \mathbf{b}$ ), and in addition, ‘only  $\mathbf{a}$ ’ ( $\mathbf{a} \wedge \neg \mathbf{b}$ ), and ‘only  $\mathbf{b}$ ’ ( $\mathbf{b} \wedge \neg \mathbf{a}$ ). Finally, applying EXH for the second time, this time with respect to the set in (22d), yields (22e). The derived meaning is, roughly,  $\mathbf{a}$  or  $\mathbf{b}$ , and not only  $\mathbf{a}$ , and not only  $\mathbf{b}$ , which is equivalent to  $\mathbf{a} \wedge \mathbf{b}$ . We have started with a disjunctive assertion, equivalent to an existential one, and ended up with a conjunctive meaning, that is—a universal one, (22f). The derivation straightforwardly extends to models with more than two antecedent worlds.

Importantly, the strengthening mechanism does not make the wrong predictions for the DE cases that initially motivated the existential semantics assumption, as in (1c) and (2). DE environments flip entailment relations, so that the prejacent entails (rather than entailed by) all the domain alternatives, see (23c). Therefore applying matrix EXH (any number of times) would not contribute anything to the semantics, cf. (23d). Thus, no strengthening from existential to universal applies when the bare conditional is embedded in a DE environment.<sup>13</sup>

<sup>12</sup>In (22f) and throughout the paper, we omit the prejacent’s contribution, namely  $\exists w \in \{h_1, h_2\} [\text{you succeed in } w]$ , whenever we provide a strengthened meaning for it. This is harmless, since we assume as is standard that quantification triggers a non-vacuity presupposition. Furthermore, given this presupposition, the antecedent of a conditional becomes a Strawson-DE environment after the application of recursive EXH. This makes our analysis in line with the generalization that NPIs are licensed in the antecedent of a conditional, if the mechanism responsible for NPI licensing applies above the exhaustivity operators.

<sup>13</sup>One might wonder what blocks recursive EXH to appear in an embedded position under the DE operator, which would give us the  $\neg\forall$  meaning we claim is absent. On our analysis, this question reduces to the issue of *embedded implicatures* in DE environments (Fox and Spector 2013, Chierchia 2013 a.o.), which are known to arise only in special, non-neutral contexts, and require a specific intonation.

(i) a. He didn’t talk to Mary or Sue. # He talked to both

- (23) a. No one will succeed if they goof off [=(1c)]  
 b.  $\llbracket \text{no one will succeed if}_{D_s} \text{ they goof off} \rrbracket$   
 $\Leftrightarrow \neg \exists x [\exists w \in \llbracket \text{goof off} \rrbracket(x) \cap D_s[x \text{ succeeds in } w]]$   
 c.  $(23b) \Rightarrow \forall D'_s \subseteq D_s [\neg \exists x [\exists w \in \llbracket \text{goof off} \rrbracket(x) \cap D'_s[x \text{ succeeds in } w]]]$   
 (All domain alternatives of (23b) are entailed by (23b))  
 d.  $\llbracket \text{no one will succeed if}_{D_s} \text{ they goof off} \rrbracket$   
 $\Leftrightarrow \llbracket (\text{EXH}) \text{ EXH no one will succeed if}_{D_s} \text{ they goof off} \rrbracket$   
 $\Leftrightarrow \neg \exists x [\exists w \in \llbracket \text{goof off} \rrbracket(x) \cap D_s[x \text{ succeeds in } w]]$   
 (Any matrix EXH attached to (23b) is vacuous)

What about cases where the bare conditional is in the scope of a universal quantifier, such as (24a)? To derive the right result for these, we must assume that the recursive EXH is embedded under the universal quantifier, (24b). The resulting semantics is in (24c), which is essentially just the embedding of (21) under *everyone*.<sup>14</sup>

- (24) a. Everyone will succeed if they work hard [=(1b)]  
 b. Everyone  $\lambda x [\text{EXH} [\text{EXH} [x \text{ will succeed if}_{D_s} x \text{ works hard} ] ]]$ .  
 c.  $\llbracket (24b) \rrbracket \Leftrightarrow \forall x [\forall w \in \llbracket \text{work hard} \rrbracket(x) \cap D_s[x \text{ succeeds in } w]]$

For now the assumption of local exhaustification under *every* is admittedly a stipulation.<sup>15</sup> However, the same stipulation is needed to account for Free Choice disjunction embedded under universal quantification as in (8b), given Fox (2007)'s analysis (see Chemla 2009; Singh et al. 2016).

#### 4.3. VP ellipsis resolution and non-monotonic contexts

We saw in section 2 that a lexical ambiguity theory along the lines of Herburger (2015b) runs into problems in the face of the behavior of conditionals in VP ellipsis constructions and in non-monotonic contexts. Regarding the VP-ellipsis data, recall that the problem was how to predict that in a case like (25) the conditional in the antecedent contributes universal semantics, and the one in the elided VP existential semantics. On our proposal, the LF of (25) is in (26).

- b. He didn't talk to Mary OR Sue. He talked to both.

The general dispreference of embedded implicatures is taken by many to result from a violable (pragmatic) principle that prohibits implicatures from weakening the global meaning of the sentence. We thus take such a principle to be responsible for the general inavailability of  $\neg\forall$  interpretations of negated bare conditionals.

Herburger (2015a) argues that universal bare conditionals in DE contexts do exist, based on examples such as (ii).

- (ii) a. It is not true that if a fair coin is flipped it will come up heads.  
 b. If a fair coin is flipped it will NOT come up heads.

We take the fact that such readings, if they exist, are only available with what is arguably "meta-linguistic negation" as in (iia) or special intonation as in (iib) to parallel the facts in (i) and thus to be in line with our approach.

<sup>14</sup>And here too, just like in (21), we ignore the SDAs that yield contradictory propositions, see footnote 9. That is, for each individual  $x$  quantified over by *everyone*, the SDAs that end up being entailed by the recursive EXH in (24b) are only those for which  $D'_s \cap \llbracket p \rrbracket(x) \neq \emptyset$ .

<sup>15</sup>This stipulation can be dispensed with if we use the exhaustification mechanism proposed by Bar-Lev and Fox (in prep.), who provide an analysis of the embedded Free Choice inference of (8b) that doesn't rely on embedded exhaustification, and instead uses only matrix EXH. In this paper we preferred to use the more familiar mechanism of recursive exhaustification from Fox (2007) over Bar-Lev and Fox's solely due to the unfamiliarity of the latter.

- (25) Every boy calls his mother if he gets an A, and no girl does.  $\approx$  [= (6)]  
 a. For every boy  $x$ , in **all** cases where  $x$  gets an A,  $x$  calls  $x$ 's mother, and  
 b. there is no girl  $x$  s.t. **there is** a case where  $x$  gets an A and  $x$  calls  $x$ 's mother.
- (26) Every boy  $\lambda x$  EXH EXH [ $\text{VP } x \text{ calls } x\text{'s mother if}_{D_s} x \text{ gets A}$ ], and  
 (EXH) no girl does  $\lambda x$  [ ~~$\text{VP } x \text{ calls } x\text{'s mother if}_{D_s} x \text{ gets A}$~~ ].

(26) produces the desired quantificational split between the antecedent and the elided VP, and at the same time both are LF-identical.<sup>16</sup> The crucial assumption is that the EXH operators can be outside the VPs, which allows the two VPs to be semantically identical even though we ultimately derive a different quantificational force for each bare conditional. This is similar to the way that generally EXH operates in VP ellipsis constructions. For example, in (27a) the antecedent VP contains *some* which is intuitively interpreted exhaustively as *some but not all*, while in the elided VP *some* is interpreted non-exhaustively under negation (see Fox 2004 for a similar data point, attributed to Tamina Stephenson, p.c.). This is explained if the representation of (27a) is (27b).

- (27) a. John solved some of the problems and Mary didn't.  
 b. EXH John [ $\text{VP}$  solved some of the problems], and  
 (EXH) Mary didn't [ ~~$\text{VP}$  solve some of the problems~~].

The proper analysis of the non-monotonic example in (7) within our framework requires some elaboration which for space limitations we cannot provide here. However, given the close analogy between (7) and the FC disjunction example (10) discussed in section 3, and given that we proposed that FC disjunction and bare conditionals share an underlying mechanism, the facts in (7) will fall out from an exhaustification-based analysis of (10). Under an ambiguity theory, on the other hand, it is not clear how the facts in (7) can be explained, given the way ambiguities usually behave.

#### 4.4. The structure of alternatives in bare vs. non-bare conditionals

For the derivation of universality in (22) to be successful, it was crucial that the bare conditional didn't have a universal alternative (which amounts to  $\mathbf{a} \wedge \mathbf{b}$  in our toy model above), as schematized in (28). Had it been present, EXH would have negated it, and we would have achieved the opposite of what our goal is.

<sup>16</sup>We are aware that the representation in (26) is problematic in light of established constraints on binding in parallelism contexts. Specifically, (26) does not respect the standard requirement that the binder of any elided bound variable be inside the parallelism domain for ellipsis (e.g. Heim 1996; Hartman 2011. See Crnič 2015 for arguments showing that EXH enters into parallelism considerations). We aim to avoid this obstacle in future work by using a mechanism that can derive universal Free Choice globally and assuming the representation in (i) (see footnote 15).

(i) [EXH Every boy [ $\text{VP } \lambda x x \text{ calls } x\text{'s mother if}_{D_s} x \text{ gets A}$ ], and  
 (EXH) no girl does [ ~~$\text{VP } \lambda x x \text{ calls } x\text{'s mother if}_{D_s} x \text{ gets A}$~~ ]]

We thank Luka Crnič for bringing up this issue.

$$(28) \quad Alt((1a)) = Alt(\mathbf{a} \vee \mathbf{b}) = \{\mathbf{a} \vee \mathbf{b}, \mathbf{a}, \mathbf{b}, \cancel{\mathbf{a} \wedge \mathbf{b}}\}. \quad (\text{cf. (22b)})$$

We justify the assumption that bare conditionals don't have the universal meaning as an alternative by the fact they don't seem to have a lexical scalar alternative at all. In this we follow other analyses that make use of the lack of a strong alternative for strengthening a weak element. See a.o. Meyer (2016); Bar-Lev and Margulis (2014); Bowler (2014); Singh et al. (2016); Oikonomou (2016). Moreover, potential stronger alternatives like *if p, must q* would involve adding lexical material to the prejacent, an operation which is ruled out by structural (complexity-based) approaches to alternatives, see Katzir (2007); Fox and Katzir (2011).

This perspective has interesting consequences when we consider *non*-bare conditionals (i.e., conditionals with an overt quantificational element, exemplified in (29)): it allows us to capture the semantic difference between bare and non-bare conditionals solely based on the kinds of alternatives they generate. We assume along with the Kratzerian tradition (Kratzer 1986) that the quantification in non-bare conditionals is contributed by the overt quantifier (and there is no additional layer of quantification).

- (29) a. If you work hard you **sometimes** succeed.  
 b. If you work hard you **always** succeed.

Of course, (29a) is not interpreted universally like (29b), and moreover it gives rise to the inference that (29b) is false. We capture this by the fact that crucially, and differently from bare conditionals, the overt quantifier in a non-bare conditional can be replaced with a stronger/weaker quantifier without making the structure more complex. Namely, (29a) has (29b) as an alternative. Given our toy model from above, this feature of non-bare conditionals amounts to admitting  $\mathbf{a} \wedge \mathbf{b}$  into the set of alternatives of (29a), in contrast to bare conditionals:

$$(30) \quad Alt((29a)) = Alt(\underbrace{\mathbf{a} \vee \mathbf{b}}_{(29a)}) = \{\mathbf{a} \vee \mathbf{b}, \mathbf{a}, \mathbf{b}, \underbrace{\mathbf{a} \wedge \mathbf{b}}_{(29b)}\}$$

Thus, only bare conditionals undergo strengthening into a universal meaning, due to the absence of a universal alternative; non-bare existential conditionals cannot undergo such strengthening, since they generate a universal alternative which blocks this derivation. We return to non-bare conditionals in the context of Conditional Perfection in section 5.4.

## 5. *Only if* and Conditional Perfection

In section 2 we presented data from VP ellipsis (6) and non-monotonic contexts (7) showing that when one occurrence of a bare conditional is involved in some way in both UE and DE contexts, the meaning it contributes splits: universality for the UE context, and existentiality for the DE context. In this section we provide one more piece of evidence showing the same behavior, from Conditional Perfection. Furthermore, we argue that Conditional Perfection data provides additional support to the conjecture that bare conditionals are underlyingly existential. Before we get to that, however, we have to take a small detour and discuss the analysis of *only if* sentences.

### 5.1. *Only if*

*Only if* sentences as in (31) have been argued to show another instance of a bare conditional interpreted existentially (see von Fintel 1997; Herburger 2015a). Since *only* is standardly assumed to presuppose its prejacent and assert the negation of its alternatives, the prejacent is in a Strawson-DE environment (von Fintel 1999). The existential interpretation is then expected given the generalization stated in section 1 upon which Higginbotham's puzzle is based.

(31) Only if you work hard you succeed.

What are the compositional details of (31) that produce the correct result? Since *only* takes a prejacent and a set of alternatives, we have to decide what alternatives are in this set. For simplicity, let us follow von Fintel (1997)'s assumption, according to which the alternative that's negated by *only* in a sentence of the form *only if p, q* is *if not-p, q*.<sup>17</sup> In our case, the relevant alternative for the prejacent of *only* in (31) would be *If you don't work hard you succeed*. The interpretation of (31) can then be paraphrased as in (32). The important observation here is that to get the right result for the assertive component, the alternative conditional that *only* negates cannot contribute a universal meaning, but must contribute an existential meaning; otherwise we would only derive the too-weak meaning in (32bii), which is compatible with there being cases where you don't work hard and succeed.

- (32) Only if you work hard you succeed. [=(31)]
- a. **Presupposition:** If you work hard you succeed. (See fn. 18)
  - b. **Assertion:**  $\neg$  if you don't work hard you succeed.
    - (i)  $\approx \neg$  **there is** a case where you don't work hard and you succeed.
    - (ii)  $\not\approx \neg$  in **all** cases where you don't work hard you succeed.

Herburger shows that the case of *only if* is predicted by the ambiguity analysis: since *only* creates a Strawson-DE environment, the prejacent *if p, q* is interpreted existentially. According to her, this correctly captures the presupposition triggered by *only if* sentences.<sup>18</sup> Crucially,

<sup>17</sup>Instead of having *if not p, q* as the alternative, a more plausible assumption from the perspective of the theory of alternative formation (Katzir 2007) is that we have a set of alternatives of the form *if r, q*, where *r* is a relevant alternative to *p*. The two options ultimately boil down to the same thing (for reasons we can't go over here), so for ease of exposition we work with the single alternative *if not-p, q*. We thank Andreas Haida for pointing this out.

<sup>18</sup>Our main focus here is capturing the assertive component of *only if*, and we take no stance on whether the presupposed prejacent of *only* should indeed be existential. Herburger argues that it should be existential based on contrasts like (i). Famously, whereas (ia) is non-contradictory, (ib) is not (von Fintel 1997):

- (i) a. Only if you work hard do you succeed, and even if you work hard you might fail.  
 b. #If you work hard you succeed, and even if you work hard you might fail.

However, we do not know whether this is a strong argument in favor of the existentiality of the prejacent, since *only* independently gives rise to presuppositions that are weaker than its prejacent, as the felicity of (ii) shows:

- (ii) Only John<sub>F</sub> can speak French, and maybe not even he can. (Ippolito 2008: ex. 37)

Furthermore, in some environments *only* does seem to presuppose its prejacent (for ill-understood reasons), e.g., under negation (as can be seen in (iiia)). And accordingly, when embedding *only if p, q* under negation, it is also much harder to cancel the universal inference that *if p, q*. Compare (ia) with (iiib):

- (iii) a. #Not only John<sub>F</sub> can speak French, and maybe he can't. (Ippolito 2008: ex. 38)  
 b. #Not only if you work hard do you succeed, and if you work hard you might fail.

For these considerations, we do not rely on the presupposition of (31) to determine the quantificational force of

since the prejacent *if p, q* is existential, the alternative *if not-p, q* which is derived from it is interpreted existentially as well.

Note, however, that for Herburger the existentiality of the alternatives only follows from the assumption that the prejacent is existential. This point will be crucial in the following discussion of Conditional Perfection inferences, where the prejacent is unarguably interpreted universally, but the alternatives are still interpreted existentially.

## 5.2. Conditional Perfection (CoP)

When an *if p, q* sentence is uttered, we often understand it as the ‘perfected’ conditional *if and only if p, q*. For example, utterance of *if you work hard you succeed* (= (1a)) “invites the inference” (as Geis and Zwicky 1971 put it) that *only if you work hard you succeed* (= (31)). The Conditional Perfection (CoP) inference is cancellable, (33a), and it disappears under negation, (33b). Therefore, it is widely accepted that CoP should be analyzed as an implicature (Geis and Zwicky 1971; von Fintel 2001, a.o.).

- (33) a. If you work hard you succeed, and you might succeed even if you don’t.  
 b. No one will succeed if they goof off. [=(1c)]  
 ≈ No one will succeed if *and only if* they goof off

The existence of CoP raises a theoretical difficulty for previous analyses of conditionals, given standard theories of implicature calculation. The challenge, as can be seen by the descriptive characterization of CoP in (34), is to derive an existential meaning at the level of the implicature, while retaining universality for the assertion. One can already see that the issue here is very similar to what we have seen with ellipsis and non-monotonic contexts in section 2: in all three cases, from one occurrence of a bare conditional we want to derive different quantificational forces for different ingredients of the overall meaning.

- (34) If you work hard you succeed. [=(1a)]  
 a. **Assertion:** In **all** cases where you work hard, you succeed.  
 b. **Implicature:**  $\neg$  **there is** a case where you don’t work hard and you succeed.

To appreciate the problem, assume (i) that the prejacent *if p, q* triggers the alternative *if not p, q*, (ii) that this alternative is derived from *if p, q* by replacing *p* with *not p*, and (iii) that this alternative is (optionally) negated, supposedly giving us the inference *only if p, q*. Hence: If the prejacent *if p, q* has universal meaning, then *if not p, q* also has universal meaning. Namely, we should expect the implicature to be the negation of a universal meaning, contrary to fact.

It is not straightforward to achieve the right results for CoP in analyses that posit a uniform universal semantics for bare conditionals.<sup>19</sup> Even under an ambiguity analysis, it is not clear

a bare conditional under *only*. The relation between this kind of data and FC disjunction embedded under *only* (see Alxatib 2014) calls for further investigation given our view. We thank Danny Fox and Sam Alxatib for very helpful discussions on this issue.

<sup>19</sup>See for instance von Fintel (2001)’s analysis, in which CoP is derived when *if p, q* has alternatives of the form

why the alternative *if not p, q* is interpreted existentially: Unlike the case of *only if* sentences, in CoP the prejacent is definitely not interpreted existentially, but rather universally as can be seen in (34a). The alternative *if not p, q*, which is generated on the basis of the prejacent, is then also expected to be interpreted universally, contrary to fact.<sup>20</sup>

### 5.3. Deriving Conditional Perfection

The assumption that bare conditionals are existential provides a simple account of CoP. We assume that *if not p, q* is an additional (and optional) alternative to *if p, q* (but see footnote 17). Namely, (34) has the alternative in (35). Being a bare conditional, its basic meaning is existential, (35a). Negating this meaning would then yield the desired CoP inference in (34b).

- (35) If you don't work hard you succeed.
- a.  $\llbracket \text{If}_{D_s} \text{ you don't work hard you succeed} \rrbracket = 1 \text{ iff}$   
 $\exists w \in \llbracket \text{You don't work hard} \rrbracket \cap D_s[\text{you succeed in } w]$

Let us show the derivation in some more detail, illustrating with our toy model from (16) in which  $\llbracket \text{You work hard} \rrbracket = \{h_1, h_2\}$  and  $\llbracket \text{You don't work hard} \rrbracket = \{nh_1, nh_2\}$ . The alternatives we generate for (34) when we add (35) are listed in (36). (36a) repeats from (18) the by-now familiar SDAs of (34). (36b) is the meaning of the new alternative (35) given our toy model. This alternative is logically independent from the prejacent in (36a-i) and the other SDAs in (36a-ii,iii), since its domain of quantification is disjoint from theirs, and we can thus name it c. The resulting set of alternatives, which we call  $C^+$ , is in (36c).

- (36) a. **Sub-Domain Alternatives of (34)** (see (18))
- (i)  $\exists w \in \{h_1, h_2\}[\text{you succeed in } w] (= (17a))$  **a  $\vee$  b**
- (ii)  $\exists w \in \{h_1\}[\text{you succeed in } w] = \text{You succeed in } h_1$  **a**
- (iii)  $\exists w \in \{h_2\}[\text{you succeed in } w] = \text{You succeed in } h_2$  **b**
- b. ***If not p, q* alternative of (34)**
- $\exists w \in \{nh_1, nh_2\}[\text{you succeed in } w] = \text{You succeed in } nh_1 \vee \text{You succeed in } nh_2$  **c**

*if r, q* where *r* denotes any proposition, and importantly propositions that pick out a singleton set of worlds. This essentially reduces universal quantification to existential quantification. On the cost of such reduction see footnote 22.

<sup>20</sup>Herburger (2015b) adopts a non-standard way of implicature calculation to get the right result within her ambiguity approach. For her, an implicature for a sentence *S* is derived by adjoining to *S* a covert *and-only-S*. Effectively, the result is that the prejacent and its alternatives are in environments of different monotonicity. Thus CoP is derived with the structure *if p, q and-only-if p, q*, where there are two occurrences of *if p, q*: the overt one is in a UE environment, hence we get a universal prejacent, and the covert one is in a DE environment, hence we get existential alternatives.

This kind of analysis faces some problems. First, recall our argument against ambiguity from ellipsis (section 2), which was based on the fact that ambiguities cannot be interpreted differently in the antecedent material and the elided material. However, Herburger's analysis of CoP essentially relies on an ellipsis construction, and on the idea that the overt *if p, q* can be interpreted universally while the elided *if p, q* is interpreted existentially. Thus our argument from ellipsis extends to her treatment of CoP. Second, it is not clear to us what motivation there is for such an analysis of implicatures other than the CoP data. Third, since the CoP data mirrors the chameleonic behavior of bare conditionals in ellipsis constructions and in non-monotonic contexts, for which such an analysis is not available, a principled analysis for all of these cases is called for.

c. **Enriched set of alternatives of (34)**

$$C^+ = \{\mathbf{a} \vee \mathbf{b}, \mathbf{a}, \mathbf{b}, \mathbf{c}\}$$

Given  $C^+$ , the result of recursive EXH is in (37). The *if not*  $p, q$  alternative  $\mathbf{c}$  is negated by the lower EXH without affecting the workings of the higher EXH. Namely, adding the *if not*  $p, q$  alternative to the set of alternatives of *if*  $p, q$  does not interfere with the generation of universality for the latter, essentially because their domains of quantification are disjoint.

$$(37) \quad \llbracket \text{EXH}_{C^+} \text{ EXH}_{C^+} \text{ if}_{D_s} \text{ you work hard you succeed} \rrbracket = 1 \text{ iff}$$

$$\underbrace{\forall w \in \{h_1, h_2\} [\text{you succeed in } w]}_{\text{Universal strengthening (matrix EXH) } (\approx(34a))} \wedge \underbrace{\neg \exists w \in \{nh_1, nh_2\} [\text{you succeed in } w]}_{\text{CoP inference (embedded EXH) } (\approx(34b))}$$

In sum, the fact that bare conditionals give rise to a universal meaning in their assertion and an existential meaning in their implicature is predicted under our analysis.

#### 5.4. Conditional Perfection with non-bare conditionals as evidence for an existential semantics for bare conditionals

In section 2 we have presented arguments against an ambiguity analysis of bare conditionals, and in section 3 we proposed a unified existential semantics based on the analogy with FC disjunction. In the previous section we have shown that the existential semantics assumption correctly predicts the CoP inferences of bare conditionals with no further complications. In what follows we present another motivation for the assumption that the basic semantics of bare conditionals is existential, coming from the behavior of CoP with *non*-bare conditionals.

A fact that (to our knowledge) has been largely unnoticed is that the behavior of non-bare conditionals is different from that of bare conditionals with respect to CoP. As Herburger (2015b) observes, when the conditional contains an overt universal adverb that the *if*-clause restricts, as in (38), we get a weaker CoP implicature than with bare conditionals, namely (38a) rather than (38b).<sup>21</sup> This difference between (38a) and the CoP inference of bare conditionals in (34b) is already surprising if we assume that bare conditionals are universals.<sup>22</sup>

- (38) If you work hard, you **always** succeed.
- a.  $\rightsquigarrow$  **Weak CoP**: if you don't work hard, you don't **always** succeed.
  - b.  $\rightsquigarrow$  **Strong CoP**: if you don't work hard, you don't succeed.

Even more striking is the fact that existential non-bare conditionals like (39) give rise to strong

<sup>21</sup>An issue that arises is why (38) doesn't have (i) as an alternative, the negation of which would produce the unattested strong CoP in (38b).

(i) If you don't work hard, you **sometimes** succeed.

A possible way to avoid it is to assume a non-weakening constraint on the generation of alternatives, as suggested in Fox (2007: fn. 35) (see also Romoli 2012; Trinh and Haida 2015), such that (i) would not be generated.

<sup>22</sup>Under von Stechow (2001)'s analysis of CoP (see footnote 19), for instance, there is no apparent reason why non-bare universal conditionals should not generate alternatives where the antecedent picks out singleton sets of worlds, while this option would be available for bare conditionals.

CoP, in (39a), just like bare conditionals do.

- (39) If you work hard, you **sometimes** succeed.  
 a.  $\sim$  **Strong CoP**: if you don't work hard, you don't succeed.

We take this pattern as further evidence that the basic semantics of bare conditionals should be existential, in light of their resemblance to existential rather than universal non-bare conditionals in terms of the kind of implicatures they give rise to. Admittedly, this is indirect evidence. However, as we have seen the chameleonic behavior of bare conditionals leaves little room for direct evidence.

## 6. Concluding remarks

Higginbotham's puzzle casts doubts on views according to which bare conditionals are uniformly interpreted universally. We have shown however that a simple ambiguity theory such as Herburger's is also questionable given the behavior of bare conditionals in VP ellipsis constructions and in non-monotonic contexts, as well as Conditional Perfection data. We argued for a unified existential semantics for bare conditionals, based on (i) the similarity in distribution between their quantificational force and the availability of Free Choice inferences for disjunction under an existential modal, and (ii) the fact that their Conditional Perfection inferences pattern with those of existential non-bare conditionals rather than universal ones.

Following the analogy with FC disjunction, we proposed an analysis that derives the universality of bare conditionals in UE contexts using the same mechanism of grammatical strengthening utilized by Fox (2007) to derive FC inferences. The crucial assumptions for this derivation to go through are (i) that bare conditionals give rise to sub-domain alternatives which are obligatorily exhausted (as in Chierchia 2013's analysis of NPIs), and (ii) that bare conditionals don't have a universal alternative.

One might wonder about the seemingly stipulative nature of assuming obligatory sub-domain alternatives for bare conditionals. We have no direct evidence for this assumption, and it is currently justified only in so far as it (together with independently suggested mechanisms) predicts the correct pattern of behavior. However, an interesting line of research worth pursuing is that sub-domain alternatives are generated for the restrictor of *every* quantificational operator, but their effect is mainly noticeable when there is no scalar alternative (see section 4.4). If this is developed successfully, then the assumption that bare conditionals give rise to sub-domain alternatives would be just a special case of this hypothesis.<sup>23</sup>

The analysis presented here opens up a new line of investigation into the research of homogeneity phenomena in general, of which Higginbotham's puzzle is arguably only one manifestation. A notable case in point is definite plurals: it has been suggested by Magri (2014), following

<sup>23</sup>The assumption that these alternatives are *obligatorily* exhausted requires further justification, which we are unable to provide yet. A promising direction, though, is to relate it to Singh et al. (2016)'s independently motivated proposal that applying EXH is highly preferred when it provides the complete answer to the Question Under Discussion. Note that the universal meaning we derive for (1a) by applying EXH provides the complete answer to the question *under what circumstances do you succeed?*, while the basic existential meaning doesn't.

Spector (2007), that definite plurals bear existential semantics which is strengthened in UE environments, on similar lines to what we propose. Independently, Schein (2003) and Schlenker (2004) have suggested an analysis of conditionals as definite plurals. Brought together, these approaches may lead to a new perspective on homogeneity phenomena. In future work we hope to compare this perspective with other approaches, most notably Križ (2015).

# Towards a model of incremental composition<sup>1</sup>

Sigrid BECK — *Universität Tübingen*

Sonja TIEMANN — *Universität Tübingen*

**Abstract.** This paper reviews some recent psycholinguistic results on semantic processing and explores their consequences for a cognitively plausible model of incremental composition. We argue that semantic composition is neither strictly incremental (in the sense that every incoming word is composed immediately) nor global (in the sense that composition only proceeds when the entire syntactic structure is available). We conjecture that incremental composition is type driven: elements in the same type domain (e.g. temporal <i>) are composed immediately; elements that concern different type domains (e.g. temporal <i> vs. event <v>) cause delayed processing.

**Keywords:** Incrementality, composition, semantic processing.

## 1. Introduction

The central question explored in this paper is how a theory of semantic composition can be combined with processing results arguing that interpretation has incremental properties. Semantic theory takes as its starting point the principle of compositionality: The interpretation of a complex expression is determined by the interpretations of its parts and the way they are combined. This is usually implemented in terms of assigning a compositional interpretation to the **complete** syntactic representation of the sentence to be interpreted (see standard introductions, e.g. Heim and Kratzer, 1998; Chierchia and McConnell-Ginet, 2000; Zimmermann and Sternefeld, 2014; Beck and Gergel, 2014). However, certain results from psycholinguistic research fairly clearly show that people begin to compose meanings **before** the end of the sentence has been perceived, so no complete tree is available. A suggestive data point is the familiar garden path effect (Bever, 1970), illustrated in (1) (Ferreira, Christianson and Hollingsworth, 2001).

(1) While Anna dressed the baby spit up on the bed.

So far, neither compositional semantics nor psycholinguistics has established a psycholinguistically plausible model of how compositional interpretation proceeds incrementally (cf. also e.g. Chater et al., 2001; Bott and Sternefeld, to appear). This is a problematic gap in linguistic theory because results on semantic processing don't get integrated into a theory of the semantic parser or aligned with the theory of composition. This paper is a contribution towards closing this gap. Our plot is to use a standard semantic framework (concretely a Heim and Kratzer, 1998, type theory) as our starting point, and revise it according to a set of concrete processing results we take to be exemplary, as a step towards a model of incremental composition.

---

<sup>1</sup> We are very grateful to Gerhard Jäger, Detmar Meurers, Lyn Frazier, Florian Schwarz, David Beaver, Mark Steedman, the members of the SFB 833 'Construction of Meaning' and the audience at Sinn und Bedeutung 21, Edinburgh, for their helpful comments on this complex and daunting enterprise. We thank the DFG grant to the SFB 833 'Construction of Meaning' for financial support.

Section 2 defines our task and outlines some relevant existing work in semantics and in psycholinguistics. In section 3, we present the evidence for incremental composition from a set of processing studies and an incremental analysis of those data points. Section 4 combines the results of section 3 and generalizes towards a model of incremental interpretation. Our conclusions are presented in section 5.

## 2. Specifying the task

### 2.1. What is needed?

Standard semantic theory defines an interpretation function  $[[\cdot]]$  recursively.  $[[\cdot]]$  maps LF trees to meanings (e.g. Heim and Kratzer, 1998). Compositional interpretation proceeds as sketched in (3) for a simple example. We call this **global interpretation**.

- (2)  $T \rightarrow [[\cdot]] \rightarrow \cup D\tau$  ( $\tau$  a semantic type)
- (3) a. John invited Bill.  
 b. structure:  $[_{IP} \text{John } [_{VP} \text{invited Bill}]]$   
 c.  $[[ [_{IP} \text{John } [_{VP} \text{invited Bill}]] ] ] = 1$  iff (2x Function Application FA)  
 $[[[\text{invited}]] ([[\text{Bill}]])] ([[\text{John}]])) = 1$  iff (Lexicon +  $\lambda$ -conversion)  
 John invited Bill.

What if we start interpreting on the basis of a partial structure (4a)? Plausibly we anticipate (4c). A theory that can predict (4c) requires the concepts defined in (5), (6) and (7).

- (4) a. partial structure:  $[_{IP} \text{John } [_{VP} \text{invited } \dots]$   
 b. from the lexicon:  $\{[[\text{John}]], [[\text{invited}]]\}$   
 c. projected meaning:  $\lambda y. [[[\text{invited}]](y)([[\text{John}]])) =$   
 $\lambda y. \text{John invited } y$
- (5) a. Let  $\Theta$  be the set of syntactic structures produced by the human parser.  
 Each  $T_i \in \Theta$  is a possibly partial syntax tree.  
 b. Let  $\Sigma$  be the set of interpretations produced by the corresponding human interpretive processor. The elements of  $\Sigma$  are sets of meanings, i.e. each  $S_i \in \Sigma$  is a set whose members are elements of  $\cup D\tau$  ( $\tau$  a semantic type).  
 c. A pair  $\langle T_i, S_i \rangle$  is a stage reached in sentence processing.
- (6) Incremental processing is a series of mappings  $\langle T_i, S_i \rangle \rightarrow \langle T_{i+1}, S_{i+1} \rangle$  ( $1 \leq i \leq n$ ) such that
- (i)  $T_n$  is an LF tree;
  - (ii) each mapping  $T_i \rightarrow T_{i+1}$  is a matter of parsing (not our concern here);
  - (iii) each  $S_i$  is a set of meanings from  $\cup D\tau$ ;
  - (iv)  $\text{card}(S_n)=1$  (i.e. everything is composed into one meaning in the end);
  - (v)  $\langle T_n, S_n \rangle \in [[\cdot]]$ .

- (7) Incremental composition is the derivation of  $S_{i+1}$  from  $S_i$ .  
 Define a function  $[[\cdot]]_h$  ('heuristic interpretation'):  
 Suppose at stage  $i$ , the processor receives the structure  $\sigma$  as input, leading to  $T_{i+1}$ .  
 $[[\cdot]]_h$  defines a mapping  $\langle T_{i+1}, S_i, [[\sigma]]_h \rangle \rightarrow S_{i+1}$ .  
 On the basis of the new tree, the available set of meanings plus the new meaning, a new semantic stage is reached.

We can think of the function  $[[\cdot]]_h$  as an interpretive heuristic. It makes predictions about the meaning of partial trees, yielding a projected or anticipated meaning (which could be proven wrong by further input). A model of incremental composition is a recursive definition of the function  $[[\cdot]]_h$ . For each stage that the parser may reach,  $[[\cdot]]_h$  defines the accompanying stage of the interpreter.

## 2.2. What has been proposed in semantics?

Several linguistic frameworks have made proposals towards incremental interpretation, prominently including the categorial grammar tradition. A representative is Combinatory Categorial Grammar CCG (e.g. Ades and Steedman, 1982; Steedman, 2000; Steedman and Baldridge, 2011) and a simple example is given below. The syntax of CCG allows the incremental parse in (8b) — we are still looking for an NP to complete the sentence — and the semantics corresponds to this, employing Function Composition (9) to compose the meaning of the subject and the meaning of the verb as in (8d).

- (8)
- |    |   |
|----|---|
| a. | John invited Bill.  |
| b. | basic syntax:   |
|    | $\begin{array}{ccc} \text{John} & \text{invited} & \text{Bill} \\ S/(S \backslash NP) & (S \backslash NP)/NP & NP \\ & S \backslash NP & \end{array}$   |
| c. | incremental parse:  |
|    | $\begin{array}{ccc} \text{John} & \text{invited} & \\ S/(S \backslash NP) & (S \backslash NP)/NP & \\ & S/NP & \end{array}$   |
| d. | semantics:  |
|    | $\begin{aligned} [[\text{John}]] &= \lambda P_{\langle e, t \rangle}. P(\text{John}) \\ [[\text{invited}]] &= \lambda y. \lambda z. z \text{ invited } y \\ [[\text{John}]] \bullet [[\text{invited}]] &= [\lambda P_{\langle e, t \rangle}. P(\text{John})] \bullet [\lambda y. \lambda z. z \text{ invited } y] \\ &= \lambda x. [\lambda P_{\langle e, t \rangle}. P(\text{John})](\lambda y. \lambda z. z \text{ invited } y)(x) \\ &= \lambda x. \text{John invited } x \end{aligned}$ |
- (9) Function composition:  
 If  $g$  is a function:  $A \rightarrow B$  and  $f$  is a function:  $B \rightarrow C$  then  
 $f \bullet g : A \rightarrow C$  is the composition of  $f$  and  $g$  with  $f \bullet g = \lambda x. f(g(x))$

The example illustrates what we call **strict incrementality**. Each new element that is parsed is added immediately to the tree and composed immediately with the semantics already available. At each stage  $i$ ,  $\text{card}(S_i) = 1$ . In section 3, we will reject strict incrementality as a property of the semantic processor. There is a tendency in the CCG tradition towards strict incrementality (recently e.g. Kato and Matsubara, 2015), though details vary and Steedman's

(2000) Strict Competence Hypothesis SCH does not lead one to always expect strict word-by-word incrementality (see e.g. Demberg, 2012; Ambati, 2016 for discussion).

Outside CCG, our most immediate predecessor in the search of a model of incremental composition is Bott and Sternefeld (to appear). Bott and Sternefeld differ from us in two important respects: (i) they aim for strict incrementality, and (ii) they use a different framework (namely a dynamic Neo-Davidsonian continuation semantics with unconstrained  $\lambda$ -conversion), which we will not present here. But they point out the same gap in linguistic theory (cf. their paper also for further references), they consult an overlapping set of psycholinguistic results to inform their model of incremental composition, and they develop an incremental perspective on complex semantic analyses e.g. of tense and aspect. We return to their paper below.

### 2.3. What has been done in processing?

First, a cautionary note: We want to know when **composition** of meanings in complex structures occurs; not all results to do with immediate semantic processing are therefore of relevance for us (e.g., a finding could be based on immediate lexical access but not immediate composition; see e.g. Altmann and Kamide, 1999; or Frazier, 1999 for an overview). In recent years, psycholinguistic research on semantics has produced a lot of results on how different phenomena are processed (e.g. quantifiers, presuppositions etc. - a recent overview is given in Pylkkänen and McElree, 2006). The findings indicate particular properties of semantic processing and define certain constraints on it. What has not been established is a semantic processing model in the sense of heuristic composition  $[[.]]_h$ , i.e. there is no model that we know of (with the exception of Bott and Sternefeld) which describes how actual incremental composition works.

There is of course more work on syntactic processing, and this is important as the input to compositional interpretation (see e.g. discussion in Crocker, 2010). Resnik (1992), building on earlier work, argues for an *arc-eager* left corner parser, i.e. a variant of a left corner parser in which nodes that are predicted bottom-up can be immediately composed with nodes that are predicted top-down. We assume that the syntactic processor continuously integrates new material in a roughly left corner parser fashion. At any point during processing, a partial tree structure like (10) is projected by the syntactic parser. In this paper we simplify in that only one parse tree will be entertained as a possible structure at a time. (Ideally, we would adopt whatever proposal about the parser is best motivated.) Importantly, the tree  $T_i$  is the LF structure (the input to compositional interpretation). The terminal nodes in  $T_i$  include the words heard so far (in their proper places in the structure). The tree is the projected syntax.

Another input to compositional interpretation is lexical meaning. There is evidence that the interpretation of lexical terminal nodes is available immediately from the lexicon (e.g. Frazier and Rayner, 1990). Hence we assume that these meanings are added to  $S_i$  (the set of meanings made available by the parse so far). And finally, compositional interpretation depends on the values assigned to variables. Free variables get their value from the context via the salient variable assignment function  $g_c$ . When all goes well, they are assigned their values immediately (e.g. Carreiras and Clifton, 1993). The resulting meanings are also added to  $S_i$ . When there is no salient referent, binding of the variable is preferred; this may lead to a revision of the LF tree in such a way as to include a binder, or to optimize the chances of including a binder (that is, it can lead to delayed semantic interpretation, see section 3.2.; Bott and Schlotterbeck, 2013).

The anticipated lexical meaning and anticipated contextual reference are the recursion basis for the function  $[[.]]_h$ : If  $\alpha$  is a terminal element,  $[[\alpha]]_h = [[\alpha]]$ .

As an **interim summary**, we note that two interpretive strategies (11), (12) are made readily available by existing theories of interpretation. As a preview of what is to come, we argue that neither type of approach is the desired model of incremental composition. (Of course Global interpretation is not claimed to be a model of the semantic processor in the first place).

(11) **Global interpretation:**

Assume a syntactically **complete** parse tree  $T$  (i.e. no "...").

The meanings in  $S$  (here, the terminal nodes in  $T$ ) are composed by  $[[.]]$  according to  $T$  and the standard composition principles.

(12) **Strictly incremental interpretation:**

Assume an incrementally generated **partial** tree  $T$ , and a set of available meanings  $S$ .

Whenever  $\text{card}(S) > 1$ , compose the meanings in  $S$  according to  $T$  and some combinatory heuristic  $[[.]]_h$ .

### 3. Some psycholinguistic findings on incremental composition

In section 3.1. we collect a set of experimental results that argue for immediate composition in certain sentence contexts, and offer an incremental analysis of these cases. In section 3.2. we consider several cases of delayed composition, i.e. experimental evidence that there is no strictly incremental composition. The section summary sets the scene for our generalizations in section 4.

#### 3.1. Results supporting immediate composition

**Subject + Verb:** There are early effects indicating that before the object is encountered, the meanings of the subject and the verb are already put together (e.g. Kuperberg et al., 2003; Kim and Osterhout, 2005; Kamide et al., 2003; Knoeferle et al., 2005). We take this to mean that subject and verb are interpreted incrementally, before the sentence is finished. (13)

illustrates the relevant structure; # marks the point where studies have found an interpretive effect in processing.

- (13) The soup greeted ...

|  
#

This invites the following interpretation: The parse tree contains (14a); this leads to a combination of the meanings of the verb and the subject as in (14b). (14b) can be derived by the heuristic rule in (15). If we suppose that the subject has the type  $\langle\langle e, t \rangle, t \rangle$  rather than  $\langle e \rangle$ , the alternative formulation in (16) is applicable. (16) amounts to function composition (17).

- (14) a. projected parse tree contains:

- b. projected meaning:

$$\lambda y. [[\text{greet}]](y)([[\text{the soup}]]) =$$

$$\lambda y. \text{the soup greet } y$$

- (15) Subject-Verb-Heuristic (SVH):

If  $\alpha = [\beta_{\text{subj}} [\gamma_{\text{verb}} \dots]$   
 then  $[[\alpha]]_h = \lambda y. [[\gamma_{\langle e, et \rangle}]]_h(y)([[\beta_{\langle e \rangle}]]_h)$

- (16) Subject-Verb-Heuristic ( $\langle\langle e, t \rangle, t \rangle$  subject) (SVH'):

If  $\alpha = [\beta_{\text{subj}} [\gamma_{\text{verb}} \dots]$   
 then  $[[\alpha]]_h = \lambda y. [[\beta_{\langle et, t \rangle}]]_h([[\gamma_{\langle e, et \rangle}]]_h(y))$   
 SVH' defines  $[[\beta]]_h \bullet [[\gamma]]_h$

- (17) Function composition:

If  $g$  is a function:  $A \rightarrow B$  and  $f$  is a function:  $B \rightarrow C$  then  
 $f \bullet g : A \rightarrow C$  is the composition of  $f$  and  $g$  with  $f \bullet g = \lambda x. f(g(x))$

**Within DP:** There is evidence that determiner and adjective are combined very early on (Sedivy et al., 1999). (18) illustrates this. Our interpretation is that the meaning of the determiner plus the meaning of the NP is incrementally interpreted as indicated in (19).

- (18) Touch the tall ...

|  
#

- (19) a. projected parse tree contains:

- b. projected meaning:  
 $\lambda P. [[the]] ([[tall]] \cap P)$

Part of predicting (19b) is the expectation that the meaning of the determiner is applied to a suitable argument, as modelled by the DP-Heuristic below. This heuristic defines predictive Function Application FA.

- (20) DP-Heuristic:

If  $\alpha = [DP \ \beta_{Det} [NP \ \gamma \ \dots]$   
 then  $[[\alpha]]_h = [[\beta]]_h ([[NP]]_h)$

**Subject + Adverb:** Under certain circumstances, people anticipate a complex meaning given the input of a subject plus an adverb, here *wieder* ‘again’ (Tiemann, 2014; Tiemann et al., 2011). We interpret this as our participants anticipating that the adverb will modify some property attributed to the subject.

- (21) a. context: Inge hat letzte Woche rote Handschuhe gekauft.  
 Inge has last week red gloves bought

- b. Susanne hat wieder...  
 Susanne has again  
 |  
 #

- (22) a. projected parse tree contains:

- b. projected meaning:  
 $\lambda P_{\langle e, vt \rangle}. [[wieder]] (\lambda e. P(e)(Susanne)) =$   
 $\lambda P_{\langle e, vt \rangle}. \lambda e. \exists e' [e' < e \ \& \ P(e')(Susanne)]. P(e)(Susanne)$

This projected meaning can be predicted by the heuristic rule in (23). Once more, if the subject is taken to be of type  $\langle\langle e, t \rangle, t \rangle$  rather than  $\langle e \rangle$ , the heuristic is rephrased in such a way as to reveal it as function composition (24).

- (23)  $\langle v, t \rangle$ -Adverb-Subject Heuristic (AdvSH):  
 If  $\alpha = [[\beta_{\text{subj}} \dots] \gamma_{\text{adverb}}]$  and  $\gamma$  is of type  $\langle vt, vt \rangle$ ,  
 then  $[[\alpha]]_h = \lambda P_{\langle e, vt \rangle}. [[\gamma]]_h (P([[ \beta ] ]_h))$
- (24)  $\langle v, t \rangle$ -Adverb-Subject Heuristic ( $\langle \langle e, t \rangle, t \rangle$  subject) (AdvSH'):  
 If  $\alpha = [[\beta_{\text{subj}} \dots] \gamma_{\text{adverb}}]$  and  $\gamma$  is of type  $\langle vt, vt \rangle$ ,  
 then  $[[\alpha]]_h = \lambda P_{\langle e, vt \rangle}. [[\gamma]]_h ([[ \beta ] ]_h (P))$   
 AdvSH' defines  $[[\gamma]]_h \bullet [[\beta]]_h$

**Temporal Adverb + Tense:** Bott (2010) found that participants respond immediately to a mismatch between verbal tense and the meaning of an adverb, as in (25). Our take on what happens in processing is (26).

- (25) Morgen      gewann...  
 tomorrow      won  
                  |  
                  #

- (26) a. projected parse tree contains:

- b. projected meaning:  
 $\lambda P_{\langle i, t \rangle}. [[\text{PAST } t_{\text{now}}]] (\lambda t'. t' \subseteq \text{tomorrow} \ \& \ P(t')) =$   
 $\lambda P_{\langle i, t \rangle}. \exists t' [t' < t_{\text{now}} \ \& \ t' \subseteq \text{tomorrow} \ \& \ P(t')]$

The heuristic predicting this anticipated interpretation and the clash contained in it can be phrased as in (27) (assuming  $\langle i, t \rangle$  type modifiers) or (28) (assuming  $\langle \langle i, t \rangle, \langle i, t \rangle \rangle$  modifiers).

- (27) Temporal adverb – Tense Heuristic (intersective modifiers):  
 If  $\alpha = [\beta_{\text{Tense}} [\gamma_{\text{adverb}} \dots]]$  and  $\gamma$  is of type  $\langle it \rangle$ ,  
 then  $[[\alpha]]_h = \lambda P_{\langle i, t \rangle}. [[\beta]]_h (\lambda t' [[\gamma]]_h (t') \ \& \ P(t'))$
- (28) Temporal adverb – Tense Heuristic (functional modifiers):  
 If  $\alpha = [\beta_{\text{Tense}} [\gamma_{\text{adverb}} \dots]]$  and  $\gamma$  is of type  $\langle it, it \rangle$ ,  
 then  $[[\alpha]]_h = \lambda P_{\langle i, t \rangle}. [[\beta]]_h ([[ \gamma ] ]_h (P))$   
 The Temporal adverb–Tense Heuristic (shifted) defines  $[[\beta]]_h \bullet [[\gamma]]_h$

**Russian Aspect:** Bott and Gattnar (to appear) found that in Russian a mismatch of aspect with an adverb (29) was detected immediately, suggesting incremental interpretation. This

finding is especially interesting when compared to the processing of German aspect, discussed in the next subsection. The Russian results indicate that the compositional step in (30) is taken immediately:

- (29) Celych tri casa vyigrala  
 Whole three hours win.pfv.Past ...  
 |  
 #

- (30) a. projected parse tree contains:

- b. projected meaning:

$$\lambda P_{\langle v, t \rangle}. \exists e[[[pfv]](e) \ \& \ [[for \ three \ hours]](e) \ \& \ P(e)]$$

No detailed analysis or heuristic is offered because the details of the analysis for Russian are not sufficiently clear to us (see Bott and Gattnar, to appear; Bott and Sternefeld, to appear, for discussion). It is clear however that there is an immediately perceived clash between the aspect information and the adverbial. Those two expressions must be part of a local tree in the AspP. We conjecture that the example is (abstractly) parallel to the temporal adverb–tense case above.

**To sum up** this subsection, we have identified five circumstances that showcase immediate composition of two semantic units that do not form a constituent in the LF. Note that in each case, the two units occur in the same LF domain (DP, VP, TP, AspP). Their combination may be understood as predicted function application or function composition. (See Bott and Sternefeld, to appear, for a different, but similarly incremental analysis of e.g. the tense and the aspect cases.)

### 3.2. Results supporting delayed composition

**Quantifiers:** Hackl et al. (2012) (see also Varoutis and Hackl, 2006; Breakstone et al., 2011; but cf. Gibson et al., 2014) argue that there is evidence for quantifier raising (QR) and delayed interpretation of quantifiers in object position (31). We illustrate our interpretation of this finding in (32): encountering the quantified determiner leads to a revision of the parse tree.

- (31) John fed every dog.  
 |  
 no composition here.

- (32) a. 1st projected parse tree contains:

- b. revised parse tree contains:

Note that consequently, it is not the case that the meaning calculated so far — presumably  $[\lambda y. \text{John fed } y]$  — is combined with the meaning of *every* (yielding e.g.  $[\lambda P_{\langle e, t \rangle}. \text{for every } y \text{ such that } P(y), \text{John fed } y])$ . Hence this is a case that does not work according to strict incrementality. It seems extremely plausible that recovering from a garden path like (1) also involves such a revision (cf. e.g. Chater et al., 2001), i.e. in addition to throwing out the parse that turned out to be misguided, the corresponding interpretation is thrown out along with it.

**German Aspect:** Bott (2013) and Bott and Gattnar (to appear) show that aspectual mismatch in German is only processed when the verb has received its full argument structure, suggesting that the meaning of an adverbial (‘for two hours’) is not immediately combined with the meaning of a verb (‘won’). Composition only happens later (in contrast to Russian).

- (33)    Zwei Stunden lang    gewann    der Boxer    den Kampf.  
           two hours for        won            the boxer    the fight  
                                   |  
                                   no composition here.

It seems plausible that the meanings of the available items are added to the set of meanings made available by the processor, but not composed. So this is an instance of delayed composition. In very general terms, the so-called sentence wrap-up effect (Just and Carpenter, 1980) may also be an indication of late processes in semantic composition.

**Further candidates:** We mention two further candidates that have been presented as indicators for late composition processes. The model in section 4 will not properly include them because they involve semantic issues we can’t yet address (variable binding and presupposition projection) but they provide general support of our position. First, Bott and Schlotterbeck (2013) present an eyetracking study investigating the processing of inverse scope as in (34a) vs. (34b) without scope inversion. Their results suggest that scope inversion is only computed at the end of the sentence (this is also the interpretation of this finding in Bott and Sternefeld).

- (34) a. Jeden seiner Schüler hat genau ein Lehrer voller Wohlwollen gelobt.  
 Each of-his pupils has exactly one teacher full-of goodwill praised  
 ‘A teacher praised each of his pupils full of goodwill.’  
 b. Jeden dieser Schüler hat genau ein Lehrer voller Wohlwollen gelobt.  
 Each of-these pupils has exactly one teacher full-of goodwill praised  
 ‘A teacher praised each of these students full of goodwill.’

Second, Schwarz and Tiemann (to appear) conducted experiments on the processing of sentences with unfulfilled embedded and unembedded presuppositions (35a,b). Whilst presupposition failure in the unembedded cases (35b) was immediately detected in online processing, there was no such effect in the embedded conditions. We take this to mean that the composition of embedded presuppositions does not happen strictly incrementally, otherwise presupposition failure should result in immediate processing effects as they do in the unembedded cases.

- (35) a. Heute war Tina nicht wieder schlittschuhlaufen.  
 Today was Tina not again ice-skating  
 ‘Today, Tina didn’t go ice skating again.’  
 b. Heute war Tina wieder nicht schlittschuhlaufen.  
 Today was Tina again not ice-skating  
 ‘Today, once more Tina didn’t go ice skating.’

**In sum**, we have evidence that semantic units are not always composed immediately. Predictive combinatory mechanisms do not seem to be explored to exhaustion to calculate a composed meaning under all circumstances. This is why we depart from strict incrementality (as developed e.g. in Bott and Sternefeld).

**Interim Conclusion:** If the above view is correct, neither global interpretation nor strict incrementality seems to be the right model of semantic processing. Composition in semantic processing has incremental properties, but it also seems to require certain units to be built before composition proceeds. The required model needs to employ what we might call **enlightened incrementality**: sometimes composition is immediate, but under other circumstances it is delayed. What would be a useful hypothesis about when the processor applies which type of strategy? The next subsection addresses this question.

#### 4. First steps towards a general framework

This section generalizes from the concrete incremental compositional analyses in section 3. The desired outcome is (the beginnings of) a framework for theories of semantic parsing: a definition of a function  $[[\cdot]]_h$  (‘heuristic interpretation’) as anticipated in section 2. Naturally, we are far from being able to propose a complete model for this mapping. But we can distill some generalizations from the case studies in section 3. We propose that a realistic semantic processor sometimes composes ‘early’ and sometimes ‘late’, depending on the linguistic input. Our evidence indicates the general possibility of four cases: (i) wait and see, (ii) revision of LF, (iii) predictive Function Application (FA), (iv) predictive Function Composition (FC). These are generalizations over the interpretive strategies that section 3 provides evidence for. Subsection 4.1. examines the ‘late’ strategies, subsection 4.2. the

‘early’ composition strategies. In subsection 4.3. we develop a hypothesis as to when the semantic processor employs which type of strategy.

#### 4.1. Delayed composition

Beginning with ‘late’ composition strategies, section 3 provides evidence for (i) wait and see. The example indicative of this strategy is German aspect (and also (34), (35)). Stages of the processor are sketched in (37).

(i) **wait and see**

Given  $\langle T, S \rangle$  and input  $\sigma$ , map to  $\langle T', S' \rangle$ ,  
 where  $T'$  is the modification of  $T$  derived by the syntactic parser and  $S'$  is defined by:  
 $[[\cdot]]_h: \langle T', S, [[\sigma]]_h \rangle \rightarrow S \cup \{[[\sigma]]_h\}$

- (36)    Zwei Stunden lang      gewann      der Boxer      den Kampf.  
           two hours for        won            the boxer      the fight  
    |  
    no composition here.

- (37)    a.  $T = [\text{CP} [\text{PP zwei Stunden lang}] \dots]$   
               $S = \{[[\text{for 2h}]]\}$   
              b.  $T' = [\text{CP} [\text{PP zwei Stunden lang}] \_ [\text{TP Past } \dots]]$   
               $S' = \{[[\text{for 2h}]], [[\text{Past}]]\}$

The second case of non-incremental interpretation we have seen is (ii) revision of LF. The example for this strategy from section 3 is quantifiers in object position (and also (1)).

(ii) **revision of LF**

Given  $\langle T, S \rangle$  and input  $\sigma$ , map to  $\langle T', S' \rangle$ ,  
 where  $T'$  is the revision of  $T$  derived by the syntactic parser, and  $S'$  is defined by:  
 $[[\cdot]]_h: \langle T', S, [[\sigma]]_h \rangle \rightarrow \{x: x \text{ is the meaning of an atom in } T\} \cup [[\sigma]]_h$

- (38)    John fed    every dog.  
                          |  
                          no composition here.

At this point we digress a little in order to explain more fully our take on what happens in (38). Revision of the parse tree from  $T$  to  $T'$  would be compatible with keeping the meanings composed so far and adding the new meaning, according to the (i) wait and see strategy, as sketched in (39). We conjecture, however, that the processor also reconsiders the store of meanings. Our motivation comes from examples that have, in addition, a quantifier in subject position, (40). If the processor kept the meanings composed so far, we would get (41). Continuing processing on this basis would in our framework (i.e. without type shifting or further scope mechanisms) lead to the inverse scope reading (40b). It seems implausible that the processor smoothly generates the intuitively harder reading. It is more plausible that the processing of the doubly quantified example involves the steps in (42) — the composition of

subject and verb is thrown out. This motivates our assumption that (ii) is operative in this case.

- (39) a.  $T = [VP \text{ John } [V' \text{ fed } \dots]]$   
 $S = \{[[\text{John fed}]]\} = \{\lambda y. \text{John fed } y\}$   
 b.  $T' = [VP [NP \text{ every } \dots][1[VP \text{ John } [V' \text{ fed } t_1]]]$   
 $S' = \{\lambda y. \text{John fed } y, [[\text{every}]]\}$
- (40) Some guy fed every dog.  
 a.  $\exists x[\forall y[\text{dog}(y) \rightarrow x \text{ fed } y]]$  (surface scope)  
 b.  $\forall y[\text{dog}(y) \rightarrow \exists x[x \text{ fed } y]]$  (inverse scope)
- (41) a.  $T = [VP [NP \text{ some guy}] [V' \text{ fed } \dots]]$   
 $S = \{[[\text{some guy fed}]]\} = \{\lambda y. \exists x[x \text{ fed } y]\}$   
 b.  $T' = [VP [NP \text{ every } \dots][1[VP [NP \text{ some guy}] [V' \text{ fed } t_1]]]$   
 $S' = \{[[\text{every}]], \lambda y. \exists x[x \text{ fed } y]\}$
- (42) a.  $T = [IP \_ [I' [VP [NP \text{ some guy}] [V' \text{ fed } \dots]]]$   
 $S = \{[[\text{some guy fed}]]\} = \{\lambda y. \exists x[x \text{ fed } y]\}$   
 b.  $T' = [IP [NP \text{ some guy}] [2[I' [VP [NP \text{ every } \dots][1[VP t_2 [V' \text{ fed } t_1]]]]]$   
 $S' = \{[[\text{some guy}]], [[\text{every}]], [[\text{fed}]]\}$

In the (ii) revision of LF case, therefore, the processor performs a revision of the parse tree and throws out a predicted meaning in S as well, reconsidering composition.

#### 4.2. Incremental composition.

Let's next turn to 'early' composition. Section 3 anticipates (iii) predictive Function Application.

##### (iii) **predictive Function Application (FA)**

Given  $\langle T, S \rangle$  and input  $\sigma$ , map to  $\langle T', S' \rangle$ ,

where  $T'$  is derived by the syntactic parser and

if there is a  $\delta \in S$  such that (a)  $[[\sigma]]_h(\delta)$  or

(b)  $\delta([[\sigma]]_h)$  is defined, then,

(a)  $S' = S \setminus \delta \cup \{[[\sigma]]_h(\delta)\}$  or

(b)  $S' = S \setminus \delta \cup \{\delta([[\sigma]]_h)\}$  (whichever is defined).

The example from section 3 is immediate compositional interpretation in the DP, (43). Predictive FA would similarly be involved in (44). This proposal could be further tested by data like (45), which we give as a suggestion for future research.

(43) Touch the tall ...

- (44) a. Every dog...  
 b.  $S = \{[[\text{every}]]\}$ ,  $S' = \{[[\text{every}]]([[\text{dog}]])\}$

- (45) a. Every dog that greeted its master was fed.  
 b. Every dog was fed that greeted its master.

The second ‘early’ composition mechanism from section 3 is (iv) predictive Function Composition (assuming the higher types for the heuristics). Examples from above were the data types in (46).

(iv) **predictive Function Composition (FC)**

Given  $\langle T, S \rangle$  and input  $\sigma$ , map to  $\langle T', S' \rangle$ ,

where  $T'$  is derived by the syntactic parser and

if there is a  $\delta \in S$  such that (a)  $\delta \bullet [[\sigma]]_h$  or

(b)  $[[\sigma]]_h \bullet \delta$  is defined, then,

(a)  $S' = S \setminus \delta \cup \{\delta \bullet [[\sigma]]_h\}$  or

(b)  $S' = S \setminus \delta \cup \{[[\sigma]]_h \bullet \delta\}$  (whichever is defined).

- (46) a. The soup greeted... (subject–verb)  
 b. Morgen gewann... (tense–adverb)  
 tomorrow won ...  
 c. Susanne hat wieder... (subject–adverb)  
 Susanne has again ...

#### 4.3. When is composition ‘early’ and when ‘delayed’ – a possible generalization

A model of semantic processing in the sense of enlightened incrementality should be an optimal compromise regarding two conflicting demands: (a) a low load on working memory: it is unrealistic that we carry around a large number of separate meanings until the end of an utterance; (b) reliable predictions: it is undesirable to randomly compose word meanings when the confidence that this is the actual interpretation is low. We offer the conjecture below for what this compromise could look like.

(47) **Enlightened Incrementality Conjecture:**

Units in the same LF domain (DP, VP, TP, AspP). are composed incrementally.

The idea is that there is incremental (‘early’) composition, but it is limited to a local LF domain. LF domains are defined by semantic type. E.g., we predictively combine the verb with its arguments within the VP  $\langle e, t \rangle$  (‘the soup greeted...’). We predictively combine tense with temporal adverbials within the TP layer  $\langle i, t \rangle$  (‘Morgen gewann...’) and event-level adverbials with expected event descriptions just above the core VP  $\langle v, t \rangle$  (‘Susanne hat wieder...’). It appears that predictive composition occurs in layers. (This does not mean that you have to finish a layer before you start the next one, cf. ‘Morgen gewann...’.) The tree below illustrates the LF architecture this proposal is based on (e.g. von Stechow and Beck, 2015).

The examples that we have seen for ‘delayed’ composition, e.g. German aspect/Aktionsart (‘Zwei Stunden lang gewann...’), concern material that in the LF is scattered over several layers (TP, AspP, VP). Quantifiers in object position also concern more than one layer: QR takes a quantifier above aspect as illustrated in (48) (e.g. von Stechow and Beck, 2015).

(48)

**In sum**, late composition facts mean that predictive FA and predictive FC cannot always apply. We conjecture that predictive composition happens in local LF domains, identifiable by semantic type, where the confidence that this is the correct composition is high.

**Next steps:** There are a couple of issues that need to be addressed for a more complete proposal. The QR data draw our attention to movement and the question of how Predicate Abstraction in standard composition transfers to incremental composition. Analyses are available in CCG (see e.g. Steedman, 2000; Demberg, 2012 for relevant discussion). Similarly, the tense and aspect data show that for an incremental analysis of a complete fragment, we need to think about the interaction of the several LF layers. A proposal is made in Bott and Sternefeld (to appear). We must leave an investigation of these issues, consideration of the available processing evidence and its integration into our proposal for future research.

## 5. Conclusions

We have seen that semantic processing has incremental properties (e.g. subject + verb seems to be composed immediately) but also ‘global’ properties, i.e. processing requires larger units (e.g. quantifiers). Standard theories of semantic composition do not model this because they require the whole LF tree and only assign meanings to constituents. Strictly incremental theories of semantic composition do not model this because every sentence prefix is assigned a meaning strictly incrementally. Hence the field is still in search of a model of incremental composition.

We formulate first ideas towards a definition of a heuristic interpretation function  $[[\cdot]]_h$  which models incremental composition (keeping as much as possible from standard semantic theories). Our goal is to offer the beginnings of a framework for theories of semantic parsing. Naturally, the question when and to what extent the semantic parser composes incrementally needs to be addressed for further phenomena (variables, decomposition phenomena, presupposition etc.).

Central to our proposal is the enlightened incrementality conjecture: incremental composition occurs within a local LF domain, when the confidence is high that the composition will prove correct.

Our model for a semantic processor concentrates on grammatically determined aspects of incremental interpretation. This is not to deny that other factors may enter into (incremental) understanding. An important factor is what we might call expectations, coming from e.g. frequency, contextual fit or background knowledge. It is clear that these factors affect processing, for example of garden path sentences (e.g. MacDonald, Perlmutter and Seidenberg, 1994) and even scope (Raffray and Pickering, 2010; Chemla and Bott, 2015). We take them to be relevant for our model as well: for instance, the very early effect on *again* noted in section 3 is plausibly due to the kind of context used in the experiment. One way this can be thought about is in terms of when to apply which heuristic rule. Hale (2003) models syntactic expectations by adding the likelihood of the application of a rule of the parser as a probability. A similar path would be open to models of the semantic processor. At any rate,

we assume that a component handling such factors can and should be added to what we propose about the processor.

We find it important to model findings on processing in terms of a compositional semantic processor, even though our empirical knowledge in this area is still quite limited. We offer the heuristics in this paper as a framework for beginning this enterprise. If semanticists don't worry about incremental interpretation, and psycholinguists don't model the composition steps, there will be a regrettable gap in linguistic theory. Individual results on semantic processing remain isolated instead of contributing towards a theory of incremental interpretation.

# Embedded disjunctions and the best response paradigm<sup>1</sup>

Anton BENZ — Leibniz–Centre General Linguistics, ZAS, Berlin

Nicole GOTZNER — Leibniz–Centre General Linguistics, ZAS, Berlin

**Abstract.** The current study investigates implicature of embedded disjunctions. We employ a paradigm in which implicatures are inferred indirectly from action choices of test subjects. This avoids meta–linguistic judgements on which previous studies relied. The focus is on four different types of implicature that may be triggered by embedded disjunctions in a situation with a competent speaker. We distinguish between local and global scalar implicatures, exhaustive and existence implicatures. The results provide evidence that varieties all four types of implicature have been inferred by a majority of subjects.

**Keywords:** experimental pragmatics, embedded implicature, disjunctions.

## 1. Introduction

The connective ‘*or*’ is one of the core examples illustrating different types of quantity implicature. In (1), the disjunction gives rise to three quantity implicatures, the *scalar* implicature which says that the sentence with ‘*or*’ replaced by ‘*and*’ is false, the so–called *ignorance* or *clausal* implicatures which says that, for all that the speaker knows, it is possible that any of the disjuncts may be true or false, and the exhaustive implicature which says that Kate did not find, for example, the green marble, if she has a green marble:

- (1) Kate found her blue or her red marble.
  - ↪ Scalar: Kate did not find her blue and her red marble.
  - ↪ Ignorance:  $\Diamond / \Diamond \neg$  Kate did find her blue marble;  
 $\Diamond / \Diamond \neg$  Kate did find her red marble;
  - ↪ Exhaustive: Kate did not find any other marble except the blue or the red one.

In this example, the connector is not embedded. The ignorance implicature is inconsistent with a situation in which the speaker knows the actual state of the world. Hence, un-embedded disjunction is generally not licensed in such situations. This marks a difference to embedded ‘*or*’. For example, ‘*All of the girls found their red or their blue marble*’ can be uttered by a competent speaker.

The current study investigates the complex sentences with embedded disjunctions in (2).

- (2) a. All of the girls found their red or their blue marble.
  - b. Some of the girls found their red or their blue marble.
  - c. All of the girls found their red, their blue, or their green marble.
  - d. Some of the girls found their red, their blue, or their green marble.

---

<sup>1</sup>This work was supported by the Bundesministerium für Bildung und Forschung (BMBF) (Grant Nr. 01UG1411), and the Deutsche Forschungsgemeinschaft (DFG) (Grant Nr. BE 4348/4-1). We are grateful to Felicitas Enders, Mady Thonicke, and Danny Belitz for preparing the experimental stimuli.

In particular, we test the status of the following types of implicature:

- (3) (A) the embedded scalar implicature of the disjunction, e.g. for (2a) the implicature ‘*all either  $r$  or  $b$* ’ leading to an exclusive reading of ‘*or*’;
- (B1) the global implicature from (2b) to none  $r \wedge b$ , and from (2d) to none  $r \wedge b$ , none  $r \wedge g$ , and none  $b \wedge g$ ;
- (B2) the global implicature from (2b) to not all  $r \vee b$ , and from (2d) to not all  $r \vee b \vee g$ ;
- (C) the exhaustive implicature from (2a) and (2b) to *none found their green marble*;
- (D) the strong existence implicature of the embedded disjunctions, for example from (2a) all  $(r \vee b)$  to some  $r \wedge$  some  $b$ .
- (D’) the weak existence implicature of the embedded disjunctions, for example from (2a) all  $(r \vee b)$  to *it is possible that some  $r$*  and *it is possible that some  $b$* .

The weak existence implicature (D’) is implied by the strong existence implicature (D). We treat them as two variants of the same type of implicature. Likewise, (B1) and (B2) are treated here as two variants of the same type of implicature. The labels have to be understood descriptively. By using them, we do not mean to commit to any specific theoretical framework.

Throughout, we only consider situations in which the speaker is commonly known to be competent, i.e. knowledgeable of the true state of the world. A further assumption is that the objects that can be connected by disjunction are also commonly known. For example, in a scenario in which (2a) is uttered, it will be assumed that each of the girls owns a commonly known finite set of marbles, each with a distinct colour, that could be found by the girl.

Theories make different predictions concerning the implicatures in (3). For example, Chierchia (2004) predicts (A) and a weaker version of (B1), e.g.  $(2b) \rightsquigarrow (\text{some } r \vee b \text{ and } \neg \text{all } r \vee b)$  but does not address (D). Franke (2009) predicts (A) and (B1), and Sauerland (2004) (B1) and for (2a) a weaker version of (A) ( $\neg \text{all } r \wedge b$ ). None of the theories predicts (C), and (D) is only explained by Sauerland (2004) and Crnič et al. (2015) for the sentences with universal quantifier. All theories predict (B2). This is only a sample of the theories about embedded implicature that could be considered (e.g. Asher, 2013; Chierchia et al., 2012; Benz, 2012; Potts et al., 2016). None of the theories addresses all types of implicature, and not all of them are specific enough to be testable.

We present clear experimental evidence that the implicature of types (A), (B1), (C), and (D’) can be drawn reliably in a scenario that is based on a game theoretical design (*best response paradigm*, Gotzner and Benz, 2018). In contrast to previous experimental studies (e.g. Geurts and Pouscoulous, 2009; Chemla and Spector, 2011), our paradigm provides an organic setting that avoids meta-linguistic judgement. In the first section, we discuss the general methodological motivation for the best response paradigm. The second section presents the experiments and their results, and the third discusses their evidence for the different types of implicature listed in (3). For example, we will see that there is no evidence for the type (B2) implicature being inferred reliably, which is surprising as they are predicted by all theories. In the fourth section we compare our results to the more recent study of Crnič et al. (2015), who found evidence for strong existence implicatures (D) in absence of implicatures of type (A) and (C).

## 2. Embedded disjunctions: some theory and some experimental issues

A large body of experimental research on implicatures has emerged over the past decade. The majority of experiments concentrate on questions of acquisition (Noveck, 2001; Papafragou and Musolino, 2003; Katsos and Bishop, 2011), the time course of implicature processing (Noveck and Posada, 2003; Huang and Snedeker, 2009; Grodner et al., 2010; Tomlinson et al., 2013), or the question whether they are generated by default or triggered in context (Breheny et al., 2006). There have been considerably fewer studies on embedded implicatures (Chemla 2009; Geurts and Pouscoulous 2009; Clifton Jr and Dube 2010; Chemla and Spector 2011; Potts et al. 2016; Crnić et al. 2015; Gotzner and Romoli 2017). These studies have employed various paradigms, picture verification tasks (e.g. Geurts and Pouscoulous, 2009), inferencing tasks (e.g. Chemla, 2009), graded acceptability tasks (e.g. Chemla and Spector, 2011), and picture selection tasks (Clifton Jr and Dube, 2010). In these studies, sentences as (2a) are considered ambiguous between a semantic and one or more pragmatic interpretations. The task is to determine whether there is a sub-population that interprets the test sentence in accordance with the critical pragmatic interpretation. There has been a sharp controversy about methodological issues. For example, on the one side it has been argued that inferencing tasks inflate the proportion of pragmatic interpretations (Geurts and Pouscoulous, 2009), and that graded acceptability judgements and picture selection tasks are susceptible to typicality effects (Geurts and van Tiel, 2013; van Tiel, 2014), so that the evidence for embedded implicatures provided by experiments based on these designs may be doubted. On the other side, it has been argued that picture verification tasks induce subjects to interpret semantically, and therefore to underestimate the real proportion of subjects adopting the critical pragmatic interpretation (Clifton Jr and Dube, 2010; Benz and Gotzner, 2014). With the exception of Crnić et al. (2015), the studies were only concerned with embedded scalar implicatures, and generally showed only low proportions of subjects choosing the critical interpretation.

The low proportions may seem unproblematic if the goal is to show that subjects *can* arrive at certain interpretations. In the standard neo-Gricean theory of conversational implicature (Levinson, 1983), implicatures are not alternative readings of a sentence but supplements to semantic content and part of communicated meaning. To show that an interpretation is implicated in this stronger sense, it has to be shown that it is understood by all addressees on a par with semantic content. We are therefore interested in the question which potential implicatures are reliably inferred such that they can count as part of communicated meaning, and which are not. Experiments show a certain degree of random behaviour. We, therefore, can only try to determine, however, which propositions are inferred with high probability, where the term '*high probability*' introduces a certain amount of vagueness.

Pragmatics is about language in use. We, therefore, devised a scenario in which critical sentences are used for communicating facts that the addressee needs to know for subsequent decision making. Our initial hypothesis was that all four types of implicature (A) to (D) are drawn reliably. We will see that the observed response pattern indicates that implicatures of type (A), (B1), (C), and (D') are drawn reliably.

### 3. The Best Response paradigm

The following experiment takes advantage of the fact that interpretations can be indirectly inferred from action choices of interpreters. In this way, meta-linguistic judgements can be circumvented. As we have argued elsewhere, meta-linguistic judgements, in particular, picture verification tasks, bias subjects towards literal interpretation (Benz and Gotzner, 2014). The presence of a substantial group of literally interpreting subjects dooms any attempt at showing that certain implicatures are communicated reliably. We therefore developed a scenario in which utterance selection and interpretation are embedded in a cooperative action selection task.

#### 3.1. Methods

##### 3.1.1. Participants

Participants with US IP addresses were recruited on Amazon's Mturk platform and were screened for their native language. In total, 20 native English speakers (mean age: 32.7, 13 female, 7 male) took part in the experiment.

##### 3.1.2. Scenario and task

In Gotzner and Benz (2018), we presented the basic version of the best response paradigm. For the current experiment, we use the same basic scenario with minor modifications. Participants in our experiment were presented with a scenario involving four girls who each own a set of three special edition marbles, consisting of a blue, a green and a red marble (a scenario introduced by Degen and Goodman 2014, which we extended with an action-based task). While the girls are playing, the marbles get lost and they have to find them again. Participants in our experiment were told that the mother of the girls wants to reward them depending on how many marbles they find. In particular, participants were presented with the following reward system in the instructions.

##### (4) Reward system:

- chocolate: all 3 marbles
- candy: 2 marbles
- gummy bear: 1 marble
  - green gummy bear: green marble
  - red gummy bear: red marble
  - blue gummy bear: blue marble
- pretzel stick: 0 marbles

The participants's task in the experiment is to buy sweets as rewards for the four girls depending on the statement the mother utters. After participants had read the instructions, they were asked control questions about the number of marbles each girl owns and which reward type a girl gets depending on how many marbles she found. Then, participants were given an example

item involving the statement ‘*None of the girls found any of their marbles*’, in which case they should buy pretzels and nothing else.

### 3.1.3. Experimental items

In the main part of the experiment, participants were asked to give binary responses (YES/NO) for each of the six types of sweets: chocolate, candy, gummy bears (red, green or blue) and pretzel sticks. There were two types of critical test sentences: either simple or complex disjunction was embedded under *all* and *some*. The test sentences are shown in (5). Our four critical sentences were repeated twice in the experiment.

- (5) a. All of the girls found their red or their blue marble.  
 b. Some of the girls found their red or their blue marble.  
 c. All of the girls found their red, their blue, or their green marble.  
 d. Some of the girls found their red, their blue, or their green marble.

An example experimental trial with All ( $r \vee b$ ) and a possible response choice is presented in (6). Participants had to check one of two radio buttons (‘YES’ or ‘NO’) for each type of sweets.

The mother says:		‘All of the girls found their red or blue marble’	
	chocolate	<input type="radio"/> YES	<input type="radio"/> NO
	candy	<input type="radio"/> YES	<input type="radio"/> NO
(6)	green gummy bear	<input type="radio"/> YES	<input type="radio"/> NO
	red gummy bear	<input checked="" type="radio"/> YES	<input type="radio"/> NO
	blue gummy bear	<input checked="" type="radio"/> YES	<input type="radio"/> NO
	pretzel stick	<input type="radio"/> YES	<input checked="" type="radio"/> NO

In addition, participants saw 15 filler items such as the statement ‘Sue and Kate found some of their marbles’ as well as the original test sentences used in Gotzner and Benz (2018) involving the quantifier *some* embedded under *all* and *some* itself. Hence, each participant saw 23 items in total.

## 3.2. Results

Figure 1 shows the mean percentage of YES responses across reward type for simple disjunctions and Figure 2 shows the data for complex disjunctions (Table 4 in the appendix details the percentages of each combination of action choices per condition). We computed two separate logit mixed models for simple and complex disjunctions. Our dependent variable was binary (choice of sweet: 1 or 0) and we included the fixed factors quantifier condition (All ( $r \vee b$ ) vs. Some ( $r \vee b$ )), reward type (candy, chocolate, red, green, blue gummy bear, pretzel stick), their interaction as well as random factors for participants and items. As reference level we chose the condition (All ( $r \vee b$ ), candy) and (All ( $r \vee b \vee g$ ), candy) respectively.

Figure 1: % YES responses for sentence *All* ( $r \vee b$ ) (left column) and *Some* ( $r \vee b$ ) (right column) across reward type. Error bars represent SEM.

Figure 2: % YES responses for sentence *All* ( $r \vee b \vee g$ ) (left column) and *Some* ( $r \vee b \vee g$ ) (right column) across reward type. Error bars represent SEM.

**Mixed model for simple disjunctions.** The model showed a significant difference across reward type: Participants chose candy less often than red bears ( $p < .001$ ) and blue bears ( $p < .001$ ). There was no difference between the two quantifier conditions at the baseline level or between candy and the other two reward types. However, the model revealed an interaction between quantifier condition and reward type (pretzel : Some ( $r \vee b$ ):  $p < .0001$ ). Table 5 in the appendix shows a summary of the mixed model.

**Mixed model for complex disjunctions.** The model showed a significant difference across reward type: Participants chose candy less often than red bears, green and blue bears (all  $p$ 's  $< .0001$ ). There was also a marginal difference compared to the condition with pretzels ( $p = .09$ ) as well as an interaction across condition and reward type (pretzel : Some ( $r \vee b \vee g$ )  $p < .001$ ). There were no further main effects nor any interactions. Table 6 in the appendix shows a summary of the mixed model.

#### 4. Evaluation of results

We tested the four sentences presented in (2). The task of the participants was to buy sweets for the four girls. They were asked to give binary responses (yes/no) for each of the six types of sweets: chocolate, candy, red, blue, and green gummy bears, and pretzel sticks. If subjects draw the implicatures (A)–(D), then their expected response pattern is that shown in (7).

condition		choc.	candy	red b.	blue b.	green b.	pretzel
(7)	(2a) All ( $r \vee b$ )	no	no	yes	yes	no	no
	(2b) Some ( $r \vee b$ )	no	no	yes	yes	no	yes
	(2c) All ( $r \vee b \vee g$ )	no	no	yes	yes	yes	no
	(2d) Some ( $r \vee b \vee g$ )	no	no	yes	yes	yes	yes

As we have seen, the observed choices conform to this prediction. The only exception are the choices with respect to pretzels in the *some*-conditions. We observe a larger proportion of subjects buying no pretzels (about 30%),<sup>2</sup> which is inconsistent with there being a group of girls that found none of their marbles. This implicature follows from an utterance of (2b) by the following reasoning: First, with (B2) Some ( $r \vee b$ ) implicates  $\neg \text{all } (r \vee b)$ ; second, (C) implies that none found the green marble. Together, this implies that some found none. If subjects would not adhere to (C), then they should have bought either chocolate, candy or green gummy bears in the '*some* ( $r \vee b$ )' condition (2b). As they did not buy them, the problem must be the implicature of type (B2). Hence, the experiments indicate that there is a significant proportion of subjects that do not draw the (B2) implicature, i.e. global scalar implicature from embedding '*some*'. However, we can conclude that the hypothesis that subjects draw implicatures (A), (B1), (C), and (D) is *consistent* with the experimental results.

We next consider the more difficult question of how far the results shown in Table 4 in the appendix *imply* that subjects infer (A), (B1), (C), and (D). As the percentage values follow the

<sup>2</sup>A mixed model analysis with disjunction embedded under *some* and the reward type pretzels as reference level revealed that this condition differed significantly from all other reward types (all  $p$ 's  $< .001$ , both for simple and complex disjunctions).

response pattern shown in (7), with the exception of the pretzel results for (2b) and (2d), we abstract from the precise numerical values and concentrate on the evidence provided by the categorical pattern in (7). What we have to show is that for all possible belief states that are consistent with the subjects's choices of sweets, the implicatures generated by (A), (B1), (C), and (D) hold true.

In our scenario, each observable world can be identified with a 4-tuple  $(m_1, m_2, m_3, m_4)$  of sets of marbles  $m_i \subseteq \{b, g, r\}$ . The set  $m_i$  represents the set of marbles found by the  $i^{th}$  girl. There are  $(2^3)^4 = 4096$  different observable worlds. The reward system with different kinds of sweets distinguishes  $2^6 - 1 = 63$  relevant states, of which  $\sum_{i=1}^4 \binom{6}{i} = 56$  can be instantiated by four girls. In the following, we mean by '*possible world*' always one of the 63 possible worlds defined by the reward system, and not one of the observable worlds.

We consider the four conditions (2a) to (2d) one after the other. First, let us consider (2a):

(2a) All of the girls found their red or their blue marble.

This sentence is semantically consistent with 24 possible worlds, 8 of which are shown in Table 1. The other 16 worlds can be found by making one copy of the table and replacing the 1s in the '*blue*' column by 0s, and then by making another copy and replacing the 1s in the '*red*' column by 0s. Of the 24 worlds only one world is consistent with the pragmatic choice as indicated by the  $\checkmark$  in the last column.

Possible worlds (8 of 24)							Information states consistent with choice						
pretzl	blue	green	red	candy	choc	cons	inf. state	pretzl	blue	green	red	candy	choc
0	1	1	1	1	1	—	I	0	1	0	1	0	0
0	1	1	1	1	0	—							
0	1	1	1	0	1	—	II	0	1	0	1	0	0
0	1	1	1	0	0	—		0	1	0	0	0	0
0	1	0	1	1	1	—	III						
0	1	0	1	1	0	—		0	1	0	1	0	0
0	1	0	1	0	1	—		0	0	0	1	0	0
0	1	0	1	0	0	$\checkmark$	IV	0	1	0	0	0	0
								0	0	0	1	0	0

Table 1: Target sentence (2a) *All of the girls found their red or their blue marble.*

If the addressee infers an exact state of the world, then we can conclude that she believes to be in the world indicated by  $\checkmark$ . However, there are three other belief states that are consistent with the choice of only red and blue gummy bears. They are also shown in Table 1. The experimental set up does not allow us to distinguish between the four states. We now have to check whether the implicatures predicted by (A), (B), (C), and (D) are supported by all four of them. (A) is the embedded implicature that none found both the red and the blue marble; if the addressee believes that this implicature might be false, then there must exist a belief world in which it is appropriate to buy hard candy; as in neither of the four belief states there exists such a world, we can conclude that the addressee does not believe it possible that the implicature is

false. Hence, the embedded implicature (A) is true. (B1) and (B2) only apply to the ‘some’ sentences. The exhaustive implicature (C) that none found the green marble is also true in all belief states. We can also immediately see that the weak existence implicature (D’) holds: each belief state contains a world with a 1 in the *red* column, and a world with a 1 in the *blue* column; hence, in each belief state it is possible that a girl found a red marble and it is possible that a girl found a blue marble. The stronger existence implicature (D) is violated in information states II, III, and IV: in each of these states there is a world in which either the *red* column contains a 0 or the *blue* column.

We next consider condition (2b):

(2b) Some of the girls found their red or their blue marble.

This sentence is semantically consistent with 48 possible worlds, 9 of which are shown in Table 2. The 48 worlds consist of the 24 worlds consistent with (2a) together with a copy of these worlds where the 0s in the ‘*pretzel*’ column are replaced by 1s. Of the 48 worlds only two worlds are consistent with the experimental results: one world consistent with the choice of the subjects who bought pretzels, and one world consistent with the choice of the subjects who did not by them. The two worlds are indicated by ✓ in the last column of Table 2.

Possible worlds (9 of 48)							Information state consistent with choice (1 of 57)						
pretzl	blue	green	red	candy	choc	cons	pretzl	blue	green	red	candy	choc	
1	1	1	1	1	1	—	1	1	0	1	0	0	
1	1	1	1	1	0	—	1	1	0	0	0	0	
1	1	1	1	0	1	—	1	0	0	1	0	0	
1	1	1	1	0	0	—	0	1	0	1	0	0	
1	1	0	1	1	1	—	0	1	0	0	0	0	
1	1	0	1	1	0	—	0	0	0	1	0	0	
1	1	0	1	0	1	—							
1	1	0	1	0	0	✓							
0	1	0	1	0	0	✓							

Table 2: Target sentence (2b) *Some of the girls found their red or their blue marble.*

For (2b), there are many more belief states than for condition (2a). One belief state is shown in Table 2. We can generate 57 belief states by taking all subsets of this state which contain a world with a 1 in the ‘*blue*’ column and a world with a 1 in the ‘*red*’ column.

If the addressee believes to be in one of the worlds indicated by ✓, then she believes in the implicature generated by (A), (B1), (C), and (D). If it is the world with a 1 in the ‘*pretzel*’ column, then she also draws the global scalar implicature for embedding ‘some’ (B2). Our results showed that this is true only for about two-third of the subjects. If no belief state contains a world where candy or chocolate has to be bought, then the addressee must believe in the (A) implicature. As all belief states are subsets of the one shown in Table 2, this holds true. The global implicature of embedded ‘or’ (B1) says that none of the girls found the red and the blue marble. This follows from the fact that no belief state contains a world in which candy or chocolate has to be bought. The global implicature (B2) stating that not all girls found the red

A	B	D	E	F
A	B			F
A		D	E	F
A		D		F
A	B			F

Table 3: A critical item probing for existence implicature from Crnić et al. (2015: p. 15).

or the blue marble is violated if a belief state contains a world with a 0 in the ‘*pretzel*’ column. We have seen that such belief states are not ruled out by our data. There is a larger proportion of subjects whose choice of sweets is consistent only if they are not drawing the (B2) implicature, as we have argued before. The exhaustive implicature (C) that none found the green marble is true in all belief states. We can again immediately see that the weak existence implicature (D’) holds. The stronger existence implicature (D) is violated in all but three belief states.

For the remaining conditions (2c) and (2d), the claims follow by analogous arguments.

- (2c) All of the girls found their red, their blue, or their green marble.  
 (2d) Some of the girls found their red, their blue, or their green marble.

The motivation for testing these sentences in addition to (2a) and (2b) was that deriving the embedded scalar implicatures (A) for double disjunction in contrast to single disjunction is more difficult in localist frameworks (Chierchia et al., 2012). However, our results do not indicate any significant difference between them.

## 5. Comparison with Crnić et al.

Our aim was to test whether the different types of implicature associated with embedded ‘*or*’ are part of communicated meaning. Within common error ranges, subjects followed the response pattern shown in (7), except for ‘*some*’ sentences, for which a substantial proportion of subjects failed to infer that some of the girls found none of the marbles. This pattern suggests that indeed implicatures from (A), (B1), (C), and (D’) are reliably drawn in our scenario. As mentioned earlier, the goal of our study contrasts with that of many other studies of embedded implicature. A relevant example is that of Crnić et al. (2015) who tested for strong existence implicature in a picture verification task. They only considered sentences of type (2a), i.e. no sentences with embedding ‘*some*’:

- (8) Every box contains an A or a C.

A critical picture is shown in Table 3. For this picture, a significant proportion of subjects rejected sentence (8) while almost all accepted the following sentences:

- (9) a. Every box contains a B or a D.  
 b. Every box contains an A or a B.  
 c. Every box contains an A or an F.

As the strong existence implicature (D) from sentence (8) is false in the given situation, it can be inferred that some subjects draw this implicature. As subjects accepted (9b) and (9c), they must have ignored the embedded scalar implicature (A), as well as the weaker global scalar implicature from ‘*all  $p \vee q$* ’ to ‘ *$\neg$ all  $p \wedge q$* ’. None of the sentences in (9) is consistent with the exhaustive implicature (C). Hence, the results differ significantly from our study. We assume that this difference is due to the different tasks the subjects had to perform. As mentioned before, picture verification tasks push subjects to purely semantic interpretations. In contrast, we provided them with an action selection task which does not directly involve reasoning about truth conditions. This does not necessarily entail that one design is deficient, and the other does it right. They simply test interpretation in different contexts. The question is what we want to find out about language use. Crnič et al. (2015) wanted to show that there exist a non-empty group of subjects that draw existence implicatures without drawing other implicatures. They are not concerned with showing that they are drawn by almost all subjects. The critical sentence was accepted in 78.4% of all occasions, in contrast to 97% and 93.1% for sentences (9b) and (9c). Hence, the existence implicature has been inferred in at most 22% of all cases in which a critical sentence was presented. In terms of individuals, they found that only 6 out of 51 subjects drew the existence implicature consistently. It is clear that these percentages could not count as evidence that they are drawn reliably.

A drawback of the design we used is that it is not sensitive to the distinction between weak and strong existence implicature. We would have to rule out uncertainty about interpretations on the hearer side. If their belief states consist of only one world, for example of the worlds marked by  $\checkmark$  in Tables 1 and 2, it would be obvious that the strong existence implicature is inferred. In order to show that uncertainty can be ruled out, we have to develop our paradigm further.<sup>3</sup>

## 6. Conclusions

The results of our study provide clear evidence that participants compute local scalar implicatures (A), global implicature for strengthened ‘*or*’ (B1), exhaustive implicatures (D), and weak existence implicature (D’). If uncertainty about interpretation on the hearer side can be ruled out, the strong existence implicature (D) can be assumed. We were concerned with implicature as part of communicated meaning. Hence, we had to show that a very high proportion of subjects draw these implicatures. As shown in the introduction, none of the existing theories can account for all these implicatures. In our previous discussions, we have not addressed the issue of how the observed implicature can be accounted for theoretically. The contrast between picture verification tasks, for example (Geurts and Poussoulous, 2009; Crnič et al., 2015), and the best response paradigm (Gotzner and Benz, 2018) show that context specific parameters, as for example shared assumptions about the speaker’s knowledge about the exact state of the world, and general domain tasks that define relevant meaning differences, play a crucial role in implicature generation.

<sup>3</sup>To simply add an answer option ‘*I don’t know*’ to the options ‘*yes*’ and ‘*no*’ would not be enough as this option introduces new uncertainties about its interpretation.

## 7. Appendix

### 7.1. Instructions

Ann, Sue, Mary and Kate are sisters. They are really into collecting marbles. Each of the sisters has a set of 3 special edition marbles. One set consists of a green, a blue, and a red marble. Each set is special, so the girls know which marble belongs to whom. Their mother is playing a game with them. She hides their marbles in the house. Then the girls search for their sets. In the end, they receive a reward.

- If a girl finds
  - all 3 of her marbles, she will win a chocolate
  - 2 of her marbles, she will win a candy
  - 1 of her marbles, she will win
    - a red gummy bear, if she found her red marble
    - a green gummy bear, if she found her green marble
    - a blue gummy bear, if she found her blue marble
  - 0 of her marbles, she will win a pretzel stick as consolation prize.

The mother is really good at hiding marbles. So, it is really difficult for the girls to find them. The girls never help each other, and if one of them spots the marble of another one, then she ignores it. In this experiment you will read sentences that were uttered by the mother after she checked the marble bags.

Before you begin the experiment, please answer the following question: How many special edition marbles does each sister own? \_\_\_

What reward will a girl get when she has found...

all 3 of her marbles? \_\_\_

only 2 of her marbles? \_\_\_

only 1 of her marbles, if she found the red one? \_\_\_

only 1 of her marbles, if she found the green one? \_\_\_

only 1 of her marbles, if she found the blue one? \_\_\_

none of her 3 marbles, if she found the red one? \_\_\_

### The Main Task:

Please decide which sweets you would buy as a reward for the girls depending on the mother's statement.

### 7.2. Detailed percentages of action choice across conditions

Reward/condition	All ( $r \vee b$ )	Some ( $r \vee b$ )	All ( $r \vee b \vee g$ )	Some ( $r \vee b \vee g$ )
candy	18%	15%	20%	13%
chocolate	8%	10%	15%	23%
green bear	8%	18%	95%	100%
red bear	93%	95%	98%	95%
blue bear	93%	93%	95%	98%
pretzel stick	11%	69%	5%	65%

# The pragmatic ingredients to get perfect biscuits<sup>1</sup>

María BIEZMA — *University of Konstanz*

Arno GOEBEL — *University of Konstanz*

**Abstract.** Building on previous work, we present a proposal for a pragmatic account of biscuit conditionals (BCs). We present a new phenomenon that we dub *biscuit perfection* to support our proposal and argue that differences between BCs and hypothetical conditionals can be explained once we consider the relation between *if*-constructions and discourse.

**Keywords:** Biscuit conditionals, contrastive topic, inferences in conditionals, causality.

## 1. Introduction

There is a contrast between the two *if*-constructions in (1):

- (1) a. If you are hungry, I'll give you some biscuits.
- b. If you are hungry, there are biscuits on the sideboard.

In its most prominent reading, an utterance of (1a) conveys that whether I give you biscuits or not depends on you being hungry. *If*-constructions with this reading are often called hypothetical conditionals, (HCs). In contrast, by uttering (1b) the speaker conveys that there are biscuits on the sideboard regardless of whether you are hungry or not, and in addition conveys a suggestion to eat the biscuits to still hunger. *If*-constructions with this reading are called *biscuit conditionals* after Austin's (1956) original example or, e.g., *relevance conditionals* (although in these cases the consequent is not at all 'conditional' on the antecedent). This contrast has been characterized as a difference in information update within a Stalnakerian model of communication (Stalnaker, 2002, 2014): the consequents in HCs update only the temporary context created by the antecedent clause, while in BCs the consequents update the entire context set. Theories of biscuit conditionals have aimed to explain this contrast, which we dub the *global update puzzle* (GUP). A second issue is why a speaker would utter (1b) instead of the plain declarative *there are biscuits on the sideboard*. We dub this second question the *conditional form puzzle* (CFP). As a third point, we would also like to understand how the 'extra meaning' pertaining to a suggestion arises in examples like (1b).

There are, roughly, two linguistic approaches to the study of BCs. Semantic theories (DeRose and Grandy 1999; Siegel 2006; Ebert et al. 2014 a.o.) claim that BCs and HCs have different logical forms that result in a different interpretation. Such accounts provide explanations for the GUP and the CFP and can also account for the fact that an utterance of (1b) conveys a suggestion.

---

<sup>1</sup>We are grateful to Ana Arregui for comments. Thanks also to Anja Arnhold, Andrea Beltrama, Marc Brunelle, Nate Charlow, Eva Csipak, Felicitas Enders, Sven Lauer, Brian Leahy, Erlinde Meertens, Thomas Müller, Doris Penka, Eric Raidl, Eva Rafetseder, Kyle Rawlins, Maribel Romero, Antje Rumberg, Wolfgang Spohn, Andreas Walker, Mark-Matthias Zymla and the audience of the XPrag-Workshop *Rationality, probability and pragmatics* and of *SuB 21* for their very useful comments. All remaining errors are our own. This research has been supported by the Deutsche Forschungsgemeinschaft (DFG, Project 1836/1-1)

Pragmatic theories (Franke 2007, 2009; Sano and Hara 2014; Lauer 2015; Francez 2015 a.o.), in contrast, argue that the semantic meaning of *if*-constructions is the same and differences between HCs and BCs are derived pragmatically taking into account the independence between antecedent and consequent.

While semantic theories are designed to explain all the points in our desiderata so far, pragmatic theories have focused on how to derive the GUP, with the other puzzles often only sketched. In this paper we defend a pragmatic view of BCs. We build on previous work to provide a fleshed-out account of the factors that result in *if*-constructions being interpreted as either HCs or BCs. We further argue that the pragmatic mechanisms underlying one or the other reading of *if*-constructions are independently motivated. This point will be made by exploring new data illustrating a phenomenon that we call *biscuit perfection*. An example is provided in (2) (with prosodic annotations resulting from a pilot study, see §4 for more details):

- (2) a. Oh, you are making pasta bolognese!  
       If you need  $\text{(L)-H}^*$  wine for  $\text{L+H}^*$  the sauce...  $\text{L-H}\%$  there is a bottle by the microwave.  
       b. Oh, you are making pasta bolognese!  
       If you need wine for  $\text{L+H}^*$  the sauce...  $\text{L-H}\%$  there is a bottle by the microwave.

The two different prosodic patterns above lead to two different interpretations. In (2a), representing a “neutral” pattern, the speaker is not suggesting that the wine should not be used for other purposes, such as drinking (though such inferences could arise as a result of world-knowledge regarding the kinds of wine we cook with.). However, with the prosody in (2b) the speaker indicates that the recommendation to use the wine by the microwave extends only to the making of the sauce (i.e. the speaker wouldn’t recommend drinking the wine). In this case, the suggestion inference we had already noted is strengthened to be applied only in the circumstances described by the antecedent. We call this *biscuit perfection*. A theory of BCs should also explain how biscuit perfection is derived, which becomes now the fourth point in our desiderata. As we will show, accounting for biscuit perfection requires taking into account the mapping between BCs and discourse structure, providing independent support for a pragmatic account of BCs.

The reminder of the paper is organized as follows: in §2 we briefly explain how pragmatic theories solve the GUP and introduce the notion of independence in BCs. In §3 we make a proposal regarding how BCs map into discourse. We argue that this mapping is what triggers the inferences in BCs. The case of perfect biscuits, §4, provides support for the idea that the mapping of BCs into discourse is crucial in the construction of meaning. Biscuit perfection is argued to be no more than C(ontrastive)T(opic)-marking in BCs. We conclude with a comparison between the resulting theory and semantic theories of BCs in §5.

## 2. Strengthening the consequent to a global update (GUP)

### 2.1. Independence

Pragmatic theories claim that independence between antecedent and consequent is key to biscuit-hood (in HCs they are dependent). However, there are different takes on how to spell out what it means for propositions to be independent (Merin, 2007; Sano and Hara, 2014; Francez, 2015; Franke, 2009). Here, we will confine ourselves to an informal characterization of independence emphasizing the core insight shared by the different positions.<sup>2</sup> Independence is regarded as an epistemic notion defined relative to an agent's information state.

#### (3) Epistemic independence of propositions

Two propositions  $\phi, \psi$  are independent relative to an information state  $\Sigma$  iff learning the truth of  $\phi$  does not provide information regarding  $\psi$  and vice-versa.

With this rough characterization of independence at hand let us turn now to the semantics of indicative *if*-constructions. We will then be prepared to tackle the GUP.

### 2.2. A dynamic semantics for the (indicative) *if*-constructions and the GUP in BCs

We employ a dynamic semantics for (indicative) *if*-constructions operating on a Stalnakerian *context set*  $c$ , the global context.<sup>3</sup> The meaning of an expression is its context change potential (CCP), i.e. a function from contexts to (updated) contexts. The CCP of a simple declarative proposes to eliminate from  $c$  all worlds in which the corresponding proposition is false. For conditionals, we adopt Heim's (1983) CCP (see Biezma and Goebel 2017 for an analysis building on Isaacs and Rawlins's 2008 proposal using a stack-based model):

- (4) Conditional declarative update: Where  $M \setminus N = M \cap (W - N)$   
 $c + \text{If } \alpha, \beta = c \setminus (c + \alpha \setminus c + \alpha + \beta)$ , where  $\alpha$  and  $\beta$  are declarative clauses.

To evaluate a conditional, the antecedent clause sets up a temporary context  $c + \alpha$  containing only worlds where the antecedent is true. Given that indicative conditionals presuppose that the antecedent proposition is a live option in  $c$ ,  $c + \alpha$  is a subset of  $c$ . Furthermore,  $c + \alpha$  is updated with the consequent  $\beta$ . Complementation in  $(c + \alpha \setminus c + \alpha + \beta)$  gives us all  $\alpha \wedge \bar{\beta}$ -worlds, i.e. those worlds eliminated when  $c + \alpha$  is updated by  $\beta$ . In the final step, all  $\alpha \wedge \bar{\beta}$ -worlds are eliminated from the global context  $c$ .

However, for BCs this is not the end of the story. In pragmatic accounts of BCs following Franke (2009), the interplay with the contextual assumption of independence has the effect of eliminating all  $\bar{\beta}$ -worlds from the global context  $c$ , not only  $\alpha \wedge \bar{\beta}$ -worlds. Why is this so? The proposal is that in the context prior to the utterance of the BC there is a shared contextual assumption of

<sup>2</sup>The reader is referred to Biezma and Goebel (2017) for a full discussion and an improved alternative.

<sup>3</sup>Here we restrict ourselves to indicative BCs. In Biezma and Goebel (2017) we extend our account to also cover subjunctive BCs as observed by Swanson (2013) and further subjunctive cases.

Figure 1: Dynamic update and strengthening in BCs

independence between antecedent and consequent (while in HC-interpretations we take them to be dependent). We follow Francez (2015) in postulating that this means that dependence is excluded by shared world-knowledge of “causal and epistemic relations”. Independence enforces that in  $c$  all possible truth-value distributions over antecedent and consequent are possible, as depicted in fig. (1a). This structure makes sure that learning that either the antecedent or the consequent is true doesn’t provide information regarding the other proposition. The utterance of the conditional proposes to update  $c$  by first creating a temporary context  $c + \alpha$  formed by all the  $\alpha$ -worlds (fig. (1b)), and then eliminating from them the  $\bar{\beta}$ -worlds, leaving us only the  $\alpha \wedge \bar{\beta}$ -worlds (grey area in fig. (1c)). At this point we return to the global context where all  $\alpha \wedge \bar{\beta}$ -worlds are eliminated (fig. (1d)). However, the induced structure on  $c$  depicted in (fig. (1d)) clashes with the independence assumption. The latter requires that learning about the truth of one proposition does not imply learning anything about the other proposition. In contrast, the structure depicted in fig. (1d) is fit for *modus ponens*, i.e. if the truth of the antecedent is learned, the truth of the consequent is also learned in  $c$  since after an update with  $\alpha$  there are only  $\alpha \wedge \bar{\beta}$ -worlds left. Hence, we arrive at a contradiction, since  $\alpha$  and  $\beta$  are *not* independent here. The clash of the independence assumption and the semantically encoded update exerts *pragmatic pressure* on the addressee to modify her view of the context while preserving the assumptions of independence and that there are worlds in the context set in which the antecedent is true. With these constraints the only way to retrieve a coherent context set is to eliminate all  $\bar{\beta}$ -worlds from the global context  $c$  (fig. (1e)). In the resulting context set, in which  $\beta$  is always true, learning whether the antecedent  $\alpha$  is true or false does not allow us to learn anything about the status of  $\beta$ , preserving in this way the assumption of independence as well. Hence, it is the assumption of independence what accounts for the GUP.

It is important to note that strengthening as described is a rational reconstruction and not an explicit reasoning process the interpreter goes through. Strengthening is a contextual entailment that is not cancellable, because it is an entailment of the context set given that certain presuppositions, i.e. independence and antecedent possibility, are met.

### 3. The discourse function of BCs

Having explained the GUP, let us tackle now the CFP: why does a speaker utter a BC when the utterance of the main clause alone (the consequent) would apparently suffice? We believe that part of the answer, following Franke (2009) and going back to DeRose and Grandy (1999), is

that BCs help to establish relevance (and hence felicity) of the utterance. The following example (adapted from Franke 2009: 275) illustrates the point:

- (5) B has been helping A to pack for a trip by handing him stuff, and is obviously tired:  
 A: There are biscuits on the sideboard.  
 [B hands out the cookies to A who starts laughing. A explains that he was just suggesting that B eat them since he looks tired and sugar would do him good.]

B's interpretation of A's utterance was perfectly coherent given the overall context, but that is not what A intended (hence the laughter). Uttering the BC 'If you are hungry, there are biscuits on the sideboard' would have avoided the confusion and would have unambiguously resulted in the intended interpretation, i.e. that the speaker is suggesting that B eat some biscuits. The BC would have informed the addressee about the presence of biscuits on the sideboard and also about the intended context for that information. In this way the BC is more informative (while relevant) than the utterance of the main clause alone.<sup>4</sup> We now must face the question of how to capture the intuition that the participants' overall interpretation is that the speaker is providing the relevant context for that information as well as suggesting that the addressee eat the biscuits.

It is worth noting that classic BCs are not the only conditionals where antecedent and consequent are independent. Other examples have been discussed in the literature under the label of *non-interference* conditionals (see discussion in Bennett 2003: 122). In these cases, the intuition is also that our beliefs about the consequent proposition are unaffected by our beliefs about the antecedent. Bennett offers the following example:

- (6) I express fear that the refrigerator will explode if you open its door, and you assure me that if I open the door, it won't explode. You base this on your belief that the door-opening and the non-explosion are irrelevant to one another, and put it in conditional form because I think they are connected. (p. 123)

In pursuing a unified analysis, we would conclude that examples like this are of the same kind as traditional BCs, with differences that should follow from pragmatics. This is interesting because in the case of non-interference conditionals, the role of the conditional does not (always?) seem to be to establish relevance. Consider the following example:

- (7) A: Oh look at the weather! It's probably going to rain. Poor Betsy is still out there. She will get completely soaked.  
 B: Don't worry. She has her umbrella.  
 A: But the poor child! This is terrible! Dreadful!  
 B: Stop exaggerating. If it rains, she has her umbrella.

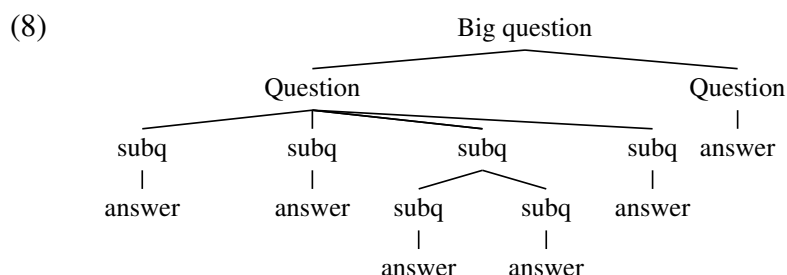

B's utterance of the conditional is not meant to establish relevance (this was already clear!). B's point is to emphasize that Mary has her umbrella. If the only discourse purpose of the 'independent' conditionals were to establish relevance, it would have been redundant, but it is

<sup>4</sup>This can be formalized in a number of neo-Gricean approaches, see Potts (2006) and reference therein a.o.

not. We will not be able to investigate all cases of *if*-constructions with independent antecedents and consequents. Our focus remains on ‘classic’ BCs. But the observation that there is a larger group, and that some members of that group do not appear to serve the discourse function of establishing relevance, is important in terms of deciding how it is that BCs come to establish relevance. A theory of BCs has to derive the old intuitions that BCs help to establish relevance, but also allow *if*-constructions with independent antecedents and consequents to serve other purposes, since they can also be used in scenarios like (7). In what follows we argue that the key is to be found in how conditionals map into discourse.

### 3.1. The mapping of *if*-constructions into discourse

We adopt the Q(uestion) U(nder) D(iscussion) discourse model (Roberts 1996; Büring 2003 a.o.) in which conversation is taken to be a cooperative inquiry and is modeled as a hierarchical order of moves. Discourse moves are understood as either answering a (implicit) question (pay-off moves) or setting up a question for participants to answer (set-up moves). The hierarchical nature of discourse can be represented by Büring’s (2003) D(iscourse)-trees:

Each node in the tree represents a *discourse move*. Participants can adopt *strategies* to address a given question (a strategy is a set of subquestions to the dominating question). Well-formedness in discourse is constrained by several notions, amongst them entailment and relevance:

(9) **Entailment:** One interrogative  $q_1$  entails another  $q_2$  iff every proposition that answers  $q_1$  answers  $q_2$  as well.

**Relevance:** A move  $M$  is *Relevant* to a question  $q$  iff  $M$  either introduces an (at least) partial answer to  $q$  in context  $c_M$  ( $M$  is an assertion) or is part of a strategy to answer  $q$  ( $M$  is a question).

The question now is how *if*-constructions map into discourse. Haiman (1978) already claimed that the antecedent clause in *if*-constructions is understood as establishing the topic of the utterance. In the QUD model this translates into the antecedent establishing the question that is being addressed. The consequent, on the other hand, provides the answer. This mapping is also suggested for BCs in Starr (2014) (although not directly in the QUD model), and Ebert et al. (2014). However, these proposals either encode the mapping in the semantics of *if*-constructions without allowing for other possibilities (which we will see is problematic), or fail to explain why this is the only possible mapping in BCs. A *default* mapping of *if*-constructions does not mean that other mappings are not possible. It has been argued, for example, that focus

particles associating with the entire antecedent proposition makes conditionals reverse this default mapping to one in which the consequent presents the QUD while the antecedent provides the answer (Biezma 2011a, b). This reverse mapping can also be forced contextually and has been claimed to be necessary in von Stechow (2009) to explain classic conditional perfection:

- (10) A: When would you give me \$5?  
 B: Well, if you mow the lawn, I'll give you \$5.  
 $\rightsquigarrow$  If you don't mow the lawn, I won't give you \$5. [Conditional perfection]

Conditional perfection arises when the antecedent is understood as an exhaustive answer to the on-going question presented by the consequent.

The discussion above argues against encoding the mapping between *if*-constructions and discourse in the semantics. In what follows we first assume that in BCs the antecedent always indicates the QUD, while the consequent provides the answer. This mapping, we argue, explains how inferences arise in BCs (when they do) and allows us to explain why some BCs are infelicitous. We close the section by explaining why this is the only possible mapping for the cases we identify as BCs.

### 3.2. Inferences in *if*-constructions and discourse-relevance

Under our unified perspective, an *if*-construction of the form *if* $\alpha$ ,  $\beta$  will be true iff in all 'relevant' worlds in which  $\alpha$  is true,  $\beta$  is also true (where 'relevant' depends on the particular theory of conditionals and how such theory restricts the domain of quantification). Assuming the default mapping of *if*-constructions, a BC (posits and) answers the following question:

- (11) 'What do the 'relevant' worlds in which  $\alpha$  is true look like?' ( $\simeq$  What if  $\alpha$ ?)<sup>5</sup>

The consequent is interpreted as a (relevant) response to such question. This relevance assumption, we argue, is what gives rise to inferences in BCs:

- (12) QUD: What do the relevant worlds in which the addressee is hungry look like?  
 ( $\simeq$  What if the addressee is hungry?)  
 Answer: There are biscuits on the sideboard.

Given that the consequent is taken to be a relevant response to the established question the addressee reasons that the speaker is trying to provide a way to solve hunger.<sup>6</sup> In paradigmatic cases of BCs like (1b), reasoning towards the relevance of the consequent as the answer to the question set by the antecedent leads the addressee to additionally infer, via pragmatic enrichment, that the speaker is suggesting that s/he eats the biscuits.

<sup>5</sup>The paraphrase *what if*  $\alpha$ ? is just a shortcut to illustrate the discourse inquiry and it may not be always suitable. We abstract away from additional meanings triggered by the utterance of these questions.

<sup>6</sup>The question established by the antecedent is rather vague, but in providing the answer, the speaker provides enough for the addressee to make out what the goal of the question is.

One prediction from this proposal is that the pragmatic inferences triggered in *if*-constructions are the same as the ones found in question-answer pairs. This prediction is borne out. (That the conditional form is congruent in giving rise to the same inferences as the distributed fragments had already been observed in Starr 2014: 18.<sup>7</sup>)

- (13) A: What if I get hungry?  
 B: There are biscuits on the sideboard.  
 ~> I suggest that you eat the biscuits.

B's utterance in (13) is interpreted as providing an answer to A's question. Assuming that participants are cooperative, the response leads to the interpretation that A is allowed to eat the biscuits. Note also that unless it is done immediately the inference triggered via relevance in this case cannot be cancelled and becomes part of the common ground.<sup>8</sup>

In each of these cases, the inference is a result of a process of pragmatic enrichment derived by the same mechanisms that are at work in pragmatic enrichment generally. An example is given in (14) where the addressee A infers by pragmatic enrichment that B wants to bring across that it is very late.

- (14) A and B are attending a party together and have been there for a while.  
 A: What time is it?  
 B: Most people already left.  
 ~> It's very late

We won't get into the matter of how the mechanism of pragmatic enrichment works exactly (see e.g. Benz 2012 for a proposal). Rather, our point is to argue that an utterance of a BC leads to a triggering of such inferences in the same way as other discourse-relevance inferences are derived (where relevance is as defined in 2).

The proposal can also explain Sano and Hara's (2014) empirical observation that BCs like (15) are (almost always) judged infelicitous. As predicted in our theory, the same is found with the corresponding question-answer pair:

- (15) If France is hexagonal, there is beer in the fridge.  
 (16) A: What if France is hexagonal?  
 B: There is beer in the fridge.

<sup>7</sup>There are several differences between Starr's (2014) proposals and the one in this paper. Most importantly, Starr establishes in the semantics of the *if*-constructions that the antecedent signals the question being addressed. It is not clear to us whether his proposal can be modified to allow for the required flexibility in the mapping between *if*-constructions and discourse argued for above.

<sup>8</sup>While we have no space to address all BCs, our proposal can also handle *discourse hedging* BCs such as *if you want to hear a big fat lie, George W. and Condi Rice are secretly married*. The QUD inquires 'what do the worlds in which the speaker tells a big fat lie look like?'. The response is that these are worlds in which the addressee says that George and Condi are secretly married. More, certainly, needs to be said about these cases and their apparently special behavior (see Csipak 2015). The reader is referred to Biezma and Goebel (2017) for discussion within the framework presented in this paper.

Our proposal allows us to predict that these BCs and the parallel question-answer pair will be bad unless the participants can come up with an explanation as to why the consequent is relevant to the QUD. There are in fact contexts in which (15) and (16) are good. Imagine a context in which a couple of friends are making a bet regarding the shape of France. While one thinks it's hexagonal, the other thinks it's a square. When clarifying what's at stake, the speaker betting for the square shape can felicitously utter (15), or respond to the question as in (16), to establish what the addressee will win were the shape be hexagonal.

Our proposal also applies to HCs and intuitions regarding 'causality'. The mapping from *if*-constructions to discourse we have been exploring for BCs is also possible for HCs (although HCs also can have the reverse one). The difference is that when interpreting the relation between question and answer in a HC via relevance, we can recover a dependence relation between the two propositions:

- (17) If you are hungry, I'll make you some sandwiches.  
 QUD: What if I'm hungry?  
 Response: I'll make you some sandwiches.

In a scenario in which it is conceivable that sandwiches wouldn't necessarily be made and that the making of the sandwiches can be dependent on someone's hunger, we can draw the inference that the addressee being hungry is what 'causes' / 'leads to' the making of the sandwiches (the intuition being that if the addressee is not hungry, the sandwiches won't be made). The intuition that there is a dependence between the antecedent and consequent proposition can be taken to respond to the mapping of *if*-constructions into discourse and the need to satisfy relevance. When there is no plausible dependence relation between antecedent and consequent, the inference of causality does not arise.<sup>9</sup>

<sup>9</sup>Ippolito (2016) also considers the mapping of BCs into discourse and their differences in interpretation with HCs in a short note on relevance conditionals, although her overall proposal is rather different. Ippolito (2016) proposes that conditionals (what we carefully term *if*-constructions) of the form *if*  $\phi$ ,  $\psi$  address a 'conditional question' of the form *if*  $\phi$ ,  $Q?$ , where  $\psi$  is a possible answer to  $Q$ . The BC in (1b), for example, is taken to address an ongoing QUD that can be paraphrased by 'If you are hungry, is there anything to eat?'. The BC addresses this question by offering the 'premise' in the consequent that, indirectly, answers it. It is not clear to us how this question is identified in Ippolito's system, i.e. what are the conventional cues in the information structure of the utterance identifying that such is the inquiry being addressed, which is essential within the QUD model. In addition, given the arbitrary choice of question, it is not clear to us how this system would account for cases of 'classic' conditional perfection like (10), or cases of 'biscuit perfection' (see §4), which are explained by assuming a mapping to discourse that does not involve conditional questions but a classic information-structural division of labor between antecedent and consequent like the one explained above and adopted in this paper. In addition, Ippolito (2016: 56) also aims to offer an explanation as to why some *if*-constructions have a 'causal' interpretations while others don't: "The proposal that I would like to make is that the difference between causal and non causal counterfactuals lies in their relation to the [QUD]. A causal counterfactual answers the [QUD] *directly*, whereas a non-causal counterfactual answers de [QUD] *indirectly* by spelling out a premise assuming which the [QUD] is then answered." In our system, causality is also an inference, but it does not result from the utterance providing a direct answer. In our account, that the HC is taken to provide a *direct* answer to a QUD is the byproduct of there being a dependence relation between antecedent and consequent.

Overall, Ippolito (2016) is not devoted to BCs but aims to explain how context dependence allows us to identify the premises relevant in the interpretation of counterfactuals. We leave for future research the evaluation of her claims once we adopt a mapping between *if*-constructions and discourse that considers their information structure.

In sum, BCs are merely *if*-constructions in which we understand that antecedent and consequent are independent. This is a possibility for *if*-constructions and can be reinforced through linguistic means. For example, many stereotypical examples of BCs involve stative predicates. This is not accidental. With stative predicates it can be easier (though not necessary) to interpret that the antecedent and consequent temporally overlap, without a causal dependency. On the other hand, linguistic means can block the independent interpretation. Following Biezma (2014), the presence of the discourse maker *then* prevents a BC-reading since it conventionally requires that two propositions (antecedent and consequent) enter into a ‘causal explanatory claim’-relation in which one (the antecedent) provides the ‘reasons’ for the other (the consequent) and causality is not cancellable anymore (but see discussion on *then* in §5).<sup>10</sup>

Let us finish this section with a discussion of why the reverse discourse-mapping for *if*-constructions, one in which the antecedent provides the answer to a question signaled by the consequent, is not available for BCs. According to the (rough) semantics of *if*-constructions adopted in this paper, the QUD for such a mapping would be *what are the propositions such that for all ‘relevant’ worlds in which those propositions are true, the consequent is true?* We can paraphrase this inquiry with the question *When q?*,<sup>11</sup> and this is indeed what we take the question to be in the ‘regular’ perfect conditional in (10). We illustrate this mapping for BCs in (18):

- (18) QUD: When are there biscuits on the sideboard?  
 Response: If you are hungry (there are biscuits on the sideboard).

A BC is not a felicitous answer to this QUD and a mapping of the BC to this discourse structure is ruled out. Given the QUD in (18), it is relevant whether or not all circumstances are such that there are biscuits on the sideboard, and, if not all, in which. The BC leads to an answer (in all of them) but only indirectly as a result of the BC-strengthening process. It also provides extra information that is not requested (i.e. that, in particular, the worlds in which you are hungry are worlds in which there are biscuits on the sideboard). One way to explain the infelicity is using the economy principle in Romero and Han (2004).<sup>12</sup>

We have claimed that considering how BCs map into discourse can explain several properties of BCs. In the following section we argue that the proposed mapping is necessary independently to explain biscuit perfection.

#### 4. Biscuit perfection

We have seen above that some BCs can give rise to inferences such as suggestions. As we have noted in §1, however, there is a contrast between (19) and (20) (‘ $\rightsquigarrow$ ’ signals any non-

<sup>10</sup>Obviously this is derived from the original temporal meaning of *then*: when found coordinating two events it requires that the two take place sequentially.

<sup>11</sup>The same caveat as above holds for this rough paraphrase, i.e. the topical question is not to be confused with proper utterance of this specific interrogative. This is merely a shortcut to illustrate the discourse inquiry.

<sup>12</sup>The principle of economy prevents the use of meta-conversational moves unless they are necessary to resolve epistemic conflicts or to ensure Quality.

conventional meaning):<sup>13</sup>

- (19) Oh, you are making pasta bolognese!  
 If you need <sub>(L)-H\*</sub> wine for <sub>L+H\* L-H%</sub> the sauce... there is a bottle by the microwave.  
 ~→ There is a bottle of wine by the microwave [BC strengthening]  
 ~→ I suggest that you use the wine by the microwave. [Discourse relevance]  
 ↗→ I only suggest that you use the wine by the microwave if it is for the sauce.
- (20) Oh, you are making pasta bolognese!  
 If you need wine for <sub>L+H\* L-H%</sub> the sauce... there is a bottle by the microwave.  
 ~→ There is a bottle of wine by the microwave [BC strengthening]  
 ~→ I suggest that you use the wine by the microwave. [Discourse relevance]  
 ~→ I only suggest that you use the wine by the microwave if it is for the sauce. [?]

We will now focus on (20). As we have noted earlier, a speaker uttering the BC in (20) provides information regarding what wine to use for the sauce while explicitly signalling that there are other circumstances in which wine may be needed that s/he is not addressing (contrary to what happens with (19)). In this sense, the BC in (20) is explicit about the fact that it offers only a partial resolution to a question regarding what wine is to be used when. This results in the inference that the use of the wine by the microwave is only a suggestion for the making of the sauce and nothing else, i.e. the suggestion-inference is strengthened. This is what we have called *biscuit perfection*. How can we derive this strengthened inference? In what follows we argue that it results from the specific details of the mapping of (20) into discourse.

Our proposal is that the strengthened reading results from mapping the BC in (20) to the D-tree in (21):

Given this D-tree, the QUD addressed by the BC is part of a larger strategy to answer a complex question. With this mapping, the speaker has clearly marked that s/he is addressing a specific (sub-)question and not others contextually salient that contrast with it. Given that the speaker was careful to signal that this answer was not provided with respect to any other salient question, the resulting inference is that the suggestion to use the wine by the microwave is only made if it is for the purpose of making the sauce. The question now is: why does (20) map into a D-tree like (21) while (19) doesn't?

<sup>13</sup>Notice that even though the shape of the complex accent is the same, the height of the pitch is different. In a pilot study the H\* in *sauce* is much higher ( $\simeq 290\text{Hz}$ ) in the perfected version, (20), than in the non-perfected one in (19) ( $\simeq 250\text{Hz}$ ). Also, the high pitch on *wine* is  $\simeq 365\text{Hz}$  in (19) whereas it only receives a pre-nuclear accent at best in (20). We are very grateful to Anja Arnhold and Marc Brunelle for their help discussing the prosodic data.

Our proposal is that the mapping of (20) into the D-tree in (21) depends on conventional linguistic devices that give rise to such a mapping. In this case, it is prosody that is (conventionally) responsible (but see below for additional mechanisms).<sup>14</sup> In what follows we argue that the phenomenon of biscuit perfection is nothing more than contrastive topic (CT) marking in BCs. The discussion revolves mostly around BCs because this data is used in this paper as an argument in favor of a pragmatic account of BCs. However, notice that similar phenomena can be observed in HCs, with the only difference that the inference that is perfected in HCs concerns causality. At the end of the day, the claim is that ‘inference perfection’ via linguistic marking in *if*-constructions is nothing more than contrastive topic in *if*-constructions.

In what follows we sketch Constant’s (2014) proposal for CT and examine a straight-forward application of this account to conditionals. We close the section with a discussion of the fact that CT-marking in *if*-constructions seems to be more complicated than it is taken to be in Constant (2014). The discussion serves the purpose of showing how *if*-constructions can serve as probes to broaden our understanding of CT-marking in English.

#### 4.1. A theory of Contrastive Topic and BCs

We adopt Constant’s (2014) theory of CT (see references therein for other accounts and discussion). In this section, we sketch Constant’s (2014) proposal and examine its application to BCs. As we will see, CTs provide the crucial insight to understand biscuit perfection.

The phenomenon of CT in simple sentences is illustrated in (22) (adapted from Constant 2014):

- (22) I arrive late to a potluck party and I am not aware of who brought what. I have asked another guest to fill me in on the details. A few minutes into the conversation, the next exchange takes place:
- A: What about Persephone and Antonio? What did *they* bring?
- B: PERSEPHONE... brought the GAZPACHO.  
       L+H\*           L-H%                                   H\*       L-L%
- Antonio, I’m not sure about.

As Constant puts it, by using these specific prosodic features B indicates that he has decided to break the asked question in two smaller pieces, one about Persephone and one about Antonio. In a way, Persephone and Antonio become “*topics* of smaller issues, and they *contrast*” (Persephone is the contrastive topic). In addition to indicating that the question is now split in two parts, the speaker provides an exhaustive answer regarding what Persephone brought, this is the constituent *the gazpacho*. (The constituent that provides the exhaustive answer is the exhaustive focus.) A paraphrase could be as follows: “As for the issue of Persephone, the answer to the question of what she brought is the gazpacho.” The claim in the literature is that there is a systematic relationship between the surface realization of B’s response and the discourse role of its constituents, so we can predict one from the other. In Constant (2014), contrastive topic is an information-structural category indicating the question that is being answered. Regarding

<sup>14</sup>Notice that not all BCs trigger extra inferences such as suggestions and hence not all biscuits can perfect via conventional mechanisms such as the use of prosody. See discussion in §4.2 below.

the interpretation, CT-marking is merely focus marking (it evokes alternatives à la Rooth as any other focus marking) with additional information of how the focus alternatives are used in the semantic computation. The instructions regarding how to manipulate the generated alternatives are cashed out in the CT-operator indicated in English by a special intonation, the complex contour L+H\* L-H%. The CT constituent is “a F-marked phrase in a particular structural position, or bound by a particular focus-sensitive operator” (Constant, 2014: 85). This proposal can be seen as belonging to a family of configurational approaches, “[a theory that tries] to establish what configuration defines a focus as CT, and to model how this configuration is spelled out in surface syntax and phonology” (see Constant 2014 for discussion).

The mapping between utterances and discourse is done via focus anaphora in the Roothian tradition: focus structure helps identify the question in discourse that the utterance is answering. This is done via the familiar ‘ $\sim$ ’ operator with a slight modification to relax the membership relation in (23ciii) (see Constant 2014 for discussion). The ‘ $\sim$ ’ introduces the presupposition that there is a discourse antecedent that is a question of a particular shape:

- (23) Constant’s (2014) ‘ $\sim$ ’
- a.  $\llbracket \sim \phi \rrbracket^o = \llbracket \phi \rrbracket^o$
  - b.  $\llbracket \sim \phi \rrbracket^f = \{ \llbracket \phi \rrbracket^o \}$
  - c. ... and presupposes that the context contain an antecedent  $C$  such that:
    - (i)  $C \subseteq \llbracket \phi \rrbracket^f$
    - (ii)  $|C| > 1$
    - (iii)  $\llbracket \phi \rrbracket^{o*} \in C$       “ $C$  contains  $\llbracket \phi \rrbracket^o$  somewhere within it.”

The other addition to the system is the mechanism that combines the focus alternatives in utterances with CT-marking. This is done via the CT-operator, with CT-hood linked in English to the complex contour L+H\* L-H% that we find in standard CT-constructions:<sup>15</sup>

- (24) **Topic abstraction**
- a.  $\llbracket \text{CT-}\lambda_i \phi \rrbracket_g^o = \lambda x. \llbracket \phi \rrbracket_{g[i \rightarrow x]}^o$  (Ordinary semantic value)
  - b.  $\llbracket \text{CT-}\lambda_i \phi \rrbracket_g^f = \{ \lambda x. \llbracket \phi \rrbracket_{g[i \rightarrow x]}^f \}$  (Focus semantic value)

The ordinary semantic value of CT- $\lambda$  is merely predicate abstraction, but at the focus value provides us with the expected result. Following Constant, let us look at the structure of the CT-utterance in (22):

- (25)  $\llbracket [\text{Persephone}]_F \text{ brought } [\text{the beans}]_F \rrbracket_g^f$
- 
- ```

graph TD
    3((③)) --- P["[Persephone]F"]
    3 --- 2((②))
    2 --- CT["CT-λ7"]
    2 --- 1((①))
    1 --- t7["t7"]
    1 --- brought["brought"]
    1 --- beans["[the beans]F"]
  
```

<sup>15</sup>Constant (2014) considers that the complex pitch accent could also adopt other forms, such as H\* or L\*+H.

- a.  $\llbracket \textcircled{1} \rrbracket_g^f = \{g(7) \text{ brought the beans, } g(7) \text{ brought the pasta} \dots\}$   
 b.  $\llbracket \textcircled{2} \rrbracket^f = \{\lambda x. \{g(7) \text{ brought the beans, } g(7) \text{ brought the pasta} \dots\}\}$   
 c.  $\llbracket \textcircled{3} \rrbracket^f = \left\{ \begin{array}{l} \{\text{Persephone brought the beans, Persephone brought the pasta, } \dots\}, \\ \{\text{Mary brought the beans, Mary brought the pasta, } \dots\}, \\ \dots \end{array} \right\}$

CT here involves left-dislocation of the contrastive topic constituent, justifying predicate abstraction and the CT-operator. Topic-abstracting the subject helps to create a nested focus value containing a set of questions varying in the position of *Persephone*. The resulting focus value is a complex question sorted by the topic-abstracted argument (*who brought what?*).<sup>16</sup> This focus value is the input of the squiggle operator enforcing the congruence that derives the interpretation of utterances with CT:

- (26)  $\llbracket \sim \llbracket [\text{Persephone}]_F \text{ CT-}\lambda_7 \ t_7 \text{ brought } [\text{the beans}]_F \rrbracket \rrbracket^f = \{\text{Persephone brought the beans}\}$   
 felicitous iff there is a question in discourse made up of multiple questions of the form “What did  $x$  bring?”, one of which is the question “What did Persephone bring?”.

That is, the utterance of *Persephone brought the beans* with the CT-marking in (22) is felicitous in a discourse structure like (27):

- (27)
- 

The structure in (27) is exactly like the one we want to derive in (21). We propose that in both cases, CTs provide the key to understanding how the D-tress are generated. The question is whether we can merely adopt Constant’s (2014) proposal to explain biscuit perfection. The answer is yes, mostly. We turn to the straight-forward application of Constant’s (2014) proposal below and discuss some problems in §4.2.

Following much of the literature (see Bhatt and Pancheva 2006 for discussion), we take it that *if*-clauses are correlative/free-relative adjuncts and assume the syntax in (28a). In *if*-constructions we do not need to assume movement of the topic-constituent. We have binding of the restrictor to the modal in the matrix clause being interpreted via predicate abstraction. With CT-marking we get the CT-operator and not just mere predicate abstraction, (28b).

- (28) a. Conditionals as correlatives
- 
- b. Conditionals as correlatives with CT-marking
- 

The interpretation of the utterance in (20), unlike the utterance in (19), is then as follows:<sup>17</sup>

<sup>16</sup>This assumes that questions denote sets of propositions, specifically, their possible answers (Hamblin 1973).

<sup>17</sup>Strictly speaking, focus marking is on *sauce* (see (20)). This is what evokes alternatives to the antecedent.

- (29)  $[[\text{If you need wine for the sauce}]_F \text{ CT-}\lambda_9 [\text{ } t_9 \text{ there is a bottle by the microwave}]_F]$
- (30)  $\llbracket \sim(29) \rrbracket^f = \{\text{If you need wine for the sauce there is a bottle by the microwave}\}$   
 felicitous iff there is a question in discourse made up of multiple questions of the form  
 “What if the addressee needs wine for  $x$ ?”, one of which is the question “What if the  
 addressee needs wine for the sauce?”.

At the core of CT is partial answerhood. In contrast with (20), in (19) we do not convey (linguistically) that there are contrasting alternatives that the speaker is not answering, hence do not mark conventionally that the utterance is embedded in a D-tree like (27).

To summarize, we have seen above that ‘biscuit perfection’ and in general conventional strengthening of the inferences in *if*-constructions is just CT-marking in *if*-constructions and can be explained by using mechanisms argued for independently of conditionals. Crucially, these mechanisms result in a mapping of BCs to discourse that explains the inferences in BCs and the effect of biscuit perfection. No special BC-specific semantics needs to be invoked.

#### 4.2. Shedding light on CT-marking in English

Constant (2014) also discusses the case of conditionals and their mapping in discourse. The claim is that conditionals “generally make good CT”, but Constant explicitly excludes BCs and factual conditionals (without considering that there are biscuits that are factual) and, hence, only (non-factual) HCs are taken to be able to encode CT. The reason, he states, is that “the antecedent of a HC makes good contrastive topics, since considering one hypothetical possibility almost inevitably leads to questions about contrasting possibilities[...]. Non-hypothetical conditionals, on the other hand, do not typically set-up contrasts with different antecedents” (Constant, 2014: 321).<sup>18</sup> He provides the following prosodic characterization of a conditional with a CT-reading. (Constant 2014 does not provide prosodic annotation for BCs):<sup>19</sup>

- (31) If it’s RAINING... we’ll have to cancel the PICNIC. (Constant, 2014: 285)  
 $\text{L+H}^* \text{ L-H}\% \qquad \qquad \qquad \text{H}^* \text{ L-L}\%$

According to Constant, it is the interpretation of factual conditionals and BCs what prevents them from being interpreted as conveying CT: to a non-factual HC like (31) one can respond with “And if it doesn’t rain?”, but that is not a possible response to the former merely because either other alternatives to the antecedent are already discarded (in factual conditionals the antecedent is taken to be true) or because the consequent is taken to be true across the board (in BCs). However, while it is true that questions about what is the case in circumstances other than the ones established in the antecedent are impossible in factual conditionals and BCs, one can ask about the inferences triggered by the utterance of a BC (if there are any). For example, given

<sup>18</sup>Constant’s discussion of conditionals aims to explain the contrast between *if*-constructions and *because*-clauses. In both cases we find the prosodic markings tied to CT-interpretations, i.e. L+H\* L-H%, but *because*-clauses do not have a CT-interpretation. His conclusion is that not all L-H% in English conveys CT: “while sentence final L-H% is robustly interpreted as CT, non-final L-H% is unreliable in this regard”.

<sup>19</sup>We take it from the discussion that he assumes this to be the default intonation for HCs.

an utterance of (2b), one could ask “And if I want to pour myself a glass? (does the suggestion still hold? shall I use the same wine?)” Notice that when a BC doesn’t trigger extra-inferences, such as in (7) (or at least these are harder to grasp), no question of this sort is possible and there, in fact, we do not (easily) get a CT interpretation.

Several questions arise at this point pertaining to CT-marking in conditionals and CT-marking in general. Given that (2b) does have a CT-reading while (2a) doesn’t, and both have L+H\* L-H% marking, it seems that it is not this specific complex contour what is responsible for the CT-reading in conditionals. The data suggests that what delivers the CT-reading is merely the marking of contrast in the constituent that is understood as establishing the QUD (the antecedent): this happens in (2b) by de-accenting everything else but one word, while in (2a) there are two words that receive H\* or L+H\*. <sup>20</sup> In *if*-constructions, L-H% is merely a continuation tone. This is also true for non-factual HCs. <sup>21</sup> The general claim is that the CT-reading appears in *if*-constructions when we understand that there are salient alternative questions to the one being addressed and that they won’t get necessarily the same answer. We can enforce this reading conventionally by using specific prosody, or by other means that indicate that the speaker is answering only a particular question amongst a contextually salient set (the others remain un-answered). An illustration is provided in (32). The presence of *only/just* in (32) ensures that the use of wine the speaker is talking about contrasts with others.

(32) Well, if you only/just need the wine for the sauce, there is a bottle by the microwave.

A CT-type interpretation can also arise in BCs without any linguistic marking as an inference from world-knowledge. In (33), it is world-knowledge what tells us that the suggestion/permission regarding killing people is tied to people turning into zombies.

(33) A virus is transforming people into zombies. A farmer in an area suspected of infection tells his farm workers:  
Farmer: If the virus breaks out, the rifles are in the safe.

It is understood that if the virus does not break out, shooting of people should not happen, i.e. we understand that there are contextually salient alternatives to the antecedent for which the answer wouldn’t be the same, leading to a CT-type interpretation without CT-marking.

The conclusion is that CT-marking is not necessarily done prosodically via the complex L+H\* L-H% contour. When the information structure of the sentence already establishes what is the

<sup>20</sup>More work needs to be done regarding the prosody of BCs. Notice however that marking contrast in *rained* in (7), where no extra-inference can arise, doesn’t seem to be felicitous. The explanation would be that the enforced discourse structure doesn’t have a plausible interpretation.

<sup>21</sup>As mentioned above, HCs often perfect. Constant (2014) argues that this is due to the prosodic marking L+H\* L-H%, but just as in the case of BCs this specific prosodic marking does not convey CT in conditionals. We do not have space to provide a fair discussion on the matter, but we would like to argue that the CT-type interpretation that often arises in HCs is an inference resulting from there being a dependence relation between antecedent and consequent, together with the fact that the speaker has decided to make a claim about only a subset of *c*. This inference, hence, arises via world-knowledge and (Gricean-) reasoning about why the claim was only made about a subdomain. However, this interpretation can also be enforced with specific prosodic marking (as discussed in fn. 13) or other means (see below), all CT-marking, and in this case the interpretation is not an inference anymore.

QUD being addressed, marking that there are other contrasting questions that are not being addressed with other prosodic means (see fn. 13), or lexically, is a type of CT-marking (i.e. it conventionally derives a CT-type reading). Research in this direction is left for the future.

## 5. Comparing theories

One question that remains to be addressed is whether the resulting theory of BCs is superior to semantic theories of BCs. While we cannot draw here a full comparison, we will conclude this paper by pointing to some advantages that this theory has over semantic approaches.

The first point is that in order to explain perfect biscuits, semantic theories would actually have to appeal to mechanisms similar to the ones proposed here in addition to stipulating that the semantics of BCs is different from that of HCs. For the remainder of this section, let us take Ebert et al.'s (2014) proposal (henceforth EEH) as a point of comparison, since this is a recent sophisticated semantic proposal and it covers the largest range of data. In EEH's proposal, all *if*-constructions introduce two speech acts: the antecedent introduces a referential speech act (identifying a maximal plurality of possible worlds compatible with the world of evaluation,  $X$ ), and the consequent introduces another speech act. HCs are *if*-constructions in which the consequent is evaluated in the worlds identified by the antecedent, (34a). In BCs the consequent is evaluated in the actual world and there is no interpretational link with the antecedent (34b):

- (34) EEH's analysis of conditionals applied to the contrast between (1a) and (1b) above:
- a. HCs (aboutness topicality) If you are hungry, I'll give you some biscuits:  
 $\text{REF}_X(w_0, \lambda w'. M_{w'}(\lambda w. \text{hungry}(w)(\text{listener}))) \& \text{ASSERT}(X, \lambda w. \text{give\_you\_some\_biscuits}(w))$
  - b. BCs (relevance topicality) If you are hungry, there are biscuits on the sideboard:  
 $\text{REF}_X(w_0, \lambda w'. M_{w'}(\lambda w. \text{hungry}(w)(\text{listener}))) \& \text{ASSERT}(w_0, \lambda w. \text{biscuits\_on\_sideboard}(w))$
- Where  $M_{w'}(p) = \sigma(\lambda w. p(w) \wedge R_{ep}(w')(w))$  and  $R_{ep}(w')(w)$  is the set of worlds epistemically compatible with  $w'$ ;  
 $\text{ASSERT}(w, p_{\langle s, t \rangle}) \equiv$  the speaker commits herself to the truth of  $p$  in  $w$   
 $\text{REF}_X(w, d_{\langle s, \sigma \rangle}) \equiv$  the speaker draws the listener's attention to  $d(w)$

EEH capitalize on the claim often repeated in the literature that *then* is not possible in BCs. Adopting a correlative account of conditionals, they take *then* to be a proform that when present at LF (if covertly) forces the consequent to be interpreted in the antecedent worlds delivering the HC-reading. The LF in BCs does not have *then*. Differences between HCs and BCs result from different LFs. We discuss this proposal below, pointing to problematic issues.

### 1. Then is possible in BCs!

When naive speakers of English are asked about (35), they often accept it without hesitation:

- (35) If you are hungry, then there are biscuits on the sideboard.

The paraphrase that is given is that “given the possibility that you are hungry, I’m telling you that there are biscuits on the sideboard”. The reading that biscuits will magically appear upon

your being hungry could also be conveyed by uttering (35), but given our knowledge of how the world works (the dependence relations), this reading is discarded because of its implausibility. It is possible if our assumptions about *dependencies* change (e.g. if the sentence is uttered in a movie involving a magical world). Another example is provided in (36), judged to be perfect:

(36) If you want to know my opinion, then I think you are making a mistake marrying him.

Again, (36) has two readings, one in which my thinking of you making a mistake is caused by your will to know my opinion, a HC-reading, and one in which my telling you what I think (which is that you are making a mistake) is the result of you wanting to know it. This last reading is still a BC in our account (since for an *if*-construction to be a BC it is the relation between the propositional content of antecedent and consequent what has to be independent).

That *then* is possible in BCs is a problem for EEH's account, since we now lack support for the proposal that there are two different LFs responsible for the two different readings. What *then* does can be explained in a theory along the lines of Biezma (2014) where *then* is a discourse marker that enforces a causal explanatory relation between an antecedent and a consequent. Crucially, in Biezma (2014) there is enough freedom to allow the fact that a particular move was made to be the content manipulated by *then* (see Biezma 2014). The different readings described above depend on the choice of content targeted by *then*.

## 2. *If they ask you how old you are, you are four*

BCs like 2 are handled very easily with the theory proposed here:

(37) In a bus, the father doesn't want to pay his kid's fare. Knowing that kids under five ride for free he says:

Father: If they ask you how old you are, you are four.

The interpretations of this BC is that the speaker is requesting the addressee to lie (which would be derived as a relevance inference in our proposal). Notice, however, that the speaker does not mean for the addressee to go right away to the ticket collector and tell him that he is four (which would, for example, be the interpretation derived in EEH, in which the consequent is headed by a command speech act regardless of the fact that the clause is a declarative).<sup>22</sup> BCs providing a command always perfect, and this is so because commands are always tied to specific circumstances and hence, to the circumstances specified in the *if*-clause. Our knowledge of commands and their dependence on the circumstances allows us to understand that when the circumstances in the antecedent are not met, the command doesn't apply. The consequent in 2 is a declarative, but this can be shown with an imperative too: *...tell them you are four*.<sup>23</sup> Obviously this anchoring to the circumstances does not arise when the imperative conveys dis-

<sup>22</sup>Note that EEH end up needing to postulate a number of rather idiosyncratic speech acts that raise questions about the predictive power of the account, such as "not run of the mill assertions", invoked in EEH:(361) to explain the interpretation of the consequent in *if you want to hear a big fat lie, George W. and Condi Rice are secretly married* (the consequent is understood here as being claimed to be false).

<sup>23</sup>This wouldn't be a BC in our account. The semantics of the imperative form can be taken to be either the content proposition or a deontic statement, and in this case it obviously depends here on the truth of the antecedent.

interested wishes or when using equivalent modal statements:

(38) If I don't see you before you leave, have a good trip!! / I wish you a good trip.

By uttering (38) I am not saying that I desire you to have a good trip only if I don't see you before you leave. Crucially, it is due to our understanding of how disinterested wishes work that we understand that in any circumstances alternative to those expressed in the antecedent, you desire the addressee a good trip.

### 3. Encoding the mapping into discourse in the semantics is not a good idea

Ebert et al. (2014) propose that we can understand the referential speech act in conditionals as identifying the QUD in discourse. However, this means encoding the mapping of conditionals to discourse in the semantics. As we have seen above, any theory that forces a unique mapping of conditionals to discourse runs into problems to explain cases in which the mapping has to be the opposite, as in classic conditional perfection illustrated in (10).

## 6. Conclusion

Taking into account discourse congruence and relevance, BCs are revealed as examples of the flexible set of strategies we deploy in the construction of meaning, requiring no departure from the semantics of other conditionals. Furthermore, BCs and perfect-BCs show that the interplay between semantic meaning and considerations regarding discourse-structure, as well as information gained in discourse reasoning, are crucial in the construction of meaning.

# Reportative deontic modality in English and German<sup>1</sup>

M. Ryan BOCHNAK — *Leipzig University*

Eva CSIPAK — *University of Konstanz*

**Abstract.** We discuss the dual uses of the English adjectival modal *be supposed to* and the German modal auxiliary *sollen* under their deontic and evidential readings. While deontic modality is a familiar category, we discuss novel data on the expression of reportative evidentiality in English. We argue for a truly unified analysis for both *be supposed to* and *sollen*, which are specified for a reportative informational conversational background. The apparent difference in “flavours” (reportative vs. deontic) is an illusion, caused by differences in the types of reports that feed the ordering source. Although we assign *be supposed to* and *sollen* an identical semantics, their distributions are not identical. We hypothesize that this is due to the fact that in German, *sollen* competes with the quotative modal *wollen*, which carries a stronger presupposition, triggering Maximize Presupposition effects which are absent in English.

**Keywords:** modality, deontic, reportative, *be supposed to*, *sollen*, *wollen*

## 1. Introduction

In this paper, we discuss the dual uses of the English adjectival modal construction *be supposed to* and the German modal auxiliary *sollen*. In both languages, these modal expressions display both deontic and evidential readings. Specifically, the evidential reading has a reportative flavour, whereby the source of evidence for a claim is a prior report. As shown in (1), sentences containing *be supposed to* and *sollen* are compatible with contexts favouring either a deontic or reportative interpretation.

- (1) **Deontic context:** A student asks the department administrator when Professor Plum will be in the office. The university’s rules state that professors must have office hours between 10-11am every day. The administrator says:

**Reportative context:** A student asks the department administrator when Professor Plum will be in the office. Earlier that day, Professor Plum’s partner called the administrator and said that they are running late but will come in at 10am. The administrator says:

- a. Professor Plum **is supposed to** be here at 10.
- b. Professor Plum **soll** um 10 hier sein.  
Professor Plum SOLL at 10 here be

While the reportative use of *sollen* has received some attention in the literature (Faller, 2006, 2012; Hinterwimmer, 2013; Kratzer, 1981, 2012; Schenner, 2008), we show here that reportative evidentiality is also lexicalized in English in *be supposed to*. This observation complements the work of von Stechow and Gillies (2010), who argue that the epistemic modal *must* in English

<sup>1</sup>We would like to thank Martina Faller, Sven Lauer, Lisa Matthewson, Hubert Truckenbrodt, audiences at the University of Konstanz, the LSA Annual Meeting 2016 in Portland, Oregon, and Sinn und Bedeutung in Edinburgh, as well as participants at the SIAS Summer Institute 2016 in Durham, North Carolina for comments and discussion. All errors are our own.

lexicalizes an indirect inferential evidential component.

Furthermore, although deontic modality is a familiar category, we show that the deontic flavour of these modal expressions is narrower than the deontic uses of *must* or *have to*. Specifically, *be supposed to* and *sollen* cannot be used performatively, i.e., they can only describe obligations that already exist, and cannot be used to place new obligations. We make use of this fact to argue for a unified analysis of the reportative and deontic uses of these modals. Specifically, we reduce the deontic use to the reportative one, arguing that these apparently different “flavours” are both derived from a circumstantial modal base and a reportative informational ordering source within a Kratzerian framework. We furthermore argue that our account fares better than recent analyses for *sollen* invoking intentional acts (Hinterwimmer, 2013) or external bouletic ordering sources (Matthewson and Truckenbrodt, 2017).

This paper proceeds as follows. We first discuss the deontic use of *be supposed to* and *sollen* in section 2. Section 3 discusses the reportative use. We present our unified analysis for both uses in section 4. Section 5 focuses on German *sollen* and its competitor, the reportative modal *wollen*, while section 6 discusses previous accounts. Section 7 concludes.

## 2. Non-performative deontic use

We first discuss the deontic use of *be supposed to* and *sollen* in more detail, as already shown in (1). Like other deontic modals, these can be used in different contexts to convey different flavours of deontic necessities. For instance in (2) they can be used to talk about laws, while in (3) they are used to talk about rules.

- (2) Context: Your friend has just parked in front of a fire hydrant. You say:
- a. You're not **supposed to** park there.
  - b. Du **sollst** hier nicht parken.  
you SOLL here not park (reports a law)
- (3) Context: Your friend has just landed on a community chest in Monopoly. You say:
- a. You're **supposed to** pick up a card.
  - b. Du **sollst** eine Karte nehmen.  
you SOLL a card take (reports a rule)

However, an important feature of *be supposed to* and *sollen* is that they cannot be used performatively. Rather, they can only be used to report on existing laws or rules. This can be shown in (4), where the context provides that the rules of the game Calvinball are not pre-determined, but made up on the spot. In such a context, *be supposed to* and *sollen* cannot be used, whereas other deontic modals such as *must*, *have to* or *müssen* ‘must’ can be.

- (4) Context: You are playing Calvinball, a game where the rules are made up on the spot, and no rule can be re-used. The players shout out the rules as they make them up.
- a. Now you {**have to/must/#are supposed to**} throw the ball across the field.
  - b. Jetzt {**musst/#sollst**} du den Ball über das Feld werfen.  
now must/SOLL you the ball across the field throw

(*Calvin and Hobbes*, Bill Watterson, originally published 26.08.1990)

Note that the problem with (4) is not that the speaker is the source of the rule. As shown in (5) and (6), the speaker can serve as the deontic authority.

- (5) Context: Parent to child:
- You're **supposed to** go to bed by 9pm.
  - Du **sollst** um 9 im Bett sein.  
you SOLL at 9 in.the bed be
- (6) Context: The speaker made a New Year's resolution to smoke less this year. On January 2, she is offered a cigarette.
- I'm **supposed to** smoke less this year.
  - Ich **soll** dieses Jahr weniger rauchen.  
I SOLL this year less smoke

Lauer (2015) discusses “anti-performative” modals, and argues that the restrictions on performativity can be derived from the temporal profile of such expressions. Lauer argues that anti-performative modals are simple stative predicates. Like other statives, they are required to be true throughout the reference time interval. In the case of present-tense modals, this means the modal statement is required to be true throughout the speech time. We can schematize this restriction in the case of *be supposed to* and *sollen* as in (7). In prose: for all moments  $m$  contained within the speech time  $\tau(u)$ , it is necessary at  $m$  that  $p$ .

$$(7) \quad \llbracket \text{be supposed to/sollen}(p) \rrbracket^u = 1 \text{ iff } \forall m \in \tau(u) : \Box_m(p) \quad (\text{sketch})$$

Performativity clashes with these temporal requirements on stative modals. Intuitively, an event of imposing an obligation will result in a state of an obligation holding. Let us assume with Lauer that if a state  $s$  is the result of an event  $e$ , then  $s$  will not obtain before the final moment of  $\tau(e)$ . It follows then, that if an obligation is created as a result of uttering a modal sentence, then a present tense stative modal statement will never be true at speech time, since the condition in (7) that the requirement that  $p$  hold throughout the speech time would be violated. Following this chain of reasoning, for a sentence containing present tense *be supposed to* or *sollen* to be

true, it must be the case that the obligation already exists before the speech time. A performative use of these modals is thus ruled out.<sup>2</sup>

The upshot of this discussion is that although *be supposed to* and *sollen* can take on a deontic flavour, they behave differently from other deontic modals in being anti-performative. That is, they require a preceding event that brings the obligation into existence. We now turn to describe the reportative use in more detail, which also requires an antecedent event, namely a report.

### 3. Reportative use

Cross-linguistic research in the last decade or so has shown that modals can encode a speaker's evidence type, and in some languages, evidence type restrictions are grammaticalized in evidential modals (e.g., Faller 2012; Matthewson et al. 2007). Even for English, it has been argued by von Fintel and Gillies (2010) that epistemic *must* lexicalizes an inferential evidential component. Whereas the reportative use of *sollen* has been discussed in the literature already (e.g., Faller 2006, 2012; Hinterwimmer 2013; Kratzer 1981, 2012; Schenner 2008), we add here novel data from English that the modal construction *be supposed to* also has a reportative use, cf. (1).

Adapting the diagnostics from von Fintel and Gillies (2010), we show that the indirect evidence component of *be supposed to* and *sollen* does not have an inferential flavour. While *must* and *müssen* are acceptable in the inferential context in (8), *be supposed to* and *sollen* are not. Meanwhile, like *must* and *müssen*, *be supposed to* and *sollen* are unacceptable when direct evidence for the prejacent proposition is available, as shown in (9).

- (8) Context: The ball is either under cup A, cup B, or cup C. It's not under A, and it's not under B.
- a. The ball must be under cup C. / Die Kugel muss unter Becher C sein.
  - b. #It's **supposed to** be under cup C. / #Sie **soll** unter Becher C sein.
- (9) Context: You look out the window and see that it is raining.
- a. It is raining. / Es regnet.
  - b. #It must be raining. / #Es muss regnen.
  - c. #It's **supposed to** be raining. / #Es **soll** regnen.

We wish to also highlight two additional properties of *be supposed to* and *sollen* in connection with the literature on modal evidentials (e.g., Faller 2012; Matthewson et al. 2007; Schenner 2008). First, note that *be supposed to* and *sollen* can be embedded.<sup>3</sup> This is shown in (10), where *be supposed to* and *sollen* occur in the antecedent of a conditional. We note that the modals are interpreted within the antecedent, and do not take scope over the entire conditional.

<sup>2</sup>On Lauer's view, there are no truly performative uses of deontic modals – rather, these are actually bouletic modals tracking speaker preferences, uttered by a speaker who has deontic authority. There is a possibly interesting connection here to the proposal by Matthewson and Truckenbrodt (2017), which we discuss further in section 6.2.

<sup>3</sup>See Schenner (2008) for discussion of the embedding possibilities for *sollen* based on corpus data.

- (10) Context: You and a friend are planning to go sightseeing in Edinburgh. Your friend asks if you should bring umbrellas. You don't know what the weather will be like, so you say:
- a. If it's **supposed to** rain, we will bring umbrellas.  
 = 'If it is reported that it will rain, we will bring umbrellas.'  
 ≠ 'It is reported that if it will rain, we will bring umbrellas.'
  - b. Wenn es regnen **soll**, bringen wir Schirme mit.  
 = 'Wenn berichtet wird, dass es regnen wird, bringen wir Schirme mit.'  
 ≠ 'Es wird berichtet, dass wenn es regnet, wir Schirme mitbringen.'

Second, note that the reportative component projects out of negation. For instance in (11), the reportative component of *be supposed to* or *sollen* is not what is being denied. It appears then that the reportative component *be supposed to* and *sollen* is presuppositional, as has been claimed for evidential modals in other languages (e.g., Matthewson et al. 2007).

- (11) Context: You and a friend are planning to go sightseeing in Edinburgh. Your friend asks if you should bring umbrellas. You say:
- a. It's not **supposed to** rain.  
 = 'It is reported that it won't rain.'  
 ≠ 'There is no reportative evidence that it will rain.'  
 ≠ 'The evidence that it will rain is not reportative.'
  - b. Es **soll** nicht regnen.  
 = 'Es wird berichtet, dass es nicht regnen wird.'  
 ≠ 'Es gibt keine Berichte darüber, dass es regnen wird.'  
 ≠ 'Die Evidenz dafür, dass es regnen wird, ist nicht reportativ.'

In sum, the projection behaviour of *be supposed to* and *sollen* is similar to what has been described for other reportative evidential modals.

We now turn to which sources for reports can serve to license *be supposed to* and *sollen*. As illustrated in (10) and (11), speakers can use information they got from a specific definite entity, such as a weather report website. The reportative context in (1) showed that a speaker's utterance can also serve as a source for a report. Below we discuss some cases where identifying the source is more difficult.

The source of a report may be indefinite or unknown. As illustrated in (12), the precise identity, and in turn the reliability of the report, may be unknown.

- (12) Context: A and B are newspaper reporters working on a story about a corrupt politician. A receives an anonymous phone call from an individual claiming that the politician accepted a bribe from a construction company. B asks what the phone call was about, and A replies:
- The politician is **supposed to** have accepted a bribe from the construction company on August 15.
  - Der Politiker **soll** am 15. August Schmiergeld von der politician **SOLL** on 15 August bribe from the Baufirma angenommen haben. construction.company accepted have

Here, the identity of the anonymous caller is unknown to A, but nevertheless serves as a source for a report made by *be supposed to/sollen*. When asked later, A is able to pick out the time of the report: namely when the call happened. However, A is not able to pick out the source of the report as A's acquaintance relation to the source does not allow this.

In some cases, speakers can use *be supposed to* and *sollen* reportatively even when they are not able to pick the individual who is the source of the report or even the exact time the report was made. Consider the following context in (13).

- (13) Context: A goes to dinner with a group of people. The conversation turns to ways to avoid sunburn. B says he has started to drink carrot juice.
- B: Carrot juice is **supposed to** protect the skin from sunburn.
- B: Möhrensaft **soll** vor Sonnenbrand schützen.  
carrot.juice **SOLL** before sunburn protect
- A: Oh, where did you hear that?
- B: I don't remember.

In this context, speaker B can use *sollen* to indicate that he has reportative evidence for his statement, even though he cannot remember the exact source of the information.

In a context where the speaker is the source of the prejacent *p* and has complete control over *p*, this may be reported using *be supposed to/sollen(p)*.<sup>4</sup> As shown in (14), a modified version of (6), the speaker may not have even said anything aloud to anyone.

- (14) Context: The speaker spent New Year's at home by herself, but made a resolution to smoke less this year. On January 2, she is offered a cigarette.
- I'm **supposed to** smoke less this year.
  - Ich **soll** dieses Jahr weniger rauchen.  
I **SOLL** this year less smoke

We also note that *be supposed to/sollen(p)* can be licensed even if a report was not literally of *p*, but where *p* is entailed or conversationally follows from a report in context.

<sup>4</sup>In terms of a public commitment, which we will make reference to in our analysis in the next section, a commitment counts as public as soon as the speaker has formed a conscious thought about it.

- (15) Context: A goes to dinner with a group of people who are discussing how to avoid sunburn. B says he has started drinking carrot juice. Then A comes home and reports what she learned.
- a. Carrot juice is **supposed to** help avoid sunburn.
  - b. Möhrensaft **soll** vor Sonnenbrand schützen.  
carrot.juice SOLL against sunburn protect

#### 4. Towards a unified analysis

Given the similarities we have observed between the deontic and reportative uses of *be supposed to* and *sollen*, we wish to provide a unified analysis for these modal expressions. We will make use of a standard Kratzerian framework (Kratzer, 1981, 1991, 2012), whereby modals quantify over possible worlds. We propose that both *be supposed to* and *sollen* are necessity modal expressions, which lexically specify a circumstantial modal base and a reportative informational ordering source. We discuss each of these ingredients in turn.

Given a circumstantial modal base, *be supposed to* and *sollen* quantify over worlds where salient facts in the evaluation world also hold (Kratzer, 2012; Portner, 2009). Crucially, one of the salient facts will be that a report of some kind has been made. This seems to be what we need for the reportative use, but for the deontic use it is possibly too strong. Specifically, what counts as a deontic report for *be supposed to* and *sollen*? It seems that someone need not have actually said anything at all. In (2), for instance, the parking prohibition may be indicated by a sign; in (3), it is likely the instruction booklet written by the creators of Monopoly that serves as the source of the rule. And even for true reportatives, the speaker may not be able to identify the individual or exact time of the relevant report, only that there was one. For these reasons, we leave fairly vague what counts as a relevant report in the circumstantial modal base, and state this “reportative” restriction on the circumstantial modal base as one where some agent  $\alpha$  has some public commitment(s) from which the prejacent proposition  $p$  follows, as in (16):

- (16) “Reportative” restriction on circumstantial modal base:  
 $\exists \alpha : p$  follows from  $\alpha$ ’s public commitments

We assume that entities such as the city councillors responsible for parking laws or the creators of Monopoly count as relevant agents  $\alpha$  for this purpose. Note that given cases like (15), it is too strong to say that  $\alpha$ ’s public commitments entail  $p$ ; in at least some cases, such as (15) above,  $p$  follows conversationally from  $\alpha$ ’s public commitments. Nevertheless, in some cases entailment will turn out to follow, as in (17).

- (17) Context: The weather report predicts rain every day next week.
- a. It’s **supposed to** rain on Wednesday.
  - b. Es **soll** am Mittwoch regnen.  
it SOLL on Wednesday rain

Note also that if it is already part of the circumstances that  $p$  follows from  $\alpha$ 's existing public commitments, this means that the temporal condition in (7) holds. That is,  $\Box p$  holds throughout the reference time  $t$ , since  $\alpha$ 's commitment to  $p$  already holds at  $t$ .

As for the ordering source, we adapt the notion of a reportative informational conversational background developed by Kratzer (2012) for evidential modals. Our proposed ordering source is stated as in (18); although we maintain the terminology “reportative”, this notion is here relativized to  $\alpha$ 's public commitments, and not literally a report.

- (18) “Reportative” informational ordering source:  
a function  $g_{\alpha,t}$  such that for any  $w$  in the domain of  $g_{\alpha,t}$ ,  $g_{\alpha,t}(w)$  represents the propositional content of  $\alpha$ 's public commitments in  $w$  at a time  $t$

Putting this all together, *be supposed to* and *sollen* take as a modal base a set of worlds where a set of relevant circumstances are true, and in particular where there is some  $\alpha$  from whose public commitments  $p$  follows. These worlds are then ordered by the ordering source. Worlds where the content of  $\alpha$ 's public commitments are true are ranked higher than worlds where this content is not true. Both *be supposed to* and *sollen* then universally quantify over the best worlds of the modal base as ranked by the ordering source. We assume that the lexical specification of the modal base and ordering source is treated as a presupposition on available conversational backgrounds in the context (cf. Matthewson et al. 2007). This is summarized in (19).

- (19)  $\llbracket be\ supposed\ to/sollen \rrbracket^{c,w,t}$   
 $= \lambda P \lambda x [\forall m \in t [\forall w' \in \max_{g_m(w)} (\bigcap f_m(w)) : P(x)(w') = 1]]$   
 defined only if the context  $c$  provides a circumstantial modal base  $f_m$  and reportative informational ordering source  $g_{\alpha,m}$

One last comment is in order regarding our semantics in (19). We follow Hinterwimmer (2013) in treating the subject as an external argument of *sollen*, and by extension *be supposed to*. In other words, we treat *be supposed to* and *sollen* as control predicates rather than raising predicates.<sup>5</sup> There is some debate over the status of (non-epistemic) modals as raising or control predicates (see von Stechow and Iatridou 2009 for discussion). We have no new syntactic tests to bear on this issue, and applying the standard tests yields unclear results. Since the reportative reading of *be supposed to* and *sollen* is plausibly epistemic, while the deontic reading is root, and our analysis merges the two, it is not clear what behaviour we would predict. As we will see in the next section, we will need the semantics to make reference to the grammatical subject when we compare *sollen* with *wollen*, another German modal with a reportative flavour. We turn to this now.

## 5. Comparing German *sollen* and *wollen*

It is quite well-known that *sollen* is dispreferred when the issuer of the report is identical with its grammatical subject (Hinterwimmer, 2013; Kratzer, 1981; Schenner, 2008). In such a case,

<sup>5</sup>This means that technically we don't have a preajacent *proposition*, but we will ignore this issue in this paper.

the quotative modal *wollen* ‘want’ is typically used in order to convey that its subject is the source of a report of the prejacent proposition. This contrast is shown in (20)-(22).

- (20) a. Anna **soll** in Oslo sein.  
           Anna SOLL in Oslo be  
           ‘Anna is said to be in Oslo.’ (someone other than Anna is the source)  
       b. Anna **will** in Oslo sein.  
           Anna want in Oslo be  
           ‘Anna claims to be in Oslo.’ (Anna herself is the source)  
       (adapted from Schenner 2008)
- (21) Context: Julia has overheard Max saying that he climbed Mount Everest.  
       Max **will** den Mount Everest bestiegen haben.  
       Max want the.ACC Mount Everest climbed have  
       ‘Max claims to have climbed Mount Everest.’  
       (adapted from Gärtner 2012)
- (22) Context: You’re at a party, and at 8pm someone asks when Maria will arrive. Earlier today, she told you she would arrive at 9pm.  
       a. Maria is **supposed to** be here at 9pm.  
       b. Maria {**will/#soll**} um 9 hier sein.  
           Maria want/SOLL at 9 here be

It would seem that our analysis as it stands now cannot account for these facts. Our analysis simply requires that the fact that some agent  $\alpha$  has a public commitment to  $p$  be part of the circumstantial ordering source associated with *sollen* (and *be supposed to*). It is thus mysterious why *sollen* is infelicitous in (22).

Our proposal to account for this data is the following. We maintain our semantics for *sollen* and *be supposed to* as in (19). However, we argue that *sollen* is infelicitous in (22) due to pragmatic competition with *wollen*. The main idea is that the quotative use of *wollen* has the same semantics as *sollen*, but with the extra presupposition that the source of the report is the same as the subject of the sentence (cf. Gärtner 2012; Schenner 2008). In such a setup, *sollen* and *wollen* compete via Maximize Presupposition (e.g., Percus 2006; Schlenker 2012; cf. Heim 1991), defined in (23).

- (23) *Maximize Presupposition:*  
       If a sentence  $S$  is a presuppositional alternative of a sentence  $S'$ , and the context  $C$  is such that  
       a. the presuppositions of  $S$  and  $S'$  are satisfied within  $C$   
       b.  $S$  and  $S'$  have the same assertive component relative to  $C$   
       c.  $S$  carries a stronger presupposition than  $S'$   
       then  $S$  should be preferred to  $S'$ . (adapted from Schlenker 2012)

Under our analysis, *sollen* and *wollen* have the same assertive component, but *wollen* carries a stronger presupposition. Namely, *wollen* is associated with the presupposition that its subject

has the public commitment to the prejacent, whereas *sollen* carries no presupposition about the identity of the agent who has a public commitment. Therefore, by (23) sentences containing *sollen* and *wollen* are presuppositional alternatives for a Maximize Presupposition competition, and *wollen* must be used whenever its presuppositions are supported in the context. In such contexts, the use of *sollen* is blocked, leading to the contrast in (22).

An analysis along these lines makes the prediction that in cases where it is not known by the speaker whether the subject carries the relevant public commitment, *sollen* can be used. This prediction is borne out, as illustrated in (24). In the context provided, the source of the public commitment could very well be the subject, but could also be someone else. The judgment here is that A's utterance with *sollen* is neutral with respect to whether A thinks that Chris or someone else is the source of the report, whereas the response in A' strongly implies that A' believes that Ben's knowledge comes directly from Chris as the source of the report.<sup>6</sup>

- (24) Context: Alex and Ben are planning a party. Their flaky friend Chris only sometimes RSVPs to parties, and one might only hear about Chris's attendance through rumours.  
 A: **Soll** Chris zur Party kommen?  
     SOLL Chris to.the party come  
     'Is Chris coming to the party?'  
     (A doesn't know whether B heard from Chris or someone else)  
 A': **Will** Chris zur Party kommen?  
     want Chris to.the party come  
     'Is Chris coming to the party?'  
     (only: A' believes Chris is the source)

In sum, we maintain an identical analysis for *sollen* and *be supposed to*. The apparent restriction of *sollen* to cases where the subject is not identical to the source of the report is due to a Maximize Presupposition competition with *wollen*. Since English *be supposed to* does not have a competitor akin to *wollen*, we observe differences in the distribution of *be supposed to* and *sollen* despite their identical semantics.

## 6. Comparison to other analyses

We have claimed that the modal expressions *be supposed to* and *sollen* both have uses that place a restriction that there exists an agent  $\alpha$  who has a public commitment towards the prejacent. We have also argued that apparently deontic uses of these modal expressions should be assimilated to reportative uses as well. In such a case, a pre-existing law or rule can count as a report to license *be supposed to* and *sollen*. In this section, we would like to defend our analysis by comparing it to two recent proposals for *sollen*, both of which deny that *sollen* is reportative per se: Hinterwimmer (2013), which invokes intentional acts rather than reports, and Matthewson and Truckenbrodt (2017), who argue for an external bouletic ordering source for *sollen*.

<sup>6</sup>Note that this example involves so-called "interrogative flip," whereby A expects B to base their answer on reportative evidence. This use of reportatives is quite common cross-linguistically (e.g., Davis et al. 2007; Faller 2002; Garrett 2001; Matthewson et al. 2007).

## 6.1. Hinterwimmer (2013)

As we have already seen, it seems too strong to say that it is strictly antecedent reports that license *be supposed to* and *sollen*. We need to at least allow pre-existing laws and rules under the umbrella of licensors. Hinterwimmer (2013) also argues that reports are strictly speaking too narrow a category to account for the uses of German *sollen*. He argues that *sollen* requires an antecedent **intentional act**, which is not necessarily a speech act. He takes cases like (25) as evidence for this claim.

- (25) Context: Peter is singing *Yesterday* to his baby daughter.  
 A: Why is he doing that?  
 B: Das **soll** das Baby beruhigen.  
     it   SOLL the baby calm.down  
     ‘It’s supposed to calm the baby down.’ (Hinterwimmer, 2013)

The idea is that in this context, there is no prior report (or rule or law for that matter) that Peter should sing in order to calm the baby down; rather, Peter is just trying anything he can think of to calm the baby down. In such a context, what licenses B’s use of *sollen* is thus not a report of any kind, but rather the singing itself. That is, the singing itself serves as an antecedent intentional act for B’s use of *sollen* in (25) – Peter’s intentional act of singing is enough to license *sollen*. Thus, Hinterwimmer claims, *sollen* requires any sort of antecedent intentional act, even if it is not strictly speaking a speech act.

We believe Hinterwimmer’s analysis is not on the right track for at least two reasons. First, native speakers we have consulted seem to agree that there is a prior report in (25) that is accommodated in contexts where it is not explicitly mentioned. This is what is predicted by our account. Under our analysis, that an agent  $\alpha$  has  $p$  as a public commitment is part of the content of the circumstantial modal base, which under our analysis is a presupposition associated with *be supposed to* and *sollen*. This means that an antecedent report (or rule/law) must be retrievable to the interlocutors. In cases where this fails, we predict that a report must be accommodated by the hearer for the use of *be supposed to* or *sollen* to be felicitous. Second, even when the context is such that no prior report can be accommodated because the interlocutors have never met each other or Peter, there is a world knowledge rule ‘singing calms the baby down’ that could in principle serve as the ‘source of the report’ and thus as a possible confound. Consider (26) which avoids this confound.

- (26) Context: Peter is stirring ketchup into his coffee.  
 A: Why is he doing that?  
 B: Das **soll** gut schmecken. = ‘It’s supposed to taste good.’  
 A: Oh. Where did you hear that?  
 B: I don’t remember, I think I read it in some magazine a while ago.  
 B’: #He’s doing it right now.

We assume that there is no world knowledge rule stating that adding ketchup to coffee will make it taste better. A’s continuation of B’s use of *sollen* is very natural here. We take this to show

that while A interprets B's utterance as referring to a prior report, but is unable to accommodate the existence of a source for such a report. It is important to note that the response of B' that 'He's doing it right now' is not a felicitous continuation of the exchange. This is unexpected if we assume the action of stirring ketchup to be an antecedent intentional act in the sense of Hinterwimmer. *Sollen* should be able to pick up Peter's intentional act.

## 6.2. Matthewson and Truckenbrodt (2017)

We next turn to a recent proposal by Matthewson and Truckenbrodt (2017), who distinguish between root and evidential *sollen* and argue that root *sollen* is 'externally bouletic', i.e., the modal flavour of root *sollen* is always bouletic, and the subject of the clause cannot be the holder of the desire. What they mean by this is illustrated in (27), their own example.

- (27) A: Why have you put on loud and unpleasant music in the basement?  
 B: It is **supposed to** chase away the mice.  
 Das **soll** die Mäuse verjagen.  
 that SOLL the mice chase.away

The context for this example is similar to, though slightly different<sup>7</sup> from, the earlier example (25) from Hinterwimmer about calming down the baby. Similar to (25), we disagree with the judgment regarding B's use of *be supposed to/sollen* in (27). In particular, we find the continuation in (27') to be the most natural follow-up to B's utterance in (27). Like in (26), A's response here seems to be a variety of a "Hey wait a minute" response (see von Stechow 2004) that challenges the presupposition of B's utterance, namely the presupposition that there is some agent from whose public commitments the prejacent follows.

- (27') A: Where did you hear that?  
 Wo hast du das gehört?

Additionally, we believe that the restriction that the subject of the clause not be equal to the holder of a desire does not quite capture all the relevant facts. This condition is both too weak and too strong. First, it is too weak because it predicts that *sollen* should be licensed whenever there is an inanimate or expletive subject, so long as there is some holder of a desire in the context. Although Matthewson and Truckenbrodt's (27) appears to show this prediction is upheld, we have already indicated that our judgments in this case do not match theirs. In (28) with an expletive subject, we see that *sollen* cannot take on the bouletic reading; only a reportative reading is available here.

- (28) Context: A and B hear that Peter, an author, has started writing another story.  
 A: In seiner Geschichte soll es um Pferde gehen.  
 in his story SOLL it about horses go  
 'His story is supposed to be about horses.' (reportative only)  
 ≠ 'Peter (or someone) wants his story to be about horses.'

<sup>7</sup>It is different in that the speaker is the bouletic source in (27).

Matthewson and Truckenbrodt predict that an externally bouletic interpretation should be available, either such that the speaker desires Peter to write his next story about horses, or that Peter has that desire himself, since Peter is not the subject of (28). Despite the availability of two plausible sources for the bouletic desire, such an interpretation of (28) is not available. The only available interpretation is a reportative one: A has heard a report that Peter's new story will be about horses and is sharing this information with B by uttering (28).

Second, the restriction that the subject be distinct from the holder of a desire also seems to be too strong in certain cases. We have already seen in (24) that in ignorance contexts, the use of *sollen* is compatible with the subject being the holder of a desire. That is, by uttering *Soll Chris zur Party kommen?* ('Is Chris coming to the party?'), the speaker is not committed to Chris not being the source of a bouletic attitude towards coming to the party. We have also seen in (6) and (14) more cases where the speaker is source of the report.<sup>8</sup>

Matthewson and Truckenbrodt could perhaps not consider these as counterexamples if they treat them as purely reportative uses of *sollen*, which they treat as distinct from their root bouletic use. Under a Kratzerian framework, this amounts to leaving underspecified the types of modal bases and ordering sources that *sollen* can take, just like other modals that can take on several modal flavours. However, given the similarities we have observed between the deontic and reportative uses of *be supposed to* and *sollen*, we believe our unified analysis provides an explanation for the lexicalization of the reportative and non-performative deontic readings together in the same modal expressions: these two readings are in essence one and the same.

Even allowing that in an example such as (1), Professor Plum's presence is bouletically desired by the university rather than mandated, it is not clear how this extends to, e.g., the city parking laws as discussed in example (2), repeated here as (29).

- (29) Context: Your friend has just parked in front of a fire hydrant. You say:
- a. You're not **supposed to** park there.
  - b. Du **sollst** hier nicht parken.  
you SOLL here not park

Here it seems like a stretch to argue that the city is an agent with desires, so assuming a bouletic flavour seems impossible. On Matthewson and Truckenbrodt's account, (29) would have a purely reportative reading with no deontic flavour. On our account, both are present.

There are some cases where Matthewson and Truckenbrodt's analysis makes different predictions than ours. First, they observe a case where the judgments come apart for *be supposed to* and *sollen* in a deontic context, namely (30). Matthewson and Truckenbrodt take this as evidence that *sollen* can not take on a deontic flavour, although *be supposed to* can.

<sup>8</sup>Note that *wollen* is also acceptable in these cases.

- (30) Context: Nobody said anything to A about locking the building. However, there is a rule that you lock the building when you are the last to leave.
- a. A to B: I'm **supposed to** lock the door.
  - b. A to B: #Ich **soll** noch das Gebäude abschließen.  
                   I   SOLL still the building lock  
 (Matthewson and Truckenbrodt, 2017)

We agree with the judgment here and have no explanation for this. We would, however, like to point out two additional factors that may influence the judgments here. The German particle *noch* 'still' seems to play a crucial role in making (30) unacceptable. Without *noch*, the utterance with *sollen* is fine. Additionally, we also observe that adding *auch* 'also' improves acceptability.

- (30') Ich **soll** (auch noch) das Gebäude abschließen.  
 I   SOLL also still the bulding lock  
 'I'm also supposed to still lock the building.'

While Matthewson and Truckenbrodt's account does not predict the acceptability of (30'), ours does not predict why (30) is unacceptable. Another possible factor causing the inacceptability of (30) is competition with *müssen*. A version of this sentence with *müssen* as in (30'') can convey both deontic necessity and inferential reasoning and thus captures both the fact that A is following a rule, and that A had to deduce that the rule applies to him.

- (30'') Ich muss noch das Gebäude abschließen.  
 I   must still the building lock  
 'I still have to lock the building.'

A case that Matthewson and Truckenbrodt can deal with easily, but which causes problems for our account, are examples like (31). In this bouletic context, *be supposed to* is unacceptable, as we predict. However, *sollen* is (marginally) acceptable here. (Note that our English translation for (31b) is not intended as an analysis of the German sentence; we simply offer this as a paraphrase that is colloquially appropriate in the given context.)

- (31) Context: I haven't yet looked at what the cafeteria is offering for lunch, but I really hope they are serving pasta.
- a. #They are **supposed to** have pasta today!
  - b. Sie **sollen** heute Nudeln haben!  
           they SOLL today noodles have  
           ≈ 'I hope they have pasta today!'

This stands in contrast to (32), where both *be supposed to* and *sollen* are unacceptable. Here, there is a report in the context that the prejacent of *be supposed to* and *sollen* is in fact false.

- (32) Context: I just checked the cafeteria's lunch offers for the day and saw that they are not offering pasta, my first choice.
- a. #They are **supposed to** have pasta today!
  - b. #Sie **sollen** aber heute Nudeln haben!  
they SOLL but today noodles have

It seems to us that the speaker of the German sentence in (31) appears to be childish or irrational. We take this to be an effect caused by using an expression expressing deontic modality where bouletic modality would be appropriate. It is our intuition that the speaker is attempting to make the desire more 'objectively necessary' by using an expression that is only compatible with deontic modality – the speaker is exploiting the fact that only deontic modality, but not bouletic modality, is available for *sollen*.

We would like to make one final comment here about the relation between bouletic and deontic modality. Lauer (2015) suggests that performative deontic modals actually convey speaker preferences. When the speaker is a deontic authority, a statement about speaker preferences can take on the force of placing an obligation on the hearer via pragmatics. Thus, there may be an important connection between deontic and bouletic modality that could go some way towards unifying our account with that of Matthewson and Truckenbrodt. However, note that Lauer's idea is about *performative* uses of deontic modals, and we have argued in this paper that the deontic uses of *be supposed to* and *sollen* are crucially anti-performative.

## 7. Conclusion

We have proposed a unified analysis for the deontic and reportative readings of *be supposed to* and *sollen*: both readings are derived from a circumstantial modal base and a reportative informational ordering source. This accounts for the fact that even the deontic use of these modals still have a reportative flavour in that they cannot be used performatively to issue an obligation on the hearer. Despite the open questions that remain, we hope to have made a contribution to the enterprise of making more precise the properties of the modal flavours associated with *be supposed to* and *sollen*.

# Nominalized clauses and reference to propositional content<sup>1</sup>

Elizabeth BOGAL-ALLBRITTEN — *University of Gothenburg*

Keir MOULTON — *Simon Fraser University*

**Abstract.** We investigate the semantics of Korean embedded clauses that bear the nominalizer *kes* and declarative marker *ta*. Such clauses can be embedded by *mit* ‘believe.’ While such clauses are not factive (Shim and Ihsane 2015), we present elicitation data that shows that nominalized (*ta-kes*) clauses are felicitously embedded by *mit* only if their conveyed content was previously asserted in the context; no such restriction arises for non-nominalized clauses. Our analysis of such nominalized embedded clauses argues that they do not denote a proposition — a set of possible worlds — but rather a definite description of a discourse event — an assertion event — that carries propositional content. The use of *ta-kes* embedded clauses allows Korean verbs like *mit* to acquire felicity conditions similar to those proposed for response-stance verbs (e.g. *agree*, *deny*) (Cattell 1978, Anand and Hacquard 2014).

**Keywords:** attitude verbs, nominalized clauses, reported discourses, Korean

## 1. Introduction

Clause-embedding verbs are often divided into different classes based on certain aspects of the embedded clause’s interpretation. Classification schemes include those by Kiparsky and Kiparsky (1970), Hooper and Thompson (1973), Cattell (1978), Hegarty (1992), and Anand and Hacquard (2009, 2014). The classification from Cattell (1978) is given below.

- (1) a. *Volunteered-stance / non-factive*: Embedded clause introduces new idea  
Alice {believed/said/assumed/thought/claimed/supposed} that Ron called.
- b. *Non-stance / factive*: Embedded clause refers to a fact  
Alice {remembered/regretted/knows/forgot/realized} that Ron called.
- c. *Response-stance*: Embedded clause refers to a familiar idea  
Alice {agreed/admitted/confirmed/denied/accepted} that Ron called.

Cross-linguistic investigations of clausal embedding have observed that complements to verbs classified as *non-stance* (1b) or *response-stance* (1c) often exhibit morphosyntactic properties suggestive of nominal structure. The exact nature of these properties varies across languages. In some languages, the relevant embedded clauses occupy syntactic positions otherwise reserved for nominal expressions, e.g. Dutch: (Barbiers, 2000; Haegeman and Ürögdi, 2010). In many other languages, embedded clauses are associated with (or perhaps headed by) proforms or demonstratives: such languages include English (Kiparsky and Kiparsky, 1970), German (Sudhoff, 2003; Zimmermann, 2016), Hebrew (Kastner, 2015), Greek (Roussou, 1991; Kallulli, 2006), Albanian (Kallulli, 2006), Bulgarian (Krapova, 2010), and Hungarian (Abrusán, 2011).

---

<sup>1</sup>New judgments (those not otherwise attributed) for Korean reported here are from Chung-hye Han, whose input was invaluable to this project. This project was funded by SSHRC Insight Grant (#435-2015-0454) to Keir Moulton and Junko Shimoyama.

Previous research largely agrees that apparent nominal morphosyntactic properties of embedded clauses do not strictly correlate with factivity.<sup>2</sup> However, there is significant variation in the characterization of these complements. Among the terms used to describe them are “referential propositions” (de Cuba and Ürögdi, 2009; Haegeman and Ürögdi, 2010), “familiar” (de Cuba, 2007), “presuppositional” (Kastner, 2015), and “given” (Zimmermann, 2016). This primarily syntactic literature does not discuss in detail the contexts that license such clauses, nor does it clarify what type of semantic object these clauses denote. For example, if they denote propositions as in Haegeman and Ürögdi (2010), what exactly does it mean for a proposition — a set of possible worlds — to ‘refer’ (Bhatt, 2010; Kastner, 2015)?<sup>3</sup>

This paper begins to examine these questions by asking what it might mean for a clause to ‘refer.’ Our focus is Korean sentences like (2). The embedded clause in (2) bears the nominalizer *kes* in addition to the declarative mood marker *ta* (Kim, 2009; Yoon, 2013; Shim and Ihsane, 2015). The nominalized clause in (2) is embedded not by a factive or response-stance verb, but rather by *mit* ‘believe,’ a volunteered-stance verb.

- (2) Kibo-nun [Dana-ka i chayk-ul ilk-ess-**ta**-nun **kes**-ul] mit-ess-ta.  
 K.-TOP D.-NOM this book-ACC read-PST-DEC-ADN *kes*-ACC believe-PST-DEC  
 ‘Kibo believed (the claim) that Dana read this book.’ (Shim and Ihsane, 2015: (4b))

After §2 places sentences like (2) in the context of prior work on other types of Korean embedded clauses (Kim, 2009; Yoon, 2013; Shim and Ihsane, 2015), §3 presents new data about the contexts that license sentences like (2): (2) is only felicitous if the content conveyed by the embedded clause was previously asserted in the context. In §4, we propose that embedded clauses like (2) do not denote propositions but instead definite descriptions of assertion events that carry propositional content. When *mit* ‘believe’ embeds a *kes*-clause (2), its interpretation resembles that of sentences with response-stance verbs (2c) under Anand and Hacquard’s (2014) proposal that such verbs report discourse moves.

## 2. The structure and basic interpretation of *kes*-clauses

Kim (2009) discusses three types of Korean *kes*-constructions: internally-headed relative clause (IHRC) (3a), perception, (3b), and factive (3c) constructions.

- (3) a. John-un [totwuk-i tomangka-n-un **kes**-ul] cap-ess-ta.  
 J.-TOP thief-NOM run.away-IMPF-ADN *kes*-ACC catch-PST-DEC  
 ‘John caught the thief that was running away.’  
*(Internally-headed relative clause (IHRC) construction, Kim, 2009: (1))*
- b. John-un [totwuk-i tomangka-n-un **kes**-ul] po-ess-ta.  
 J.-TOP thief-NOM run.away-IMPF-ADN *kes*-ACC see-PST-DEC  
 ‘John saw (the event) of the thief running away.’  
*(Perception construction, Kim, 2009: (2))*

<sup>2</sup>For arguments that factivity is the crucial notion in Albanian and Greek, see Kallulli (2006, 2010).

<sup>3</sup>Treatments of reference to propositions that can be found in Asher (1993) and Chierchia (1984) are not addressed in the literature on nominalized clauses cited above.

- c. John-un [totwuk-i tomangka-n-un **kes-ul**] al-ess-ta.  
 J.-TOP thief-NOM run.away-IMPF-ADN *kes*-ACC know-PST-DEC  
 ‘John knew (the fact) that the thief was running away.’  
 (*Factive construction*, Kim, 2009: (3))

In each example above, the *kes*-clause is an invariant string but its interpretation appears to depend on the nature of the verb that embeds it. Kim (2009) gives a compositional and largely unified account of *kes*-clauses where *kes* denotes individuals of different sorts: ordinary entities (3a), events (3b), and facts (3c). This treatment of *kes* is superficially supported by the translation of such Korean sentences into English using the nouns *event* (3b) and *fact* (3c).<sup>4</sup> However, Kim (2009) does not discuss *kes*-clauses of the shape in (4), which are our focus:

- (4) Kibo-nun [Dana-ka i chayk-ul ilk-ess-**ta**-nun **kes-ul**] mit-ess-ta.  
 K.-TOP D.-NOM this book-ACC read-PST-DEC-ADN *kes*-ACC believe-PST-DEC  
 ‘Kibo believed (the claim) that Dana read this book.’ (Shim and Ihsane, 2015: (4b))

Unlike the *kes*-clauses in (3a)–(3c), the embedded clause in (4) contains the declarative mood marker *ta* in addition to nominalizer *kes*. The morpheme *ta* also occurs on verbs in main clauses that express assertions, as in *mit-ess-ta* ‘believed’ in (4). It is in complementary distribution with elements like the question and imperative markers. The embedded *kes*-clause in (4) is translated into English with the noun *claim*, rather than *event* (cf. (3b)) or *fact* (cf. (3c)).

The main previous discussion of sentences like (4) comes from Shim and Ihsane (2015), who demonstrate that Korean verbs such as *mit* ‘believe’ can embed *kes*-clauses that contain *ta* (4) as well as *kes*-clauses of the shape in (5). The *kes*-clause in (5) has the same morphosyntactic form as the *kes*-clauses investigated by Kim (2009): (5) lacks the declarative marker *ta*.

- (5) Kibo-nun [Dana-ka i chayk-ul ilk-ess-nun **kes-ul**] mit-ess-ta.  
 K.-TOP D.-NOM this book-ACC read-PST-ADN *kes*-ACC believe-PST-DEC  
 ‘Kibo believed (the fact) that Dana read this book.’ (Shim and Ihsane, 2015: (4c))

In addition to both types of *kes*-clauses, *mit* also embeds clauses of the shape in (6), which bear declarative marker *ta* but lack *kes*; the clause instead bears complementizer *ko*, which is not nominal (does not accept case).

<sup>4</sup>As discussed by Chae (2007) and references therein, the Korean morpheme *kes* has been variously characterized as a nominalizer, pronoun, and complementizer. For terminological consistency, we refer to *kes* as a nominalizer below. Morphological evidence that for the nominal character of *kes*-clauses comes from the presence of *un* (a relativizer or adnominalizer) and case marking (e.g. accusative marker *ul*). It is not possible for a *kes*-clause to occur without an embedding verb (i).

(i) \*Lee-ka hoyngryengha-ss-ta-nun **kes-ul**  
 Lee-NOM embezzle-PST-DEC-ADN *kes*-ACC  
 (*Intended*: ‘The fact, claim that Lee embezzled.’) (Yoon, 2013: (12))

- (6) Kibo-nun [Dana-ka i chayk-ul ilk-ess-**ta-ko**] mit-ess-ta.  
 K.-TOP D.-NOM this book-ACC read-PST-DEC-*ko* believe-PST-DEC  
 ‘Kibo believed that Dana read this book.’ (Shim and Ihsane, 2015: (4a))

Shim and Ihsane show that the constructions in (4) and (6) are both non-factive. The continuation ‘...but Dana didn’t read it’ was felicitous after embedded clauses containing both *ta* and *kes* (7a) and embedded clause containing both *ta* and *ko* (7b).

- (7) a. Kibo-nun [Dana-ka i chayk-ul ilk-ess-**ta-nun kes-ul**] mit-ess-ta,  
 K.-TOP D.-NOM this book-ACC read-PST-DEC-ADN *kes*-ACC believe-PST-DEC  
 kulente sasil-un Dana-nun i chayk-ul ilk-ci anh-ass-ta.  
 but fact-TOP D.-TOP this book-ACC read-NEG-PST-DEC  
 ‘Kibo believed (the claim) that Dana read this book, but D. didn’t read it.’  
 (Shim and Ihsane, 2015: (5b))
- b. Kibo-nun [Dana-ka i chayk-ul ilk-ess-**ta-ko**] mit-ess-ta,  
 K.-TOP D.-NOM this book-ACC read-PST-DEC-*ko* believe-PST-DEC  
 kulente sasil-un Dana-nun i chayk-ul ilk-ci anh-ass-ta.  
 but fact-TOP D.-TOP this book-ACC read-NEG-PST-DEC  
 ‘Kibo believed that Dana read this book, but D. didn’t read it.’  
 (Shim and Ihsane, 2015: (5a))

The absence of factivity in (7a) and (7b) is not surprising: as a canonical volunteered-stance verb, *mit* ‘believe’ is not among those verbs we expect to have factive interpretations.<sup>5</sup> However, Shim and Ihsane observe that when *mit* embeds clauses that contain *kes* but lack *ta*, a factive interpretation arises:

- (8) #Kibo-nun [Dana-ka i chayk-ul ilk-ess-**nun kes-ul**] mit-ess-ta,  
 K.-TOP D.-NOM this book-ACC read-PST-ADN *kes*-ACC believe-PST-DEC  
 kulente sasil-un Dana-nun i chayk-ul ilk-ci anh-ass-ta.  
 but fact-TOP D.-TOP this book-ACC read-NEG-PST-DEC  
 #‘Kibo believed (the fact) that Dana read this book, but D. didn’t read it.’  
 (Shim and Ihsane, 2015: (5c))

We elicited additional data that support the restriction of factivity for *mit* sentences to those whose embedded clauses contain only *kes*. For a false embedded proposition (*that Sydney is the capital of Australia*), it is infelicitous for *mit* to embed the clause marked with *kes* alone (9a). By contrast, *mit* can felicitously embed clauses that contain both *kes* and the declarative marker (realized here as *la*) (9b) as well as clauses that contain both *ko* and the declarative marker (9c). (The declarative marker is realized as *la* in (9) rather than *ta*.)

<sup>5</sup>As Shim & Ihsane (2015) point out, sentences with *yukamsuleweha* ‘regret’ as the embedding verb have a factive interpretation regardless of the morphosyntax of the embedded clause. This suggests that while choice of embedded morphology may drive factivity with verbs like *mit* ‘believe,’ other verbs may lexically impose factivity on their complements, as in Kiparsky & Kiparsky (1970) and subsequent work.

- (9) *Context:* Kibo's stupid friend Dana told him that Sydney is the capital of Australia. Kibo missed the day of class where the children learned that Sydney is not the capital of Australia.
- a. # Kulayse acikto Kibo-nun [Sydney-ka Australia-uy swuto-i-n **kes-ul**]  
     so       still   K.-TOP   S.-NOM   A.-GEN       capital-COP-ADN *kes*-ACC  
     mit-e.  
     believe-DEC  
     #‘Kibo still believes (the fact) that Sydney is the capital of Australia.’
- b. Kulayse acikto Kibo-nun [Sydney-ka Australia-uy swuto-**la**-nun **kes-ul**]  
     so       still   K.-TOP   S.-NOM   A.-GEN       capital-DEC-ADN *kes*-ACC  
     mit-e.  
     believe-DEC  
     ‘Kibo still believes (the claim) that Sydney is the capital of Australia.’
- c. Kulayse acikto Kibo-nun [Sydney-ka Australia-uy swuto-**la-ko**] mit-e.  
     so       still   K.-TOP   S.-NOM   A.-GEN       capital-DEC-*ko* believe-DEC  
     ‘Kibo still believes that Sydney is the capital of Australia.’

Following Shim and Ihsane (2015), we conclude that the morphosyntactic shape of clauses embedded by *mit* ‘believe’ correlates with the factivity of the sentence as a whole: factive interpretations arise if the embedded clause contains only *kes*, but not if the embedded clause contains both *ta* and *kes* or both *ta* and *ko*.

### 3. Licensing *ta-kes*-marked clauses

While we agree with Shim and Ihsane (2015) that clauses with *ta* and *kes* and those with *ta* and *ko* are both non-factive, Shim and Ihsane (2015) — nor any other prior work on Korean embedded clauses, to our knowledge — do not discuss differences in the distribution or interpretation of these two types of embedded clauses. We turn to this now.

#### 3.1. $\phi$ -*ta-kes*: $\phi$ previously asserted in local discourse

As previously discussed, the Korean verb *mit* ‘believe’ can embed clauses marked with declarative *ta* and nominalizer *kes* (abbreviated  $\phi$ -*ta-kes*) or clauses marked with *ta* and complementizer *ko* (abbreviated  $\phi$ -*ta-ko*). In the following discourse, both utterance B1 ( $\phi$ -*ta-ko*) and utterance B2 ( $\phi$ -*ta-kes*) were judged felicitous.

- (10) **A:** Na-nun swukecey-lul ta ha-yess-e. Pakk-ey naka nola-to toy?  
       I-TOP homework-ACC all do-PST-DEC outside-at go play-also can  
       ‘I finished my homework. Can I go outside and play?’
- B:** An toy. **A:** Na-lul an mit-e?  
       not can I-ACC not believe-INT  
       ‘No.’ ‘Don’t you believe me?’

- B1:** Um. Na-nun [ney-ka swukecey-lul ta ha-yess-**ta-ko**] mit-e.  
 Yes. I-TOP you-NOM homework-ACC all do-PST-DEC-*ko* believe-DEC  
 Haciman cikum-un cenyek siksa sikan-i-ya.  
 but now-TOP evening meal time-COP-DEC  
 ‘Yes, I believe that you finished your homework. But it’s dinner time.’
- B2:** Um. Na-nun [ney-ka swukecey-lul ta ha-yess-**ta-nun kes-ul**]  
 Yes. I-TOP you-NOM homework-ACC all do-PST-DEC-ADN *kes*-ACC  
 mit-e. Haciman cikum-un cenyek siksa sikan-i-ya.  
 believe-DEC but now-TOP evening meal time-COP-DEC  
 ‘Yes, I believe (the claim) that you finished your homework. But it’s dinner time.’

In the following discourse, by contrast, only utterance B1 ( $\phi$ -*ta-ko*) was accepted. The consultant rejected utterance B2, where *mit* embeds  $\phi$ -*ta-kes*.

- (11) **A:** Cyoni-nun pakk-ey naka nola-to toy?  
 J.-TOP outside-at go play-also can  
 ‘Can Johnny go outside and play?’
- B1:** Um. Na-nun [kay-ka swukecey-lul ta ha-yess-**ta-ko**] mit-e.  
 Yes. I-TOP he-NOM homework-ACC all do-PST-DEC-*ko* believe-DEC  
 ‘Yes, I believe that he finished his homework.’
- B2:#**Um. Na-nun [kay-ka swukecey-lul ta ha-yess-**ta-nun kes-ul**] mit-e.  
 Yes. I-TOP he-NOM hmwrk-ACC all do-PST-DEC-ADN *kes*-ACC believe-DEC  
 #‘Yes, I believe (the claim) that he finished his homework.’

The key difference between the discourses in (10) and (11) is that only (10) contains a previous assertion that carries content comparable — if not string identical — to the  $\phi$  later uttered by B: A asserts *I finished my homework*. In such discourses, both  $\phi$ -*ta-kes* and  $\phi$ -*ta-ko* were licit in utterances by B. When such a previous assertion is missing as in (11), only  $\phi$ -*ta-ko* is licit.

It is not the case that  $\phi$ -*ta-kes* is only licensed where  $\phi$  corresponds to a direct quotation. The  $\phi$  uttered by B in (10) is not string identical to the string previously uttered by A: whereas A’s utterance contains a first person pronoun, B’s utterance contains a second person pronoun. This point is made even more dramatically in the discourse in (12). Here, A’s utterance of *I ate peas* only entails the proposition corresponding to the  $\phi$  uttered by B. In addition to  $\phi$ -*ta-ko* (B1),  $\phi$ -*ta-kes* (B2) was also judged felicitous:

- (12) *Context:* B has a rule that A must eat vegetables before having cake.  
**A:** I ate peas! Can I have cake now?
- B:** No, you can’t. **A:** But why? Don’t you believe me?

**B1:** Na-nun [ney-ka yachae-lul mek-ess-**ta-ko**] mit-e...  
 I-TOP you-NOM vegetable-ACC eat-PST-DEC-*ko* believe-DEC  
 ‘I believe that you ate vegetables (...but the cake’s not ready).’

**B2:** Na-nun [ney-ka yachae-lul mek-ess-**ta-nun kes-ul**] mit-e...  
 I-TOP you-NOM vegetable-ACC eat-PST-DEC-ADN *kes*-ACC believe-DEC  
 ‘I believe that you ate vegetables (...but the cake’s not ready).’

However, while  $\phi$  need not be string identical to a previous assertion, the propositional content associated with  $\phi$  must be consistent with the content associated with the prior assertion. The consistency requirement was met in the entailment discourse in (12). However, it is not met in the discourse in (13), in which  $\phi$  occurs in the scope of negation in A’s previous assertion. As shown, A is not allowed to go on to use  $\phi$ -*ta-kes* in a subsequent assertion. (Although not shown here,  $\phi$ -*ta-ko* would have been licit.)

(13) **A:** Kibo has certainly heard in his geography class that Toronto is not the capital of Canada...

**A:** ...#Kulayto Kibo-nun [Toronto-ka Canada-uy swuto-**la-nun kes-ul**]  
 even.so K.-TOP T.-NOM C.-GEN capital-DEC-ADN *kes*-ACC  
 mit-e.  
 believe-DEC  
 ‘Even so, Kibo still believes that Toronto is the capital of Canada.’  
*C.H. Han’s Comment:* “This sounds really odd to me, if Kibo has never heard anybody tell him that ‘Toronto is the capital of Canada’.”

The prior act of *assertion* of  $\phi$  — or material consistent with  $\phi$  — is necessary for the felicity of  $\phi$ -*ta-kes* under *mit* ‘believe.’ In the following discourse, we find that A’s polar question (*Has Johnny finished his homework*) is not sufficient to license B’s utterance of  $\phi$ -*ta-kes* in B2, despite  $\phi$  being string identical to the proposition on which A’s polar question was formed. The infelicity of  $\phi$ -*ta-kes* in B2 contrasts with the felicity of  $\phi$ -*ta-ko* in utterance B1.

(14) **A:** Johnny-nun swukcey-lul ta ha-yess-ni?  
 J.-TOP homework-ACC all do-PST-Q

**B1:** Na-nun [Johnny-ka swukcey-lul ta ha-yess-**ta-ko**] mit-nun-ta.  
 I-TOP J.-NOM homework-ACC all do-PST-DEC-*ko* believe-DEC  
 ‘I believe that Johnny finished his homework.’

**B2:** #Na-nun [Johnny-ka swukcey-lul ta ha-yess-**ta-nun kes-ul**]  
 I-TOP J.-NOM homework-ACC all do-PST-DEC-ADN *kes*-ACC  
 mit-e.  
 believe-DEC  
 #‘I believe (the claim) that Johnny finished his homework.’

The importance of assertion — as opposed to a question — distinguishes Korean  $\phi$ -*ta-kes* from structures in other languages that have also been described as imposing a ‘familiarity’ requirement and exhibiting nominal morphosyntactic properties. For instance, Schwabe et al. (2016) citing Sudhoff (2003) show for German that a polar question is sufficient to license ‘familiar’ clauses, which contain the sentential proform *es*.

(15) **A:** Ist Lea krank?

is Lea ill  
‘Is Lea ill?’

**B:** Max behauptet **es**, dass sie krank ist.

Max claims it that she ill is  
‘Max claims it that she is ill.’ (Schwabe, Frey, and Meinunger, 2016: (4))

We turn to a final restriction on  $\phi$ -*ta-kes* when embedded by *mit* ‘believe.’ The prior assertion of  $\phi$  must be familiar to the subject (attitude holder) of *mit*. It appears that the ‘familiarity’ requirement is satisfied if the subject of *mit* is among those to whom  $\phi$  was asserted. In addition to [ $\phi$ -*ta-ko*] *mit* (A1) being felicitous in this context, [ $\phi$ -*ta-kes*] *mit* (A2) was also accepted. Here, the subject of *mit* is *Johnny’s mother*, to whom  $\phi$  was previously asserted.

(16) **A:** Johnny-ka ku-uy emma-eykey [ku-ka swukcey-lul ta ha-yess-ta-ko]  
J.-NOM he-GEN mother-to he-NOM homework-ACC all do-PST-DEC-*ko*  
malha-yess-ta...

ha-yess-**ta-nun kes-ul**] mit-nun-ta.  
do-PST-DEC-ADN *kes*-ACC believe-PRES-DEC  
‘...so Johnny’s mother believes that he finished his homework.’

In discourse (17), however, only [ $\phi$ -*ta-ko*] *mit* (B1) was accepted whereas [ $\phi$ -*ta-kes*] *mit* (B2) was judged to be infelicitous. In this discourse, *Johnny’s mother* is once again the subject of *mit* ‘believe’ but  $\phi$  was not asserted previously to *Johnny’s mother*: instead,  $\phi$  was asserted to speaker A. It appears that the felicity of [ $\phi$ -*ta-kes*] *mit* hinges on whether  $\phi$  was asserted specifically within in the ‘reported’ or ‘local’ discourse (the one that the matrix subject participates in).

- (17) **A:** Johnny told me—but hasn’t said anything to his mother—that he finished all his homework. Do you believe him?

do-PST-DEC-ADN *kes*-ACC believe-DEC  
‘...so Johnny’s mother believes that Johnny finished his homework.’  
*Comment:* “I feel that Johnny’s mom herself must have heard the claim that Johnny finished the homework.”

In summary, whereas  $\phi$ -*ta-ko* imposes no restrictions on discourses in which it occurs,  $\phi$ -*ta-kes* is only felicitous under the following conditions, informally characterized:

- (18) *The familiarity requirement of  $\phi$ -ta-kes:*  
Utterance of [ $\phi$ -*ta-kes*] *mit* is felicitous just in case  $\phi$  — or some utterance associated with propositional content that is consistent with  $\phi$  — has been previously asserted in a local discourse (a discourse that includes the subject of *mit*).

In §4, we arrive at these conditions by appealing to the individual contributions of declarative marker *ta* and nominalizer *kes*.  $\phi$ -*ta-kes* presupposes the existence of a prior assertion  $\phi$  (or material consistent with  $\phi$ ) which is familiar to the subject of *mit*.<sup>6</sup>

---

<sup>6</sup>Our claim that  $\phi$ -*ta-kes* presupposes a previous assertion event of  $\phi$  recalls presuppositional characterizations of reportative expressions in German and Tagalog (Schenner, 2008; Fabricius-Hansen and Sæbø, 2004; Schwager, 2010). Elements like German *sollen* and Tagalog *daw* “induce a presupposition that the prejacent has been asserted” (Schwager, 2010: 238).

However, while the meanings can be described similarly, *ta-kes* differs from reportatives in at least three ways. First, whereas reportatives introduce this presupposition, the presupposition in Korean arises through semantic contributions of independent markers *ta* and *kes*, neither of which can itself be characterized as a reportative. Second, while reportatives can occur as main clauses that express assertions, Korean *ta-kes* clauses cannot (i). Third, whereas *mit* ‘believe’ readily embeds Korean *ta-kes* clauses, German *glauben* ‘believe’ is reluctant to embed reportative *sollen* (Schenner, 2008).

### 3.2. Comparison with response-stance verbs

Our characterization of belief attributions with a complement of shape  $\phi$ -*ta-kes* in (18) is strongly reminiscent of previous descriptions of Cattell's (1978) response-stance verbs:

- (19) *Response-stance*: Embedded clause refers to a familiar idea  
 Alice {agreed/admits/confirmed} that Ron called.

Authors including Cattell (1978), Hegarty (1992), de Cuba (2007), and Kastner (2015) observe that response-stance verbs embed 'familiar' complements. Hegarty suggests that this familiarity requirement is satisfied when such complements express common knowledge or a point of current discussion in the reported discourse. As (20) shows, assertions with response-stance verbs that embed  $\phi$  cannot be followed by a denial that  $\phi$  was previously asserted.

- (20) Alice agreed/admits/confirmed [that Ron called]...  
 #...but no one had said that Ron called.

De Cuba (2007) and Kastner (2015) observe that Hungarian and Hebrew response-stance verbs prefer to embed clauses that exhibit nominal morphosyntactic properties, namely nominal pro-forms and clause-taking determiners. The same is true of Korean. The consultant readily allowed  $\phi$ -*ta-kes* clauses to be embedded by response-stance verbs *tonguyha* 'agree' (21a), *incengha* 'acknowledge, accept' (21b), and *pwuinha* 'deny, reject' (21c). By contrast, the consultant strongly dispreferred sentences in which these verbs instead embedded  $\phi$ -*ta-ko* clauses.

### 4. Toward an account of reference to prior asserted content

We propose that the parallels between Korean *ta-kes* clauses and clauses with responses-stance verbs are no accident, but rather that typically volunteered-stance verbs like *mit* 'believe' take on the profile of a response-stance verb by virtue of the individual semantic contributions of *ta* and *kes*.

#### 4.1. The contributions of *ta* and *kes*

We begin with the contribution of the declarative marker *ta*. As was first noted (to our knowledge) by S.S. Kim (2011), *ta* introduces a separate layer of embedding when found in clauses embedded under nouns, such as the relative in (22). In (22a), the clause without *ta* is translated as simply ‘the rumor that Chelswu told me.’ By contrast, the clause in (22b) contains *ta*, which is reflected in its translation with an additional verb of saying.

- (22) a. [Chelswu-ka na-eykey allye cwu-n] somwun  
 C.-NOM I-DAT tell-ADN rumor  
 ‘the rumor<sub>i</sub> that Chelswu told me t<sub>i</sub>’

 ‘the rumor<sub>i</sub> that (people say that) Chelswu told me t<sub>i</sub>’  
 \*‘the rumor<sub>i</sub> that Chelswu told me t<sub>i</sub>’ (S.S. Kim 2011: 13a,b)

We suggest that *ta*-clauses evoke events of assertion of *p*.<sup>7</sup> We record this meaning as in (23):<sup>8</sup>

- (23)  $\llbracket ta_{embedded} \rrbracket = \lambda p \lambda e.e$  is an event of asserting *p*

Next, we consider what *kes*-clauses do independently of *ta*. We rely here on M.-J. Kim (2009). Kim (2009) offers a largely unified account of three structures that feature *kes*: internally-headed relative clause (IHRC) constructions (24a), perception constructions (24b), and factive constructions (24c).

- (24) a. John-un [totwuk-i tomangka-n-un **kes-ul**] cap-ess-ta.

 ‘John knew (the fact) that the thief was running away.’  
*(Factive construction, Kim, 2009: (3))*

<sup>7</sup>When *ta* is in a root clause or combined with *ko*, its semantics is not as transparent. We leave a full treatment of *ta* for future work.

<sup>8</sup>We treat its contribution as an entailment here, although it is possible it’s a presupposition. It’s hard to tell since *ta*-clauses make this contribution when embedded, and we only have examples where the embedding noun phrase carries a uniqueness presupposition, and hence determining whether the assertion component is entailed or presupposed has been challenging.

Kim (2009) proposes that *kes* introduces a salient individual or situation which stands in some contextually-supplied relation *R* to the proposition *p*. (See also Kim (2007), Hoshi (1995), and Shimoyama (1999) on IHRCs.) We adopt a version of Kim's analysis of *kes*, which departs from the original in largely trivial ways. *Kes* takes as its argument the embedded clause *p* (a set of situations) and returns what amounts to a definite description (25), which we characterize as a familiarity definite.<sup>9,10</sup>

- (25)  $\llbracket kes \rrbracket^C = \lambda p \iota x. R(p)(x)$   
 $x$  is in the domain of ordinary individuals or situations  
 $R$  is a suitable relation  
defined iff  $x$  is familiar in  $C$

Kim identifies several relations that are suitable for *R* in different *kes*-constructions. For IHRCs, theta-relations (26) pick out an individual from the situation denoted by the embedded clause, e.g. the thief who is the agent of the running situation described in (27). The entity denoted by the entire *kesP* functions as an argument to a verb in the main clause (e.g. *caught*).

- (26) a.  $R_{agent} = \lambda p' \lambda x'. \exists s[p'(s) \ \& \ Agent(x')(s)]$   
b.  $R_{theme} = \lambda p' \lambda x'. \exists s[p'(s) \ \& \ Theme(x')(s)]$
- (27) John-un [totwuk-i tomangka-n-un **kes-ul**] cap-ess-ta.  
John-TOP thief-NOM run.away-IMPF-ADN *kes*-ACC catch-PST-DEC  
'John caught the thief that/while he was running away.'

- (28) a.  $\llbracket kes \rrbracket = \lambda p \iota x. R_{agent}(p)(x)$   
 $= \lambda p \iota x. [\lambda p' \lambda x'. \exists s[p'(s) \ \& \ Agent(x')(s)]](p)(x)$   
 $= \lambda p \iota x. \exists s[p(s) \ \& \ Agent(x)(s)]$   
b.  $\llbracket kesP \rrbracket = \lambda p \iota x. \exists s[p(s) \ \& \ Agent(x)(s)](\lambda s'. run-away(thief)(s'))$   
 $= \iota x. \exists s[run-away(thief)(s) \ \& \ Agent(x)(s)] \quad \rightsquigarrow \text{the thief}$

While we must constrain the possible values for *R* (see below), we also want to allow it a certain flexibility. As Kim (2007) shows with (29a), *R* can return a sum of individuals in IHRC, each with distinct thematic roles (Kim, 2007: 8). In (29b), *R* returns an individual that is part of a result state described by the IHRC predicate (Grosu and Landman, 2012 after (40) in Chung and Kim (2003)).

<sup>9</sup>Further work is needed to determine if there is a uniqueness requirement.

<sup>10</sup>For Kim, *kes* takes as its argument the trace left by LF movement of the embedded clause. She also separates definiteness from *kes*, but we have built definiteness in simply for ease of exposition.

- (29) a. Jinho-un [koyangi-ka cwi-lul coch-ko iss-n-un **kes**]-ul capassta.  
 J.-TOP [cat-NOM mouse-ACC chase-ko COP-IMPF-ADN *kes*]-ACC catch-PST-DEC  
 ‘A cat chased a mouse & J. caught {the cat/the mouse/the mouse & cat}.’
- b. Jinho-un [paci-ka teleweci-un **kes**-ul ] takkanay-ss-ta  
 J.-TOP pants-NOM got.dirty-ADN *kes*-ACC wipe.out-PST-DEC  
 ‘The pants got dirty and J. wiped the dirt off the pants.’

*Kes*-constructions arrive at factive (30) and perception (31) meanings via different values for R. Following Kim (2007) and Kratzer (2002), we treat factive complements as denoting situations that exemplify propositions; the fact-producing R ( $R_{fact}$ ) in (30b) delivers this. Perception complements denote bare events—i.e. the individual situation described by the complement (Higginbotham 1983). The R found in such *kes*-clauses (31b) is simply the identity function.

- (30) *Factive construction*
- a. John-un [totwuk-i tomangka-n-un **kes**-ul] al-ess-ta.  
 J.-TOP thief-NOM run.away-IMPF-ADN *kes*-ACC know-PST-DEC  
 ‘John knew (the fact) that the thief was running away.’
- b.  $R_{fact} = \lambda p' \lambda x'. x'$  is a fact that exemplifies  $p'$   
 (Treatment of facts after Kim (2009); Kratzer (2002))
- c.  $\llbracket kesP \rrbracket = \iota x. x$  is a fact that exemplifies  $[\lambda s'. run-away(thief)(s')]$
- (31) *Perception construction*<sup>11</sup>
- a. John-un [totwuk-i tomangka-n-un **kes**-ul] po-ess-ta.  
 John-TOP thief-NOM run.away-IMPF-ADN *kes*-ACC see-PST-DEC  
 ‘John saw (the event) of the thief running away.’
- b.  $R_{id} = \lambda p' \lambda s'. p'(s')$
- c.  $\llbracket kesP \rrbracket = \iota s. run-away(thief)(s)$

There are questions, of course, that arise about how to constrain R. One way to constrain R would be to say that the individual  $x/s$  must refer to a (possibly non-proper) ‘part’ of the situation described by  $p$ : individuals in the situation, the situation itself (for perception), or the fact. We also note that the entries we give for  $R_{fact}$  and  $R_{id}$  are closely related — or identical, in the case of  $R_{fact}$  — to the denotations of complementizers given by Kratzer (2006), so there is precedent for linguistically encoding these functions.

## 4.2. Combining *ta* and *kes*

It is now a matter of combining *kes* with a clause that contains *ta*. (We assume the adnominal marker *un* makes no semantic contribution.) If R is valued as  $R_{id}$  as in the perception construction, then the  $\phi$ -*ta-kes* structure simply denotes the set of assertion eventualities denoted by the *ta*-clause. For instance, the embedded clause in (32) refers to the familiar event of assertion of  $p$  in the context:

<sup>11</sup>Kim (2007) suggests *kes* may pick out something more like the ‘image’ or ‘sound’ of an event. We’ve eliminated that step for simplicity.

- (32) Na-nun [<sub>kesP</sub> Johnny-ka swukcey-lul ta ha-yess-**ta**-nun **kes**-ul] mit-e.  
 I-TOP J.-NOM homework-ACC all do-PST-DEC-ADN kes-ACC believe-DEC  
 ‘I believe that Johnny finished his homework.’
- (33) a.  $\llbracket ta \rrbracket$  (*that Johnny finished his homework*)  
           =  $\lambda e.e$  is an event of asserting *that Johnny finished his homework*  
 b.  $\llbracket kes \rrbracket = \lambda p \lambda s.[R_{id}(p)(s)]$   
 c.  $\llbracket kesP \rrbracket (\llbracket ta \rrbracket$  (*that Johnny finished his homework*))  
       =  $\lambda s.s$  is an event of asserting *that Johnny finished his homework*  
        $\leadsto$  the event of asserting that Johnny did his homework

In §4.3, we discuss how a verb like *believe* combines with an individual event like the one in (33c). Even before doing so, however, we can already appreciate how treating *ta-kes* clauses as definite descriptions of assertion events will capture the data in §3 2–(13). When the assertion has been made in the context, it can be referred to successfully because it is familiar in the context of utterance:

- (34) A: Johnny finished his homework. (=an event of asserting p)  
 B: ✓(32)

In (35) (an excerpt from (14)), there is no event of asserting that Johnny did his homework (only a question): as a result, *ta-kes* will not be defined and will be — as attested — infelicitous. (We return in the next section to the additional requirement of  $\phi$ -*ta-kes* that  $\phi$  have been asserted within a local discourse.)

- (35) A: Has Johnny done his homework? (not an event of asserting p)  
 B: ✗(32)

We can envision an alternative account, which would treat the contribution of *ta* as presupposition that its complement is asserted in the context, but would semantically just pass up a propositional meaning rather than introduce an event description in the object language. That presupposition would be accommodated globally when the attitude holder is a first person (utterance context participant) or locally under *believe* with a third person attitude holder. We explore this possibility in ongoing work. We do not pursue that approach here, however, because we do not see how it would account for the fact that *ta* is required for a non-factive meaning. If all *ta* did was place a presupposition on the propositional complement—that it was uttered—then modulo that presupposition, *ta-kes* clauses and *kes*-clauses under *believe* should behave alike. But that is not the case: as first demonstrated by Shim and Ihsane (2015), bare *kes*-clauses under *believe* are factive. The *ta* needs to make enough of a contribution to alleviate that factivity, and that is what our proposal will do.

Our proposal, however, requires further elaboration to rule out  $R_{fact}$  being used with *ta-kes* clauses under *believe*.

#### 4.3. Response-stance *believe*

Traditionally, we think of attitude verbs as selecting propositions. By contrast, our proposal is that a *ta-kes* clause refers to an event, which is not in any obvious way what a verb like *believe* would select. In this section, we treat *ta-kes*-taking predicates as response-stance verbs in a fashion similar to the

account of such verbs developed in Anand and Hacquard (2014): in their account, verbs like *claim*, *agree*, *dispute*, *etc.* report discourse moves whose goal is to update a reported common ground,  $CG_R$ , with the complement proposition.

- (36)  $\llbracket \textit{claim} \rrbracket^{c,w,g} = \lambda p \lambda e. \textit{claim}'(e,w) \ \& \ \forall w' \text{ compat. with Goal}(e) [\forall w'' \in CG_R(w') [p(w'')]]$   
(Anand & Hacquard, 2014: 78)

The part of their proposal we will capitalize on is the notion of updating a reported common ground: the discourse situation that the discourse move described by the verb is a part of. We suggest that response-stance *believe* reports acceptance of (the propositional content of) of a certain discourse move into the attitude holder's belief set, where a discourse move is an event of assertion (whose own goal is to update the reported common ground). We sketch a denotation for response-stance *believe*<sub>RS</sub> in (37) which relates an attitude holder to an event of assertion *e*. Condition (37a) guarantees that *e* be uttered in the reported common ground; this accounts for the contrast in felicity between (16) and (17). Condition (37b) guarantees that *e* be an assertion event: the goal of *e* is to introduce its propositional content to the reported common ground.

- (37) Sketch of denotation of Response-stance (RS) *believe*:  
 $x \text{ believes}_{RS} e \text{ in a reported common ground } (CG_R) \text{ in } w \text{ iff:}$   
 a. *e* is a **discourse move** in  $CG_R$   
 b. **goal**(*e*) is to add the **CONTENT**(*e*) to  $CG_R$   
 c.  $DOX(x)(w) \subset \text{CONTENT}(e)(w)$

The notion of an event's propositional content is defined in (38b). Following Hacquard (2006) and Kratzer (2013), we take **CONTENT** to be a function that takes some particular with informational content (books, information sources, assertion events, belief states) and packages that informational content as a set of possible worlds. This set of worlds can then be related to the attitude holder's doxastic alternatives in standard Hintikka fashion. The end result is that to believe an assertion event is to believe the content of that event.

- (38) a.  $DOX(x)(w) = \{w' : w' \text{ is compatible with what } x \text{ believes in } w\}$   
 b.  $\text{CONTENT}(e)(w) = \{w' : w' \text{ is the informational content of } e \text{ in } w\}$

There are many open questions that arise from this preliminary report. Among these questions is the full range of predicates that embed *ta-kes* clauses. We might predict that embedding *ta-kes* clauses under a verb of communication like *malha* 'say' would conflict with the claim being presupposed in the CG or  $CG_R$ . We also have not broached the question of what *kes*-clauses that lack *ta* mean when embedded by *believe*, e.g. (8). We described these as factive following Shim and Ihsane (2015), but remain agnostic as to whether they should be equated with knowledge ascriptions.

## 5. Conclusion

We set out to examine what it could mean to say that a clause "refers," taking as our focus Korean embedded clauses that bear the nominalizer *kes* and declarative marker *ta*. We suggested that they might not refer to propositions or even to propositional content directly (whatever that might be), but to assertion events that carry propositional content. Korean *ta-kes* clauses are best understood as denoting definite descriptions of an assertion event. Assertion events are easily equated with propositions, as the recent trend in projecting possible worlds from information sources ("anchors") has demonstrated

(Hacquard, 2006; Kratzer, 2013). When *ta-kes* is present, Korean *mit* ‘believe’ behaves like a response stance verb, reporting a discourse move: the uptake of an assertion (Anand and Hacquard 2014). The results from Korean are interesting because things could have been different: nominalized *ta-kes*-clauses instead might have referred to content that was *not* necessarily previously asserted. Both Chierchia (1984) and Asher (1993) allow propositions to denote entities, and these can be anaphorically referred to. But nothing on that view requires there be an assertion event of the proposition.

It may be useful to apply the contexts used here to other languages that have been claimed to have ‘referential clauses’ with nominal morphosyntactic properties. Our results reinforce the need to clearly distinguish factive from so-called ‘familiar’ (de Cuba, 2007), ‘referential’ (de Cuba and Ürögdi, 2009; Haegeman and Ürögdi, 2010), and ‘presuppositional’ (Kastner, 2015) clauses. When used to study embedded clauses with nominal properties in other languages, our contexts may show that such structures are best understood in terms of belief as a discourse-move reporting predicate. Preliminary results show that when Kastner’s (2015) Hebrew “presuppositional clauses” (bearing demonstrative *ze*) are embedded by belief verbs (39b), they have felicity conditions similar to those of Korean *ta-kes* clauses.

# A surface-scope analysis of authoritative readings of modified numerals<sup>1</sup>

Brian BUCCOLA — *The Hebrew University of Jerusalem*

Andreas HAIDA — *The Hebrew University of Jerusalem*

**Abstract.** A sentence like *You're allowed to draw at most three cards* has a so-called authoritative reading characterized by two kinds of inference: an upper-bound inference (you're not allowed to draw more than three cards) and a free-choice inference (you're allowed to draw any number of cards in the range  $[0, 3]$ ). We show that authoritative readings are available for a variety of expressions beyond just *at most*, and we provide the first (as far as we know) surface-scope account of such readings, building on the recursive exhaustification account of free-choice disjunction proposed by Fox (2007).

**Keywords:** modified numerals, free-choice inferences, exhaustivity, recursive exhaustification

## 1. The puzzle

Sentence (1) has two readings, which Büring (2008) calls a *speaker insecurity reading* (or ignorance reading) and an *authoritative reading*. On its speaker insecurity reading, the sentence conveys that the maximum number of cards you're allowed to draw is either three or fewer than three, and the speaker is ignorant about which is true. This reading can be brought out by following the sentence with *but I don't know exactly how many*.

(1) You're allowed to draw at most three cards.

We will be concerned in this paper with the authoritative reading of (1), which is characterized by two kinds of inference: (i) an *upper-bound* (UB) inference, viz. that you're not allowed to draw four or more cards, and (ii) a *free-choice* (FC) inference, viz. that you're allowed to draw any number of cards in the range  $[0, 3]$ .<sup>2</sup> Authoritative readings constitute a well-known puzzle for the semantics of modified numerals (Geurts and Nouwen, 2007; Büring, 2008; Penka, 2014), which we describe in two parts.

First, on standard assumptions about the meanings of *allow* and *at most three*, a surface-scope analysis of (1) predicts a weak literal meaning, 'There is a permissible world in which you draw three cards or fewer', notated henceforth as  $\Diamond[\leq 3]$ . Neither an UB inference ( $\neg \Diamond[\geq 4]$ ) nor a FC inference ( $\Diamond[= 3] \wedge \Diamond[= 2] \wedge \dots$ ) logically follows from this interpretation. Moreover, an

1. For many helpful comments, questions, and discussions, we would like to thank Luis Alonso-Ovalle, Moyshe Bar-Lev, Emmanuel Chemla, Luka Crnić, Danny Fox, Doris Penka, Bernhard Schwarz, Stephanie Solt, Benjamin Spector, and Tue Trinh, as well as the audiences at the Institut Jean Nicod (École normale supérieure, LANGUAGE seminar series, July 6, 2016), at *Sinn und Bedeutung* 21 (University of Edinburgh, September 4–6, 2016), at *Logic in Language and Conversation (LogiCon)* (Utrecht University, September 19–20, 2016), and at ZAS (*Semantikzirkel*, September 21, 2016). This research was supported by the Israel Science Foundation (ISF 1926/14) and by the German-Israeli Foundation for Scientific Research (GIF 2353).

2. Our empirical claim regarding FC inferences deviates from that of Penka (2014), who assumes only partial, rather than total, FC: (1) conveys only that you may draw exactly three cards and may draw fewer than three cards, not that you may draw any number of cards in the range  $[0, 3]$  (though the sentence is compatible with such a state of affairs). This partial view is also in line with claims about ignorance inferences, which have been argued to be partial, not total (Schwarz, 2016). We take a different stance, which is that these inferences are normally total, but in certain contexts can be partial. The system we propose will be able to account for such weakening (by 'pruning' certain alternatives from consideration), as we discuss at the end of the paper, in §4.4.

inverse-scope analysis (*at most three* > *allow*) derives only the speaker insecurity reading, and the reason for this is that when *at most three* takes widest scope, a speaker insecurity reading obligatorily emerges. For instance, (2) is incompatible with the speaker knowing exactly how many cards Ann drew; he knows it's either three or fewer than three, but is ignorant about which is true (Geurts and Nouwen, 2007; Büring, 2008; Nouwen, 2010, 2015; Schwarz, 2016).<sup>3</sup>

(2) Ann drew at most three cards.

Second, the antonym of *at most*, *at least*, does not give rise to authoritative readings. For example, (3) cannot be used to convey that you're allowed to draw three or more cards, with FC in the range  $[3, n]$  (for some contextually specified UB  $n$ , e.g. 52, the number of cards in a standard deck), and a lower bound (LB) that prohibits drawing two cards or fewer. To see this, notice the oddity of embedding (3) under an expression like *The rules state that ...*, or of a game master uttering (3).<sup>4</sup>

(3) You're allowed to draw at least three cards.

To summarize, the puzzle has two parts: why does (1) have an authoritative reading, and why does (3) not have an authoritative reading? The most prominent and successful solution to this puzzle, as far as we are aware, is due to Penka (2014). She takes *at most* to be the oddity in this puzzle, and she solves it by decomposing *at most* into a negative component, *ANT*, plus *at least*, and giving (1) a split-scope analysis: *ANT three* scopes above *allow*, which in turn scopes above *at least* (hence, the scope of *at most three* is 'split').

- (4) a. *at most three*  $\rightsquigarrow$  *ANT* + *three* + *at least* (Penka, 2014)  
 b. *ANT three*  $[\lambda n$  [allowed [at least  $n$  [ $\lambda m$  you draw  $m$  cards]]]]  
 c.  $\forall n. n > 3 \rightarrow \neg \Diamond [\geq n]$  ( $\equiv \neg \Diamond [\geq 4]$ )

On this account, the literal meaning of (1) immediately entails an UB; FC then follows from neo-Gricean reasoning, given certain assumptions about the Horn scales responsible for generating alternatives. Together, these ingredients solve the first half of the puzzle. The second half is solved simply because *at least* has no analogous decomposition: parsing (3) with surface scope (*allow* > *at least three*) or with inverse scope (*at least three* > *allow*) leads only to an ignorance reading, not to a LB authoritative reading. (See Penka's paper for details.)

## 2. New observations

Penka's (2014) proposal attributes the contrast between *at most*, which gives rise to authoritative readings, and *at least*, which doesn't, to a special property of *at most*, namely that it's composed of a negative part, *ANT three*, that can take scope separately from its remainder, *at least*. We

3. There are a number of proposals for how to derive ignorance readings (e.g. Geurts and Nouwen, 2007; Büring, 2008; Nouwen, 2010; Coppock and Brochhagen, 2013; Nouwen, 2015; Schwarz, 2016). Our point here is that whichever one of these accounts one adopts, the prediction is that parsing (1) with *at most three* taking scope above *allow* will necessarily derive only an ignorance reading (not an authoritative reading) by whatever mechanism the account assumes is responsible for (2).

4. One might think that an authoritative reading of (3) is somehow 'blocked' due to competition with the more natural and straightforward sentence *You're required to draw at least three cards*. We discuss (and provide arguments against) this idea in §4.3.

now show that a variety of expressions, beyond just *at most*, give rise to authoritative readings, including both members of certain other antonym pairs.<sup>5</sup>

To start, (5) has a natural authoritative reading characterized by a LB inference (the catering premises may not open earlier than 5:00 AM) and a FC inference (they may open at 5:00 AM and at any time later than that).

(5) The catering premises may open at the earliest at 5:00 AM.

Similarly, (6) has a natural authoritative reading characterized by an UB inference (deductions may not occur later than the time of submission) and a FC inference (they may occur at the time of submission and at any time earlier than that).

(6) Deductions may occur at the latest at the time of submission.

Thus, unlike *at least* and *at most*, both of *at the earliest* and *at the latest* give rise to authoritative readings.<sup>6</sup>

Furthermore, other numeral modifiers besides *at most* can have authoritative construals. For example, (7), with *between three and seven*, has both a LB inference (the Speaker is not allowed to appoint fewer than three MPs, maybe because that one or those two MPs would hold too much power) and an UB inference (the Speaker is not allowed to appoint more than seven MPs, maybe because that would give, overall, too much power to too many MPs), as well as a FC inference (the Speaker is allowed to appoint any number of MPs in the range [3, 7]).

(7) The Speaker is allowed to appoint between three and seven MPs to exercise his powers to issue recess writs when he is out of the country.

What's more, we find cases where *at least* actually *does* give rise to a LB authoritative reading, e.g. when conjoined with *at most*. For instance, (8c) conveys that the guild may not have fewer than three members, nor more than 100, and that it may have any number of members in the range [3, 100].

- (8) a. You're allowed to nominate at least two and at most four authors this week!  
 b. Each bidder is allowed to bid for at least five lots and at most fifteen lots.  
 c. The guild may have at least three and at most 100 members.

Finally, we note the robust contrast in (9). In particular, while *at least* in (9a) cannot be construed authoritatively, in (9b) it can be: if you choose to write a paper, then you're not allowed to write fewer than three pages (LB inference), and you're allowed to write exactly three, four, ... pages (FC inference).

5. The examples in (5–8) come from Google and the Wikipedia corpus.

6. One potentially important difference between *at least/most* and *at the earliest/latest* is the presence of the definite determiner *the* in the latter. We're unsure exactly what role *the* plays here, but we observe that adding *the* to *at least* surprisingly improves sentences intended to be interpreted authoritatively: (*The rules state that*) *you're allowed to draw three cards at the least*, though not perfect, sounds much better to our ears than (3).

- (9) The syllabus states that ...
- # You're allowed to write at least three pages.
  - You're allowed to (either) give a presentation or (else) write at least three pages.

The LB authoritative uses of *at least* noted above are prima facie evidence against a decompositional account of the puzzle, i.e. an account that solves the puzzle by attributing a special property to *at most*.

Moreover, the availability of authoritative readings for both members of antonym pairs like *at the earliest* and *at the latest* casts doubt on a decompositional explanation of the asymmetry between *at least* and *at most*. For example, while it's possible to decompose *at the earliest* into something like 'not earlier than' and to decompose *at the latest* into something like 'not later than', doing so would undermine the explanation of the contrast between *at least* and *at most*: why not decompose *at least* into 'not fewer than'?<sup>7</sup>

Finally, extending the decompositional account to non-superlative expressions would require some rather ad hoc syntactic assumptions: *between three and seven* would need to decompose into something like 'not fewer than three and not more than seven'. It's unclear to us how such an approach would proceed, nor how conceptually appealing it would be.

Before concluding this section, it's important to establish that, just like for (1), an inverse-scope analysis of the above examples would not account for their authoritative readings. The reason is because, just like for *at most*, when *at the earliest*, *at the latest*, *between*, and *at least ... and at most* do not occur in the scope of an operator like *allow*, as in the examples in (10), ignorance readings obligatorily emerge, and consequently, an inverse-scope analysis would predict ignorance inferences across the board.<sup>8</sup>

7. To be more precise, the meaning of *ANT*, for Penka (2014), encodes the relation  $>$ :  $ANT\ d\ D$  ( $D$  a predicate of degrees) means  $\neg\exists d'. d' > d \wedge d' \in D$ . Presumably, this could be extended to *at the latest*, where  $>$  would refer not to the 'greater than' ordering over degrees, but to the 'later than' ordering over points (or intervals) of time:  $ANT\ t\ T$  ( $T$  a predicate of points of time) would mean  $\neg\exists t'. t' > t \wedge t' \in T$ . However, using *ANT* to decompose *at the earliest* wouldn't work; for that, one would need a different expression that involves the 'earlier than' relation,  $<$ . Call it  $ANT_{<}$ . The point now is that one would need a principled explanation why *at least* does not decompose into something involving  $ANT_{<}$ , which would lead to LB authoritative readings for sentences like (3). In other words, one would need to explain why *at least* is exceptional in this regard.

8. That *between* obligatorily implies ignorance (like superlative modifiers) is debatable. For instance, in his influential article on modified numerals, Nouwen (2010) classifies *at least* and *at most* as class B modifiers (they obligatorily imply ignorance when unembedded), but he classifies *between* (in contrast to *from ... to*) as class A. However, Nouwen does not devote any detailed discussion to *between*, and we think that it patterns a lot like superlative modifiers, e.g., when it comes to Nouwen's hexagon example:

(i) A hexagon has  $\left\{ \begin{array}{l} \text{more than three/fewer than eleven} \\ \text{\#at least four/at most ten} \\ \text{\#between four and ten} \end{array} \right\}$  sides.

Nevertheless, as Benjamin Spector points out to us, there may still be some truth to the notion that the potential ignorance inferences associated with *between* are more fragile than those associated with superlative modifiers. If so, then an inverse-scope analysis of examples like (7) might be possible after all. However, one would still need to account for the rest of our new observations. Instead, we hope to show that all the observations can be subsumed under a single account.

- (10) a. Bill arrived at the earliest (latest) at 8:00 AM.  
 b. The Speaker appointed between three and seven MPs to exercise his powers to issue recess writs when he is out of the country.  
 c. Cindy nominated at least two and at most four authors.

The take-home message is that it's not *at most* which is the oddity in this puzzle, nor is it *at least*, per se. Rather, it's more specifically *at least* in just some sentences, like (3), but not (8c) or (9b). We therefore want to try to analyze all the above cases uniformly, without proposing that *at most* or any other expression has any special (non-standard) morphosyntax.

### 3. Proposal

#### 3.1. Free-choice disjunction

Our starting point is to highlight some striking similarities between authoritative readings of *at most* in the scope of *allow* and FC readings of disjunction in the scope of *allow*.<sup>9</sup> Specifically, disjunction in the scope of an existential modal like *allow* licenses similar FC and 'bound' inferences. For example, in a context where the relevant desserts are cake, gelato, and pie, (11) licenses two inferences: (i) you're not allowed to have pie (a kind of 'bound' inference, in the sense that, as far as desserts go, you're bound to the set {cake, gelato}), and (ii) you're allowed to have cake, and you're allowed to have gelato (a FC inference) (von Wright, 1969; Kamp, 1973).<sup>10</sup> However, similar to what we saw for (1), a surface-scope analysis of (11) predicts a weak literal meaning, 'There is a permissible world in which you have cake or gelato' ( $\Diamond c \vee g$ ), from which neither a 'bound' inference ( $\neg \Diamond p$ ) nor a FC inference ( $\Diamond c \wedge \Diamond g$ ) logically follows.

- (11) You're allowed to have cake or gelato.

An influential account of FC disjunction is due to Fox (2007), who proposes that the meaning of (11) is a strengthened version of the weak surface-scope meaning  $\Diamond(c \vee g)$ . Strengthening is due to the presence of a grammatical device, *exh*, a covert analog of *only* that is responsible for scalar implicatures (Chierchia et al., 2012). What *exh*  $S$  means is that  $S$  is true and that each 'innocently excludable' member of  $\text{alt}(S)$  (the set of alternatives of  $S$ ) is false, where, intuitively, a proposition  $q \in \text{alt}(S)$  is innocently excludable (relative to  $\llbracket S \rrbracket$ ) just in case the negation of  $q$  doesn't contradict  $\llbracket S \rrbracket$  and also doesn't force any disjunction of members of  $\text{alt}(S)$  to be true (unless that disjunction is already entailed by  $\llbracket S \rrbracket$ ).<sup>11</sup>

- (12)  $\llbracket \text{exh } S \rrbracket = \llbracket \text{exh} \rrbracket(\text{alt}(S))(\llbracket S \rrbracket)$ ,  
 where  $\llbracket \text{exh} \rrbracket(A)(p) = p \wedge \bigwedge \{ \neg q : q \in \text{IE}(p, A) \}$ ,  
 and  $\text{IE}(p, A) = \bigcap \{ A' : A' \text{ is a maximal subset of } A \text{ s.t. } \{p\} \cup \{ \neg q : q \in A' \} \text{ is consistent} \}$

9. Comparing superlative modifiers with disjunction is by no means a novel idea. Büring's (2008) landmark paper established an exciting line of inquiry into how to analyze the ignorance inferences associated with *at least* and *at most* by building on well-understood accounts of the ignorance inferences associated with *or*. However, to our knowledge, no one has extended this line of inquiry to analyze authoritative construals of *allow* ... *at most* along the same lines as that of FC construals of *allow* ... *or*.

10. There is, potentially, a third inference, viz. that you're not allowed to have both cake and gelato ( $\neg \Diamond(c \wedge g)$ ). We ignore this exclusivity inference henceforth, as there is no detectable analog to it when it comes to modified numerals (it's logically impossible to, e.g., draw exactly two cards and exactly three cards).

11. We write ' $q$  is IE (relative to  $p$  and  $A$ )' to mean  $q \in \text{IE}(p, A)$ , and we omit 'relative to  $p$  and  $A$ ' when it's clear from context.

For example, suppose that  $\text{alt}(\text{John ate cake or gelato}) = \{c \vee g, c, g, c \wedge g\}$  (Sauerland, 2004; Fox, 2007). Then, relative to  $c \vee g$ , neither  $c$  nor  $g$  is IE: negating  $c$  would force  $g$  to be true, and conversely, negating  $g$  would force  $c$  to be true. (While it's consistent with  $c \vee g$  to negate  $c$  or to negate  $g$ , the intuition is that we can't arbitrarily pick which of  $c$  or  $g$  to negate; thus, we don't negate either one.) However,  $c \wedge g$  is IE, and so  $\llbracket \text{exh} [\text{John ate cake or gelato}] \rrbracket = (c \vee g) \wedge \neg(c \wedge g)$ , i.e. the proposition that John ate cake or gelato but not both, which corresponds to the exclusive interpretation of ordinary disjunction.

Crucially, recursive application of *exh* is predicted to be possible. In a simple case like above, additional applications are vacuous, but when disjunction occurs in the scope of *allow*, recursive exhaustification is not vacuous and in fact delivers precisely the attested FC reading. To see this, consider the LF in (13). Let's start with the constituent *exh S*, and assume that  $\text{alt}(S) = \{\Diamond(c \vee g), \Diamond c, \Diamond g, \Diamond p\}$ .<sup>12</sup> Then, relative to  $\llbracket S \rrbracket$  and  $\text{alt}(S)$ , we see that  $\Diamond p$  is IE, but neither  $\Diamond c$  nor  $\Diamond g$  is IE: negating  $\Diamond c$  would force  $\Diamond g$  to be true, and vice versa. Thus,  $\llbracket \text{exh } S \rrbracket = \Diamond(c \vee g) \wedge \neg \Diamond p$ , the proposition that there is a permissible world in which you have cake or gelato, and no permissible world in which you have pie. Thus, the inner *exh* immediately derives the 'bound' inference (pie is not allowed), but not the FC inferences.

(13)  $\text{exh} [\text{exh} [{}_S \text{ allowed} [\text{you have cake or gelato}]]]$

Let's move now from *exh S* to the entire sentence, *exh exh S*. Assume, along with Fox (2007), that  $\text{alt}(\text{exh } S)$  is the set of strengthened alternatives to *S*.

(14)  $\text{alt}(\text{exh } S) = \{\llbracket \text{exh} \rrbracket (\text{alt}(S))(p) : p \in \text{alt}(S)\}$

Computing  $\text{alt}(\text{exh } S)$  requires computing  $\llbracket \text{exh} \rrbracket (\text{alt}(S))(p)$  for each  $p \in \text{alt}(S)$ . This is given below.

$$(15) \quad \text{alt}(\text{exh } S) = \left\{ \begin{array}{l} \llbracket \text{exh} \rrbracket (\text{alt}(S))(\Diamond(c \vee g)), \\ \llbracket \text{exh} \rrbracket (\text{alt}(S))(\Diamond c), \\ \llbracket \text{exh} \rrbracket (\text{alt}(S))(\Diamond g), \\ \llbracket \text{exh} \rrbracket (\text{alt}(S))(\Diamond p) \end{array} \right\} = \left\{ \begin{array}{l} \Diamond(c \vee g) \wedge \neg \Diamond p, \\ \Diamond c \wedge \neg \Diamond g \wedge \neg \Diamond p, \\ \Diamond g \wedge \neg \Diamond c \wedge \neg \Diamond p, \\ \Diamond p \wedge \neg \Diamond c \wedge \neg \Diamond g \end{array} \right\}$$

Having computed  $\text{alt}(\text{exh } S)$ , we are now in a position to compute  $\llbracket \text{exh} \rrbracket (\text{alt}(\text{exh } S))(\llbracket \text{exh } S \rrbracket)$ , i.e.  $\llbracket \text{exh} [\text{exh } S] \rrbracket$ . It's the conjunction of  $\llbracket \text{exh } S \rrbracket$  (computed above as  $\Diamond(c \vee g) \wedge \neg \Diamond p$ ) and the negation of all innocently excludable alternatives of *exh S*, i.e. the negation of the members of some subset of (15). Which subset? The answer is  $\text{alt}(\text{exh } S) - \{\llbracket \text{exh } S \rrbracket\}$ , i.e. every proposition except the strengthened meaning of *S* is IE. Thus, the overall meaning is  $\llbracket \text{exh } S \rrbracket$  conjoined with the negation of each of these alternatives. We give the negations of all the propositions in (15) below, but for clarity's sake, we write them as material implications.<sup>13</sup>

12. We could also include the alternative  $\Diamond(c \wedge g)$ , which would turn out to be IE, and its negation would deliver the exclusivity inference mentioned in fn. 10.

13. This is licit because  $\neg(p \wedge \neg q \wedge \neg r) \equiv p \rightarrow (q \vee r)$ .

- (16) a.  $\Diamond(c \vee g) \rightarrow \Diamond p$  (contradicts  $\llbracket \text{exh } S \rrbracket$ )  
 b.  $\Diamond c \rightarrow (\Diamond g \vee \Diamond p)$   
 c.  $\Diamond g \rightarrow (\Diamond c \vee \Diamond p)$   
 d.  $\Diamond p \rightarrow (\Diamond c \vee \Diamond g)$  (already entailed by  $\llbracket \text{exh } S \rrbracket$ )

Putting all the pieces together, the meaning of *exh exh S* is  $\Diamond(c \vee g) \wedge \neg \Diamond p$  (the strengthened meaning of *S*, i.e.  $\llbracket \text{exh } S \rrbracket$ ), plus the conjunction of the material implications  $\Diamond c \rightarrow (\Diamond g \vee \Diamond p)$  and  $\Diamond g \rightarrow (\Diamond c \vee \Diamond p)$ . Some reflection reveals that these implications, together with  $\llbracket \text{exh } S \rrbracket$ , are equivalent to  $\Diamond c$  and  $\Diamond g$ .<sup>14</sup> Thus, the overall meaning derived is the following, which is precisely the reading we wanted to derive.

$$\begin{aligned}
 (17) \quad & \llbracket \text{exh} [\text{exh} [_S \text{ allowed} [\text{you have cake or gelato}]]] \rrbracket \\
 &= \underbrace{\underbrace{\underbrace{\Diamond(c \vee g)}_{\text{weak meaning}} \wedge \underbrace{\neg \Diamond p}_{\text{'bound'}}}_{\text{strengthened meaning}} \wedge \underbrace{\Diamond c \wedge \Diamond g}_{\text{FC}}}_{\text{recursively strengthened meaning}} \quad (\equiv \Diamond c \wedge \Diamond g \wedge \neg \Diamond p)
 \end{aligned}$$

**Our proposal in a nutshell.** Given the inferential (and syntactic) similarity between (1) (*You're allowed to draw at most three cards*) and (11) (*You're allowed to have cake or gelato*), our goal is to provide a surface-scope analysis of (1), whereby its weak meaning is recursively strengthened as we just saw for FC disjunction. More precisely, we propose that (1) is parsed with two applications of *exh*, which results in an authoritative reading, as schematized in (18).

$$\begin{aligned}
 (18) \quad & \llbracket \text{exh} [\text{exh} [_S \text{ allowed} [\text{you draw at most three cards}]]] \rrbracket \\
 &= \underbrace{\underbrace{\underbrace{\Diamond[\leq 3]}_{\text{weak meaning}} \wedge \underbrace{\neg \Diamond[\geq 4]}_{\text{UB}}}_{\text{strengthened meaning}} \wedge \underbrace{\Diamond[= 3] \wedge \Diamond[= 2] \wedge \dots}_{\text{FC}}}_{\text{recursively strengthened meaning}}
 \end{aligned}$$

The clear similarities between (17) and (18) may give the impression that a solution to (the first half of) the puzzle is straightforward. However, as we hope to show, although there is a solution in sight, it ultimately requires a conservative, but non-trivial amendment to the theory of exhaustification. We therefore proceed in three steps: first, we present what seems like a straightforward account and show the problem it faces; second, we propose an ad hoc amendment that fixes the problem; finally, we show that our amendment can be generalized in a non-stipulative way.

$$\begin{aligned}
 14. \text{ More precisely: } & \Diamond(c \vee g) \wedge \neg \Diamond p \wedge (\Diamond c \rightarrow (\Diamond g \vee \Diamond p)) \wedge (\Diamond g \rightarrow (\Diamond c \vee \Diamond p)) \\
 & \equiv (\Diamond c \vee \Diamond g) \wedge \neg \Diamond p \wedge (\Diamond c \rightarrow (\Diamond g \vee \Diamond p)) \wedge (\Diamond g \rightarrow (\Diamond c \vee \Diamond p)) \\
 & \equiv (\Diamond c \vee \Diamond g) \wedge \neg \Diamond p \wedge (\Diamond c \rightarrow \Diamond g) \wedge (\Diamond g \rightarrow \Diamond c) \\
 & \equiv (\Diamond c \vee \Diamond g) \wedge \neg \Diamond p \wedge \Diamond c \wedge \Diamond g \\
 & \equiv \Diamond c \wedge \Diamond g \wedge \neg \Diamond p
 \end{aligned}$$

### 3.2. *At most*: first attempt

To achieve our goal, it's necessary (and sufficient) to show that the sets of alternatives  $\text{alt}(S)$  and  $\text{alt}(\text{exh } S)$  derived by standard means (e.g. [Katzir, 2007](#); [Fox and Katzir, 2011](#)) deliver the right results. Demonstrating this is difficult because of the space of possible alternative sets; however, we believe that the following characterization is plausible:  $\text{alt}(S)$  is the set of propositions obtained by replacing *at most* with *fewer than*, *exactly*, *at least* or *more than*, plus those obtained by replacing *three* with any numeral, plus those obtained by doing both replacements simultaneously. Thus, we assume the following equality.<sup>15</sup>

$$(19) \quad \text{alt}(S) = \begin{array}{l} \{\diamond[<n] : n \in \mathbb{N}_0\} \\ \cup \{\diamond[\leq n] : n \in \mathbb{N}_0\} \\ \cup \{\diamond[=n] : n \in \mathbb{N}_0\} \\ \cup \{\diamond[\geq n] : n \in \mathbb{N}_0\} \\ \cup \{\diamond[>n] : n \in \mathbb{N}_0\} \end{array} = \begin{array}{l} \{\diamond[\leq n] : n \in \mathbb{N}_0\} \\ \cup \{\diamond[=n] : n \in \mathbb{N}_0\} \\ \cup \{\diamond[\geq n] : n \in \mathbb{N}_0\} \end{array}$$

The first step is to compute  $\llbracket \text{exh } S \rrbracket = \llbracket \text{exh} \rrbracket(\text{alt}(S))(\llbracket S \rrbracket)$ . All alternatives of the form  $\diamond[=n]$  and  $\diamond[\geq n]$ , for  $n \geq 4$ , are IE. As a result, we negate all such alternatives, which immediately derives our UB. Moreover, alternatives that ‘overlap’ with (are compatible with)  $\diamond[\leq 3]$ , e.g.  $\diamond[\geq 1]$ ,  $\diamond[\leq 2]$ , and  $\diamond[=2]$ , are not IE; for instance, negating  $\diamond[=2]$  would entail the disjunction  $\diamond[=0] \vee \diamond[=1] \vee \diamond[=3]$ . So the first round of exhaustification delivers the following result.

$$(20) \quad \llbracket \text{exh} \rrbracket(\text{alt}(S))(\diamond[\leq 3]) = \diamond[\leq 3] \wedge \neg \diamond[=4] \wedge \neg \diamond[\geq 4] \wedge \neg \diamond[=5] \wedge \neg \diamond[\geq 5] \wedge \dots$$

$$\equiv \underbrace{\underbrace{\diamond[\leq 3]}_{\text{weak meaning}} \wedge \underbrace{\neg \diamond[\geq 4]}_{\text{UB}}}_{\text{strengthened meaning}}$$

Turning now to the recursive layer of exhaustification, let's continue to assume, with [Fox \(2007\)](#), that  $\text{alt}(\text{exh } S)$  is the set of strengthened alternatives to  $S$ , repeated below from (14).

$$(14) \quad \text{alt}(\text{exh } S) = \{\llbracket \text{exh} \rrbracket(\text{alt}(S))(p) : p \in \text{alt}(S)\}$$

The hope is that we now derive the desired FC inferences:  $\wedge\{\diamond[=n] : n \in \mathbb{N}_0 \cap [0, 3]\}$ . However, it turns out that the FC we derive is too weak. To see why, we first need to compute  $\text{alt}(\text{exh } S)$ .

$$(21) \quad \text{alt}(\text{exh } S) = \begin{array}{l} \{\llbracket \text{exh} \rrbracket(\text{alt}(S))(\diamond[=n]) : n \in \mathbb{N}_0\} \\ \cup \{\llbracket \text{exh} \rrbracket(\text{alt}(S))(\diamond[\leq n]) : n \in \mathbb{N}_0\} \\ \cup \{\llbracket \text{exh} \rrbracket(\text{alt}(S))(\diamond[\geq n]) : n \in \mathbb{N}_0\} \end{array} = \begin{array}{l} \{\diamond[=n] \wedge \neg \diamond[<n] \wedge \neg \diamond[>n] : n \in \mathbb{N}_0\} \\ \cup \{\diamond[\leq n] \wedge \neg \diamond[>n] : n \in \mathbb{N}_0\} \\ \cup \{\diamond[\geq n] \wedge \neg \diamond[<n] : n \in \mathbb{N}_0\} \end{array}$$

Next, we must determine which members of  $\text{alt}(\text{exh } S)$  are IE relative to  $\llbracket \text{exh } S \rrbracket = \diamond[\leq 3] \wedge \neg \diamond[\geq 4]$ . As before, we list all the negations as material implications.

15. We assume here that the equivalences  $\diamond[<n] \equiv \diamond[\leq (n-1)]$  and  $\diamond[>n] \equiv \diamond[\geq (n+1)]$  hold, i.e. that the relevant scale of numbers operative in (1) is the natural numbers. However, we believe that assuming a dense scale, as proposed by [Fox and Hackl \(2006\)](#), would not alter our main results.

- (22) a.  $\{\diamond[=n] \rightarrow (\diamond[<n] \vee \diamond[>n]) : n \in \mathbb{N}_0\}$   
 b.  $\{\diamond[\leq n] \rightarrow \diamond[>n] : n \in \mathbb{N}_0\}$  (contradicts  $\llbracket \text{exh } S \rrbracket$  when  $n \geq 3$ )  
 c.  $\{\diamond[\geq n] \rightarrow \diamond[<n] : n \in \mathbb{N}_0\}$  (contradictory when  $n = 0$ )

We see that all the strengthened *exactly*  $n$  alternatives are IE, all the strengthened *at most*  $n$  alternatives for  $n < 3$  are IE (but not for  $n \geq 3$ ), and all the strengthened *at least*  $n$  alternatives for  $n > 0$  are IE (but for  $n \geq 4$ ,  $\llbracket \text{exh } S \rrbracket$  already entails their negation). Putting all the pieces together, the meaning of *exh exh S* is  $\diamond[\leq 3] \wedge \neg \diamond[\geq 4]$  (the strengthened meaning of  $S$ , i.e.  $\llbracket \text{exh } S \rrbracket$ ), plus the conjunction of the material implications below.

- (23) a.  $\{\diamond[=n] \rightarrow (\diamond[<n] \vee \diamond[>n]) : n \in \mathbb{N}_0\}$   
 b.  $\{\diamond[\leq n] \rightarrow \diamond[>n] : n \in \mathbb{N}_0 \cap [0, 2]\}$   
 c.  $\{\diamond[\geq n] \rightarrow \diamond[<n] : n \in \mathbb{N}_0 \cap [1, \infty)\}$

Some reflection reveals that these inferences, together with  $\diamond[\leq 3] \wedge \neg \diamond[\geq 4]$ , are equivalent to  $\diamond[=0]$  and  $\diamond[=3]$ . In other words, the FC inference we derive for (1) is that you're allowed to draw 0 cards and you're allowed to draw exactly 3 cards, which is weaker than what we were hoping to derive: we're missing the inferences  $\diamond[=1]$  and  $\diamond[=2]$ . We take it that this result is incorrect.<sup>16</sup>

### 3.3. *At most*: second attempt

Intuitively, the problem we just encountered is that the members of  $\text{alt}(\text{exh } S)$  are too strong, hence their negation results in inferences that are too weak. What we need is for  $\text{alt}(\text{exh } S)$  to include weaker alternatives, whose exclusion will result in stronger inferences, namely total FC.<sup>17</sup> Our idea is that the set of alternatives for the second *exh* includes not just all strengthened propositions taken from  $\text{alt}(S)$ ; rather, it includes all strengthened alternatives taken from the disjunctive closure of  $\text{alt}(S)$ , notated as  $\text{alt}(S)^\vee$ . (For now, this is just a stipulation; in the next subsection, show that if we assume that sets of alternatives are always closed under disjunction, we retain our main result for recursive exhaustification without disrupting cases of non-recursive exhaustification.)

$$(24) \quad \text{alt}(\text{exh } S) = \{\llbracket \text{exh } S \rrbracket(\text{alt}(S))(p) : p \in \text{alt}(S)^\vee\} \quad (\text{cf. (14)})$$

By allowing  $p$  in (24) to range over propositions taken from the disjunctive closure of  $\text{alt}(S)$ , we introduce weaker alternatives into  $\text{alt}(\text{exh } S)$ , whose exclusion turns out to derive total FC. To see this, let  $p = \diamond[=0] \vee \diamond[=1] \vee \diamond[=3]$ .  $p$  is not in  $\text{alt}(S)$ , but it is in  $\text{alt}(S)^\vee$ .  $\llbracket \text{exh } S \rrbracket(\text{alt}(S))(p)$ , which is now in  $\text{alt}(\text{exh } S)$ , is equal to  $p \wedge \neg \diamond[=2] \wedge \neg \diamond[\geq 4]$ . This strengthened alternative is

16. What we derive is a kind of partial FC, which is stronger than the partial FC that Penka (2014) derives (cf. fn. 2), and weaker than the total FC that we want to derive. In the oral talk version of this material, we assumed for simplicity that only the *exactly* alternatives were active, and we showed that this derives an even weaker FC inference than what we derive here: namely, that there are (at least) two distinct numbers  $m$  and  $n$  in  $[0, 3]$  such that  $\diamond[=m]$  and  $\diamond[=n]$ . Again, we take this result to be incorrect.

17. This method is not a guaranteed recipe for deriving stronger inferences overall: the addition of weaker alternatives could instead introduce new symmetries (in the sense of Fox (2007)), which would result in fewer inferences overall. (Thanks to Emmanuel Chemla for stressing this point to us.) However, our amendment turns out not to do this, but instead has the desired effect.

IE relative to  $\text{alt}(\text{exh } S)$  and  $\llbracket \text{exh } S \rrbracket$ . Its negation, which is equivalent to  $p \rightarrow (\Diamond[= 2] \vee \Diamond[\geq 4])$ , and  $\llbracket \text{exh } S \rrbracket$ , which is  $\Diamond[\leq 3] \wedge \neg \Diamond[\geq 4]$ , jointly entail  $\Diamond[= 2]$ . Extrapolating from this example, we see that we derive  $\Diamond[= n]$  for every  $n \in \mathbb{N}_0 \cap [0, 3]$ , just as desired.

Thus, the overall meaning derived for (1) is:

$$\begin{aligned}
 (25) \quad & \llbracket \text{exh} \rrbracket \left( \text{alt}(\text{exh } S) \right) \left( \llbracket \text{exh} \rrbracket \left( \text{alt}(S) \right) \left( \llbracket S \rrbracket \right) \right) \\
 &= \underbrace{\underbrace{\Diamond[\leq 3]}_{\text{weak meaning}} \wedge \underbrace{\neg \Diamond[\geq 4]}_{\text{UB}}}_{\text{strengthened meaning}} \wedge \underbrace{\underbrace{\Diamond[= 3] \wedge \Diamond[= 2] \wedge \Diamond[= 1] \wedge \Diamond[= 0]}_{\text{FC}}}_{\text{recursively strengthened meaning}}
 \end{aligned}$$

### 3.4. Generalizing the amendment

Instead of stipulating something special about how  $\text{alt}(\text{exh } S)$  is computed, we now show that our amendment can be generalized in a simple way: for *any* sentence  $S$ , we take  $\text{alt}(S)$  to be closed under disjunction. Formally, if  $\text{alt}'(S)$  is the set of usual alternatives of  $S$ , e.g. those derived by the algorithm proposed by Fox and Katzir (2011), then  $\text{alt}(S) = \text{alt}'(S)^\vee$ . The meaning of *exh* is the same as before, as given in (12), and in particular still refers to  $\text{alt}(S)$ ; it's just that  $\text{alt}(S)$  has been updated to be closed under disjunction.

Importantly, for a non-recursive occurrence of *exh*, this amendment makes no difference, in the sense that we don't derive stronger inferences than before. For instance, assume, for some sentence  $S$ , that  $\text{alt}'(S)$  includes  $p$  and  $q$  but not  $p \vee q$ . Exhaustifying  $S$  now involves potentially excluding  $p \vee q$ , since this proposition is in  $\text{alt}(S)$ . However, excluding  $p \vee q$  is possible ( $p \vee q$  is IE) if and only if excluding both  $p$  and  $q$  is possible ( $p$  and  $q$  are both IE). And in turn, excluding  $p \vee q$  is logically equivalent to excluding both  $p$  and  $q$ . Thus, we don't gain anything at this level: either  $p$  and  $q$  are both IE, in which case so is  $p \vee q$ , and negating the former is equivalent to negating the latter; or  $p$  and  $q$  are not both IE, in which case  $p \vee q$  is not IE, and not negating both  $p$  and  $q$  is equivalent to not negating  $p \vee q$ . (See also Spector (2017).)

The effect only surfaces for recursive *exh*, and here's why. The overall meaning is of *exh exh S* is:

$$(26) \quad \llbracket \text{exh} \rrbracket \left( \text{alt}(\text{exh } S) \right) \left( \llbracket \text{exh} \rrbracket \left( \text{alt}(S) \right) \left( \llbracket S \rrbracket \right) \right)$$

Again following Fox (2007),  $\text{alt}(\text{exh } S)$  is the set of strengthened alternatives of  $S$ ,<sup>18</sup> but now we get something different from before our pre-amendment set in (14). What we get is precisely what we stipulated earlier, in (24), except now we derive it as a consequence of closing *all* alternative sets under disjunction.

18. Whether this set, too, is closed under disjunction doesn't matter: closing it under disjunction doesn't result in any additional inferences, for the same reason that closing the usual alternative set under disjunction for non-recursive exhaustification doesn't matter. (At least, this is true for double exhaustification. It could, in principle, matter for triple exhaustification, i.e. for a sentence of the form *exh exh exh S*, but we don't pursue this line of inquiry here.)

$$\begin{aligned}
(27) \quad \text{alt}(\text{exh } S) &= \{ \llbracket \text{exh} \rrbracket (\text{alt}(S))(p) : p \in \text{alt}(S) \} \\
&= \{ \llbracket \text{exh} \rrbracket (\text{alt}'(S)^\vee)(p) : p \in \text{alt}'(S)^\vee \} \\
&= \{ \llbracket \text{exh} \rrbracket (\text{alt}'(S))(p) : p \in \text{alt}'(S)^\vee \} \\
&= (24)
\end{aligned}$$

Finally, we note that closing the alternative set under disjunction allows us to assume that for (1),  $\text{alt}'$  delivers just the *exactly* alternatives, and this is because any *at least* or *at most* alternative can be written as a disjunction of *exactly* alternatives.

$$(28) \quad \text{alt}(S) = \left( \begin{array}{c} \{ \diamond[\leq n] : n \in \mathbb{N}_0 \} \\ \cup \{ \diamond[= n] : n \in \mathbb{N}_0 \} \\ \cup \{ \diamond[\geq n] : n \in \mathbb{N}_0 \} \end{array} \right)^\vee = \{ \diamond[= n] : n \in \mathbb{N}_0 \}^\vee$$

We don't claim this is in fact what  $\text{alt}'$  does, but making this assumption will simplify discussion of other examples in §4.2.

## 4. Discussion

### 4.1. Free-choice disjunction revisited

Importantly, our amendment doesn't disrupt the analysis of FC disjunction like (11) (*You're allowed to have cake or gelato*). The reason is because, in this case, closing the alternative set under disjunction doesn't add any new IE alternatives. For example, if, as we assumed earlier,  $\text{alt}'(S) = \{ \diamond(c \vee g), \diamond c, \diamond g, \diamond p \}$ , then  $\text{alt}(S)$  is as follows, where the underlined alternatives are those that we gain (relative to before) by closing the set of alternatives under disjunction:<sup>19</sup>

$$(29) \quad \text{alt}(S) = \left\{ \begin{array}{c} \diamond c, \quad \diamond g, \quad \diamond p, \\ \quad \quad \quad \underline{\diamond(c \vee g)} \end{array} \right\}^\vee = \left\{ \begin{array}{c} \diamond c, \quad \diamond g, \quad \diamond p \\ \underline{\diamond(c \vee g)}, \quad \underline{\diamond(c \vee p)}, \quad \underline{\diamond(g \vee p)} \\ \quad \quad \quad \underline{\diamond(c \vee g \vee p)} \end{array} \right\}$$

For the first round of exhaustification, none of the three new alternatives are IE, and so  $\llbracket \text{exh } S \rrbracket$  is still  $\diamond(c \vee g) \wedge \neg \diamond p$ . For the second round, we compute  $\text{alt}(\text{exh } S)$ .

$$(30) \quad \text{alt}(\text{exh } S) = \left\{ \begin{array}{c} \llbracket \text{exh} \rrbracket (\text{alt}(S))(\diamond c), \\ \llbracket \text{exh} \rrbracket (\text{alt}(S))(\diamond g), \\ \llbracket \text{exh} \rrbracket (\text{alt}(S))(\diamond p), \\ \llbracket \text{exh} \rrbracket (\text{alt}(S))(\underline{\diamond(c \vee g)}), \\ \llbracket \text{exh} \rrbracket (\text{alt}(S))(\underline{\diamond(c \vee p)}), \\ \llbracket \text{exh} \rrbracket (\text{alt}(S))(\underline{\diamond(g \vee p)}), \\ \llbracket \text{exh} \rrbracket (\text{alt}(S))(\underline{\diamond(c \vee g \vee p)}) \end{array} \right\} = \left\{ \begin{array}{c} \diamond c \wedge \neg \diamond g \wedge \neg \diamond p, \\ \diamond g \wedge \neg \diamond c \wedge \neg \diamond p, \\ \diamond p \wedge \neg \diamond c \wedge \neg \diamond g, \\ \underline{\diamond(c \vee g) \wedge \neg \diamond p}, \\ \underline{\diamond(c \vee p) \wedge \neg \diamond g}, \\ \underline{\diamond(g \vee p) \wedge \neg \diamond g}, \\ \underline{\diamond(c \vee g \vee p)} \end{array} \right\}$$

The negations of all the members of  $\text{alt}(\text{exh } S)$  are provided below. As before, we write the negations of all the conjunctive alternatives as material implications.

19. Note that for any two propositions  $p$  and  $q$ ,  $\diamond p \vee \diamond q \equiv \diamond(p \vee q)$ . We use the latter form in the following set.

- (31) a.  $\Diamond c \rightarrow (\Diamond g \vee \Diamond p)$   
 b.  $\Diamond g \rightarrow (\Diamond c \vee \Diamond p)$   
 c.  $\Diamond p \rightarrow (\Diamond c \vee \Diamond g)$  (already entailed by  $\llbracket \text{exh } S \rrbracket$ )  
 d.  $\Diamond(c \vee g) \rightarrow \Diamond p$  (contradicts  $\llbracket \text{exh } S \rrbracket$ )  
 e.  $\frac{\Diamond(c \vee p) \rightarrow \Diamond g}{\Diamond(g \vee p) \rightarrow \Diamond c}$   
 f.  $\frac{\Diamond(g \vee p) \rightarrow \Diamond c}{\neg \Diamond(c \vee g \vee p)}$  (contradicts  $\llbracket \text{exh } S \rrbracket$ )  
 g.  $\neg \Diamond(c \vee g \vee p)$

Previously, we saw that (a–b), together with  $\llbracket \text{exh } S \rrbracket$ , amount to the FC inferences  $\Diamond c$  and  $\Diamond g$ . Now, in addition to those, there are three potential new inferences, (e–g); however, (e) and (f), together with  $\llbracket \text{exh } S \rrbracket$ , again amount to  $\Diamond c$  and  $\Diamond g$ , and (g) contradicts  $\llbracket \text{exh } S \rrbracket$ . Overall, then, no new inferences are derived relative to what we derived earlier.

#### 4.2. New observations revisited

Our account extends naturally to all the new data introduced in §2. We just have to assume that the relevant *exactly* alternatives are available. (Other alternatives may also be available, but recall that, since we take the set of alternatives to be closed under disjunction, the *exactly* alternatives already generate the complete set that we’re interested in; therefore, we ignore those alternatives in what follows.)

For example, the alternative set of (6) (*Deductions may occur at the latest at the time of submission*) must include the (meanings of) alternatives of the form *Deductions may occur at (exactly) t*, for some  $t$  in the set of points of time  $T$ .

$$(32) \quad \text{alt}(6) = \{\Diamond[=t] : t \in T\}^\vee$$

This set is exactly the same as what we assumed for the alternative set of (1), except now we have points of time  $t$  instead of natural numbers  $n$ , and so it’s no surprise that the results here will be the same. In particular, the first round of exhaustifying the meaning of (6) ( $\Diamond[\leq \text{time.of.submission}]$ ) will exclude all *exactly* alternatives involving times later than the time of submission, since those alternatives are all IE, while the second (recursive) round will derive FC inferences regarding all *exactly* alternatives involving times equal to or earlier than the time of submission.

Similarly, let’s assume the exact same set of alternatives for (5) (*The catering premises may open at the earliest at 5:00 AM*). Then, in a completely parallel way, the first round of exhaustifying the meaning of (5) ( $\Diamond[\geq 5:00 \text{ AM}]$ ) will exclude all *exactly* alternatives involving times earlier than 5:00 AM, since those alternatives are all IE, while the second (recursive) round will derive FC inferences regarding all *exactly* alternatives involving times equal to or later than 5:00 AM.

Finally, we turn to (7) (*The Speaker is allowed to appoint between three and seven MPs*), and assume the set of alternatives below. The first round of exhaustifying the meaning of (7) ( $\Diamond[3, \dots, 7]$ ) will exclude all *exactly* alternatives involving numbers less than 3 or more than 7, since those alternatives are all IE (this derives both a LB and an UB), while the second (recursive) round will derive FC inferences regarding all *exactly* alternatives involving numbers in the range  $[3, 7]$ .

$$(33) \quad \text{alt}(7) = \{\diamond [= n] : n \in \mathbb{N}_0\}^\vee$$

Examples like (8c) (*The guild may have at least three and at most 100 members*) can be analyzed in the same way.

#### 4.3. Open problem

The reader has by now probably noticed that our account also predicts a LB authoritative reading for sentences like (3) (*You're allowed to draw at least three cards*). The reason why we derive such a reading is essentially the same as the reason why we derive the attested reading of (5) (*The catering premises may open at the earliest at 5:00 AM*): recursive exhaustification excludes *exactly* alternatives with numbers below 3, and derives FC regarding all *exactly* alternatives with numbers greater than or equal to 3.

This prediction is only partially correct. Recall the contrast in (9), repeated below.

- (9) The syllabus states that ...
- a. #You're allowed to write at least three pages.
  - b. You're allowed to (either) give a presentation or (else) write at least three pages.

Unfortunately, we still have no explanation for this contrast, or more generally why *at least* only sometimes has a LB authoritative reading.

A tempting explanation for why (3) has no LB authoritative reading is that it's somehow 'blocked' by the more natural, straightforward, and seemingly equivalent sentence with *required*, given in (34). One rationale would be that, all else being equal, it's more economical to use *require* than to use *allow* with recursive exhaustification.

- (34) You're required to draw at least three cards.

However, we're doubtful whether a coherent and convincing story along these lines can be told, and here's why: (3) (on what would be its LB authoritative reading) and (34) are not completely equivalent. Given the infelicity of using (3) authoritatively, this non-equivalence is hard to detect, but we can observe a clear contrast when we move to *between*. Specifically, (35a), on its authoritative reading, says nothing about whether the speaker is required to appoint any MPs at all; in fact, it seems to imply that not appointing any MPs at all is a possibility (it's just that, if the Speaker decides to appoint some number of MPs, that number must fall in the range [3, 7]). By contrast, (35b) clearly excludes the possibility of not appointing any MPs.

- (35) a. The speaker is allowed to appoint between three and seven MPs.  
 b. The speaker is required to appoint between three and seven MPs.

We can highlight the contrast even further with the minimally different pair of examples in (36). In particular, if one of the laws of Absurdistan is (36a), then presumably you won't be breaking the law if you have no children; it's just that, if you have children, then the number of children you have must not exceed three. By contrast, if the law is (36b), then anyone (of child-bearing age, etc.) without children is a criminal.

- (36) a. In Absurdistan, you're allowed to have between one and three children.  
 b. In Absurdistan, you're required to have between one and three children.

The point here is that a sentence of the form *allow* ...  $[m, n]$ , on its authoritative reading, is not in general equivalent to *required* ...  $[m, n]$  (on its strengthened, FC reading): specifically, for  $m > 0$ , the *allow* sentence says nothing about the 'zero' case, whereas the *required* sentence explicitly excludes it, as the *between* examples above illustrate. Moreover, for  $m = 0$ , judgments are clear that the resulting *allow* and *require* sentences are not only both felicitous, but also equivalent to one another, which is unexpected under a blocking account.<sup>20</sup>

- (37) a. In Absurdistan, you're allowed to have between zero and three children. ✓  
 $\Leftrightarrow$   
 b. In Absurdistan, you're required to have between zero and three children. ✓
- (38) a. Abstracts may be at most three pages long. ✓  
 $\Leftrightarrow$   
 b. Abstracts must be at most three pages long. ✓

Thus, a blocking account of the infelicity of an authoritative use of (3) that relies on semantic equivalence between the blocking sentence, (34), and the blocked sentence, (3), cannot be right, for two reasons: (3) and (34) are not actually equivalent, and cases of actual equivalence, e.g. (37a) and (37b), and (38a) and (38b), do not in fact give rise to blocking effects.<sup>21</sup>

#### 4.4. Concluding remarks

We showed that authoritative readings of sentences like (1), (7), and many others can be accounted for by assuming that their weak, surface-scope meanings are recursively strengthened in the same way that weak meanings of disjunctive permission sentences like (11) are. We conclude by addressing an important question raised by our analysis.

We assumed that FC inferences are total, not partial (cf. fn. 2), and our amended system of recursive exhaustification delivers exactly this. However, there are clear cases where FC is not total. For example, (39) is a perfectly coherent two-sentence discourse, but a blind application of our proposal predicts it to be contradictory: the second sentence should entail, e.g., that you're allowed to draw exactly five cards, which contradicts the first sentence.

20. Parallel observations arise even for FC disjunction. For instance, compare (11) (*You're allowed to have cake or gelato*), which of course does not entail that you must have a dessert, and *You're required to have cake or gelato*, which does. In addition, *You're allowed to have cake or gelato or neither* and *You're required to have cake or gelato or neither* are both intuitively equivalent, but the *require* sentence does not block the *allow* sentence.

21. Because we assume that *exactly*  $n$  alternatives include *exactly* 0 alternatives ( $n$  ranges over the set  $\mathbb{N}_0$ , which includes 0), our account *does* exclude the 'zero' cases for sentences like (7). However, this issue can be resolved simply by assuming that a numeral like *three* cannot be replaced by *zero*, an assumption that doesn't seem too far-fetched, given the odd nature of *zero* compared to all other numerals. Note that taking this route would then mean that the authoritative reading of (1), with *at most*, does not actually entail the possibility of drawing zero cards, but is nonetheless compatible with such a state of affairs. We think that this result is adequate and that the inference that drawing zero cards is possible (to the extent that it's available) is either a contextual entailment or an implicature.

- (39) You're required to draw an even number of cards. You're allowed to draw at most ten cards.

We think that our account is compatible with such observations, once we acknowledge that relevance considerations can restrict what counts as an alternative (Fox and Katzir, 2011), and/or that alternatives may, under certain conditions, be 'pruned' (Crnič et al., 2015). In this particular case, one effect of the first sentence is to rule out *exactly*  $n$  alternatives where  $n$  is odd.

However, as intuitive as this resolution may appear, it must be constrained in certain ways. For example, FC regarding the numeral mentioned in the sentence seems to always be available, which suggests that the corresponding *exactly* alternative must always be active. Witness the oddity of the two-sentence discourse in (40): the second sentence implies that you're allowed to draw exactly nine cards, which contradicts the first sentence.

- (40) #You're required to draw an even number of cards. You're allowed to draw at most nine cards.

An obvious line to pursue is to say that if a numeral  $n$  is mentioned, then the *exactly*  $n$  alternative is relevant and cannot be pruned. Independent support for this approach comes from FC disjunction: each disjunct, because it's explicitly mentioned, must be a possibility, as the oddity of the following discourse illustrates.<sup>22</sup>

- (41) #You're required to eat only green vegetables (non-green vegetables are not allowed). You're allowed to eat broccoli, spinach, or red cabbage.

22. An important caveat: the parallelism drawn here is not perfect. In the case of FC disjunction, the non-prunable (obligatorily relevant) alternative is derived by replacing the full disjunction with a single disjunct (one of the ones mentioned); in the case of (40), the non-prunable alternative is derived by replacing *at most* with *exactly*. In some sense, the former case is more natural, insofar as the lexical material required for the alternative is fully present in the utterance (thus, the appeal to 'mentioning' is sensible), whereas in the latter case, it's not (*exactly* was not mentioned). However, both cases involve structural manipulation of the uttered sentence, and so from a formal perspective, there's little distinction between the two.

# The Vietnamese perfect<sup>1</sup>

Thuy BUI — *University of Massachusetts Amherst*

**Abstract.** The paper seeks to advance understanding of cross-linguistic variation in the semantics of tense and aspect by investigating the distribution and interpretation of the temporal marker *da* in Vietnamese. The study first explores the possibility of accounting for such a marker as an optional past tense. By testing this hypothesis against empirical data, this paper argues that *da* is neither a referential nor a quantificational past tense, but a perfect marker in Vietnamese. The second part of the paper provides a formal analysis of *da*. Based on *da*'s interaction with different adverbial phrases, this study suggests that *da* behaves similarly to the German perfect rather than the English perfect. The discussion relates directly to recent approaches to other languages and offers data from a superficially tenseless language to the discussion on the cross-linguistic semantic variation in 'perfect puzzle.'

**Keywords:** tense, aspect, Vietnamese.

## 1. Introduction

Vietnamese lacks obligatory overt tense morphology. Out of the blue, finite matrix clauses with temporally unmarked verbs are compatible with past and present temporal reference, and their viewpoint aspect is perfective, as illustrated in (1):

- (1) Boba lam viec cho Jabba.  
Boba do work for Jabba  
'Boba works / worked for Jabba.'

There is nonetheless a temporal marker that one may be tempted to describe as a tense: *da*. As shown in (2), if *da* appears in the sentence in (1), that sentence appears to receive a past interpretation:

- (2) Boba **da** lam viec cho Jabba.  
Boba DA do work for Jabba  
'Boba worked / had worked for Jabba.'

The goal of this paper is to explore the meaning of *da* and its contribution to the temporal interpretation of Vietnamese clauses. The organization of the paper is as follows. In Section 2, I present the background framework for tense and aspect, the basic data for Vietnamese temporal expressions, as well as the semantic proposed for superficially tenseless languages. Then, in Sections 3 and 4, I focus on the puzzle concerning past interpretations in Vietnamese, and show that *da* is neither a referential nor a quantificational past tense, respectively. Section 5 discusses cross-linguistic variation in the 'perfect puzzle,' and demonstrates that *da* behaves

---

<sup>1</sup>For their helpful advice and extended discussions on this topic, I would like to thank Seth Cable and Barbara Partee. I am also grateful to the participants of the UMass Semantics Workshop as well as the audience at Sinn und Bedeutung 21 for their insightful comments. Particular thanks go to Alex Göbel and Ai Taniguchi for providing judgements for German and Japanese, respectively. Responsibility for shortcomings rests with me.

more similarly to the German perfect than the English one. Then, in Section 6, I propose a formal analysis of the perfect marker *da*, and demonstrate how the proposed semantics captures certain key facts. Section 7 concludes the paper.

## 2. Formal semantic and linguistic background

### 2.1. The framework

Tense and aspect are conceptualized in the framework of Reichenbach (1947) and Klein (1994). Following Reichenbach (1947), this paper assumes a three-way distinction between the utterance time (UT), the reference time (RT), and the event time (ET):

- (3) a. UT: The time at which the sentence is uttered.
- b. ET: The time for which the predicate holds of the subject.
- c. RT: The time about which the claim is made.

Furthermore, following Klein (1994), this paper assumes tense express a relation between the RT and the UT. In particular, while past tense encodes the precedence relation between the two ( $RT < UT$ ), present tense locates the RT at the UT ( $RT = UT$ ), and future tense locates the RT after the UT ( $RT > UT$ ). In contrast, aspect morphology contributes information regarding the relationship between the RT and the ET. An aspect is perfective when the ET is included within the RT ( $ET \subset RT$ ). On the other hand, an aspect is imperfective when the inclusion relation between the ET and the RT is reversed ( $RT \subset ET$ ).

Moreover, this study presumes the pronominal approach to the semantics of tense provided in Kratzer (1998). In this framework, the Tense (T) head, which is of type  $i$ , is proposed to be sister to the Aspect Phrase (ASPP), which denotes a property of times. As a result, the whole Tense Phrase (TP) denotes a proposition, as illustrated in (4) below:

- (4) *The Syntax for Tense and Aspect in English* (Kratzer, 1998):

### 2.2. Temporal reference in Vietnamese

Given that there is no obligatory grammaticalized expressions that impose constraints on the temporal relation between the RT and the UT in Vietnamese, one may be tempted to describe Vietnamese as a superficially tenseless language. Bare verb sentences describe events that are located before or at the UT. When uttered out of the blue, such sentences are only compatible with present or past frame adverbials, as illustrated in (5):

- (5) Hom qua / Bay gio / #Ngày mai Chewie bay den Endor.  
 yesterday / now / tomorrow Chewie fly to Endor  
 ‘Chewie flew / flies to Endor yesterday / now / #tomorrow.’

Following Matthewson’s (2006) analysis of Lillooet, the non-future temporal reference observed in the Vietnamese sentences in (1) and (5) will be assumed to be contributed by a phonologically empty NONFUT tense morpheme whose semantics is shown in (6):

- (6) *The Semantics for Tense in Superficially Tenseless Sentences (Matthewson, 2006):*

$\llbracket \text{NONFUT}_i \rrbracket^{g,c}$  is only defined if  $g(i) \leq t_c$   
 If defined,  $\llbracket \text{NONFUT}_i \rrbracket^{g,c} = g(i)$

Under Matthewson’s (2006) analysis, the example in (5) is translated by the formula in (7):

- (7)  $\llbracket (5) \rrbracket^{g,c} = \lambda w \exists e [ \text{fly-to-Endor}(e)(w) \ \& \ \text{agent}(\text{Chewie})(e)(w) \ \& \ \tau(e) \subseteq g(i) ]$   
 (where  $g(i) < t_c$ )  
 ‘There is an event  $e$  of Chewie flying to Endor, whose flying  $\tau$  is included in the contextually salient past time  $g(i)$ .’

The semantics correctly predicts that superficially tenseless sentences like (5) are compatible only with past or present time reference. In consequence of this semantic restriction, future time reference in Vietnamese must always be marked overtly with the marker *se*, which will not be addressed in the discussion of this paper.

### 3. Not a referential past

#### 3.1. Referential tense hypothesis

Duffield’s (2007) study on the syntax of Vietnamese clausal structure claims that Vietnamese expresses assertion independently of tense or aspect. While he does not focus on the semantics of tense and aspect in Vietnamese, he does propose that Vietnamese is not a tenseless language, and that *da* is a past tense whose marking is almost always optional, which contrasts with the obligatory presence of tense morphology in English.

According to Duffield (2007), Vietnamese tense morphemes, including *da*, have the same syntactic distribution as English ones, but are without the assertion (ASR) component associated with English finite auxiliaries. As a result, Duffield (2007) suggests that the tense morphemes in Vietnamese occupy the Tense node, with lexical verbs remaining in vP, as illustrated below:

(8) *The Syntax for Tense in Vietnamese (Duffield, 2007):*

If *da* is an optional past tense morpheme realized as a Tense head, then it is expected to restrict the temporal reference of a sentence to be past. In this case, *da* requires the RT to temporally precede the evaluation time (EVALT), which is the UT in matrix clauses. Then, under the view in which Vietnamese has a referential tense system, the semantics of a temporally unmarked verb ( $\emptyset$ ) should be similar to (9a), while that of *da* should be like (9b):

(9) *The Semantics for Referential Tenses in Vietnamese:*

- a.  $\llbracket \emptyset \rrbracket = \llbracket \text{PRES}_i \rrbracket^{w, t, g, c} = [ \lambda P_{\langle i, t \rangle} : \exists t' . t' = t \ \& \ P(t') = T ]$  'There is a time  $t'$  such that  $t'$  equals the EVALT  $t$  and  $P$  is true at  $t'$ .'
- b.  $\llbracket \text{DA} \rrbracket = \llbracket \text{PST}_i \rrbracket^{w, t, g, c} = [ \lambda P_{\langle i, t \rangle} : \exists t' . t' < t \ \& \ t' \in g(i) \ \& \ P(t') = T ]$  'There is a time  $t'$  such that  $t'$  is before the EVALT  $t$  and within the interval  $g(i)$ , and  $P$  is true at  $t'$ .'

This semantics explains the difference in meaning between (1) and (2). Since *da* imposes a precedence relation between the RT and the EVALT, it plays a role in excluding the present time reference from the matrix clause in (2). Despite the fact the analysis seems to provide a satisfactory record for the contrast in (1) and (2), it still fails to account for many other data points in the language. By showing the behavior of *da* in the sequence of tense constructions in Vietnamese, I argue against the claim that *da* is a referential past tense marker.

3.2. Embedded *da* in complement clauses

Firstly, when the main verb in the matrix clause and the embedded verb in the complement clause are both temporally unmarked (Unmarked-under-Unmarked), the sentence appears to be ambiguous, allowing for either a simultaneous or a back-shifted reading, as illustrated in (10):

(10) *Unmarked-under-Unmarked in Vietnamese Complement Clauses:*

- a. Nam 1980 Obi-Wan  $\emptyset$  noi la Luke  $\emptyset$  song o Tatooine luc do.  
 year 1980 Obi-Wan  $\emptyset$  say that Luke  $\emptyset$  live on Tatooine time that  
 'In 1980, Obi-Wan said that Luke lived on Tatooine then.'  
 (Lit.: 'In 1980, Obi-Wan says / said that Luke lives / lived on Tatooine then.')

- b. Nam 1980 Obi-Wan Ø noi la Luke Ø song o Tatooine nam 1977.  
 year 1980 Obi-Wan Ø say that Luke Ø live on Tatooine year 1977  
 'In 1980, Obi-Wan said that Luke lived on Tatooine in 1977.'  
 (Lit.: 'In 1980, Obi-Wan says / said that Luke lives / lived on Tatooine in 1977.')

This is one of the cases showing that the presence of *da* is not obligatory in Vietnamese clauses. Both the matrix and the embedded clauses can obtain the past readings with a temporally unmarked verb. Furthermore, the event in the embedded clause can be anchored at the matrix time as well as any point of time before that. This contrasts to the behaviors of referential tenses in English, as illustrated in the case of Present-under-Present sentences like (11) below:

(11) *Present-under-Present in English Complement Clauses:*

- a. \*In 1980, Obi-Wan **says** that Luke **lives** on Tatooine then.  
 b. \*In 1980, Obi-Wan **says** that Luke **lives** on Tatooine in 1997.

When both of the the matrix and the embedded verbs denote present tense, the sentences are unacceptable whether the embedded time is located at or prior to the matrix time. The same behavior also shows when a past tense morpheme is embedded under a present tense matrix verb, as illustrated below:

(12) *Past-under-Present in English Complement Clauses:*

- a. \*In 1980, Obi-Wan **says** that Luke **lived** on Tatooine then.  
 b. \*In 1980, Obi-Wan **says** that Luke **lived** on Tatooine in 1997.

In this case, whenever the matrix time happens before the UT in English, the matrix verb cannot be in present tense. Secondly, Vietnamese sentences in which an unmarked verb is embedded in a complement clause under *da*, which appears in the matrix clause, (Unmarked-under-*Da*), also allow for either a simultaneous or a back-shifted reading, as shown in (13):

(13) *Unmarked-under-*Da* in Vietnamese Complement Clauses:*

- a. Nam 1980 Obi-Wan **da** noi la Luke Ø song o Tatooine luc do.  
 year 1980 Obi-Wan **DA** say that Luke Ø live on Tatooine time that  
 'In 1980, Obi-Wan said that Luke lived on Tatooine then.'  
 (Lit.: 'In 1980, Obi-Wan said that Luke lives / lived on Tatooine then.')
- b. Nam 1980 Obi-Wan **da** noi la Luke Ø song o Tatooine nam 1977.  
 year 1980 Obi-Wan **DA** say that Luke Ø live on Tatooine year 1977  
 'In 1980, Obi-Wan said that Luke lived on Tatooine in 1977.'  
 (Lit.: 'In 1980, Obi-Wan said that Luke lives / lived on Tatooine in 1977.')

(13) shows that when *da* appears in the matrix clause, a temporally unmarked verb in the embedded clause can still locate the event of Luke living on Tatooine at or prior to the past matrix time. In contrary to the flexibility shown in the Vietnamese data, it is unacceptable for Present-under-Past sentences in English to have a present tense embedded verb when the ET denoted in the embedded clause occurs before the UT:

(14) *Present-under-Past in English Complement Clauses:*

- a. \*In 1980, Obi-Wan **said** that Luke **lives** on Tatooine then.
- b. \*In 1980, Obi-Wan **said** that Luke **lives** on Tatooine in 1997.

However, in English complement clauses, the interpretation of a past tense morpheme under another past tense morpheme (Past-under-Past) is ambiguous between a simultaneous reading and a back-shifted reading (Ogihara and Sharvit, 2012), as indicated in (15) below:

(15) *Past-under-Past in English Complement Clauses:*

- a. In 1980, Obi-Wan **said** that Luke **lived** on Tatooine then.
- b. In 1980, Obi-Wan **said** that Luke **lived** on Tatooine in 1977.

Similarly, in Hebrew, a language that makes use of referential tenses like English, Past-Under-Past sentences also allow for simultaneous readings (Ogihara and Sharvit, 2012), as shown in (16) below:

(16) *Past-under-Past in Hebrew Complement Clauses:*

- Han **xasav** se Leia **ahava** oto az.  
 Han thought that Leia loved him then  
 ‘Han thought that Leia loved him then.’

If *da* behaves like a referential past tense, *Da-under-Da* sentences in Vietnamese should also allow simultaneous readings like the Past-under-Past ones in English and Hebrew. Nevertheless, in Vietnamese, sentences in which *da* is embedded under another *da* (*Da-under-Da*) never allows for a simultaneous reading, as shown in (17):

(17) *Da-under-Da in Vietnamese Complement Clauses:*

- a. \*Nam 1980 Obi-Wan **da** noi la Luke **da** song tren Tatooine luc do.  
 year 1980 Obi-Wan DA say that Luke DA live on Tatooine time that  
 ‘In 1980, Obi-Wan said that Luke lived on Tatooine then.’
- b. Nam 1980 Obi-Wan **da** noi la Luke **da** song tren Tatooine nam 1977.  
 year 1980 Obi-Wan DA say that Luke DA live on Tatooine year 1977  
 ‘In 1980, Obi-Wan said that Luke lived on Tatooine in 1977.’

A *da* embedded under another *da* in complement clauses always forces a back-shifted reading. This fact suggests that *da* does not behave similarly to the referential past tenses in English and Hebrew. As a result, the possibility of *da* being a referential past tense is ruled out. The behavior of *da* in embedded contexts is further investigated with the sequence of tense cases observed in relative clauses.

### 3.3. Embedded *da* in relative clauses

Similarly to the Unmarked-Under-Unmarked cases in complement clauses, sentences in which unmarked verbs are present in both the matrix clause and the relative clause allow for either a simultaneous or back-shifted reading, as shown in (18):

(18) *Unmarked-under-Unmarked in Vietnamese Relative Clauses:*

- a. Nam 1980 Obi-Wan  $\emptyset$  gap mot nguoi  $\emptyset$  song o Tatooine luc do.  
 year 1980 Obi-Wan  $\emptyset$  meet one person  $\emptyset$  live on Tatooine time that  
 ‘In 1980, Obi-Wan met a person who lived on Tatooine then.’  
 (Lit.: ‘In 1980 Obi-Wan meets / met a person who lives / lived on Tatooine then.’)
- b. Nam 1980 Obi-Wan  $\emptyset$  gap mot nguoi  $\emptyset$  song o Tatooine nam 1977.  
 year 1980 Obi-Wan  $\emptyset$  meet one person  $\emptyset$  live on Tatooine year 1977  
 ‘In 1980, Obi-Wan met a person who lived on Tatooine in 1977.’  
 (Lit.: ‘In 1980 Obi-Wan meets / met a person who lives / lived on Tatooine in 1977.’)

Likewise, sentences in which an unmarked verb is embedded in a relative clause under a matrix verb marked with *da* are also ambiguous, allowing for either a simultaneous or back-shifted interpretation, as illustrated in (19):

(19) *Unmarked-under-Da in Vietnamese Relative Clauses:*

- a. Nam 1980 Obi-Wan **da** gap mot nguoi  $\emptyset$  song o Tatooine time that.  
 year 1980 Obi-Wan **DA** meet one person  $\emptyset$  live on Tatooine time that  
 ‘In 1980, Obi-Wan met a person who lived on Tatooine then.’  
 (Lit.: ‘In 1980, Obi-Wan met a person who lives / lived on Tatooine then.’)
- b. Nam 1980 Obi-Wan **da** gap mot nguoi  $\emptyset$  song o Tatooine year 1977.  
 year 1980 Obi-Wan **DA** meet one person  $\emptyset$  live on Tatooine year 1977  
 ‘In 1980, Obi-Wan met a person who lived on Tatooine in 1977.’  
 (Lit.: ‘In 1980, Obi-Wan met a person who lives / lived on Tatooine in 1977.’)

The key fact shown in (19) is that Vietnamese allows a simultaneous reading, even when *da* appears in the matrix clause. This is where an important difference between English and Vietnamese manifests itself. In particular, in English relative clauses, the availability of a simultaneous reading of the present depends on the matrix tense (Ogihara and Sharvit, 2012). In Present-under-Past sentences, a matrix past blocks a simultaneous reading, as in (20):

(20) *Present-under-Past in English Relative Clauses:*

- a. \*In 1980, Obi-Wan **met** a person who **lives** on Tatooine then.
- b. In 1980, Obi-Wan **met** a person who **lives** on Tatooine now.

The fact that an indexical reading is allowed in (20b) shows that the time of the embedded event is required to overlap the present. In Vietnamese, however, such restriction does not exist in the relative clauses. Moreover, this availability of simultaneous readings of  $\emptyset$ -under-*Da* sentences in Vietnamese, a superficially tenseless language, shares parallels to the patterns observed in

Japanese, a tensed language. In particular, Japanese sentences in which a past tense morpheme in a relative clause is embedded under a present tense matrix verb also allows for both the simultaneous and indexical readings, as demonstrated in (21):

(21) *Present-under-Past in Japanese Relative Clauses:*

- a. 1980-nen-ni Obi-Wan-wa Tatooine-ni sono-toki **sun-deiru** hito-ni  
 1980-year-DAT Obi-Wan-TOP Tatooine-DAT that-time live-PRES person-DAT  
**at-ta.**  
 meet-PST  
 ‘In 1980, Obi-Wan met a person who lived on Tatooine then.’  
 (*Lit.*: ‘In 1980, Obi-Wan met a person who lives on Tatooine then.’)
- b. 1980-nen-ni Obi-Wan-wa Tatooine-ni genzai **sun-deiru** hito-ni  
 1980-year-DAT Obi-Wan-TOP Tatooine-DAT now live-PRES person-DAT  
**at-ta.**  
 meet-PST  
 ‘In 1980, Obi-Wan met a person who lives on Tatooine now.’

The behavior of the embedded *da* in relative clauses once again shows that *da* does not behave like the English past, further supporting the claim that *da* is not a referential past tense. However, the embedded *da* in Vietnamese appears to share similarities with the embedded past tense in Japanese. This pattern then raises a possibility that tenses in Vietnamese behave like those in Japanese. If this is the case, then it is plausible for *da* to be argued to function similarly to a quantificational past tense.

#### 4. Not a quantificational past

##### 4.1. Quantificational tense hypothesis

If tenses in Vietnamese behave like those in Japanese, then they are ambiguous, and may get quantificational interpretations (Ogihara and Sharvit, 2012). In particular, one can assume that unmarked verbs are by default interpreted in the present, and thus can have similar semantics to Japanese present tense. Meanwhile, since *da* is more temporally marked than an unmarked verb, past temporal reference is more strongly preferred. As a result, under this quantificational tense approach, the semantics of temporally unmarked verbs as well as *da* in Vietnamese is as follows:

(22) *The Semantics for Quantificational Tenses in Vietnamese:*

- a.  $\llbracket \emptyset \rrbracket = \llbracket \text{PRES} \rrbracket^{w, t, g, c} = [ \lambda P_{\langle i, t \rangle} : [ \lambda t' : \exists t'' . t'' = t' \ \& \ P(t'') = T ] ]$   
 ‘There is a time  $t''$  such that  $t''$  equals the time  $t'$  and  $P$  is true at  $t''$ .’
- b.  $\llbracket \text{DA} \rrbracket = \llbracket \text{PST} \rrbracket^{w, t, g, c} = [ \lambda P_{\langle i, t \rangle} : [ \lambda t' : \exists t'' . t'' < t' \ \& \ P(t'') = T ] ]$   
 ‘There is a time  $t''$  such that  $t''$  is before the time  $t'$  and  $P$  is true at  $t''$ .’

In this case, the quantificational tenses in (23) are of type  $\langle \langle i, t \rangle, \langle i, t \rangle \rangle$ . In movement of quantificational tense, the lambda created by movement is  $\lambda t$ . Moreover, the trace of movement is  $[t^*]$ , which always denotes EVALT. In other words,  $\llbracket t^* \rrbracket^{w, t, g, c}$  equals  $t$ . Then, the sentence

in (19a) has the Logical Form (LF) structure as well as the predicted truth conditions as follows:

(23) In 1980, Obi-Wan met a person who lives / lived on Tatooine then.

- a.
- 
- b.  $\llbracket (19a) \rrbracket^{w, t, g, c} = \exists t' . t' < t \ \& \ \exists x . x \text{ is a person in } w \ \& \ x \text{ lives on Tatooine in } w \text{ at } t' \ \& \text{ Obi-Wan meets } x \text{ in } w \text{ at } t' .$   
 'There is a time  $t'$  such that  $t'$  is before the time  $t$ , and there is an  $x$  such that  $x$  is a person in world  $w$ , and  $x$  lives on Tatooine in  $w$  at  $t'$ , and Obi-Wan meets  $x$  in  $w$  at  $t'$ .'

The semantics of *da* as a quantificational past tense correctly predicts that the Unmarked-Under-*Da* cases in Vietnamese relative clauses should allow for a simultaneous reading. This analysis further rejects the hypothesis that *da* is a referential past tense. In this case, the function of *da* has now been narrowed down to be either that of a quantificational past tense or a perfect. I then argue that *da* is not a quantificational tense, since not only does *da* is shown to have the ability to arrange events in a sequence but it also felicitously appears in future contexts.

#### 4.2. Event ordering

When it comes to arranging events in a sequence, the presence of *da* is mandatory. As demonstrated in (24) below, *da* puts one event further into the past than the other. In particular, when it is uttered in the scenario described in (24), (24a) is infelicitous because it denotes that the two events occur simultaneously. On the other hand, (24b) is felicitous because *da* puts the event of R2-D2 fixing C-3PO before the event of Lando entering the room.

- (24) *Context:* Lando walks into the room, and he finds R2-D2 standing next to a newly repaired C-3PO.
- a. #Lando di vào phòng. Chewie sửa C-3PO.  
 Lando walk into room Chewie fix C-3PO  
 'Lando walked into the room. Chewie fixed C-3PO.'

- b. Lando di vào phòng. Chewie **da** sua C-3PO.  
 Lando walk into room Chewie DA fix C-3PO  
 ‘Lando walked into the room. Chewie had fixed C-3PO.’

In this case, the first sentence, which has a NONFUT tense, sets up the RT for the next sentence. *Da* then requires the second sentence to be interpreted within the past of the event of the first sentence. Then, *da* appears to function similarly to a perfect marker. Furthermore, the fact that the presence of *da* is acceptable in cases like (25) provide further evidence supporting the claim that *da* is a perfect rather than a tense.

- (25) Lando di vào phòng lúc 2 giờ. Đến 2 giờ 15 phút, R2-D2 **da** sua C-3PO.  
 Lando walk into room at 2 hour. By 2 hour 15 minute R2-D2 DA fix C-3PO  
 ‘Lando walked into the room at 2. By 2:15, R2-D2 had fixed C-3PO.’

In (25), the first sentence does not set up the RT for the sentence that follows it. In fact, it is the temporal adverbials *đến 2 giờ 15 phút* ‘by 2:15’ that sets up the RT for the second sentence. Given that *da* can combine with this adverbial phrase, it suggests that *da* does not pick out one particular point of time in the past. Rather, *da* contributes an interval of time running from one salient point in the past up until 2:15. Then, the possibility of *da* being a quantificational tense has been ruled out.

## 5. The ‘present perfect’ puzzle

### 5.1. Modification by ‘yesterday’

In English, the present perfect is not compatible with specific past time adverbs like ‘yesterday’ (Pancheva and von Stechow, 2004), as demonstrated in (26) below:

- (26) Luke: “Why **is** Yoda tired?”  
 a. Obi-Wan: “He **trained** hard yesterday.”  
 b. Obi-Wan: \*“(He **has trained** hard yesterday.”  
 c. Obi-Wan: #“(He **had trained** hard yesterday.”

In the scenario in which Luke asks a question like the one in (26), the only acceptable answer that Obi-Wan can utter is (26a). Since the question is put in present tense, it sets up the present time reference for the whole discourse. Since there is no past time in the discourse to impose a pluperfect interpretation, (26c) is infelicitous when uttered in this context. Meanwhile, even though the present perfect does not encounter such problem, the sentence in (26b) is still ill-formed. This problem in English, which arises due to the incompatibility between the present perfect and adverbs like ‘yesterday’, has been discussed in the literature as the ‘present perfect puzzle’.

In order to account for the unacceptability in cases like (26b), Pancheva and von Stechow (2004) proposes three main ingredients, which are the Perfect Time Span (PTS), the perfect aspect (PERF), and the semantics for ‘yesterday’, as illustrated below:

(27) *The ingredients for the ‘present perfect puzzle’ (Pancheva and von Stechow, 2004):*

- a.  $\text{PTS}(t', t) = t$  is a final subinterval for  $t'$
- b.  $\llbracket \text{PERF} \rrbracket^{w, t, g, c} = [ \lambda P_{\langle i, t \rangle} : [ \lambda t' : \exists t'' . \text{PTS}(t'', t') \& P(t'') ] ]$   
‘There is a time  $t''$  such that  $t'$  is a final subinterval for  $t''$  and  $P$  is true at  $t''$ .’
- c.  $\llbracket \text{yesterday} \rrbracket^{w, t, g, c} = [ \lambda t' : t' \subseteq \text{the day preceding } c(\text{time}) ]$   
‘ $t'$  is a subinterval of the day preceding the context time.’

Then, the LF structure as well as the predicted truth conditions for the sentence in (26b) without the modification of the adverbial phrase ‘yesterday’ are as follows:

(28) Yoda trained hard.

a.

- b.  $\llbracket (26b) \rrbracket^{w, t, g, c} = \exists t' . \text{PTS}(t', c(\text{time})) \& \exists e . \text{train}(e, w) \& \text{Ag}(e, w) = \text{Yoda} \& \text{T}(e) \subseteq t'$   
‘There is a time  $t'$  such that the context time is a final subinterval for  $t'$ , and there is an  $e$  such that  $e$  is an event of training in world  $w$ , and the agent of  $e$  is Yoda, and the time of  $e$  is a subinterval of  $t'$ .’

Given the semantics in (27), there is nowhere in (28) that the adverb ‘yesterday’ can be added consistently. In particular, if ‘yesterday’ modifies  $\text{ASP}_1\text{P}$ , its contribution is an internal contradiction, as illustrated in (29):

(29)  $[ \exists t' . \text{PTS}(t', c(\text{time})) \& \exists e . \text{train}(e, w) \& \text{Ag}(e, w) = \text{Yoda} \& \text{T}(e) \subseteq t' \& \text{c}(\text{time}) \subseteq \text{the day preceding c}(\text{time}) ]$

Meanwhile, if ‘yesterday’ modifies  $\text{ASP}_2\text{P}$ , its contribution contradicts the statement that the context time is a final subinterval for  $t'$ , as demonstrated in (30):

(30)  $[ \exists t' . \text{PTS}(t', \text{c}(\text{time})) \& \exists e . \text{train}(e, w) \& \text{Ag}(e, w) = \text{Yoda} \& \text{T}(e) \subseteq t' \& t' \subseteq \text{the day preceding c}(\text{time}) ]$

As a result, it is not possible to combine the present perfect with specific past time adverbials in English. However, unlike English, in Vietnamese, a sentence containing *da* can also contain ‘specific’ past time adverbs like *hom qua* ‘yesterday,’ as illustrated in (31):

- (31) Hom qua Yoda **da** luyen tap cuc kho.  
 yesterday Yoda DA train hard  
 ‘Yoda trained hard yesterday.’  
 (Lit.: ‘Yoda trained / has trained hard yesterday.’)

As discussed above, because the question that Luke asks sets up the present tense for the discourse, *da* cannot be interpreted as a pluperfect. Consequently, *da* functions as a present perfect in this case. Therefore, this behavior of *da* as a perfect marker contrasts what has been observed in the English perfect. Nevertheless, this pattern of *da* is remarkably similar to the German perfect, as illustrated in (32) below:

- (32) Yoda **hat** gestern hart **trainiert**.  
 Yoda have.3SG.PRES yesterday hard trained.PTCP  
 ‘Yoda trained hard yesterday.’  
 (Lit.: ‘Yoda has trained hard yesterday.’)

Similar to Vietnamese *da*, the German perfect is also compatible with specific past time adverbials like ‘yesterday.’ This suggests that the ‘present perfect puzzle’ that is present in English and other languages is absent in German and Vietnamese. As a result, *da* is more alike to the German perfect than the English one.

## 5.2. Interaction with ‘always’

In English, even when a past tense morpheme co-occurs with the adverb ‘always,’ it still indicates that the event discussed is no longer true at the UT. In contrast, when the present perfect appears with the adverb ‘always,’ it ends up entailing that the state in question still holds at the present (Pancheva, 2004), as demonstrated in (33) below:

- (33) a. Finn always **was** a Stormtrooper.  
 b. Finn **has** always **been** a Stormtrooper.

In this case, Finn is no longer a Stormtrooper in (33a). On the other hand, (33b) entails that he is still a Stormtrooper. The semantics for (33a) and (33b) is provided in (34a) and (34b), respectively:

- (34) a.  $\llbracket (33a) \rrbracket^{w, t, g, c} = [ \exists t' . t' < c(\text{time}) \ \& \ \forall t'' . t'' \in t' \rightarrow \exists e . \text{Finn-is-a-Stormtrooper}(e, w) \ \& \ T(e) \subseteq t' ]$   
 ‘There is an interval  $t'$  which completely precedes  $c(\text{time})$ , every subpart of which contains an eventuality of Finn being a Stormtrooper.’

- b.  $\llbracket (33b) \rrbracket^{w, t, g, c} = [ \exists t' . \text{PTS}(t', c(\text{time})) \ \& \ \forall t'' . t'' \in t' \rightarrow \exists e . \text{Finn-is-a-Stormtrooper}(e, w) \ \& \ T(e) \subseteq t' ]$   
 ‘There is an interval  $t'$  which contains  $c(\text{time})$ , every subpart of which contains an eventuality of Finn being a Stormtrooper.’

The semantics in (34) correctly predicts that (33a) can be followed consistently with the phrase ‘until he ran away from the First Order,’ while (33b) cannot, as illustrated in below:

- (35) a. Finn always **was** a Stormtrooper, until he ran away from the First Order.  
 b. \*Finn **has** always **been** a Stormtrooper, until he ran away from the First Order.

On the other hand, besides *da*’s interaction with ‘yesterday’ discussed earlier, the combination between *da* and *luon* ‘always’ shows that the function of *da* is distinct from that of the English perfect. In particular, when *da* appears with *luon* ‘always,’ it does not end up entailing that the state in question also holds at the present, as illustrated in (36):

- (36) a. Finn **da luon** la Stormtrooper.  
 Finn DA always COP Stormtrooper  
 ‘Finn has always been / had always been / always was a Stormtrooper.’  
 b. Finn **da luon** la Stormtrooper cho den khi no chay khoi First Order.  
 Finn DA always COP Stormtrooper for till when 3SG ran away First Order  
 ‘Finn always was a Stormtrooper until he ran away from the First Order.’  
 (Lit.: ‘Finn has always been / had always been / always was a Stormtrooper until he runs / ran away from the First Order.’)

In (36a), like English, the combination of *da* as a perfect marker and adverbials like *luon* ‘always’ entails that the state in question also holds at the present. Nevertheless, unlike what has been observed in the English sentence in (35b), the Vietnamese sentence in (36b) is not ungrammatical at all. In this case, the state in question only holds until the time at which Finn ran away from the First Order. The fact that sentences like (36b) are acceptable further demonstrates that *da* in Vietnamese behaves more like the German perfect, as shown in (37):

- (37) Finn **ist** immer ein Sturmtrupppler **gewesen** bis er vor des Ersten  
 Finn is.3SG.PRES always a Stormtrooper been until he from the First  
 Ordnung wegrannte  
 Order ran-away.3SG.PST  
 ‘Finn always was a Stormtrooper until he ran away from the First Order.’  
 (Lit.: ‘Finn has always been a Stormtrooper until he ran away from the First Order.’)

Based on the interaction of *da* with different types of adverbs such as *hom qua* ‘yesterday’ and *luon* ‘always’, it is shown that if *da* is indeed a perfect, then it shares similarities to the German perfect rather than the English perfect.

## 6. Formal analysis

### 6.1. Proposal

Based on the language data as well as the comparisons with other languages, a formal analysis for the Vietnamese perfect is proposed. Firstly, as for the syntax, a NONFUT tense morpheme occupies the head of the TP, and *da* is the head of the ASPP, as illustrated below:

(38) *The Syntax for Tense and Aspect in Vietnamese:*

Secondly, the semantics for *da* is provided below:

(39) *The Semantics for the Perfect in Vietnamese:*

$$\llbracket \text{DA} \rrbracket^{w, t, g} = [ \lambda P_{\langle i, t \rangle} : [ \lambda t' : \exists t'' . t'' \leq t' \ \& \ P(t'') ] ]$$

‘There is an interval  $t''$  that either strictly precedes  $t'$  or has  $t'$  as a final subinterval such that  $P(t'') = T$ .’

The proposed semantics captures certain key facts in Vietnamese, including the availability of simultaneous readings with complement clauses, as well as the semantic consequences of interactions with different adverbial phrases.

### 6.2. Availability of simultaneous readings

As mention earlier in the paper, the simultaneous reading can be obtained in Unmarked-under-*Da* in Vietnamese complement clauses, as in (13a). Meanwhile, *Da*-under-*Da* sentences like (17a) always forces a back-shifted reading. These crucial cases showing the different temporal interpretations when it comes to sequences of tense in Vietnamese are repeated below:

- (40) a. Nam 1980 Obi-Wan **da** noi la Luke Ø song o Tatooine luc do.  
 year 1980 Obi-Wan DA say that Luke Ø live on Tatooine time that  
 ‘In 1980, Obi-Wan said that Luke lived on Tatooine then.’  
 b. \*Nam 1980 Obi-Wan **da** noi la Luke **da** song o Tatooine luc do.  
 year 1980 Obi-Wan DA say that Luke DA live on Tatooine time that  
 ‘In 1980, Obi-Wan said that Luke had lived on Tatooine then.’

Under the proposed semantics, the contrast between these two sentences is correctly predicted. In particular, in (40a), a simultaneous reading can be obtained via a *de re* NONFUT tense. Meanwhile, in (40b), the embedded PERF *da* places the PTS *t'* prior to the EVALT *t*. The semantics of the embedded clause in (40b) is then proposed to be as follows:

- (41)  $\llbracket (50b) \rrbracket^{w, t, g, c} = [ \lambda w' : [ \lambda t' : \exists t'' . t'' \leq t' \ \& \ \exists e . \text{Luke-live-on-Tatooine}(e, w') \ \& \ T(e) \subseteq t'' ] ]$   
 ‘There is an interval *t''* which could completely precede *t'*, every subpart of which contains an eventuality of Luke living on Tatooine.’

As a result, under this semantics, the state of being a Stormtrooper does not properly overlap the EVALT in sentences like (40b). This means that the semantics proposed for *da* correctly predicts that it is impossible to get the simultaneous reading when *da* is embedded in the lower clause.

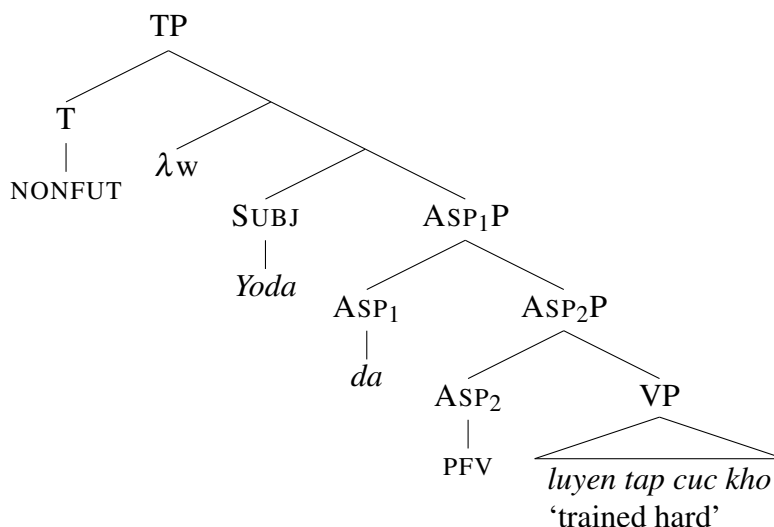

### 6.3. Semantic consequences of modification by ‘yesterday’

Furthermore, the proposed semantics can also account for the interaction between *da* and specific past time adverbials like *hom qua* ‘yesterday’ (Pancheva, 2004), as shown in cases like (31), repeated as (42) below:

- (42) Hom qua Yoda **da** luyen tap cuc kho.  
 yesterday Yoda DA train hard  
 ‘Yoda trained hard yesterday.’  
 (Lit.: ‘Yoda trained / has trained hard yesterday.’)

The syntax for the sentence in (42) without the modification of the adverbial phrase yesterday is as follows:

(43) Yoda has trained hard.

With the structure proposed in (43), if the adverbial phrase *hom qua* 'yesterday' modifies ASP<sub>1</sub>P, its contribution still leads to an internal contradiction. This is because in matrix clause, the time  $t$  equals the context time, as demonstrated in (44):

(44)  $[ \exists t' . t' \leq t \ \& \ \exists e . \text{train}(e, w) \ \& \ \text{Ag}(e, w) = \text{Yoda} \ \& \ T(e) \subseteq t' \ \& \ t \subseteq \text{the day preceding } c(\text{time}) ]$

Nevertheless, if the adverbial phrase (ADVP) *hom qua* 'yesterday' modifies Asp<sub>2</sub>P, its contribution is consistent, since it locates the PTS, and so the ET, within the day preceding the context time, as demonstrated in (45) below:

(45)  $[ \exists t' . t' \leq t \ \& \ \exists e . \text{train}(e, w) \ \& \ \text{Ag}(e, w) = \text{Yoda} \ \& \ T(e) \subseteq t' \ \& \ t' \subseteq \text{the day preceding } c(\text{time}) ]$

Following the logic presented in (45), then the syntax as well as the predicted truth conditions for the sentence in (42) is as follows:

(46) Yoda has trained hard yesterday.

- a.
- 
- The syntax tree for (46a) is as follows: TP branches into T and  $\lambda w$ . T branches into NONFUT.  $\lambda w$  branches into SUBJ and ASP<sub>1</sub>P. SUBJ branches into Yoda. ASP<sub>1</sub>P branches into ASP<sub>1</sub> and ASP<sub>2</sub>P. ASP<sub>1</sub> branches into *da*. ASP<sub>2</sub>P branches into ADVP and ASP<sub>2</sub>P. ADVP branches into *hom qua* 'yesterday'. The second ASP<sub>2</sub>P branches into ASP<sub>2</sub> and VP. ASP<sub>2</sub> branches into PFV. VP branches into *luyen tap cuc kho* 'trained hard'.
- b.  $\llbracket (52) \rrbracket^{w, t, g, c} = [ \exists t' . t' \leq t \ \& \ \exists e. \text{come}(e, w) \ \& \ \text{Ag}(e, w) = \text{Yoda} \ \& \ T(e) \subseteq t' \ \& \ t' \subseteq \text{the day preceding } c(\text{time}) ]$   
 'There is an interval  $t'$  which could completely precede the context time  $t$  by one day, every subpart of which contains an eventuality of Yoda training hard.'

As a result, with the semantics for 'yesterday' in (27c), the proposed semantics of *da* in (39) correctly predicts that the contribution of adverbs like *hom qua* 'yesterday' is consistent.

#### 6.4. Semantic consequences of interaction with 'always'

Lastly, the proposed semantics of *da* also captures the fact that the interaction between *da* and *luon* 'always' does not necessarily entail that the state in question holds at the present. Instead, it can just hold up until some point of time in the past, as shown in cases like (36).

Then, the semantics for (36a) is as follows:

- (47)  $\llbracket (36a) \rrbracket = [ \exists t' . t' \leq t \ \& \ \forall t'' . t'' \in t' \rightarrow \exists e. \text{Finn-is-a-Stormtrooper}(e, w) \ \& \ T(e) \subseteq t' ]$   
 'There is an interval  $t'$  which could completely precede the context time  $t$ , every subpart of which contains an eventuality of Finn being a Stormtrooper.'

The semantics in (36a) accounts for the fact that the sentence in (36b) does not entail that Finn is a Stormtrooper now.

## 7. Conclusion

In this study, I have investigated the behavior of the morpheme *da* in both matrix and embedded contexts, and argued that *da* in Vietnamese functions similarly to neither a referential past tense

in English nor a quantificational one in Japanese. Then, based on the role it plays in a sequence of events, I have concluded that *da* in Vietnamese is a perfect marker.

Furthermore, after examining *da*'s interaction with different adverbial phrases, I suggested that *da* is more alike to the German perfect than the English perfect. This discussion relates directly to recent approaches to other languages such as English or German, and contributes data from Vietnamese to the discussion on the semantic variation on the 'present perfect puzzle' across languages.

# Loose talk, negation and commutativity: A hybrid static-dynamic theory<sup>1</sup>

Sam CARTER — *Rutgers, The State University of New Jersey*

**Abstract.** This paper investigates the interaction of phenomena associated with loose talk with embedded contexts. §1 introduces core features associated with the loose interpretation of an utterance and presents a sketch of how to theorise about such utterances in terms of a relation of ‘pragmatic equivalence’. §2 discusses further features of loose talk arising from interaction with ‘loose talk regulators’, negation and conjunction. §§3-4 introduce a hybrid static/dynamic framework and show how it can be employed in developing a fragment which accounts for the data surveyed in §§1-2.

**Keywords:** loose talk, order effects, dynamic semantics, pragmatic equivalence, inexactness, granularity, imprecision, slack regulators, non-literal language use.

## 1. Introduction: Loose talk phenomena

Loose talk is an example of the non-literal use of language. In cases of loose talk, the **communicated content** of an utterance (i.e., the proposition with which a hearer can be expected to update their doxastic state) deviates from its **literal content** (i.e., the proposition corresponding to the truth conditions of the utterance). Relatedly, the conditions under which the uttered sentence is true can differ from the conditions under which an utterance of that sentence is felicitous.

This paper examines a number of ways in which the communicated content and felicity conditions of loose utterances interact with operators and logical connectives in English. In particular, it is argued that, while sensitive to conversational context, the communicated content of such utterances can be derived compositionally in a dynamic framework and is dependent upon aspects of the lexical meaning of constituent expressions which outstrip their contribution to truth conditions.

An utterance of (1) in its specified context can be expected to exhibit loose talk phenomena.

- (1) The British Library owns 14 million books.

*Context.1:* The interlocutors are trying to determine roughly how many books are owned by a range of major world libraries.

*Circumstances.1:* The British Library owns (approximately) 13,950,000 books.<sup>2</sup>

In *Context.1*, the communicated content of (the utterance of) (1) will be a proposition true iff the number of books owned by the British Library falls within some non-trivial interval of 14 million. Whereas the literal content of the utterance will be false if the British Library in fact

<sup>2</sup> *British Library thirty-seventh annual report and accounts 2009/10.*

([https://www.gov.uk/government/uploads/system/uploads/attachment\\_data/file/247725/0153.pdf](https://www.gov.uk/government/uploads/system/uploads/attachment_data/file/247725/0153.pdf))

owns 13,950,000, its communicated content will be true. Similarly, the utterance of (1) in *Context.1* and *Circumstances.1* appears felicitous, despite the falsehood of its literal content.

### 1.1. Pragmatic equivalence

The degree to which the communicated content of a loose utterance differs from its literal content depends, in part, upon the conversational interests of the interlocutors. In *Context.1*, since the conversational participants are trying to determine only roughly how many books each major library owns, (1) can be expected to communicate a proposition which is true if it owns 13,950,000 books. In contrast, let *Context.2* be a context in which the conversational participants are trying to determine whether the British Library owns more books than the Library of Congress, which owns, say, 13,990,000. In *Context.2*, the proposition communicated by (1) can be expected to be false.

Say that two worlds are pragmatically equivalent at a context iff they do not differ in any way which is relevant to the conversational interests of the interlocutors. For example, at *Context.1*, a world in which the BL owns 13,950,000 and one in which it owns 14 million will be pragmatically equivalent. In contrast, at *Context.2*, they will not, since the worlds differ with respect to a state of affairs relevant to the interlocutors' interests, namely whether the BL owns more books than the Library of Congress. Pragmatic equivalence can be expected to be reflexive and symmetric, but need not be transitive. No world differs from itself in ways which are pragmatically relevant, and if  $w$  does not differ from  $w'$  in any way which is pragmatically relevant, then  $w'$  does not differ from  $w$  in any way which is pragmatically relevant. However,  $w$  may differ from  $w''$  in ways which are pragmatically relevant, despite being pragmatically equivalent to some  $w'$  which is itself pragmatically equivalent to  $w''$ ; pragmatically irrelevant differences can add up to form a pragmatically relevant difference.

Given the relation of pragmatic equivalence, we can outline an approach to thinking about the communicated content and felicity conditions of loose utterances of simple sentences such as (1). A loose utterance of a simple sentence  $\phi$  is felicitous at a context  $C$  and world  $w$  iff there is some world pragmatically equivalent to  $w$  at  $C$  at which the literal content of  $\phi$  is true.<sup>3</sup> At any world in which the BL owns 13,950,000 books, a loose utterance of (1) would be felicitous at *Context.1*, but infelicitous at *Context.2*. Stated succinctly, a loose utterance of a simple sentence is felicitous iff any difference between the world of utterance and one in which the sentence is true is pragmatically irrelevant.

Correspondingly, a loose utterance of a simple sentence  $\phi$  at a context  $C$  and world  $w$  communicates the proposition true at all worlds  $w'$  such that there is some world pragmatically equivalent to  $w'$  at which the literal content of  $\phi$  is true. If determining the number of books owned by major libraries were exhaustive of the conversational interests in *Context.1*, then (1) might be expected to communicate the proposition that the number of books the BL owns is between  $13.5 \times 10^6$  and  $14.5 \times 10^6$ . Likewise, if determining whether the

<sup>3</sup> Strictly speaking, only the left-to-right direction of the biconditional is true, since other conditions on felicity unrelated to loose talk might fail to be satisfied. For present purposes, we can treat the biconditional as embedded under a *ceteris paribus* clause.

British Library or the Library of Congress owns more books were exhaustive of the conversational interests in *Context.2*, then (1) might be expected to communicate the proposition that the number of books owned by the BL exceeds 13,990,000.

For simple sentences, the truth of  $\phi$  at a world pragmatically equivalent to the world of utterance appears necessary and sufficient for both the felicitous utterance of  $\phi$  and the truth of that utterance's communicated content. However, as §2 demonstrates, the same generalisations cannot be extended to account for the loose utterance of complex constructions.

## 2. Loose talk: Further data

### 2.1. LT-regulators

As has been noted elsewhere (Lasersohn, 1999; Sauerland and Stateva, 2011; Solt, 2014; a.o.), there exist a range of expressions which function lexically to modify the relation between the communicated and literal contents of loose utterances. Call such expressions **loose talk (LT-) regulators**.<sup>4</sup> The class of LT-regulators can be subdivided into **LT-strengtheners** (e.g., 'exactly' in (2a)) and **LT-weakeners** (e.g., 'roughly' in (2b)).

- (2) a. The British Library owns exactly 14 million books.  
 b. The British Library owns roughly 14 million books.

As Lasersohn notes, in contrast to (1), when uttered in context the communicated contents of sentences like (2a)-(2b) coincide with their literal content (1999: 545). The communicated content of an utterance of (2a) is strictly stronger than (i.e. asymmetrically entails) the communicated content of (1) and the utterance is, intuitively, infelicitous if the BL owns less than 14 million books. In contrast, the literal content of (2b) is strictly weaker than (i.e., asymmetrically entailed by) the literal content of (1), and the utterance is, intuitively, true if the BL owns 13,950,000 books. Stated informally, the effect of the LT-strengthener in (2a) is to assimilate the communicated content of the utterance to its literal content, whereas the effect of the LT-weakener in (2b) is to assimilate the literal content of the utterance to its communicated content.<sup>5</sup> Note that 'exactly' also appears to have an effect on the truth-conditional meaning of numerical determiners, making them 'upper-bounded'. For present purposes, this effect can be set aside. Note that despite differing in felicity, both (1) and (2a) communicate a literal content which is false in *Circumstance.1*, regardless of whether the numerical determiner is upper-bounded. Hence the effect of LT-strengtheners on numerical determiners is clearly not exhausted by their truth-conditional contribution.

As the contrast between (3a-b) suggests, LT-regulators such as 'exactly'/'roughly' do not function as sentential operators, but rather take sub-clausal complements:

<sup>4</sup> Lasersohn uses the terminology 'slack regulators' whereas Solt, following Sauerland and Stateva, adopts 'approximators'.

<sup>5</sup> LT-weakeners also appear to have a non-trivial effect on the communicated content of loose talk utterances. For example, the communicated content and felicity of (ia-b) differ:

- (i) a. ?? The British Library does not own exactly 14 million books, but it does own 14 million.  
 b. The British Library does not own exactly 14 million books, but it does own roughly 14 million.

- (3) a. Exactly/roughly 100 libraries own 1 million books.  
 b. 100 libraries own exactly/roughly 1 million books.

This suggests that whatever treatment of LT-regulators is developed, it will need to account for the contrast between (3a-b) compositionally, in terms of the difference in constituent structure.

In (2a-b), the LT-regulator combines with numerical determiner ‘14 million’.<sup>6</sup> However, we can also identify apparent LT-regulators taking quantified DPs (e.g. (4b)), PPs (e.g., (5b)), adjectives/APs (e.g. (6b)), and temporal NPs (e.g. (7b)) as complements.

- (4) a. Everybody likes the new Scorsese film.  
 b. Absolutely/pretty much everybody likes the new Scorsese film.
- (5) a. The helicopter landed in the centre of the field.  
 b. The helicopter landed precisely/roughly in the centre of the field.
- (6) a. The bin is full.<sup>7</sup>  
 b. The bin is completely/effectively full.
- (7) a. Katja arrived at 6pm.  
 b. Katja arrived at exactly/roughly 6pm.

Correspondingly, the potential for contrast in felicity between utterances of (4-7a) and (4-7b) suggests that, in appropriate contexts, (4-7a) all permit a loose interpretation.

While many of the features of loose talk and LT-regulators addressed above have been discussed in previous work, most notably in Lasersohn (1999), little attention has been paid

<sup>6</sup> The ability of ‘exactly’ and ‘roughly’ to combine with numerical determiners as in (3a) might be thought to motivate an analysis on which they take ‘6’ as their complement in (2a-b), before combining with ‘pm’ to form a temporal NP. On this account, ‘exactly’/‘roughly’ could be understood as univocally taking numerical arguments. However, constructions such as (i) demonstrate the possibility of their combining directly with temporal NPs, and suggest that they are equivocal across (3a-b).

(i) Katja arrived at exactly/roughly the same time as Jonas.

<sup>7</sup> Here I follow Kennedy (2007) and Kennedy and McNally (2005) in assuming that, as constructions such as (i) suggest, absolute gradable adjectives such as ‘full’ require their subject to possess a maximal degree of the relevant property.

(i) ??The bin is full but it could be more full.

They argue that the possibility of felicitously of predicating such adjectives of subjects with only a close-to-maximal degree of the relevant property then needs to be explained in terms of loose talk. Correspondingly, in (6b) and (ii), ‘completely’ will need to be understood as an LT-regulator rather than a degree modifier. Similar examples with non-gradable adjectives can be constructed (as in (iii)):

(ii) The bin is full but it is not completely full.  
 (iii) The result is (effectively) unprecedented, but it is not completely unprecedented.

to their behaviour in complex constructions. §2.2-3 survey novel phenomena involving the interaction of loose talk with negation and conjunction.

## 2.2. Negation

As uttered in context, the communicated content of (1) is asymmetrically entailed by its literal content. This has frequently been taken to be amongst the defining features of loose talk (Lasersohn, 1999; Yablo, 2014; Lauer, 2012; though cf. Davis, 2007: 411). For example, Lauer claims that “loose talk is a phenomenon in which the communicated content is weaker than the semantic content” (p. 389).

However, the loose utterances of sentences embedded under negation generate counter-examples to this claim.<sup>8</sup> If the communicated content of an utterance of  $\phi$  is *weaker* than its literal content, the communicated content of an utterance of  $\neg\phi$  will be *stronger* than its literal content.

(8) The British Library doesn’t own 14 million books.<sup>9</sup>

In *Context.1*, the communicated content of (the utterance of) (8) is a proposition true iff the number of books owned by the BL does not fall within some non-trivial interval of 14 million. Whereas the literal content of the utterance will be true if the library owns 13,950,000 books, its communicated content will, plausibly, be false. Similarly, whereas in *Context.1*, an utterance of (1) is felicitous despite being false, in the same context, an utterance of (8) will be infelicitous but true.

The observed effect of negation suffices to demonstrate that the explanation of communicated content/felicity conditions for loose utterance of simple sentences in terms of literal truth at a pragmatically equivalent world cannot be trivially generalised to the utterance of sentences embedded under negation. There if the BL owns 13,950,000 books, then there is a world pragmatically equivalent at *Context.1* to  $w$  in which the literal content of (8) is true (since every world is trivially pragmatically equivalent to itself). Nevertheless, under these

---

<sup>8</sup> Not all counter-examples to the claim involve negation, and not all utterances of sentences embedded under negation constitute counter-examples to the claim. The communicated content of loose utterances of sentences such as (ia-b) involving minimal standards gradable adjectives will be strictly stronger than their literal content (in an appropriate context):

- (i) a. The stick is curved.
- b. The road is wet.

Correspondingly, the communicated content of loose utterances of their negations will be strictly weaker than the literal content.

<sup>9</sup> The same effect can be elicited in other constructions which exhibit loose talk phenomena in appropriate contexts:

- (i) Not everybody likes the new Scorsese film.
- (ii) The helicopter did not land in the centre of the field.
- (iii) The bin is not full.
- (iv) Katja did not arrive at 6pm.

circumstances its utterance would be infelicitous in *Context.1* and its communicated content false.

### 2.3. Commutativity

The felicity of loose utterances of certain conjunctive sentence is dependent upon to order of the conjuncts. Whereas (9a) is felicitous in any context in which the LH-conjunct has a true communicated content but a false literal content, (9b) is infelicitous in every context.

- (9) a. The British Library owns 14 million books, though it does not own exactly 14 million.  
 b. ??The British Library does not own exactly 14 million books, though it does own 14 million.<sup>10</sup>

We can describe this phenomenon by saying that conjunction fails to commute with respect to the felicity of loose utterances. The felicity of a loose utterance of  $\phi \wedge \psi$  does not entail the felicity of a loose utterance of  $\psi \wedge \phi$ .

§3, below, introduces a framework in which to theorise about loose talk, employing both a static and dynamic interpretation function. §4 presents a fragment in this framework and shows how it accounts for the phenomena in §2.

## 3. Dynamic Loose Talk (DLT)

### 3.1 Overview

This section presents a hybrid static-dynamic framework for theorising about loose talk. The primary idea behind the framework is that the lexically encoded meaning of a loose utterance of a sentence is not exhausted by its truth conditions. For example, (1) and (2a) have the same **truth conditions**, but they differ in total **compositional meaning**. In addition to explaining the difference in their felicity conditions/communicated content, this difference in meaning can account for the difference in the effect they have in embedded contexts, as demonstrated in (8) and (9a-b).

---

<sup>10</sup> The same effect can be elicited in constructions with LT-regulators taking expressions of different lexical categories:

- (i) a. Everybody, but not absolutely everybody, likes the new Scorsese film.  
 b. ?? Not absolutely everybody, but everybody, likes the new Scorsese film.
- (ii) a. The helicopter landed in the centre of the field but it did not land precisely in the centre.  
 b. ?? The helicopter did not land precisely in the centre of the field, but it landed in the centre.
- (iii) a. The bin is full, but it is not completely full.  
 b. ?? The bin is not completely full, but it is full.
- (iv) a. Katja arrived at 6pm, but she did not arrive at exactly 6pm.  
 b. ?? Katja did not arrive at exactly 6pm, but she arrived at 6pm.

This idea can be seen as analogous to observations made in dynamic treatments of anaphora (e.g., Kamp, 1981; Heim, 1982, 1983; Roberts, 1989; Groenendijk and Stokhof, 1991a; a.o.), modals (e.g., Veltman, 1996; Roberts, 1989; Groenendijk and Stokhof, 1991b; a.o.) and presupposition (Karttunen, 1973; Heim, 1983; a.o.). For example, on the basis of the contrast between (10a-b), Heim concludes that “the salience-shifting potential of an utterance is not predictable from its truth-conditions and the surrounding circumstances alone” (1982, 22).

- (10) a. I dropped ten marbles and found all of them, except for one. It is probably under the sofa.  
 b. I dropped ten marbles and found only nine of them. ??It is probably under the sofa.<sup>11</sup>

That is, in (10a-b) the first sentences of the discourses are truth-conditionally equivalent, but differ in meaning.

In the Dynamic Loose Talk (DLT) framework, every utterance of a sentence is treated as playing a dual role: (i.) it expresses a proposition, corresponding to its literal content; and (ii.) it modifies, potentially trivially, the relation of pragmatic equivalence at the context. Since the effect of an utterance on the relation of pragmatic equivalence is not a function of its literal content, it must be included independently as an additional part of the lexically encoded meaning of the sentence uttered.<sup>12</sup>

A DLT-model contains two interpretation functions: a static interpretation function  $\llbracket \cdot \rrbracket$ , mapping a sentence to its literal content, and a dynamic interpretation function  $[\cdot]$ , mapping it to its effect on a context. The static denotation of a sentence is a **proposition** – a function from worlds to truth values. The dynamic denotation of a sentence is a **context change potential** – a function from contexts to contexts. In DLT, a context  $C$  is identified with an **accessibility relation**  $R^C$  – a relation between worlds. Intuitively,  $\langle w, w' \rangle \in R^C$  iff  $w'$  is pragmatically equivalent to  $w$  in  $C$ .

Sentences are evaluated in DLT relative to a pair  $\langle w, R \rangle$  consisting of world and accessibility relation. Where  $\llbracket \varphi \rrbracket(w) = 1$ , we say that  $\varphi$  is **true-at- $\langle w, R \rangle$** . Where  $R[\varphi](w)$  is non-empty, we say that  $\varphi$  is **consistent-at- $\langle w, R \rangle$** . Stated alternatively, a sentence is consistent-at- $\langle w, R \rangle$  iff  $R[\varphi]$  – the result of updating  $R$  with  $[\varphi]$  – relates  $w$  to at least one world. An utterance of  $\varphi$  is held to be **felicitous** in a conversation  $C$  and world  $w$  iff  $\varphi$  is consistent-at- $\langle w, R^C \rangle$ . The communicated content of a sentence  $\varphi$  at  $R$  is (the characteristic function of) the set of worlds at which  $\varphi$  is consistent relative to  $R$ .

### 3.2. DLT-models

The set  $T$  of DLT-types is defined recursively from basic types  $s$ ,  $e$ , and  $t$  (corresponding to worlds, individuals and truth-values, respectively).

<sup>11</sup> Attributed to Partee, p.c., Heim (ibid).

<sup>12</sup> Grice’s non-detachability constraint, which states that any content conveyed in a non-conventionalised manner by an utterance must be conveyed by any utterance with the same conventionalised meaning (with a proviso for implicatures generated by Manner) (1975, 43-6), can be seen as articulating this point.

(DEF.1)  $s, e$ , and  $t$  are **DLT-types**. If  $\tau, \tau'$  are **DLT-types**, then  $\langle \tau, \tau' \rangle$  is a **DLT-type**.  
Nothing else is a DLT-type.

A DLT-model  $\mathcal{M}$  is a tuple consisting of a set  $\mathcal{D}^{\mathcal{M}}$  of domains of each **DLT-type**, plus static and dynamic interpretation functions,  $\llbracket \cdot \rrbracket^{\mathcal{M}}$  and  $[\cdot]^{\mathcal{M}}$ , which map a set  $\mathcal{L}$  of expressions into the corresponding domain. Indexation to a model is disregarded where no confusion arises.

(DEF.2)  $\mathcal{M} = \langle \mathcal{D}, \llbracket \cdot \rrbracket, [\cdot] \rangle$  is a **DLT-model**, s.t.:

- $\mathcal{D} = \bigcup \{ \mathcal{D}_{\tau} : \tau \in \mathbf{T} \}$ 
  - $\mathcal{D}_s, \mathcal{D}_e$  and  $\mathcal{D}_t$  are pairwise disjoint non-empty sets.
  - $\mathcal{D}_i = \{0, 1\}$ .
  - $\mathcal{D}_{\langle \tau, \tau' \rangle} = \mathcal{D}_{\tau} \rightarrow \mathcal{D}_{\tau'}$ .
- $\llbracket \cdot \rrbracket : \mathcal{L} \rightarrow \mathcal{D}$ .
- $[\cdot] : \mathcal{L} \rightarrow \mathcal{D}$ .

Contexts are identified with **accessibility relations**.

(DEF.3) Let  $\langle s, t \rangle = \sigma$ .

- $R, R', \dots \in \mathcal{D}_{\sigma}$  are **accessibility relations**.

(DEF.4) Where  $\varphi \in \mathcal{L}$  is a **sentential expression**:

- $\llbracket \varphi \rrbracket \in \mathcal{D}_{\langle s, t \rangle}$
- $[\varphi] \in \mathcal{D}_{\langle \sigma, \sigma \rangle}$ .

The static denotation of a **sentential expression**  $\varphi \in \mathcal{L}$  is a **proposition** – a function from worlds to truth values. The dynamic denotation of a **sentential expression**  $\varphi \in \mathcal{L}$  is a **context change potential (CCP)** – a function from accessibility relations  $R, R', \dots \in \mathcal{D}_{\sigma}$  to accessibility relations.

A sentential expression denotes an **update** iff for some  $w, R$ , it returns a non-empty subset of  $R(w)$  when the result of applying it to  $R$  is applied to  $w$ . It denotes a **test** iff for all  $w$  it returns either  $R(w)$  or  $\emptyset$  when the result of applying it to  $R$  is applied to  $w$ .<sup>13</sup>

(DEF.5) Where  $[\varphi] \in \mathcal{D}_{\langle \sigma, \sigma \rangle}$ :

- $[\varphi]$  is an **update** iff  $\exists R, w: \emptyset \subset R[\varphi](w) \subset R(w)$ .
- $[\varphi]$  is a **test** iff  $\forall R, w: R[\varphi](w) = R(w) \vee R[\varphi](w) = \emptyset$ .

Truth,  $\models_{\mathbf{T}}$ , and consistency,  $\models_{\mathbf{C}}$ , are defined relative to world, context-pairs. Where  $w, R \models_{\mathbf{T}} \varphi$ , we say that  $\varphi$  is true-at- $\langle w, R \rangle$ . Where  $w, R \models_{\mathbf{C}} \varphi$ , we say that  $\varphi$  is consistent-at- $\langle w, R \rangle$ .  $\Gamma \models_{\mathbf{T}} \varphi$  iff  $\varphi$  is true at  $\langle w, R \rangle$  only if every  $\psi \in \Gamma$  is true-at- $\langle w, R \rangle$ . *Mutatis mutandis* for  $\Gamma \models_{\mathbf{C}} \varphi$ .

(DEF.6) Where  $w \in \mathcal{D}_s$  and  $R \in \mathcal{D}_{\sigma}$ :

- $w, R \models_{\mathbf{T}} \varphi$  iff  $\llbracket \varphi \rrbracket(w) = 1$ .
- $w, R \models_{\mathbf{C}} \varphi$  iff  $R[\varphi](w) \neq \emptyset$ .

<sup>13</sup> Under the requirement that, for all  $\varphi$ ,  $[\varphi]$  is eliminative (i.e.,  $R[\varphi] \subseteq R$ ), every sentential expression denotes either an update or a test.

- $\Gamma \models_{\mathcal{T}} \phi$  iff  $\forall w, R, (\forall \psi \in \Gamma \ w, R \models_{\mathcal{T}} \psi) \supset w, R \models_{\mathcal{T}} \phi$ .
- $\Gamma \models_{\mathcal{C}} \phi$  iff  $\forall w, R, (\forall \psi \in \Gamma \ w, R \models_{\mathcal{C}} \psi) \supset w, R \models_{\mathcal{C}} \phi$ .

For every  $R \in \mathcal{D}_{\sigma}$ ,  $\mathcal{C}^R$  is a function from sentential expressions  $\phi \in \mathcal{L}$  into  $\mathcal{D}_{\langle \text{st} \rangle}$ .  $\mathcal{C}^R(\phi)$  is the proposition which maps  $w$  to 1 iff  $\phi$  is consistent-at- $\langle w, R \rangle$ .

(DEF.7) Let  $\mathcal{C}^R(\phi) \in \mathcal{D}_{\langle \text{st} \rangle}$  be the **communicated content** of  $\phi$  at  $R$ :

- $\mathcal{C}^R(\phi) = (\lambda w. w, R \models_{\mathcal{C}} \phi)$

§4 presents a fragment of English in the DLT-framework and shows how it is able to account for the data presented in §1-2.

## 4. Fragment

### 4.1. Basic sentences

We assume that the static and dynamic interpretation functions coincide for singular terms, verbs and common nouns in the fragment. Singular terms are treated as denoting individuals (type  $e$ ), whereas common nouns and verbs denote (intensions of) properties (type  $\langle e(\text{st}) \rangle$ ) and relations (type  $\langle e(\langle e(\text{st}) \rangle) \rangle$ ), respectively.

- (I.) a.  $\llbracket \text{The British Library} \rrbracket = \llbracket \text{The British Library} \rrbracket = \text{THE BRITISH LIBRARY}.$   
 b.  $\llbracket \text{book} \rrbracket = \llbracket \text{book} \rrbracket = \lambda x \lambda w. \text{BOOK}(x)(w).$   
 c.  $\llbracket \text{owns} \rrbracket = \llbracket \text{owns} \rrbracket = \lambda x \lambda y \lambda w. \text{OWN}(y)(x)(w).$

The static and dynamic interpretation functions diverge in value for numerical determiners. The static denotation assigned to ‘14 million’ will be its standard value as a determiner (type  $\langle \langle e(\text{st}) \rangle \langle e(\text{st}) \rangle t \rangle$ ). For simplicity, we will assume the upper-boundedness of bare numerical determiners. In contrast, the dynamic denotation of ‘14 million’ will be a function from a pair of (intensions of) properties to a CCP. Let  $F, G, \dots$  be variables over  $\mathcal{D}_{\langle e(\text{st}) \rangle}$ :

- (II.) a.  $\llbracket 14 \text{ million} \rrbracket = \lambda F \lambda G \lambda w. | \lambda x (F(x)(w)) \cap \lambda x (G(x)(w)) | = 1.4 \times 10^7.$   
 b.  $\llbracket 14 \text{ million} \rrbracket = \lambda F \lambda G \lambda R \lambda w \lambda w'. w' \in R(w) \wedge R(w) \cap (\lambda w. \llbracket 14 \text{ mil.} \rrbracket (F)(G)(w)) \neq \emptyset.$

The static denotation specified in (II.) maps a pair of properties to the proposition true at a world  $w$  iff the cardinality of their intersection at  $w$  is 14,000,000. The dynamic denotation specified in (II.) maps a pair of properties to a CCP (a function from accessibility relations to accessibility relations).

Assuming the DP to undergo QR out of direct object position, (1) is assigned the simplified LF in (11), generating the static and dynamic denotations in (12)-(13) respectively:<sup>14</sup>

- (11)  $\llbracket 14 \text{ million books} \rrbracket \lambda_1 \llbracket \llbracket \text{the BL} \rrbracket \llbracket \text{owns } t_1 \rrbracket \rrbracket$ .

<sup>14</sup> Slanted brackets,  $\llbracket \rrbracket$ , are used to represent constituent structure in order to avoid confusion with the dynamic interpretation function,  $\llbracket \cdot \rrbracket$ .

$$(12) \llbracket (11) \rrbracket = \lambda w. |\lambda x. (\text{BOOK}(x)(w)) \cap \lambda x. (\text{OWN}(\text{THE BL})(x)(w))| = 14,000,000.$$

$$(13) \llbracket (11) \rrbracket = \lambda R \lambda w \lambda w'. w' \in R(w) \wedge R(w) \cap \llbracket (11) \rrbracket \neq \emptyset.$$

The static denotation of (11) is the proposition true at  $w$  iff the number of individuals which are both books at  $w$  and owned by the British Library at  $w$  is 14,000,000.

The dynamic denotation of (11) is a test. Given an accessibility relation  $R$  it returns the relation  $R[(11)]$  such that, for all  $w$ ,  $R[(11)](w) = R(w)$  if there is some  $R$ -accessible world from  $w$  at which  $\llbracket (11) \rrbracket$  is true; otherwise  $R[(11)](w) = \emptyset$ . Identifying the felicity of the utterance of  $\phi$  at a world  $w$  and context  $C$  with the consistency of  $\phi$  at  $\langle w, R^C \rangle$ , this correctly predicts the felicity judgements regarding (1) in §1. Where  $R^C$  is the relation of pragmatic equivalence at  $C$ , an utterance of (11) will be felicitous at  $w$  and  $C$  iff there is some world  $R^C$ -accessible from  $w$  at which the British Library owns 14 million books. Alternatively stated, felicitous utterance of (11) requires that the actual world does not differ from one in which the British Library owns 14 million books in any ways which are pragmatically relevant.

For example, let  $C^\pm$  be a context in which any difference between the number of books owned by the BL and the number of books owned by the BL when rounded to the nearest million is pragmatically irrelevant.<sup>15</sup> That is,  $w' \in R^{C^\pm}(w)$  iff  $\forall n \in \mathbb{N}: 10^6(n) - |\lambda x. (\text{BOOK}(x)(w')) \cap \lambda x. (\text{OWN}(\text{THE BL})(x)(w'))| \leq \pm 500,000$  iff  $10^6(n) - |\lambda x. (\text{BOOK}(x)(w)) \cap \lambda x. (\text{OWN}(\text{THE BL})(x)(w))| \leq \pm 500,000$ . Let  $w^*$  be a world at which there are 13,950,000 books owned by the library. Then an utterance of (11) is predicted to be felicitous at  $w^*$ , since there exists a world  $w'$   $R^{C^\pm}$ -accessible from  $w$  such that  $\llbracket (11) \rrbracket(w') = 1$ .<sup>16</sup>

By (DEF.7), the communicated content of (11) at  $C^\pm$  will be strictly weaker than its literal content. For all  $R$ ,  $C^R((11))(w) = 1$  iff there is some world  $w'$   $R$ -accessible world from  $w$  such that  $\llbracket (11) \rrbracket(w') = 1$ . Thus, an utterance of (11) at  $C^\pm$  communicates the proposition true at a world  $w$  iff the number of books owned by the British Library in  $w$  falls within the interval  $[1.35 \times 10^7, 1.45 \times 10^7]$ . Clearly, this proposition is asymmetrically entailed by the literal content of (11).

<sup>15</sup> Assume in addition that the books owned by the British Library is the only thing of pragmatic relevance at  $C^\pm$ .

<sup>16</sup> Note that, for all that has been said, an utterance of (i) at  $C^\pm$  and  $w$  is predicted to be equally felicitous:

- (i) The British Library owns 14 million and one books.

Furthermore, the conjunction of (1) and (i) is predicted to be felicitous at certain contexts.

In order to accommodate the apparent infelicity of (i) at  $C^\pm$  and  $w^*$  (and the infelicity of its conjunction with (1) at all contexts), we can posit that the choice of numerical determiner in (i) is treated as evidence that the speaker is presupposing a stricter relation of pragmatic equivalence than would be indicated by the utterance of (1). If certain numerical determiners (such as ‘14 million’) are taken to be preferred over others (such as ‘14 million and one’), then the contrast between (i) and (1) can be explained in terms of optimality maximisation (Krifka, 2002, 2007; Klecha, 2014).

## 4.2. LT-regulators

Let  $\downarrow$  be a function from (intensions of) properties to CCPs.

$$(DEF.8) \quad \downarrow = \lambda F \lambda R \lambda w \lambda w'. w' \in R(w) \wedge (\lambda x. F(x)(w)) = (\lambda x. F(x)(w')).$$

For any  $F$  such that for some  $x$ ,  $\lambda w. F(x)(w)$  is a non-constant function,<sup>17</sup>  $\downarrow F$  is an **update**. Given an accessibility relation  $R$ , it returns that  $R' \subseteq R$  such that  $w'$  is  $R'$ -accessible from  $w$  iff  $w'$  is  $R$ -accessible from  $w$  and for all  $x$ ,  $F(x)(w') = 1$  iff  $F(x)(w) = 1$ . That is,  $R(\downarrow F)$  is the subset of  $R$  which relates only worlds which agree regarding the extension of  $F$ . For convenience, we adopt postfix notation for  $\downarrow F$ , so that  $R(\downarrow F)$  denotes the result of applying  $\downarrow F$  to  $R$ .

The LT-regulator ‘exactly’ is treated as a determiner-modifier. Let  $Q, Q' \dots$  and  $\mathcal{Q}, \mathcal{Q}', \dots$  be variables over  $D_{\langle\langle e(st) \rangle \rangle \langle e(st) \rangle t}$  and  $D_{\langle\langle e(st) \rangle \rangle \langle e(st) \rangle \langle \sigma, \sigma \rangle}$  (i.e., the static and dynamic denotations of determiners respectively):

- (III.) a.  $\llbracket \text{exactly} \rrbracket = \lambda Q \lambda F \lambda G \lambda w. Q(F)(G)(w).$   
 b.  $\llbracket \text{exactly} \rrbracket = \lambda \mathcal{Q} \lambda F \lambda G \lambda R \lambda w \lambda w'. w' \in R(\downarrow G)(w). w' \in R(\downarrow G)(\mathcal{Q}(F)(G))(w).$

The static denotation of ‘exactly’ is the identity function for functions of type  $\langle\langle e(st) \rangle \rangle \langle e(st) \rangle t$ ;  $\llbracket \text{exactly} N_{DET} \rrbracket = \llbracket N_{DET} \rrbracket$ . The dynamic denotation of ‘exactly’ is a function mapping functions of type  $\langle\langle e(st) \rangle \rangle \langle e(st) \rangle \langle \sigma, \sigma \rangle$  (that is, the type of the dynamic denotation of determiners) to functions of the same type.

(2a) can be assigned the LF in (14), generating the static and dynamic denotations in (15) and (16), respectively.

$$(14) \quad \llbracket \llbracket \text{Exactly 14 million} \rrbracket \text{ books} \rrbracket \llbracket \lambda_1 \llbracket \llbracket \text{the BL} \rrbracket \llbracket \text{owns } t_1 \rrbracket \rrbracket \rrbracket.$$

$$(15) \quad \llbracket \llbracket (14) \rrbracket \rrbracket = \llbracket \llbracket (11) \rrbracket \rrbracket.$$

$$(16) \quad \llbracket \llbracket (14) \rrbracket \rrbracket = \lambda R \lambda w \lambda w'. w' \in R(\downarrow (\lambda x. \lambda w. \text{OWN}(\text{THE BL})(x)(w))) (w). R(\downarrow (\lambda x \lambda w. \text{OWN}(\text{THE BL})(x)(w))) \llbracket \llbracket (11) \rrbracket \rrbracket.$$

(11) and (14) statically denote the same proposition. However, the CCPs dynamically denoted by (11) and (14) differ. Unlike (11), the dynamic denotation of (14) is divisible into two components: an ‘at-issue’ update on the input relation  $R$  and a ‘not-at-issue’ domain restriction on the output of this update.

The ‘not-at-issue’ effect of  $\llbracket (14) \rrbracket$  is to make the relation returned by the CCP only partially defined in its second argument place. Given an input  $R$ ,  $\llbracket (14) \rrbracket$  returns a relation  $R[\llbracket (14) \rrbracket]$  such that, for all  $w$ ,  $R[\llbracket (14) \rrbracket](w)$  is defined on  $w'$  iff the set of entities owned by the British Library in  $w$  and  $w'$  are the same (and  $w' \in R(w)$ ). That is, for all  $w$ , the domain of  $R[\llbracket (14) \rrbracket](w)$  is  $\{w' \in R(w) : (\lambda x. \text{OWN}(\text{THE BL})(x)(w')) = (\lambda x. \text{OWN}(\text{THE BL})(x)(w))\}$ .

Unlike its counterpart (11) (which constitutes only a test on contexts), update with  $\llbracket (14) \rrbracket$  restricts the output relation so that it is only defined on worlds which agree with respect to the

<sup>17</sup> That is, any  $F$  such that  $F$  does not correspond to an essential property.

extension of the property denoted by the scope of its determiner. By treating the effect of LT-regulators as partially consisting in a domain restriction, this effect is made accessible to higher operators such as negation.

The ‘at-issue’ update associated with [(14)] can be further sub-divided into two component operations. First, it restricts its input  $R$  to that subset which relates  $w$  and  $w'$  iff the set of entities owned by the BL is the same in  $w$  and  $w'$ . Intuitively, this can be thought of as a modification of the input context which makes any difference with respect to what the BL owns pragmatically relevant. Second, it applies the test denoted by [(11)] to this relation. Thus,  $R[(14)](w) = \emptyset$  if there is no world  $w'$   $R$ -accessible from  $w$  at which the things owned by the British Library are the same at  $w$  and  $w'$  and number of books that it owns at  $w'$  is 14 million. Otherwise,  $R[(14)](w)$  is that subset of  $R(w)$  which agrees with  $w$  regarding the things owned by the British Library. Clearly, it follows that (14) will be consistent at  $\langle w, R \rangle$  iff the number of books owned by the BL at  $w$  is 14 million.<sup>18</sup>

For example, consider the evaluation of an utterance of (14) at  $C^\pm$  and  $w^*$ .  $R^{C^\pm}[(14)](w^*)$  is only defined on that subset of  $R^{C^\pm}(w^*)$  which agrees with  $w^*$  on the things owned by the British Library.  $R[(14)](w^*) = \emptyset$  unless that subset contains a world at which the British Library owns 14 million books. Otherwise,  $R[(14)]$  relates  $w^*$  to the members of the subset of  $R^{C^\pm}(w^*)$  which agrees with  $w^*$  on the things owned by the library, and is elsewhere undefined. Yet, since the British Library owns 13,950,000 books at  $w^*$ , there is no world which agrees with  $w^*$  regarding the things owned by the library at which it owns 14 million books. Hence, (14) is predicted to be infelicitous at  $C^\pm$ .

By (DEF.7), for any context  $C$ , the communicated content of (14) at  $C$  will be identical to the literal content of (11), since, for any  $C$ , (14) is consistent at  $\langle w, R^C \rangle$  iff  $\llbracket (14) \rrbracket$  is true at  $w$ . Thus, we correctly predict that (14) can be felicitously uttered only if its literal content is true, and that it communicates the same proposition as it literally expresses.

### 4.3. Negation

Let the static and dynamic denotations of negation be introduced syncategorematically:

- (IV.) a.  $\llbracket \neg\phi \rrbracket = \lambda w. \llbracket \phi \rrbracket(w) = 0$ .  
 b.  $\llbracket \neg\phi \rrbracket = \lambda R \lambda w \lambda w'. w' \in R(w) \wedge R[\phi](w) = \emptyset \wedge w' \in \text{DOM}(R[\phi](w))$ .

The static denotation of  $\neg\phi$  is simply  $\mathcal{D}_s\llbracket \phi \rrbracket$ . The dynamic denotation of  $\neg\phi$ , given an input  $R$ , returns that relation  $R[\neg\phi]$  such that, for all  $w$ ,  $w' \in R[\neg\phi](w)$  iff conditions (i.)–(iii.) are satisfied:

- (i.)  $R[\phi](w) = \emptyset$ ;
- (ii.)  $w' \in R(w)$ ;
- (iii.)  $w' \in \text{DOM}(R[\phi](w))$ .

<sup>18</sup> Assuming, at least, that if  $x$  is something owned by the BL, then it is pragmatically relevant whether  $x$  is a book.

Condition (i.) requires that  $\phi$  be inconsistent at  $\langle w, R \rangle$ . If this condition fails, then  $R[\neg\phi](w) = \emptyset$ . Condition (ii.) requires that  $w'$  be  $R$ -accessible from  $w$ . Accordingly,  $R[\neg\phi](w) \subseteq R(w)$ . Finally, the failures of commutativity observed in §2.3 suggest that the effects of LT-regulators project out of negation. Thus, condition (iii.) requires that  $R[\phi](w)$  be defined on  $w'$ . Accordingly,  $R[\neg\phi](w)$  includes only those members of  $R(w)$  which satisfy the domain restrictions (if any) introduced by  $[\phi]$ . Combining (i.)-(iii.), if  $R[\phi](w) = \emptyset$ , then  $R[\neg\phi](w)$  is that subset of  $R(w)$  in the domain of  $R[\phi](w)$ ; otherwise  $R[\neg\phi](w) = \emptyset$ .

Since  $\llbracket(11)\rrbracket = \llbracket(14)\rrbracket$ , the static denotations of their negations of are identical. However, the dynamic denotations of  $\neg(11)$  and  $\neg(14)$  differ substantially. To see why, consider the difference in the effect of their utterance at  $C^\pm$  and  $w$ .

Suppose, first, that  $\neg(11)$  is uttered. By condition (i.),  $R^{C^\pm}[\neg(11)](w^*) = \emptyset$  if  $R^{C^\pm}[\llbracket(11)\rrbracket](w^*) \neq \emptyset$ . Yet, as noted in §4.1, if the BL owns 13,950,000 books in  $w^*$ , then there is a world  $w'$   $R^{C^\pm}$ -accessible from  $w^*$  at which it owns 14 million. Hence,  $\emptyset \subset R^{C^\pm}[\llbracket(11)\rrbracket](w^*) = R^{C^\pm}(w^*)$ , and, accordingly,  $R^{C^\pm}[\neg(11)](w^*) = \emptyset$ .

In contrast, suppose  $\neg(14)$  is uttered. Since, as noted in §4.2,  $R^{C^\pm}[\llbracket(14)\rrbracket](w^*) = \emptyset$ , condition (i.) is satisfied. Thus,  $R^{C^\pm}[\neg(14)](w^*)$  is that subset of  $R^{C^\pm}(w^*)$  on which  $R^{C^\pm}[\llbracket(14)\rrbracket](w^*)$  is defined.  $R^{C^\pm}[\llbracket(14)\rrbracket](w^*)$  is defined on  $w'$  iff  $w' \in R(w^*)$  and agrees with  $w^*$  regarding the things owned by the BL. Thus,  $R^{C^\pm}[\neg(14)](w^*)$  is that subset of  $R(w^*)$  which agrees with  $w^*$  regarding the things owned by the BL. Thus, for all  $w' \in R^{C^\pm}[\neg(14)](w^*)$ , the BL owns 13,950,000 books in  $w'$ .

By (DEF.7), the communicated content of  $\neg(11)$  will be strictly stronger than its literal content. For all  $w$ , there is some world  $R^{C^\pm}$ -accessible from  $w$  at which the BL owns 14 million books iff the number of books the library owns at  $w$  is within the interval  $[13.5 \times 10^6, 14.5 \times 10^6]$ . Thus, an utterance of  $\neg(11)$  at  $C^\pm$  communicates the proposition that the number of books the library owns falls outside this interval. Clearly, this proposition asymmetrically entails the literal content of  $\neg(11)$ .

#### 4.4. Conjunction and failures of commutativity

Let the dynamic denotation of conjunction be introduced syncategorematically:

- (V.) a.  $\llbracket\phi \wedge \psi\rrbracket = \lambda w. \llbracket\phi\rrbracket(w) = \llbracket\psi\rrbracket(w) = 1$ .  
 b.  $[\phi \wedge \psi] = \lambda R. R[\phi][\psi]$ .

The static denotation of  $\phi \wedge \psi$  is the intersection of  $\llbracket\phi\rrbracket$  and  $\llbracket\psi\rrbracket$ . The dynamic denotation of  $\phi \wedge \psi$ , given a relation  $R$ , returns the result of sequentially updating  $R$  with  $[\phi]$  and  $[\psi]$ . Say that conjunction is statically commutative iff  $\phi \wedge \psi \models_{\text{T}} \psi \wedge \phi$ ; say that conjunction is dynamically commutative iff  $\phi \wedge \psi \models_{\text{C}} \psi \wedge \phi$ . Under (V.),  $\wedge$  is statically but not dynamically commutative. In particular,  $(11) \wedge \neg(14) \not\models_{\text{C}} \neg(14) \wedge (11)$ . To see why, consider the difference in the effect of the utterance of  $(11) \wedge \neg(14)$  and  $\neg(14) \wedge (11)$  at  $C^\pm$  and  $w^*$ .

Suppose, first, that  $(11) \wedge \neg(14)$  is uttered. As noted in §4.1, there is a world  $R^{C^\pm}$ -accessible from  $w^*$  at which the BL owns 14 million books. Thus,  $R^{C^\pm}[(11)](w^*) = R^{C^\pm}(w^*)$ . As such,  $R^{C^\pm}[(11) \wedge \neg(14)](w^*) = R^{C^\pm}[\neg(14)](w^*)$ . Yet as noted in §4.3, since (14) is inconsistent at  $\langle w^*, R^{C^\pm} \rangle$ ,  $R^{C^\pm}[\neg(14)](w^*)$  is that subset of  $R^{C^\pm}(w^*)$  which agrees with  $w^*$  on the things owned by the BL. Thus, since  $w^*$  is itself one such world,  $R^{C^\pm}[\neg(14)](w^*) \neq \emptyset$ . Utterances of  $(11) \wedge \neg(14)$  are correctly predicted to be felicitous at  $C^\pm$  and  $w^*$ .

In contrast, suppose that  $\neg(14) \wedge (11)$  is uttered. As noted,  $R^{C^\pm}[\neg(14)](w^*)$  is that subset of  $R^{C^\pm}(w^*)$  which agrees with  $w^*$  on the things owned by the BL. Thus, for any  $w'$  which is  $R^{C^\pm}[\neg(14)]$ -accessible from  $w^*$ , the BL owns 13,950,000 books in  $w'$ . Yet, from §4.1, for any  $R$ ,  $R[(11)](w^*) = \emptyset$  unless there is some world  $R$ -accessible from  $w^*$  at which the library owns 14 million books. Thus,  $R^{C^\pm}[\neg(14)][(11)](w^*) = \emptyset$ . Utterances of  $\neg(14) \wedge (11)$  are correctly predicted to be infelicitous at  $C^\pm$  and  $w^*$ .

More generally,  $(11) \wedge \neg(14)$  is predicted to be consistent at any  $\langle w, R \rangle$  such that  $w, R \models_c(11)$  but  $w, R \not\models_t(11)$ ; that is, at which (11) is false but felicitously assertable. In contrast,  $\neg(14) \wedge (11)$  is predicted to be inconsistent at all  $\langle w, R \rangle$ . As such, we correctly predict the contrast observed between (9a) and (9b).

## 5. Conclusion

Loose utterances display two central features which have gone widely unobserved: First, the communicated content of certain loose utterances of negated sentences is strictly stronger than the utterance's literal content. Second, the felicity of the loose utterance of certain conjunctions fails to commute. Under the present proposal, these features have been proposed to be related, and to arise from the interaction of negation, conjunction and LT-regulators in cases of loose talk.

More generally, it has been argued that in order to account for these phenomena it is important to recognize that loose utterances are not merely *dependent* upon contexts for their felicity, but also serve to *change* the context in systematic ways. Due to the effect of LT-regulators two sentences, such as (1) and (2b), which agree in their truth conditions may have different effects on context. To accommodate the role of LT-regulators, the effect of an utterance on a context must be taken to be determined by components of its meaning which outstrip its truth conditions. The fragment presented in §4 offers one way of implementing this observation.

# Implicatures of modified numerals: quality or quantity?<sup>1</sup>

Ivano CIARDELLI — *University of Amsterdam*

Liz COPPOCK — *University of Gothenburg*

Floris ROELOFSEN — *University of Amsterdam*

**Abstract.** This paper presents a theory of modified numerals that derives a three-way distinction in the implicature profile between superlative modifiers, comparative modifiers, and bare numerals. In contrast to the recent proposal by Schwarz (2016a), and drawing on elements from Coppock and Brochhagen's (2013) inquisitive analysis, the proposal decouples ignorance implicatures from upper-bounding implicatures, and thereby captures an important difference between *more than* and *at least*, which differ in their ignorance implicatures but both lack an upper-bounding implicature. At the same time, it accounts for the context-sensitivity in the ignorance implicatures of modified numerals found by Westera and Brasoveanu (2014), and addresses a problem with Coppock and Brochhagen (2013) pointed out by Schwarz (2016b). The key feature of the proposal is the fact that ignorance implicatures may arise in two different ways, namely, both from the Maxim of Quantity and from the Maxim of Quality.

**Keywords:** modified numerals, ignorance implicatures, inquisitive semantics.

## 1. Introduction

### 1.1. Empirical targets

We will be concerned with three types of modified numerals: *at least n*, *more than n*, and *n or more*. Many authors have observed that these contrast with each other, as well as with bare numerals, in the implicatures that they give rise to. The basic empirical picture, which is assumed in most work on the topic, is as follows (where the ignorance implicature of *at least six* and *six or more* is not just that the speaker does not know exactly how many sides a hexagon has, but also that she considers it possible that it has precisely six sides).

- |     |    |                                     |                            |                          |
|-----|----|-------------------------------------|----------------------------|--------------------------|
| (1) | a. | A hexagon has six sides.            | $\leadsto$ exactly six     | $\nrightarrow$ ignorance |
|     | b. | A hexagon has more than five sides. | $\nrightarrow$ exactly six | $\nrightarrow$ ignorance |
|     | c. | A hexagon has at least six sides.   | $\nrightarrow$ exactly six | $\leadsto$ ignorance     |
|     | d. | A hexagon has six or more sides.    | $\nrightarrow$ exactly six | $\leadsto$ ignorance     |

Westera and Brasoveanu (2014) argue based on experimental data that this basic empirical picture is actually a bit too simplistic. They presented experimental participants with a courtroom dialogue, in which a judge asks the witness a question (e.g. *What did you see under the bed?*) and the witness responds with a sentence containing a modified numeral, e.g. *I saw at most 10*

---

<sup>1</sup>We would like to thank the audience at Sinn und Bedeutung 21 in Edinburgh, as well as Stavroula Alexandropoulou, Dominique Blok, Alexandre Cremers, Jakub Dotlačil, Sven Lauer, Yaron McNabb, Rick Nouwen, Paul Portner, and Matthijs Westera for valuable feedback and discussion. Finally, we gratefully acknowledge financial support from the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (Starting Grant, agreement number 680220), and from the Riksbankens Jubileumsfond (Pro Futura Scientia scholarship).

The judge asks: "What did you see under the bed?"  
The witness responds:

\_\_\_ most \_\_\_

Based on this, the judge concludes:

"The witness doesn't know exactly how many  
of the coins she saw under the bed."

How justified is the judge in drawing that conclusion?

(not justified at all) 1 2 3 4 5 (strongly justified)

☐ ☐ ☐ ☐ ☐

POLAR Did you find {at most / less than} ten of the diamonds under the bed?

WHAT What did you find under the bed?

HOWMANY How many of the diamonds did you find under the bed?

APPROX Approximately how many of the diamonds did you find under the bed?

EXACT Exactly how many of the diamonds did you find under the bed?

DISJUNCT Did you find eight, nine, ten, or eleven of the diamonds under the bed?

Figure 1: Westera and Brasoveanu's (2014) design and results.

*diamonds under the bed*. The type of question was experimentally manipulated as indicated in Figure 1 below, and the witness's response always contained either *at most 10* or *less than 10*. The participant is then told that the judge concludes that the witness does not know exactly how many of the relevant kind of items she saw under the bed (the *ignorance inference*), and asked how justified the judge is in drawing that conclusion, on a 1-5 scale.

Their results (see Figure 1) show that comparative modifiers can signal ignorance (e.g. in response to 'how many' questions), and that ignorance can disappear for superlative modifiers (in response to certain polar questions). Note, however, that in most contexts, in particular in response to 'how many' questions, superlative modifiers do give rise to stronger ignorance implicatures than comparative modifiers, in line with what had been assumed in the literature. Another point to notice is that W&B's 'polar question' context involves an echo response.

- (2) A: Did you find at most 10 of the diamonds under the bed?  
B: I found at most 10 of the diamonds under the bed.

This may be essential for the ignorance implicature not to arise. Compare:

- (3) A: Did Johnny eat at least four apples today?  
B: Yes, he ate at least four apples.  $\nearrow$  ignorance

- (4) A: Did Johnny eat more than three apples today?  
B: Yes, he ate at least four apples.  $\leadsto$  ignorance

If we compare *more than* and *at least* in non-echo responses to a polar question, the latter seems to implicate ignorance but the former doesn't:

- (5) Context: *Johnny's diet prescribes that he eat at most three apples per day.*  
A: Did Johnny stick to his diet today?  
B: No, he ate more than three apples.  $\nearrow$  ignorance  
B': No, he ate at least four apples.  $\leadsto$  ignorance

Moreover, 'out of context', *at least* signals ignorance as well, unlike *more than*:

- (6) a. I grew up with more than two parents.  
b. ??I grew up with at least three parents.

Finally, ignorance implicatures triggered by *at least*, unlike implicatures triggered by *more than*, do not seem to be cancelable.

- (7) a. He has more than 10 cars. In fact, he has 12.  
b. He has at least 10 cars. #In fact, he has 12.

So, while we concede that *more than* can trigger an ignorance implicature in response to a 'how many' question, and that the ignorance implicature for *at least* can disappear in the context

of certain polar question-answer scenarios (of the echo variety), it seems that the ignorance implicature triggered by *at least* arises more widely than the one triggered by *more than*, and it is of a more obligatory and more robust nature.<sup>2</sup> What is the source of this difference?

## 1.2. Quality or quantity?

At least two approaches have been explored in the literature to explain the ignorance implicatures for superlative modifiers. One approach (e.g., Mayr, 2013b; Kennedy, 2015; Schwarz, 2016a) is to derive ignorance from a particular way of computing **quantity** implicatures. Differences between the various kinds of bare/modified numerals are accounted for on this approach by assuming that they activate different pragmatic alternatives.

Another approach (Coppock and Brochhagen, 2013) is to derive ignorance as a **quality** implicature. The standard Gricean quality maxim, however, does not suffice for this purpose. Rather, Coppock and Brochhagen invoke a quality maxim that is not only concerned with the *informative* content of the uttered sentence, but also with its *inquisitive* content, i.e., the semantic alternatives that it introduces. Differences between the various kinds of bare/modified numerals are accounted for on this approach by assuming that they introduce different semantic alternatives.

Note that in other empirical domains (e.g., free choice effects of disjunction under modals or in the antecedent of a conditional), these two approaches have also both been pursued. We will suggest that, in the domain of modified numerals, a **combination** of the two approaches is in fact needed. We will develop such a combined account, and show that it improves on earlier proposals which placed the entire explanatory burden either on quantity or on quality.

## 2. Previous approaches

### 2.1. Quantity-based

We will first review a specific quantity-based account of ignorance implicatures, reformulating it in a way that will allow for easy comparison with our own approach. We focus on the proposal of Schwarz (2016a), but see Mayr (2013a) and Kennedy (2015) for closely related proposals.

Schwarz is concerned with *at least n* (not with *more than n* or with *n or more*). He assumes that  $\langle \textit{at least, only} \rangle$  forms a Horn scale, along with  $\langle 1, 2, 3, \dots \rangle$ . This yields the following set of pragmatic alternatives for *Al hired at least two cooks*:

---

<sup>2</sup>Shortly before the deadline for submitting the present paper, we became aware of the work of Mayr and Meyer (2014), who make very similar empirical observations, and offer an alternative account of the crucial datapoints. Detailed comparison with the present approach must be left for a future occasion.

|     |        |    |    |    |     |     |   |            |
|-----|--------|----|----|----|-----|-----|---|------------|
| [1] | only 1 | [1 | 2  | 3  | 4   | ... | ) | at least 1 |
| [2] | only 2 |    | [2 | 3  | 4   | ... | ) | at least 2 |
| [3] | only 3 |    |    | [3 | 4   | ... | ) | at least 3 |
| [3] | only 4 |    |    |    | [4  | ... | ) | at least 4 |
| ... | ...    |    |    |    | ... |     |   | ...        |

The meanings are visually represented in a way that brings out the fact that none of them are *innocently excludable*, as we will explain below.

To articulate the pragmatics, we introduce the following background notions and notation:

- A speaker's **information state** is a non-empty set of worlds.
- A state  $s$  **supports** a sentence  $\varphi$  iff  $s \subseteq \llbracket \varphi \rrbracket$ .
- A state  $s$  **rejects** a sentence  $\varphi$  iff  $s \cap \llbracket \varphi \rrbracket = \emptyset$ .
- We use  $A_\varphi$  to denote the set of **lexically determined pragmatic alternatives** for  $\varphi$ .

Implicatures can be seen as imposing constraints on what the speaker's information state might be. On Schwarz's approach, they are derived using the following recipe, based on Innocent Exclusion. Start with the **quality implicature** that the speaker's state  $s$  supports  $\varphi$ :

$$0_\varphi := \{s \mid s \text{ supports } \varphi\}$$

Now derive **primary quantity implicatures**: the speaker's state does not support any alternative  $\psi \in A_\varphi$  that is stronger than  $\varphi$  itself. Let  $A_\varphi^\subseteq$  be the set of those stronger alternatives:

$$A_\varphi^\subseteq := \{\psi \in A_\varphi \mid \llbracket \psi \rrbracket \subset \llbracket \varphi \rrbracket\}$$

$$1_\varphi := \{s \in 0_\varphi \mid s \text{ does not support any } \psi \in A_\varphi^\subseteq\}$$

Now derive **secondary quantity implicatures** by identifying all alternatives  $\psi \in A_\varphi^\subseteq$  satisfying the following two conditions:

1.  $\psi$  is **not known** by the speaker according to  $1_\varphi$ . That is, no  $s \in 1_\varphi$  supports  $\psi$ .
2.  $\psi$  is **innocently excludable** relative to  $\varphi$  (Gazdar, 1979; Fox, 2007).

In a nutshell,  $\psi$  is innocently excludable if, whenever a set of alternatives in  $A_\varphi^\subseteq$  has been consistently rejected we can always go on to reject  $\psi$  in addition, maintaining consistency. More precisely: for every subset  $A'$  of  $A_\varphi^\subseteq$ , if there are information states that validate the quality implicature and primary quantity implicatures of  $\varphi$  while rejecting every sentence in  $A'$ , i.e., if:

$\{s \in 1_\varphi \mid s \text{ rejects every sentence in } A'\}$  is **non-empty**

then there are also information states that validate the quality implicature and primary quantity implicatures of  $\varphi$  while rejecting every sentence in  $A'$  *as well as*  $\psi$ :

$\{s \in 1_\varphi \mid s \text{ rejects every sentence in } A' \cup \{\psi\}\}$  is **non-empty**

If  $\psi \in A_\varphi^\subseteq$  is not known by the speaker according to  $1_\varphi$  and innocently excludable relative to  $\varphi$ , then we say that  $\psi$  is **eligible for a secondary quantity implicature**.

$2_\varphi := \{s \in 1_\varphi \mid s \text{ rejects every } \psi \in A_\varphi^\subseteq \text{ eligible for a secondary quantity implicature}\}$

Uttering a sentence  $\varphi$  against the background of a question  $Q$  in information state  $s$  is **licensed** only if  $s \in 0_\varphi$  (speaker adheres to Quality) and  $s \in 1_{\varphi,Q} \cap 2_{\varphi,Q}$  (speaker adheres to Quantity). Since  $0_\varphi \subseteq 1_{\varphi,Q} \subseteq 2_{\varphi,Q}$ , this amounts to saying that  $s \in 2_{\varphi,Q}$ .

None of the pragmatic alternatives that Schwarz assumes for *Al hired at least two cooks* (see above) is innocently excludable. For instance, rejecting ‘only two’ is not consistent with rejecting ‘at least three’, given the quality assumption that ‘at least two’. So we get primary quantity implicatures, but no secondary ones. Hence ignorance is derived, and no ‘upper bounding’ implicature (exactly  $n$ ) arises, as desired.

**Shortcomings** This approach entails a very tight coupling between ignorance implicatures and upper bounding implicatures. A consequence of this is that it is unclear how to distinguish *more than* from *at least*; as mentioned above, both lack upper bounding implicatures, but behave differently with respect to ignorance.

Furthermore, the effects of the QUD documented by Westera and Brasoveanu (2014) are not immediately accounted for (although Schwarz makes it clear that the theory should ultimately be refined, restricting the set of pragmatic alternatives to those that are contextually relevant). We aim to remedy both of these shortcomings in the proposal below.

## 2.2. Quality-based

The quality-based approach that we will build on (Coppock and Brochhagen, 2013) is formulated in inquisitive semantics (Ciardelli et al., 2013). In this framework, every sentence generates a set of semantic alternatives (where each semantic alternative is a set of possible worlds). If a sentence generates two or more alternatives, it is thought of as expressing an issue as to which of these alternatives holds.

Coppock and Brochhagen propose that the set of alternatives generated by an *at least* sentence consists of all those alternatives that are pragmatically at least as strong as one of the alternatives

generated by the prejacent. For example, *At least two apples fell* generates the set of alternatives corresponding to *Two apples fell*, *Three apples fell*, *Four apples fell*, etc. Assuming a one-sided analysis of bare numerals, this amounts to the following:

- (8) *At least two apples fell*:  $\{[2,...], [3,...], [4,...], \dots\}$

On a two-sided analysis, the denotation would be:

- (9) *At least two apples fell*:  $\{[2], [3], [4], \dots\}$

Coppock and Brochhagen further assume, besides the standard Gricean quality maxim, ‘Don’t claim things you don’t believe to be true’, an inquisitive quality maxim as well, which can be characterized informally as: ‘Don’t utter an inquisitive sentence if you already know how to resolve the issue that it expresses’ (cf. Groenendijk and Roelofsen, 2009). More technically, if a sentence generates multiple alternatives, then, when restricted to the speaker’s state, it should still generate multiple alternatives. This, together with the semantics in (8) or (9), derives ignorance implicatures for *at least* sentences.

**Shortcomings** C&B capture the fact that *at least* generates ignorance implicatures but no upper bounding implicatures, and the fact that bare numerals exhibit exactly the opposite pattern. The analysis is also QUD-sensitive. However, for *more than* they predict that ignorance implicatures do not arise at all, which is in conflict with Westera and Brasoveanu’s (2014) experimental results. Moreover, they do not derive the lack of upper bounding implicatures for *more than*. This is a symptom of a deeper problem, which C&B share with the quantity-based approach: the coupling between ignorance implicatures and the lack of upper bounding implicatures is too tight. This means that it becomes difficult, if not impossible, to capture the differences and similarities between *more than* and *at least*: they behave differently with respect to ignorance, but they both lack upper bounding implicatures.

Even if we focus just on *at least*, the C&B account is not fully satisfactory, because, as pointed out by Schwarz (2016b), the ignorance implicature that is derived for *at least n* is too weak: the approach predicts that a speaker uttering (9) should not know exactly how many apples fell, but not that she should consider it possible that exactly *n* apples fell.

Finally, there is framework issue: C&B formulate their account in ‘unrestricted’ inquisitive semantics,  $\text{Inq}_U$ , an extension of the standard, basic inquisitive semantics framework,  $\text{Inq}_B$ .  $\text{Inq}_U$  makes more meanings available than  $\text{Inq}_B$  does: the latter does not allow for one alternative to be nested in another—as is the case for instance in (8)—while in  $\text{Inq}_U$  there are no restrictions on alternative-sets (hence the label ‘unrestricted’). However, this extra richness of  $\text{Inq}_U$  comes at a price. First, the resulting notion of meaning is less well-behaved from a logical point of view. In particular, it does not come with a suitable notion of entailment and therefore lacks the usual algebraic operations on meanings, like *meet* and *join* (cf., Roelofsen, 2013; Ciardelli et al., 2016). Second,  $\text{Inq}_U$  is arguably also less well-behaved from an empirical point of view: as discussed in detail in Ciardelli and Roelofsen (2016), while  $\text{Inq}_B$  straightforwardly facili-

tates an uniform redundancy-based account of so-called *Hurford effects* across declaratives and interrogatives (building on [Katzir and Singh, 2013](#), among others),  $\text{Inq}_U$  seems to render such an account impossible. One question, then, is whether an analysis of modified numerals along the lines of C&B really needs the full expressive power of  $\text{Inq}_U$ , or whether it could also be formulated in  $\text{Inq}_B$ .

### 3. Proposal

We now spell out a hybrid approach, combining insights from the quality- and quantity-based approaches, and overcoming their respective shortcomings. We provide the necessary background notions and notation from  $\text{Inq}_B$  in Section 3.1, spell out our lexical assumptions in Section 3.2, and then turn to the pragmatic component of the account in Section 3.3.

#### 3.1. Background notions and notation

In  $\text{Inq}_B$ , the meaning of a sentence  $\varphi$ , denoted  $\llbracket \varphi \rrbracket$ , is a set of propositions encoding both the information that is conveyed and the issue that is expressed by  $\varphi$ . Namely,  $\varphi$  is taken to convey the information that the actual world is contained in  $\text{info}(\varphi) := \bigcup \llbracket \varphi \rrbracket$ , and to express an issue which is resolved precisely by those propositions that are in  $\llbracket \varphi \rrbracket$ . It is assumed that if a proposition  $p$  resolves an issue, then any stronger proposition  $q \subseteq p$  resolves that issue as well. Thus,  $\llbracket \varphi \rrbracket$  is always *downward closed*: if it contains a proposition  $p$  it also contains any  $q \subseteq p$ . Furthermore, it is assumed that the inconsistent proposition,  $\emptyset$ , resolves any issue. Thus,  $\llbracket \varphi \rrbracket$  always contains  $\emptyset$  and is therefore always non-empty. Taken together, sentence meanings in  $\text{Inq}_B$  are defined as non-empty, downward closed sets of propositions.

In some cases the issue expressed by  $\varphi$  is *trivial*, in the sense that it is already resolved by the information provided by  $\varphi$  itself. This occurs precisely if  $\text{info}(\varphi) \in \llbracket \varphi \rrbracket$ . A sentence  $\varphi$  is called **inquisitive** just in case the issue it expresses is non-trivial, i.e., just in case  $\text{info}(\varphi) \notin \llbracket \varphi \rrbracket$ .

Finally, the **alternatives** associated with a sentence  $\varphi$  in  $\text{Inq}_B$  are those propositions that contain precisely enough information to resolve the issue expressed by  $\varphi$ . Technically, these are the maximal elements of  $\llbracket \varphi \rrbracket$ :

$$\text{alt}(\varphi) := \{p \in \llbracket \varphi \rrbracket \mid \text{there is no } q \in \llbracket \varphi \rrbracket \text{ such that } p \subseteq q\}$$

Note that, as remarked above, this characterization of alternatives entails that one alternative can never be properly contained in another, otherwise it could not be a maximal element of  $\llbracket \varphi \rrbracket$ . Also note that if  $\varphi$  is non-inquisitive, it is always associated with a unique alternative, namely  $\text{info}(\varphi)$ . Vice versa, if  $\varphi$  generates multiple alternatives, then it must be inquisitive.<sup>3</sup>

<sup>3</sup>We should note here that there are several perspectives one can take on the connection between inquisitiveness, a semantic notion, and the communicative effects of sentences when uttered in discourse. The perspective assumed here, in the spirit of [Groenendijk \(2009\)](#) and [Coppock and Brochhagen \(2013\)](#), is that even if a sentence is inquisitive, i.e., even if it semantically expresses a non-trivial issue, a speaker who utters this sentence in discourse does not necessarily *raise* this issue. In particular, she does not necessarily *request* a response that addresses the issue. Under this perspective, it is possible to assume that a disjunctive declarative like *John ate*

### 3.2. Lexical assumptions

Following C&B, we assume that *at least* sentences generate multiple alternatives. However, we adopt a suggestion made by Schwarz (2016b) in his critique of C&B and analyze *at least n* as having the same meaning as *n or more* would have in inquisitive semantics.<sup>4</sup> For example:

$$(10) \quad \text{alt}( \textit{At least two apples fell} ) = \text{alt}( \textit{Two or more apples fell} ) = \{ [2], [3, \dots] \}$$

Notice that, unlike in the C&B analysis, the alternatives for *at least n* are not nested within each other; in fact, they are mutually exclusive. This means that the analysis we are proposing can be formulated in the standard inquisitive semantics framework  $\text{Inq}_B$ , allowing us to avoid the problems that arise in the unrestricted framework  $\text{Inq}_U$ .<sup>5</sup>

Following C&B we assume that *more than n* contrasts with *at least n* and with *n or more* in that it is associated with a single semantic alternative:<sup>6</sup>

$$(11) \quad \text{alt}( \textit{More than two apples fell} ) = \{ [3, \dots] \}$$

Turning now to pragmatic alternatives, we assume that the lexically determined pragmatic alternatives for *at least n* are  $\{ \textit{at least m} \mid m \in \mathbb{N} \}$  and  $\{ m \mid m \in \mathbb{N} \}$ , and similarly for *n or more* and for *more than n*:

- (12) Lexically determined pragmatic alternatives
- a. *at least n*:  $\{ \textit{at least m} \mid m \in \mathbb{N} \} \cup \{ m \mid m \in \mathbb{N} \}$
  - b. *n or more*:  $\{ m \textit{ or more} \mid m \in \mathbb{N} \} \cup \{ m \mid m \in \mathbb{N} \} \cup \{ \textit{more than m} \mid m \in \mathbb{N} \}$
  - c. *more than n*:  $\{ \textit{more than m} \mid m \in \mathbb{N} \} \cup \{ m \mid m \in \mathbb{N} \}$

*two or three apples* (with falling intonation) is inquisitive, just like the corresponding interrogative *Did John eat two apples, or three?*. One could say that the former is used to make an *assertion* and the latter to ask a *question*, and that in making an assertion, speakers do not raise the issue that the uttered sentence expresses (perhaps their assertion still ‘evokes’ the issue, but the effect is weaker than in the case of a question). Another perspective that one could take (see, e.g., Farkas and Roelofsen, 2016) is that the issue expressed by a sentence is always raised when the sentence is uttered in discourse. Under this perspective, it does not make sense to treat a disjunctive declarative as being inquisitive, on a par with the corresponding disjunctive question. This perspective allows for a more economical interface between semantics and discourse pragmatics, but is not directly compatible with the present proposal.

<sup>4</sup>The idea of treating *at least n* on a par with *n or more* goes back to Büring (2008).

<sup>5</sup>The meaning for *at least n* given here should, of course, be obtained from a general analysis of *at least*, one that allows us to analyze *at least* in combination with arguments other than numerals. Building on Solt (2011) and Coppock (2016), we assume that an expression of the form *at least P* is interpreted relative to a context providing (i) a *comparison class*, which is a set  $\Phi$  of propositions, including the proposition associated with the prejacent *P* and (ii) a *pragmatic strength ordering*, which is a partial order on  $\Phi$ , possibly but not necessarily coinciding with entailment. Relative to such a context, *at least P* is associated with two semantic alternatives: one is the exhaustification of the prejacent *P* with respect to the stronger propositions in  $\Phi$ ; the other is the union of all propositions in  $\Phi$  which are strictly stronger than *P*. The meaning that we assume in this paper for *at least n* is obtained from this general account by taking the comparison class to be  $\Phi = \{ [0], [1], [2], \dots \}$ , where the strength ordering corresponds to the usual ordering on natural numbers.

<sup>6</sup>The account of *more than n* given here can be lifted to a general treatment of *more than*, allowing for arguments other than numerals, in a way similar to the one sketched in footnote 5 for *at least*.

In general, we assume that the lexical pragmatic alternatives for an expression  $\varphi$  are obtained either by deleting parts of  $\varphi$ , or by replacing a scalar item in  $\varphi$  with an element of the same scale.<sup>7</sup> This makes our pragmatic assumptions less stipulative than those of Schwarz (2016a), and more in line with general theories of pragmatic alternatives (see, in particular, Katzir, 2007).

Following Kennedy (2015), we assume that numerals are ambiguous between a one-sided and a two-sided reading, and the choice between these readings is determined by which yields a stronger interpretation. A two-sided meaning is stronger in a simple positive context, so that is what the  $m$  alternatives amount to in such a context.

### 3.3. Pragmatic assumptions

#### 3.3.1. Quality

Following C&B and earlier work on inquisitive pragmatics (Groenendijk and Roelofsen, 2009), we assume that Quality pertains both to the informative and the inquisitive content of the sentence that is uttered. **Informative sincerity** (Gricean Quality) requires that if a speaker utters a sentence  $\varphi$ , her information state  $s$  should support the informative content of  $\varphi$ :<sup>8</sup>  $s \subseteq \text{info}(\varphi)$ .

On the other hand, **inquisitive sincerity** requires that a speaker should not utter an inquisitive sentence if she already knows how to resolve the issue that the sentence expresses. That is, if  $\varphi$  is inquisitive, then the speaker's information state  $s$  should not already resolve the issue expressed by  $\varphi$ :<sup>9</sup>  $s \notin \llbracket \varphi \rrbracket$ . Together:

$$(13) \quad s \in \text{sincere}(\varphi) \quad \text{iff} \quad s \subseteq \text{info}(\varphi) \text{ and if } \varphi \text{ is inquisitive, then } s \notin \llbracket \varphi \rrbracket$$

#### 3.3.2. Quantity

Following Schwarz (2016a) and many others, we assume that the maxim of quantity is concerned with alternative expressions that the speaker could have used. However, only expressions that are relevant to the question under discussion should be taken into consideration. Thus, unlike Schwarz, we distinguish **lexical** pragmatic alternatives from **contextual** prag-

<sup>7</sup>Strictly speaking, this means that expressions of the form *m* and *more* also count as alternatives for *n* or *more*. However, since such expressions are inconsistent, their presence does not affect the predictions of the theory. Therefore, they are left out of consideration and not listed above.

<sup>8</sup>Of course, this maxim and the ones below are only assumed to be in force in a specific type of conversation, namely one in which the participants exchange information in a fully cooperative way.

<sup>9</sup>The original formulation of the inquisitive sincerity maxim in Groenendijk and Roelofsen (2009) makes reference to the common ground: "If a speaker utters a sentence  $\varphi$  that is inquisitive w.r.t. the common ground, then  $\varphi$  should be inquisitive w.r.t. the speaker's information state as well." For our current purposes this qualification is not necessary. Note also that Coppock & Brochhagen operate with a stronger sincerity maxim, which they call the maxim of *interactive sincerity*. On their account this is needed because the predictions that inquisitive sincerity delivers are too weak. On our present account, inquisitive sincerity delivers the right predictions, and interactive sincerity would do so as well; indeed, interactive sincerity boils down to inquisitive sincerity in InqB.

matic alternatives. The set of lexical pragmatic alternatives for a sentence  $\varphi$  is denoted as  $A_\varphi$ . The set of contextual pragmatic alternatives for  $\varphi$  relative to a question under discussion  $Q$ , denoted  $A_{\varphi,Q}$ , contains only those lexical pragmatic alternatives that are **relevant** to  $Q$ :

$$(14) \quad A_{\varphi,Q} = \{\psi \in A_\varphi \mid \psi \text{ is relevant to } Q\}$$

What does it mean for  $\psi$  to be relevant to  $Q$ ? Recall that the semantic alternatives in  $\text{alt}(Q)$  are propositions that contain precisely enough information to resolve the issue expressed by  $Q$ . They can be thought of, then, as wholly relevant, complete resolutions of  $Q$ . Similarly, any union of two or more such alternatives can be thought of as a wholly relevant, partial resolution of  $Q$ . Thus, we say that  $\psi$  is relevant to  $Q$  if and only if  $\text{info}(\psi)$  coincides with the union of a set of semantic alternatives in  $\text{alt}(Q)$ .

For our current purposes we will stay as close as possible to Schwarz's Innocent Exclusion-based recipe for deriving implicatures. The only serious change is that the standard Gricean Quality requirement is replaced by the requirement that the speaker be both informatively and inquisitively sincere; we also restrict attention to relevant alternatives. So the recipe runs as follows:

The first step, as before, is to compute the **quality implicature**:

$$0_\varphi = \{s \mid s \in \text{sincere}(\varphi)\}$$

Next, also as before, we compute **primary quantity implicatures**, based on the assumption that any pragmatic alternative for  $\varphi$  that would have been more informative was apparently not sincerely utterable, either the speaker's information state doesn't support its informative content, or because the speaker can already resolve the issue that it expresses. We restrict the set of pragmatic alternatives here to those that are relevant,  $A_{\varphi,Q}$ . Let  $A_{\varphi,Q}^\subseteq$  be the set of such alternatives that are stronger than  $\varphi$  itself:  $A_{\varphi,Q}^\subseteq = \{\psi \in A_{\varphi,Q} \mid \text{info}(\psi) \subset \text{info}(\varphi)\}$ .

$$1_{\varphi,Q} = \{s \in 0_\varphi \mid \text{for all } \psi \in A_{\varphi,Q}^\subseteq : s \notin \text{sincere}(\psi)\}$$

Finally, again as before, we compute **secondary quantity implicatures**. The recipe for doing so is the same as on Schwarz's proposal, except that we now take  $Q$  into consideration. That is, we identify all pragmatic alternatives  $\psi$  in  $A_{\varphi,Q}^\subseteq$  such that:

1.  $\psi$  is **not known** by the speaker according to  $1_{\varphi,Q}$ . That is, no  $s \in 1_{\varphi,Q}$  supports  $\text{info}(\psi)$ .
2.  $\psi$  is **innocently excludable** relative to  $\varphi$  and  $Q$ .

The second condition is satisfied just in case for every subset  $A'$  of  $A_{\varphi,Q}^\subseteq$ , if there are information states that validate the quality implicature and primary quantity implicatures of  $\varphi$  while rejecting every sentence in  $A'$ , i.e., if:

$\{s \in 1_{\varphi, Q} \mid s \text{ rejects every sentence in } A'\}$  is **non-empty**

then there are also information states that validate the quality implicature and primary quantity implicatures of  $\varphi$  while rejecting every sentence in  $A'$  *as well as*  $\psi$ :

$\{s \in 1_{\varphi, Q} \mid s \text{ rejects every sentence in } A' \cup \{\psi\}\}$  is **non-empty**

If  $\psi \in A_{\varphi, Q}^{\subset}$  is not known by the speaker according to  $1_{\varphi, Q}$  and innocently excludable relative to  $\varphi$  and  $Q$ , then we say that  $\psi$  is **eligible for a secondary quantity implicature**.

$2_{\varphi, Q} = \{s \in 1_{\varphi, Q} \mid s \text{ rejects any } \psi \in A_{\varphi, Q}^{\subset} \text{ eligible for a secondary quantity implicature}\}$

As before, uttering a sentence  $\varphi$  against the background of a question  $Q$  in information state  $s$  is **licensed** only if  $s \in 2_{\varphi, Q}$ , that is, only if the speaker adheres to Quality and Quantity.

#### 4. Predictions

We now discuss the predictions that our account makes for sentences involving bare or modified numerals.

##### 4.1. Predictions in the context of a *how many* question

Suppose the question under discussion is (15a), which we take to be associated with the set of alternatives in (15b).

- (15) a. How many apples did John eat?  
b.  $Q = \{[0], [1], [2], [3], [4], [5], \dots\}$

**Bare numerals** First let us consider our predictions for the sentence (16a), involving the bare numeral *three*. Again, following Kennedy (2015), we assume that numerals are scopally ambiguous between a one-sided interpretation (e.g.  $[3, \dots]$ ) and a two-sided one (e.g.  $[3]$ ), and that the interpretation that yields the strongest meaning is the one that is chosen. This means that the basic interpretation of the bare numeral example in (16a) is an ‘exactly’ reading:

- (16) a.  $\varphi$ : John ate three apples.  
b.  $\text{alt}(\varphi) = \{[3]\}$

Since this sentence is not inquisitive, quality simply requires the speaker to believe that the number of apples that John ate is indeed three.

- (17)  $0_{\varphi} = \text{sincere}(\varphi) = \{s \mid s \subseteq [3]\}$

It is easy to see that, given this strong quality implicature, quantity implicatures cannot lead to any stronger conclusion about the speaker's state. Thus, for (16a) we predict an exact interpretation, and no ignorance implicature.

**Superlative modifiers** Next, let us consider the sentence (18a), involving the superlative modifier *at least*. The semantic alternatives for this sentence in our account are given in (18b).

- (18) a.  $\varphi$  : John ate at least three apples.  
 b.  $\text{alt}(\varphi) = \{[3], [4, \dots]\}$

Consider the quality implicatures that are drawn about the state  $s$  of the speaker. As before, sincerity requires that  $s \subseteq \text{info}(\varphi)$ , that is,  $s \subseteq [3, \dots)$ . However, since  $\varphi$  is inquisitive, now sincerity also requires  $s \not\subseteq \llbracket \varphi \rrbracket$ ; that is, it requires  $s$  not to be included in either of the alternatives for  $\varphi$ ; in other words, the speaker should not believe that the number of apples was exactly three, nor should she believe that the number is larger than three. Formally, we have:

- (19)  $0_\varphi = \text{sincere}(\varphi)$   
 $= \{s \mid s \subseteq [3, \dots) \text{ and } s \not\subseteq [3] \text{ and } s \not\subseteq [4, \dots)\}$

So, from quality considerations we already infer not only that the speaker believes that the number of apples John ate is at least 3, but also that she considers it possible that this number is exactly 3, and that she considers it possible that it is larger than 3.

Next, consider quantity implicatures. We have assumed that the lexical pragmatic alternatives for  $\varphi$  are sentences of the form  $\psi_n = \text{John ate at least } n \text{ apples}$  or of the form  $\chi_n = \text{John ate } n \text{ apples}$ , for  $n \in \mathbb{N}$ . All of these sentences are relevant for the question  $Q$ , and therefore they qualify as contextual pragmatic alternatives. Thus,  $A_{\varphi, Q}^\subseteq$  consists of the sentences  $\psi_n$  with  $n > 3$ , as well as  $\chi_n$  with  $n \geq 3$ . Primary quantity implicatures require that none of these sentences could be sincerely uttered by the speaker. However, this is already guaranteed by quality. For take any state  $s \in 0_\varphi$ . Since  $s \not\subseteq [4, \dots)$ , whenever  $n > 3$  we have that  $s \not\subseteq \text{sincere}(\psi_n)$  and  $s \not\subseteq \text{sincere}(\chi_n)$ , because informative sincerity fails for these sentences. Moreover, since  $s \not\subseteq [3]$ , we also have  $s \not\subseteq \text{sincere}(\chi_3)$ . What this shows is that  $1_{\varphi, Q} = 0_\varphi$ , which means that nothing new is concluded by drawing primary quantity implicatures.

Finally, we will show that no contextual alternative in  $A_{\varphi, Q}^\subseteq$  is eligible for a secondary quantity implicature. Consider for example the 'at least' sentence  $\psi_5$ , *John ate at least 5 apples*. This alternative is not innocently excludable. To see this, consider the set  $A' = \{\chi_4\}$ , where  $\chi_4 = \text{John ate 4 apples}$ , which receives an two-sided ('exactly') interpretation in this context because the two-sided interpretation is stronger than the one-sided one. Rejecting  $\chi_4$  is consistent with the primary quantity implicatures; some information states in  $1_{\varphi, Q}$  reject it (as a witness, take the state  $[3] \cup [5]$ ). But, given the primary and secondary implicatures, rejecting  $\chi_4$  is not consistent with rejecting our candidate alternative  $\psi_5$  (*John ate at least 5 apples*); no information state in  $1_{\varphi, Q}$  rejects both. In a nutshell, since rejecting  $\psi_5$  forces acceptance of  $\chi_4$ , the former is not innocently excludable. Similar reasoning holds for all of the other 'at

least' formulas  $\psi_n$  with  $n > 3$ .<sup>10</sup> Similarly, to show that each bare numeral alternative  $\chi_n$  is not innocently excludable we can take  $A'_n = \emptyset$  if  $n = 3$ , and  $A'_n = \{\chi_m \mid m \geq 4, m \neq n\}$  if  $n > 3$ .

This shows that no element of  $A_{\varphi, Q}^{\subseteq}$  is eligible for a secondary quantity implicature, which means that  $2_{\varphi, Q} = 1_{\varphi, Q}$ . This means that no secondary quantity implicatures are derived, or more precisely, nothing new is concluded about the state of the speaker by drawing secondary quantity implicatures.

In conclusion, we have  $2_{\varphi, Q} = 0_{\varphi} = \{s \mid s \subseteq [3, \dots) \text{ and } s \not\subseteq [3] \text{ and } s \not\subseteq [4, \dots)\}$ . Thus, we predict that, from an utterance of (18a) in the context of question (15a), an ignorance implicature is drawn, and no upper bounding implicature. Importantly, the relevant ignorance implicature is not just that the speaker does not know exactly how many apples John ate, but also that the speaker does not know whether John eat exactly three apples or more.

***n or more*** Disjunctions of the form *n or more* are predicted to behave in a parallel fashion to *at least n*. They have the same denotation:

- (20) a.  $\varphi$ : John ate three or more apples.  
b.  $\text{alt}(\varphi) = \{[3], [4, \dots)\}$

The lexical alternatives are sentences of the form *m*, *m or more*, and *more than m* for all natural numbers *m*. All of these will be relevant in the context of a 'how many' question, and none of them will be innocently excludable for reasons parallel to the ones just given for *at least*. Thus, once again we will predict a strong ignorance implicature, and no upper bounding implicatures.

**Comparative modifiers** Finally, consider (21a). We have assumed that this sentence has a unique semantic alternative, given in (21b).

- (21) a.  $\varphi$ : John ate more than two apples.  
b.  $\text{alt}(\varphi) = \{[3, \dots)\}$

Let us compute what implicatures are predicted for  $\varphi$  in the context of  $Q$ . First consider quality implicatures: since  $\varphi$  is not inquisitive, only the condition  $s \subseteq \text{info}(\varphi)$  is relevant to sincerity. Therefore, we have:

- (22)  $0_{\varphi} = \text{sincere}(\varphi) = \{s \mid s \subseteq [3, \dots)\}$

So, from quality we infer that the speaker believes that John ate at least three apples.

Now let us turn to quantity implicatures. The set of lexical pragmatic alternatives to  $\varphi$  consists

<sup>10</sup>To see this, consider the set  $A'_n = \{\chi_4, \dots, \chi_{n-1}\}$  (in particular, take  $A'_4 = \emptyset$ ). Some information states in  $1_{\varphi, Q}$  reject all elements of  $A'_n$ : if  $n = 4$ , this holds trivially, as  $A'_4 = \emptyset$ ; if  $n > 4$ , we can take as a witness the state  $[3] \cup [n]$ . However, no information state in  $1_{\varphi, Q}$  rejects all elements of  $A'_n$  in addition to  $\psi_n$ .

of all sentences of the form  $\psi_n = \text{John ate more than } n \text{ apples}$  or  $\chi_n = \text{John ate } n \text{ apples}$  for  $n$  a natural number. All of these pragmatic alternatives are relevant to the question  $Q$  we are considering, and therefore qualify as contextual pragmatic alternatives. Therefore,  $A_{\varphi,Q} = \{\psi_n | n \in \mathbb{N}\} \cup \{\chi_n | n \in \mathbb{N}\}$  and  $A_{\varphi,Q}^{\subseteq} = \{\psi_n | n \geq 3\} \cup \{\chi_n | n \geq 3\}$ . Just like  $\varphi$ , all pragmatic alternatives  $\psi_n$  are non-inquisitive, nor are the pragmatic alternatives  $\chi_n$ , which means that the sincerity condition boils down to  $s \subseteq \text{info}(\psi_n)$  and  $s \subseteq \text{info}(\chi_n)$ . Therefore, we have the following primary quantity implicatures:

$$(23) \quad \begin{aligned} 1_{\varphi,Q} &= \{s \in 0_{\varphi} \mid s \not\subseteq \text{sincere}(\psi_n) \text{ for } n \geq 3\} \cap \{s \in 0_{\varphi} \mid s \not\subseteq \text{sincere}(\chi_n) \text{ for } n \geq 3\} \\ &= \{s \subseteq [3, \dots) \mid s \not\subseteq [n, \dots) \text{ for } n > 3\} \cap \{s \subseteq [3, \dots) \mid s \not\subseteq [n] \text{ for } n \geq 3\} \\ &= \{s \mid s \subseteq [3, \dots) \text{ and } s \not\subseteq [3] \text{ and } s \not\subseteq [4, \dots)\} \end{aligned}$$

Thus, from the primary quantity implicatures we infer that the speaker does not know the exact number of apples that John ate and, in fact, that she does not know whether John ate exactly three apples or more.

Finally, consider secondary quantity implicatures. Clearly, each pragmatic alternative  $\psi \in A_{\varphi,Q}^{\subseteq}$  is not known by the speaker according to  $1_{\varphi,Q}$ . But none of these alternatives is innocently excludable, for reasons parallel to those given for *at least* above. Thus, we have  $2_{\varphi,Q} = 1_{\varphi,Q}$ , that is, nothing new is inferred in drawing secondary quantity implicatures.

Summing up, for (21a) in the context of the ‘how many’ question (15a) we predict an ignorance implicature and no upper bounding implicature. While the relevant ignorance inference is exactly the same that was derived above for (18a), there is a crucial difference between the two cases: the inference is derived as a *quantity* implicature for (21a), but as a *quality* implicature for (18a). Quality implicatures are viewed as being of a more fundamental nature than other kinds of implicatures.<sup>11</sup> Moreover, they are difficult to cancel (as exhibited by the oddness of Moore sentences) and there is no reason to imagine that they would depend on the question under discussion any more than the content of the utterance does. We take this to account for our observations in Section 1.1, which show that in the case of *at least*, ignorance implicatures arise more robustly and more widely, and are harder to cancel, than in the case of *more than*.<sup>12,13</sup>

#### 4.2. Predictions in the context of a polar question

Let us now consider a context in which not all of the lexical pragmatic alternatives to our sentences are relevant, and therefore available in the computation of quantity implicatures.

<sup>11</sup>For instance, Grice (1975: p.27) writes: “It is obvious that the observance of some of these maxims is a matter of less urgency than is the observance of others; a man who has expressed himself with undue prolixity would, in general, be open to milder comment than would a man who has said something he believes to be false”.

<sup>12</sup>Lauer (2014) argues that the ignorance implicatures generated by disjunctions are also of a mandatory nature.

<sup>13</sup>Interestingly, note that in the case of (18a), even if an addressee does not derive the inference as a quality implicature (i.e., if she takes it for granted that the speaker adheres to informative sincerity, but not necessarily to inquisitive sincerity as well), then she would *still* derive ignorance as a quantity implicature, in a way parallel to what we discussed for (21a). This, we suggest, lends additional robustness to the ignorance implicature of *at least* in comparison to that of *more than*.

Suppose that John's diet prescribes that he eat at most two apples per day, and does not prescribe anything else. Consider the polar question in (24a). Given our contextual assumptions, the alternatives for this question are the ones displayed in (24b).

- (24) a. Did John stick to his diet today?  
 b.  $Q = \{[0, 2], [3, \dots]\}$

Compare the following responses to (24a):

- (25) a. No, he ate more than two apples.  
 b. No, he ate at least three apples.

Intuitively, upon hearing the response (25a) we do not conclude that the speaker is ignorant as to the number of apples that John ate, whereas we do so upon hearing (25b). In other words, the ignorance implicature associated with (25b) still arises in this context, but the implicature stemming from (25a) does not.

This is indeed predicted on our account. To see why, first consider (25b): we have seen above that for this sentence, the ignorance inference arises as a quality implicature; since quality implicatures are context-independent on our account, this implicature is still predicted in the present setting. The same holds for *n or more*.

The situation is different for (25a). For this sentence, an ignorance inference in the context of question (15a) was derived as a quantity implicature. However, on our account the computation of quantity implicatures is sensitive to the question  $Q$  under discussion: only lexical pragmatic alternatives which are relevant to  $Q$  are taken into account. In the present context, no lexical alternative to  $\varphi$ —except for the sentence  $\varphi$  itself—is relevant to  $Q$ . Thus,  $A_{\varphi, Q}^{\subseteq} = \emptyset$ , which means that no primary or secondary quantity implicatures are derived. Thus, we predict that the ignorance implicature that we found above for (25a) disappears in the context of the polar question (24a).<sup>14</sup>

## 5. Conclusion

The proposal we have made here allows us to overcome the shortcomings of previous accounts. It achieves a three-way contrast between superlative modifiers, comparative modifiers, and numerals, in contrast to Schwarz (2016a). It furthermore accounts for the QUD-sensitivity observed by Westera and Brasoveanu (in contrast to both Schwarz and C&B). It predicts ignorance with respect to the prejacent of *at least* (overcoming Schwarz's critique of C&B). And it brings C&B's approach in line with recent theorizing on inquisitive semantics, where one alternative can never entail another.

Most importantly, we account for the following facts: *more than* indeed can imply ignorance in *how many* contexts, as observed by Westera & Brasoveanu, but the ignorance implicature

<sup>14</sup>In addition, notice that, due to the absence of contextually relevant alternatives, we still correctly predict the lack of upper bounding implicatures for both (25a) and (25b).

of *at least* is more robust, as witnessed by (i) the fact that it is perceived to be stronger than the ignorance implicature of *more than* in *how many* contexts; (ii) the fact that it persists in non-echoic responses to polar questions; and (iii) the fact that it contrasts with *more than* ‘out of context’, as in the following example, repeated from the introduction:

- (26) a. I grew up with more than two parents.  
b. ??I grew up with at least two parents.

To obtain these results, it is crucial to be able to derive ignorance implicatures through two distinct routes: quality for *at least*, and quantity for *more than*.

# Discourse-structuring conditionals and past tense<sup>1</sup>

Eva CSIPAK — *Universität Konstanz*

**Abstract.** In this paper I present some data that challenges the view that a unified semantics of biscuit conditionals and hypothetical conditionals is possible. There is a class of biscuit conditionals that cannot occur with past temporal reference. In these cases, the antecedent serves to structure the discourse and as such must be true of the discourse situation. I argue that this is the reason why the past tense is incompatible with these conditionals, and therefore we can nevertheless maintain a unified semantics for hypothetical and biscuit conditionals.

**Keywords:** biscuit conditionals, conditionals, (past) tense, discourse structure.

## 1. Introduction

The literature on conditionals generally distinguishes between *hypothetical conditionals* as in (1) and *biscuit conditionals* as in (2).

(1) If Alex went shopping this morning, there are biscuits on the sideboard.

(2) If you are hungry, there are biscuits on the sideboard.

The default interpretation of (1) includes the notion that the speaker is not committed with respect to whether the consequent *there are biscuits on the sideboard* holds in the actual world  $w_0$ . We typically assume that conditionals reason about what could be the case, for example if Alex went shopping in the morning. By contrast, it is generally understood that the speaker of (2) is in fact committed to it being true in  $w_0$  that there are biscuits on the sideboard. So it is intuitively clear why we consider (1) as a conditional: the speaker doesn't know whether the antecedent holds, but she is willing to commit to the consequent holding just in case the antecedent does. The status of (2) is less clear since the speaker is taken to be committed to the truth of the consequent whether the antecedent holds or not. Still, in recent years a number of authors have proposed analyses which allow for a uniform semantics of sentences like (1) and (2), such as Franke (2009), Francez (2015) and Csipak (2015). There are two main arguments for why we may want a unified analysis: the form of both (1) and (2) is *if p, q*, and moreover, we observe that cross-linguistically many languages use the same form to express both meanings. This suggests that this is not simply a coincidence of the English language, but a systematic extension of the form from hypothetical conditionals to biscuit conditionals.

The literature on biscuit conditionals typically discusses examples that are similar in spirit to (2) and its ancestor *There are biscuits on the sideboard if you want them* (discussed first in Austin 1956). This paper is concerned with another type of example that sometimes gets mentioned in connection with biscuit conditionals, but is not treated in more detail. This type of conditional

I thank Thomas Weskott for help with the experimental design and statistics. I would also like to thank the audiences at the LSA 2016 annual conference and Sinn und Bedeutung 21 for their insights.

is exemplified in (3).

- (3) If I may be frank, you look awful.

This paper will be dedicated to identifying the ways in which conditionals like (3) differ from biscuit conditionals such as (2), and whether it is possible to come up with a unified analysis that captures the properties of both.

The rest of the paper is structured as follows. In section 2, I discuss the relevant data. Section 3 discusses why we cannot extend the existing analyses to account for the data in 2. Section 4 contains my analysis. Section 5 takes a brief detour into the realm of counterfactuals, and sketches how the data presented here also present a challenge to theories of counterfactuals. Section 6 concludes.

## 2. The empirical picture

A first glance at sentences like (3) suggests that they share two properties with biscuit conditionals: they have the form *if p, q*, and the speaker uttering them is taken to be committed to the truth of *q*. We will take this seriously and assume that sentences like (3) are in fact a species of biscuit conditional. For reasons that will become apparent below, we will call them *discourse-structuring* conditionals. The insight that biscuit conditionals can fulfill different functions in the discourse is not new; for instance Günthner (1999) proposes to distinguish between the categories of discourse-structuring conditionals, meta-communicative conditionals, and relevance conditionals. The goal of the present section is to investigate the properties of hypothetical conditionals, biscuit conditionals, and discourse-structuring conditionals, and to identify which properties are shared and which are not. I will use the term *biscuit conditional* to refer to conditionals which can co-occur with past reference, but which have a biscuit interpretation (i.e., whose speaker is taken to be committed to the truth of the consequent in the actual world), and reserve the term *discourse-structuring conditional* to the conditionals that are the focus of this paper.

We observe that hypothetical and biscuit conditionals, but not discourse-structuring conditionals, can occur with past temporal reference. Consider first the hypothetical conditionals in (4) and the biscuit conditionals in (5).

- (4) HYPOTHETICAL CONDITIONAL
- a. If Alex is in San Francisco right now, she is having iced coffee.
  - b. If Alex was in San Francisco yesterday, she was having iced coffee.
- (5) BISCUIT CONDITIONAL
- a. If you are hungry right now, there are biscuits on the sideboard.
  - b. If you were hungry yesterday, there were biscuits on the sideboard.

In the (b) variants of both (4) and (5) the antecedent refers to a time prior to the utterance time, and both sentences are perfectly acceptable even out of the blue. Now compare this to (6)

through (9). In these cases, the (a) variant with the antecedent referring to the present utterance time are perfectly acceptable. The (b) variants whose antecedents refer to a time prior to the time of utterance are unacceptable, at least on a biscuit conditional interpretation. Note that when these conditionals are presented out of the blue, it is difficult to imagine a context in which a hypothetical conditional interpretation is available (more on this in section 4).

- (6) a. If I am being frank, you look awful.  
b. #If I was being frank yesterday, you looked awful.
- (7) a. If you promise not to tell anyone, I ran into Alex last week.  
b. #If you promised not to tell anyone yesterday, I ran into Alex last week.
- (8) a. If you ask me, Alex is getting ready to leave.  
b. #If you asked me yesterday, Alex was getting ready to leave.
- (9) a. Alex is a little odd if you know what I mean.  
b. #Alex was a little odd if you knew what I meant yesterday.

What properties do (6)–(9) have in common, apart from not being able to occur with past temporal reference? In all of these cases the antecedent refers to the present discourse situation instead of facts outside of the discourse situation. Typically, the antecedents of hypothetical and biscuit conditionals refer to facts outside of the discourse situation, such as *if you get hungry* or *if Alex went shopping this morning*. But reference to the current discourse situation is not what makes discourse-structuring conditionals special. Hypothetical conditionals, for instance, can also refer to the utterance situation. In these cases, their antecedents remain compatible with past reference, as illustrated in (10) and (11).

- (10) a. If I am being frank, you should tell me.  
b. If I was being frank yesterday, you should have told me.
- (11) a. If you understand why this is important, I present the next example.  
b. If you understood why this was important, I presented the next example.

Another property that discourse-structuring conditionals have is that whether their antecedents are true in the actual world can be decided directly by the interlocutors. Interlocutors can immediately agree on whether *I may be frank* or *You promise not to tell anyone* are true in  $w_0$ . Typical antecedents of hypothetical or biscuit conditionals are not like this.

- (12) If Alex gets hungry later, there are biscuits on the sideboard.
- (13) If Alex went shopping, there are biscuits on the sideboard.

In these cases, the interlocutors cannot decide immediately whether Alex will get hungry later or whether Alex went shopping earlier. Importantly, while hypothetical and biscuit conditionals can also have antecedents whose truth in the actual world can be decided on the spot, discourse-

structuring conditionals necessarily have this type of antecedent. There are no discourse-structuring conditionals where the interlocutors cannot decide on the truth of the antecedent based on the current discourse situation.

Finally, discourse-structuring conditionals have one more property in common, to the exclusion of other biscuit conditionals and hypothetical conditionals: the proposition expressed by their antecedents is taken to be true of the discourse situation. Moreover, it corresponds to an action that is taken to have been committed by the interlocutors. For antecedents such as *if I am being frank* this is easy to see: simply by uttering the conditional itself, the speaker is being frank. Moreover, she can decide herself – on the spot, for a given discourse situation – whether to frankly communicate or not. Below we will discuss more tricky cases, such as *if we now turn to page 5* or *if you promise not to tell anyone* where the interlocutors together have to decide to make the antecedent true.

Note moreover that the construction is quite productive: any proposition commenting on the current discourse situation that is taken to be true by the interlocutors can be used as the antecedent of a discourse-structuring conditional.<sup>2</sup> Moreover, they can be combined with consequents that are questions and imperatives as well as declaratives.

- (14) a. If we are discussing people's teeth, have you noticed Alex's new crown?  
 b. If you want to hear my opinion, leave him already!  
 c. If I can add to this, Alex is also never on time.  
 d. If I may introduce a new topic, I have finally booked my vacation.  
 e. If we take it one step further, I suggest we invite Alex.

In sum, we have seen that discourse-structuring conditionals have the following properties.

|                                           | hypothetical conditional | biscuit conditional | discourse-structuring conditional |
|-------------------------------------------|--------------------------|---------------------|-----------------------------------|
| can occur with past tense                 | ✓                        | ✓                   | ✗                                 |
| $q$ taken to be true in $w_0$             | ✗                        | ✓                   | ✓                                 |
| $p$ can refer to discourse situation      | ✓                        | ✓                   | ✓                                 |
| truth of $p$ in $w_0$ decided immediately | ✗                        | ✗                   | ✓                                 |
| $p$ taken to be true in $w_0$             | ✗                        | ✗                   | ✓                                 |

### 3. A unified analysis?

The literature on biscuit conditionals consists of two main lines of argument. Several authors have argued that there is a fundamental difference in the syntax and semantics of hypothetical

<sup>2</sup>The antecedent and consequent propositions also have to be conditionally independent in the sense of Franke (2009) as discussed in section 3.2.

conditionals and biscuit conditionals (e.g., Iatridou 1994, Ebert et al. 2008, 2014, Scheffler 2008, and Siegel 2006).

Others argue that both kinds of conditionals share the same syntax and semantics, and propose pragmatic mechanisms that cause the difference in interpretation (e.g., Franke 2009, Francez 2015, Lauer 2015, Biezma and Goebel this volume).

The data presented in section 2 pose a puzzle for the view that biscuit conditionals have the same syntax and semantics as hypothetical conditionals: if discourse-structuring conditionals are a species of biscuit conditional, and biscuit conditionals have the same syntax and semantics as hypothetical conditionals, then it should follow that discourse-structuring conditionals are acceptable under the same circumstances where hypothetical conditionals are acceptable. In particular, we would expect them to be acceptable with past temporal reference, since hypothetical conditionals and biscuit conditionals are compatible with it. On a non-unified view, we could simply stipulate that discourse-structuring conditionals are not compatible with past temporal reference, or move away even farther from a unified analysis by claiming that the data in (6) through (9) are simply not conditionals at all. This view is unattractive in light of the fact that many languages use the form *if p, q* to express discourse-structuring conditionals.

The arguments in Franke (2009) and Francez (2015) for a unified analysis for hypothetical and biscuit conditionals are convincing. Still, the present section aims to add some additional empirical arguments for a unified analysis. Section 4 then sketches how we can account for the puzzling data in section 2 even within a Franke-style unified analysis.

### 3.1. A different syntax and semantics

Let us first take a look at some of the empirical differences that are claimed to exist between biscuit conditionals and hypothetical conditionals. Iatridou (1991, 1994) argues that biscuit conditionals in English do not allow *then*-insertion, unlike hypothetical conditionals.

- (15)    a.    If Alex went shopping, then there are biscuits on the sideboard.  
           b.    If you are hungry, (#then) there are biscuits on the sideboard.

Crucially, her analysis rests on this fact: the presence of *then* is what allows the hearer to interpret the consequent with respect to the worlds selected by the antecedent. Conversely, when *then* cannot occur, this interpretation is impossible and a biscuit interpretation is required instead. A more recent discussion of the (pragmatic) role of *then* is found in Biezma (2014), which mostly sets aside the issue of biscuit conditionals. Here I present some conditionals that clearly have a biscuit interpretation even though they contain *then*.

- (16)    If you are hungry then there is a Sainsbury's just behind the main complex that does a reasonably priced breakfast.

<http://www.lancaster.ac.uk/colleges/graduate/wp-content/uploads/2016/09/DAY-TRIP-TO-CHESTER.CESHIRE-OAKS.pdf>

- (17) If you are hungry, then there is a tempting menu.

[http://www.newsshopper.co.uk/news/10879271.PubSpy\\_reviews.The.Rose.and.Crown.Green.Street.Green/](http://www.newsshopper.co.uk/news/10879271.PubSpy_reviews.The.Rose.and.Crown.Green.Street.Green/)

Thus the empirical claims on which this analysis is based do not hold.

Another empirical difference that is claimed to exist between biscuit conditionals and hypothetical conditionals applies to German (the claim originates in Davison 1983 and is widely cited, e.g. in Iatridou 1994 and Ebert et al. 2008, 2014). It is claimed that word order in the consequent determines whether a conditional receives a biscuit interpretation or a hypothetical conditional interpretation. For conditionals with a preposed antecedent, the verb can occur either as the second constituent (directly following the antecedent) or as the third constituent (following the antecedent and one more constituent). Davison claims that V2 (i.e., with the verb directly following the antecedent) word order in the consequent only allows a hypothetical conditional interpretation, whereas V3 word order (with the verb following the antecedent and another constituent) only allows a biscuit interpretation.

- (18) *Wenn du mich brauchst, bin ich in meinem Büro.* V2 WORD ORDER  
 if you me need am I in my office  
 'If you need me, I will be in my office.'

- (19) *Wenn du mich brauchst, ich bin in meinem Büro.* V3 WORD ORDER  
 if you me need I am in my office  
 'If you need me, I will be in my office.'

Davison reports that (18) only has an interpretation as a hypothetical conditional, whereas (19) only has an interpretation as a biscuit conditional. The literature further claims that whenever a conditional with V2 consequent word order occurs where only a biscuit interpretation makes sense, speakers reject the conditional. Some analyses, such as Ebert et al. (2008), crucially rely on this difference for their analysis. They propose that the V3 word order in the consequent of biscuit conditionals is not a speaker preference, but rather grammaticalized. Thus, the consequent V3 word order triggers an obligatory biscuit interpretation even in contexts where world knowledge suggests that this does not make sense. In the same way they propose that consequent V2 word order forces a hypothetical conditional interpretation, again even in contexts where world knowledge suggests only a biscuit interpretation makes sense.

Empirically these claims do not hold. Naturally occurring data suggests that speakers do choose consequent V2 word order in contexts where a biscuit conditional interpretation is necessary, as in (20).

- (20) *Wenn du Durst hast, habe ich etwas für dich.*  
 if you thirst have have I something for you  
 'If you are thirsty, I have something for you.' Jan Paul: Paul und die Monsterpflanze

Speakers also produce consequent V3 conditionals with a clearly hypothetical conditional interpretation, as in (21).

- (21) **Context:** A user on a knitting website is talking about how fast knitters from Finland knit socks.

*Die sind so schnell, ich glaube, wenn ich das 'trainieren' würde, ich wäre*

they are so fast I believe if I that train would I would.be

*nie so schnell!*

never so fast

'They are so fast – I think if I 'trained' [speed knitting] I would never be so fast!'

Furthermore there is experimental evidence against the view that syntax determines conditional interpretation. Köpcke and Panther (1989) asked speakers to rate conditional sentences with consequent V2 word order on a 5-point scale where 1 was 'fully acceptable' and 5 was 'not at all acceptable'. Interestingly, speakers rated the sentence *Wenn Sie mich fragen, wird es bald schneien* 'if you ask me, it's going to snow soon' on average at 1.85. The same sentence was rated at 1.73 when *dann* 'then' was inserted. Other biscuit conditionals were less acceptable for the speakers, e.g. *Wenn du durstig bist, ist Bier im Kühlschrank* 'If you are thirsty, there is beer in the fridge' was rated at 2.68 without *dann* 'then', and 2.73 with *dann*.

In Csipak (2015) I report on an acceptability judgment study I conducted with 24 speakers of Standard German from Göttingen (Lower Saxony). These speakers were asked to rate the acceptability of biscuit conditionals and hypothetical conditionals on a 7-point scale, with 7 being completely acceptable and 1 being completely unacceptable. The results showed that speakers found conditionals with a hypothetical conditional interpretation with the (atypical) V3 word order less acceptable than with V2 word order, both by subject ( $F_1(1,23)=218.8$ ,  $p<.001$ ,  $\eta_G^2=.79$ ) and by item ( $F_2(1,11)=195.2$ ,  $p<.001$ ,  $\eta_G^2=.89$ ). However, the lowest rated conditionals (hypothetical conditionals with V2 consequent word order) were still significantly more acceptable than ungrammatical filler sentences that contained word order violations ( $F_1(1,23)=42.00$ ,  $p<.001$ ,  $\eta_G^2=.19$ ). For the biscuit conditionals, there was a marginal preference for V3 word order.

Thus, while speakers do display a preference for hypothetical conditionals to occur with V2 consequent word order, they do not seem to exhibit a preference for consequent word order for biscuit conditionals. We conclude that speakers are able and willing to assign the less preferred interpretation to both kinds of conditionals where world knowledge makes it necessary. This suggests that the speaker preference for one or the other word order, to the extent that it exists, is not grammaticalized, and it should not be the basis from which we derive an obligatory syntactic or semantic difference between hypothetical and biscuit conditionals.

### 3.2. The pragmatic view

The previous section has shown that a syntactic or semantic difference between biscuit and hypothetical conditionals runs into empirical problems. We therefore turn to an alternative story proposed in Franke (2009). He argues that biscuit conditionals have the same semantics that we assume for hypothetical conditionals (for example a modal restrictor analysis along the lines of Kratzer 1986, 2012). The difference in interpretation that we observe between biscuit

and hypothetical conditionals on this view is not a semantic one, but comes about pragmatically. Franke introduces the notion of conditional independence and proposes that two propositions  $p$  and  $q$  are conditionally independent if changing one's beliefs about one will not cause a change in one's belief about the other. On his view, hypothetical conditionals are conditionally dependent. Consider the following example.

(22) If Alex went shopping, there are biscuits on the sideboard.

Imagine that the speaker is undecided about whether Alex went shopping, and equally undecided about whether there are biscuits on the sideboard. Upon learning that Alex went shopping (that is, a change in belief about  $p$ ), the speaker will likely also change her beliefs about whether there are biscuits on the sideboard (that is, a change in belief about  $q$ ). Compare this to a biscuit conditional such as (23).

(23) If you are hungry, there are biscuits on the sideboard.

Will learning that the addressee is hungry change the speaker's beliefs about whether there are biscuits on the sideboard? World knowledge suggests that it should not. Thus, the antecedent and consequent propositions are *conditionally independent*. Franke proposes that whenever two propositions that are conditionally independent, they are nevertheless linked via a conditional structure, the hearer undergoes the following chain of reasoning:

- (24)
- a. The speaker used a conditional to link  $p$  and  $q$ , suggesting conditional dependence.
  - b.  $p$  and  $q$  are conditionally independent.
  - c. The speaker knows that the hearer knows this but used the construction nonetheless.
  - d. The hearer concludes that the speaker must be uncertain about the truth of  $p$ .
  - e. Since  $p$  and  $q$  are conditionally independent, the speaker must have independent evidence for the truth of  $q$ .

This is how the biscuit interpretation of conditionals like (23) comes about, allowing us to maintain a unified syntax and semantics for both types of conditionals.

What predictions does this proposal make for discourse-structuring conditionals? World knowledge suggests that the antecedent and consequent of a discourse-structuring conditional are conditionally independent.

(25) If you ask me, Alex is tall.

World knowledge suggests that changing one's belief about whether the addressee is asking to hear the speaker's opinion will not change one's belief about whether Alex is tall. So on Franke's view, (25) could be treated as a biscuit conditional. On Franke's view biscuit conditionals and hypothetical conditionals have the same syntax and semantics. This means that we expect discourse-structuring conditionals, which are essentially biscuit conditionals, to have

the same properties that hypothetical conditionals have. In particular, they should be able to co-occur with past temporal reference, as biscuit conditionals do (recall the examples (4) and (5) in section 1). But the examples discussed in sections 1 and 2 have shown that this is not the case. In section 4, I argue that there are independent reasons why discourse-structuring conditionals are not available with past temporal reference, and that we can in fact maintain a Franke-style unified analysis nevertheless.

### 3.3. Present counterfactual uses

Before turning to the analysis, let us briefly consider some additional data. It is well-known that English uses past tense morphology in the antecedents of counterfactual conditionals. Since section 2 has shown that run-of-the-mill past temporal reference is excluded in discourse-structuring conditionals, we might ask what is going on in counterfactuals that use past tense morphology. (26b) illustrates a present counterfactual conditional. Most importantly, we observe the simple past form *was* in the antecedent, and the form *would be having* in the consequent.

- (26)    a.    If Alex was in San Francisco last week, she was having iced coffee.  
           b.    If Alex was in San Francisco right now, she would be having iced coffee.

In recent years counterfactual conditionals like (26b) have received a lot of attention. The past tense morphology in particular has been the subject of much debate. There are currently two lines of argument: some authors propose that the past tense morphology is not semantically interpreted as a ‘real’ past tense. On this view, the past tense does not refer to a past time, but instead tracks remoteness on another dimension, namely across worlds (see Iatridou 2000, Schulz 2014). Others have argued that the past tense that we observe is in fact interpreted temporally (see for instance Arregui 2009, Ippolito 2013). On this view, the past tense takes us back to a time when the consequent was still a live possibility in  $w_0$ .

The two types of accounts differ slightly in the predictions that they make for the availability of discourse-structuring counterfactual conditionals. The fake tense approach assumes that the past tense in the antecedent is not interpreted temporally in counterfactuals like (27). Therefore we conclude that in principle, nothing in this approach directly predicts that discourse-structuring counterfactuals are unacceptable, so long as the antecedent refers to counterparts of the utterance time in counterfactual worlds. And we find some discourse-structuring present counterfactuals that are acceptable, as in (27).

- (27)    If I was being frank right now, you look awful.

But we also find some discourse-structuring present counterfactuals which are not acceptable, as in (28).

- (28)    #If you promised not to tell anyone right now, Alex is getting ready to leave.

In fact, the majority of discourse-structuring conditionals seems to behave like (28), i.e., they are unacceptable as counterfactuals as well as with run-of-the-mill past temporal reference. This unacceptability is a puzzle for the fake tense approach since on this view, ‘fake’ tense should behave differently semantically from ‘real’ past tense.

The counterfactual-past-as-regular-past (‘past-as-past’) approaches run into similar but different problems. They assume that a past tense operator takes scope over the entire conditional, which causes the counterfactual interpretation. The simple past observed in the antecedent and the *would* in the consequent are reflexes of this higher past tense operator. Thus in principle this account would predict that neither conditionals with run-of-the-mill past temporal reference nor counterfactual conditionals should be available with a discourse-structuring flavour, and this is indeed what we find for most antecedents – except for (27), which is a puzzle for this view.

But this view has a more serious problem. Speakers of English disprefer biscuit conditionals with consequents containing *would*, as in (29). Note that speakers seem to vary on whether they find a biscuit reading of (29) unacceptable, or whether they simply prefer (27).

(29) #/?If I was being frank right now, you would look awful.

This is true of biscuit conditionals more generally. For counterfactual biscuit conditionals, speakers prefer past tense morphology in the antecedent, but present tense morphology in the consequent. The past-as-past approach to counterfactuals cannot straightforwardly account for this.<sup>3</sup>

- (30) a. If you wanted something to nibble on later, there are biscuits on the sideboard.  
b. #/?If you wanted something to nibble on later, there would be biscuits on the sideboard.

Solving this puzzle goes beyond the scope of the present paper.

#### 4. My proposal

The present section will make a proposal for how to tackle discourse-structuring conditionals.

A first analysis that suggests itself from examples like (3) is one in terms of self-verifying utterances in the sense of Eckardt (2012). She proposes that utterances are self-verifying iff they become true by virtue of being uttered.

- (31) a. I am using a verb.  
b. I promise to mow the lawn.

It is easy to see that the speaker of (31a), by virtue of uttering (31a), is making the sentence true

<sup>3</sup>Note that conditionals like (30) are not discussed in Swanson (2013). He only discusses examples where the consequent shows the past tense morphology that is predicted under the past-as-past analyses.

since it contains the verb *am using*. The speaker of (31b) makes a promise by uttering (31b) (the word *promise* is being used *performatively*), and again it is by virtue of being uttered that (31b) becomes true. Now let us consider how to translate this to biscuit conditionals.

- (32) a. If I am being frank, you look awful.  
b. In all the worlds closest to  $w_0$  where I am being frank, you look awful.
- (33) a. By uttering (32a) I am being frank.  
b. Thus  $w_0$  itself is the world closest to  $w_0$  where *I am being frank* is true.  
c. (32a) is a biscuit conditional; thus the speaker has independent evidence for the consequent.  
d. The speaker believes that *you look awful* is true in  $w_0$ .  
e. (32a) is true in  $w_0$ .
- (34) *If I am being frank, you look awful.*  
a.  $\forall w' \in \max_g(\cap f(w_0) \cup \llbracket \text{I-AM-BEING-FRANK} \rrbracket^{w'})$ :  $\text{YOU-LOOK-AWFUL}(w')=1$  because  
b.  $\forall w' \in \max_g(\cap f(w_0) \cup (\text{sp sends } \mathbf{m} \text{ to } \mathbf{add} \text{ and FRANK}(\varepsilon, \mathbf{m}), \text{ and } R \subseteq t(\varepsilon) \text{ and } S \subseteq R))$ :  $\text{ADD-LOOKS-AWFUL}(w')=1$ .

The indexicals *sp* for *speaker*, *add* for *addressee*, *m* for *message* and  $\varepsilon$  for *event* receive their values relative to the utterance context. When the speaker utters *if I am being frank, you look awful*, there is an event  $\varepsilon$  of sending a message *m*, and the message counts as frank. Without going into the lexical semantics of *frank* in too much detail, let us assume that one of the ways in which a message counts as frank is if it is both true with respect to the speaker's beliefs, and exceeding a contextual standard of what counts as rude. I assume that speakers will in a next step associate the message *m* with the consequent proposition, *q*. We can then verify that the speaker's message ('*you look awful*') indeed counts as frank. Crucially, the speech time falls into the time of this event. This serves to verify the utterance.

When combined with past temporal reference, the conditional no longer self-verifies the antecedent, causing oddness.

- (35) *#If I was being frank yesterday, you looked awful.*  
a.  $\forall w' \in \max_g(\cap f(w_0) \cup \llbracket \text{I-WAS-BEING-FRANK-YESTERDAY} \rrbracket)$ :  
 $\text{YOU-LOOKED-AWFUL}(w')=1$ .  
b.  $\forall w' \in \max_g(\cap f(w_0) \cup (\text{sp sends } \mathbf{m} \text{ to } \mathbf{add} \text{ and FRANK}(\varepsilon, \mathbf{m}), \text{ and } R \subseteq t(\varepsilon) \text{ and } R < S))$ :  
 $\text{ADD-LOOKED-AWFUL}(w')=1$ .

Here the speaker claims to have made a frank utterance prior to speech time (there was an event  $\varepsilon$  of sending a frank message *m* which lies before speech time). But because the event connected to the frank message lies before the speech time, it cannot serve as a witness to automatically verify the utterance. The resulting interpretation is a hypothetical conditional about the past ('all the (relevant best) worlds in which I was frank yesterday are worlds in which you looked awful') that is pragmatically odd.

This proposal cannot straightforwardly account for those cases where the addressee is addressed in the antecedent: *if you promise not to tell anyone; if you know what I mean* or even *if we now turn to page 5* are not antecedents that can self-verify; that is, the speaker cannot guarantee that by virtue of uttering the conditional, these antecedents become true. We therefore broaden the proposal to account for these cases.

The intuition we are trying to capture is that by uttering a discourse-structuring conditional, the speaker uses the antecedent to communicate under which conditions she is willing to share the contents of the consequent, and then shares the consequent. This invites the inference that the speaker takes the antecedent to be true. To illustrate, we consider (36).

(36) If you promise not to tell anyone, Alex is asleep.

We can then assign the following semantics to (36).

(37)  $\forall w' \in \max_g(\cap f(w_0) \cup (\text{promise}(\varepsilon, \mathbf{add}, \neg \text{tell}(\mathbf{add}, \mathbf{m})) \text{ and } S \subseteq R \subseteq t(\varepsilon))$ : Alex-asleep( $w'$ )=1

In prose, in all the (relevant best) worlds where there is a promising event happening at speech time involving the addressee not telling anyone about message  $m$ ,  $q$  holds. Again I assume that the interlocutors will associate  $m$  and  $q$ ; thus, in all the best worlds where the addressee promises not to tell anyone that  $q$ ,  $q$  holds. Since the antecedent and  $q$  are conditionally independent, the speaker is taken to be committed to the fact that  $q$  holds in  $w_0$ . It is now up to the addressee to ensure that the entire conditional is true in  $w_0$  by simply not telling anyone about  $q$ , i.e., by keeping the promise not to tell anyone.

The proposal spelled out for (36) can be extended to other antecedents: *if you know what I mean (by message  $m$ )*, *if you ask me (about message  $m$ )*, etc.

The analysis also derives why past tense uses are odd.

(38) #If you promised not to tell anyone yesterday, Alex was asleep.

(39)  $\forall w' \in \max_g(\cap f(w_0) \cup (\text{promise}(\varepsilon, \mathbf{add}, \neg \text{tell}(\mathbf{add}, \mathbf{m})) \text{ and } R \subseteq t(\varepsilon) \text{ and } R < S))$ : Alex-asleep( $w'$ )=1

In all the (relevant best) worlds where there was a promising event at some time prior to speech time that involved the addressee not telling anyone about message  $m$ ,  $q$  holds. Again  $p$  and  $q$  are conditionally independent, but since the antecedent is about whether or not the addressee told anyone about a message  $m$  at a time prior to speech time, there is no reason to associate  $m$  with  $q$ . But without this connection, the conditional is simply uninterpretable on a discourse-structuring interpretation (and it is difficult to imagine a context where a hypothetical conditional interpretation is available).

Before concluding, I will point out that as with other types of discourse effects, we expect that the antecedents of discourse-structuring conditionals should be acceptable with past temporal

reference in contexts where they are not used to refer to the present discourse and there is some other interpretation available. This prediction is indeed borne out, as illustrated with (40).

- (40) a. If you knew what I meant when I called Alex ‘organized’ yesterday, you will understand what I mean when I call Jesse ‘disorganized’.  
 b. If I was being frank yesterday I may have offended Alex.  
 c. If you asked me yesterday, I don’t recall.

All of the conditionals in (40) have reasonable interpretations as hypothetical conditionals. For instance, in (40b) the speaker is unsure whether what she said yesterday counts as frank (presumably she is uncertain whether her statement exceeded the standard for rudeness), and consequently she is unsure whether she offended Alex.<sup>4</sup>

Finally, I speculate on the contextual clues that turn a conditional into a discourse-structuring (biscuit) conditional. Consider (41), which has an interpretation as a hypothetical conditional, but not as a discourse-structuring conditional.

- (41) If you promise not to tell anyone, I will tell you a secret.

Given the right context, this example is perfectly acceptable with past temporal reference.

- (42) Context: After waking up with amnesia, A and B are trying to figure out what happened the night before.  
 A: If you promised not to tell anyone, I told you a secret.

On my view, the reason why (42) is acceptable and the reason why (41) is not interpreted as a discourse-structuring conditional is the same. In the antecedent, the speaker is referring to an event of the addressee not telling anyone the message *m*. However, the consequent proposition is both conditionally dependent on the antecedent proposition, and it is also not ‘juicy’, i.e., the interlocutors are unlikely to associate the message *m* with the consequent proposition. Compare this to (43).

- (43) If you promise not to tell anyone, I will tell Peter about the baby tomorrow.

We observe that (43) is ambiguous between a biscuit interpretation on which the speaker’s telling Peter is conditionally independent from the addressee agreeing not to tell anyone. On this interpretation, the past tense reading is out.

- (44) #If you promised not to tell anyone last week, I told Peter about the baby the next day.

But on a hypothetical conditional interpretation where the two propositions are conditionally

<sup>4</sup>Remember that a verb like *promise* can be used performatively with present temporal reference, and reportatively with past temporal reference.

- (i) a. I promise to let you sleep in on Sunday. *performative*  
 b. I promised to let you sleep in last Sunday. *reportative*

dependent, the past tense interpretation is available.

- (45) A and B have amnesia. Looking through the records, they see that B signed a non-disclosure agreement, but they do not find one signed by A. They also read in Peter's diary that someone told him about the baby.

A: If you promised not to tell anyone, I told Peter about the baby.

Thus we conclude that given the particular interplay of context and content that is necessary for a discourse-structuring conditional interpretation, it follows that this interpretation is simply unavailable when the antecedent is interpreted with past temporal reference. But as the examples have shown, there is no reason to assume a separate syntax or semantics for discourse-structuring conditionals. Thus we can maintain a unified syntax and semantics for hypothetical and biscuit conditionals.

## 5. Conclusion

The present paper has provided some challenging evidence for a unified account of hypothetical and biscuit conditionals: there are some biscuit conditionals that cannot co-occur with past temporal reference, namely discourse-structuring conditionals. This is unexpected given that both hypothetical conditionals and most biscuit conditionals can occur with past temporal reference. I have argued that a unified analysis of the two can be maintained. The reason why discourse-structuring conditionals are unacceptable with past temporal reference has to do with the relationship between antecedent and consequent: the antecedent refers to an event that is assumed to involve the consequent proposition. Such a relationship between antecedent and consequent is not available when the antecedent is temporally located in the past, but the consequent proposition is uttered in the present.

# Bare nouns, number, and definiteness in Teotitlán del Valle Zapotec<sup>1</sup>

Amy Rose DEAL — *University of California, Berkeley*

Julia NEE — *University of California, Berkeley*

**Abstract.** How is definiteness expressed in number-marking languages lacking a definite article? May bare nouns in such languages simply be read as definites or indefinites, without constraint? Dayal (2004) demonstrates that the interpretation of bare nouns with respect to definiteness is significantly constrained in Hindi and Russian. In these languages, singular and plural bare nouns present different possibilities for indefinite interpretation, in a way that receives a natural explanation within a neo-Carlsonian theory of noun meaning (Chierchia, 1998). This makes for a close connection between the meanings of bare nouns in English and those in Hindi and Russian. Does this connection extend to the meanings of bare nouns in number-marking languages in general, even outside of Indo-European? In this paper, we demonstrate that the answer is yes. Our evidence comes from bare noun interpretation in Teotitlán del Valle Zapotec, a language of Oaxaca, Mexico. The Zapotec findings closely replicate Dayal's findings for Indo-European languages, providing support for the viability of the neo-Carlsonian approach as a set of constraints on semantic variation in general.

**Keywords:** Bare nouns, plural, number, definite, pseudo-incorporation, Zapotec

## 1. Introduction

Teotitlán del Valle Zapotec is a language with a singular/plural distinction and without a definite determiner. Arguments in this language frequently consist of just a bare noun, as in (1).<sup>2</sup>

- (1) Ka-zhuniḥ kabai / d-kabai.  
      PROG-run horse / PL-horse  
      The horse(s) is/are running.

This paper is about the interpretation of Teotitlán del Valle Zapotec bare nouns, in particular as concerns definiteness and the role of number marking. Conventional wisdom holds that bare nouns in languages lacking definite articles are able to freely function both as definites and as indefinites.<sup>3</sup> If true, this would make bare nouns in such languages quite different from their counterparts in Germanic languages, such as English bare plurals and bare mass nouns. Those arguments are well-known to show a highly restricted range of interpretations, differentiating them both from definites and from ordinary indefinites with the article *a* (Carlson, 1977).

<sup>1</sup>Our deepest thanks are due to language consultants Enedina Bazán Chávez, Tomasa Chávez, Sergio Martínez, and Teresa Martínez Chávez. Thanks as well to audience members at SuB in Edinburgh, and at the Definiteness Across Languages conference in Mexico City.

<sup>2</sup>The TdVZ data in this paper are written in a practical orthography that is similar in pronunciation to Spanish with a few modifications. *ts* and *dz* represent voiceless and voiced alveolar affricates, and *ch* and *dx* their post-alveolar counterparts. *ll* is a geminate alveolar lateral. The following abbreviations are used in TdVZ glosses: ANIM animal gender, COP copula, EMPH emphatic, FUT future, HAB habitual, NEG negation, NEUT neutral (aspect), PERF perfective, PL plural, PROG progressive, PRT particle, SBJ subjunctive, Y.N yes/no question.

<sup>3</sup>See, for instance, Lee (2006: p 9) on closely related language San Lucas Quiaviní Zapotec.

The work of Dayal (2004) poses an important challenge to the conventional wisdom about languages lacking definite articles. In Hindi and Russian, Dayal shows, only definite and kind-level readings are freely available for all arguments. All other types of interpretation are subject to significant restrictions. Bare plural arguments allow indefinite interpretations, but only weak indefinite readings are ever permitted. Bare singular arguments allow indefinite interpretations only in contexts of (pseudo-)incorporation. The distribution of definite and indefinite readings is thus significantly more complex than expected on the conventional view.

What sort of theory is required to account for these restrictions on bare noun interpretation? Dayal shows that the answer is more familiar than might be expected. With only a minor modification, the range of restrictions on bare noun interpretation in Hindi and Russian falls out from Chierchia's (1998) neo-Carlsonian theory for English bare nouns. The overall conclusion is that a unified theory of bare noun interpretation remains in reach, bringing together (number-marking) languages with and without definite articles.

This paper contributes new evidence in support of this conclusion from Teotitlán del Valle Zapotec, a language typologically and genetically distinct from the languages investigated by Dayal. Quite strikingly, the interpretation of singular and plural bare nouns in Teotitlán del Valle Zapotec shows the same intricate distribution predicted by the Dayal/Chierchia theory. In this language, too, only definite and kind-level readings are freely available to all arguments; existential readings show a complex distribution that involves both the number marking of the noun and the argument structure of the verb. Plural and mass bare nouns generally allow existential readings, though only with narrowest scope. Singular bare nouns show existential readings only with narrowest scope and only in contexts of plausible pseudo-incorporation. The findings overall lend support to the theoretical framework of Chierchia (1998) and Dayal (2004), as this approach successfully predicts both the range of readings possible for bare nouns and the way that number marking influences bare noun interpretation. Science depends on replication, and the prospects for formal semantic approaches to linguistic typology depend on teasing apart core constraints on semantic variation from accidental similarities owing to shared history or language contact. By showing that a familiar system for bare noun meaning is active in an unrelated, geographically distant language, this study suggests that core mechanisms of semantic competence are involved in regulating the interpretation of bare nouns.

The paper is laid out as follows. In the next section, we introduce Chierchia's (1998) approach to English bare nouns and consider certain of its crosslinguistic predictions, particularly in view of a modification suggested by Dayal (2004). In section 3, we present the core data on bare plural and mass nouns in Teotitlán del Valle Zapotec, showing that they behave as expected in this system. In section 4, we then discuss the special properties of singular kind terms, drawing especially on the discussion in Chierchia (1998); in section 5 we show how this approach leads to correct predictions for the analysis of Teotitlán del Valle Zapotec bare singulars. In section 6, we discuss how the numeral *te* 'one' fits into the system. Section 7 briefly concludes.

We round out this introduction with some background information on Teotitlán del Valle Zapotec and the data presented in this paper. Teotitlán del Valle Zapotec is spoken in Teotitlán del Valle, a community of approximately 5000 people located 25 km outside of Oaxaca City,

## 2. Interpreting bare nouns

### 2.1. Bare nouns in English

(2)    a. Cats are common.                      b. Gold is rare.

(3)    a. Cats purr.                                  b. Gold is shiny.

(4)    a. Cats are purring.  
         b. Gold is missing from the safe.

In presenting the approach pursued by Chierchia (1998) and taken up by Dayal (2004), it will be helpful to start with mass nouns. Chierchia proposes that nouns like *gold* inherently denote kinds. Kinds are modeled as individual concepts, mapping any world or situation to the maximal sum of the relevant material (in this case, gold) in that world or situation. Once evaluated at a world or situation, a kind term is of type *e*. This semantic type explains why kind terms may function as arguments without the help of a determiner. The kind-level predicate simply

applies directly to the kind-level noun.<sup>4</sup>

- (5) Gold is rare. *rare(GOLD)*

To handle existential readings, Chierchia (developing ideas from Carlson 1977) proposes a special composition operation that applies as the kind-denoting argument combines with the predicate. This operation, ‘Derived Kind Predication’ or DKP, introduces local existential quantification over instances of the kind. In so doing, it makes use of the operator  $\cup$  ‘Up’ which maps kinds to properties, (6). The DKP rule itself is defined as in (7).

- (6) Let  $d$  be a kind. Then for any world  $s$ , (Chierchia, 1998: 350)

$$\cup d = \begin{cases} \lambda x [x \leq d_s], & \text{if } d_s \text{ is defined} \\ \lambda x [FALSE], & \text{otherwise} \end{cases}$$

where  $d_s$  is the plural individual that comprises all of the atomic members of the kind.

- (7) *Derived Kind Predication (DKP)*: (Chierchia, 1998: 364)

If  $P$  applies to objects and  $k$  denotes a kind, then  $P(k) = \exists x [\cup k(x) \wedge P(x)]$

The existential quantification introduced by DKP is necessarily limited in scope; it applies as soon as the predicate composes with its arguments. This explains why the existential quantification associated with bare arguments standardly fails to outscope negation (Carlson, 1977).

- (8) John didn’t find gold.  $\neg \exists x [\cup GOLD(x) \wedge find(j, x)]$

Partially similar mechanisms are proposed for the generic reading, which plays a relatively more minor role in the overall system. In this case the generic operator is restricted by a description obtained from the kind-level argument via accommodation; the restriction contains a variable over instances of the kind, via the freely available shifter  $\cup$  (Chierchia, 1998: 366-7).<sup>5</sup>

- (9) Gold is shiny.  $Gn_{x,s} [\cup GOLD(x) \wedge C(x, s)] [shiny(x, s)]$

For count nouns, Chierchia proposes a basic property-type denotation. Singular count nouns like *cat* denote singular properties (sets of cat-atoms) whereas plural count nouns like *cats* denote plural properties (sets of sums of cat-atoms). The plural property is similar to a mass property in that it has a supremum; we may speak, relative to a world or situation, of the maximal sum of cats or of gold in that world or situation. The intensionalization of this sum is formally identified with the kind. To map plural properties to kinds, Chierchia introduces the operator  $\cap$  ‘Down’:

- (10) For any property  $P$  and world/situation  $s$ , (Chierchia, 1998: 351)

$$\cap P = \begin{cases} \lambda s \iota x [P_s(x)], & \text{if } \lambda s \iota x [P_s(x)] \text{ is in the set } K \text{ of kinds} \\ \text{undefined,} & \text{otherwise} \end{cases}$$

<sup>4</sup>Here and below, we use capital letters for names of kinds.

<sup>5</sup>Following Chierchia,  $C$  is a contextual variable restricting the individual ( $x$ ) and situation ( $s$ ) arguments the  $Gn$  operator ranges over.

Application of  $\cap$  to the plural property  $\llbracket \text{cats} \rrbracket$  produces a kind, CAT. Supposing  $\cap$  is freely available as a type shift, bare plurals will freely shift to a kind-level interpretation. Evaluated at a particular world or situation, the noun will then be able to function as a bare argument of type  $e$ , much as mass nouns do. As a kind term, it will be able to give a kind-level reading; a narrow scope existential reading, via DKP; or a generic reading, via accommodation and  $\cup$ .

(11) Cats are common.  $\text{common}(\cap \text{cats})$

(12) I don't see cats.  $\neg \exists x[\cup \cap \text{cats}(x) \wedge \text{see}(I, x)]$

(13) Cats purr.  $Gn_{x,s}[\cup \cap \text{cats}(x) \wedge C(x, s)][\text{purr}(x, s)]$

This system provides an initial explanation for why singular count nouns cannot function as bare arguments in English, in view of the definedness conditions of  $\cap$ . This operation is undefined when applied to a singular property like  $\llbracket \text{cat} \rrbracket$ , given that a single individual cannot be a kind.<sup>6</sup> Unable to type shift, the singular noun *cat* thus remains strictly property-type. This explains why it cannot function as an argument without the help of a determiner or quantifier.

This explanation is potentially threatened if additional type shifts beyond  $\cap$  are available in natural language. Chierchia proposes that two additional type shifts are indeed available. One is the  $\iota$  type shift, forming definite descriptions. The other is the  $\exists$  type shift, forming existential generalized quantifiers. These type shifts cannot be applied to English bare singulars because lexical determiners *the* and *a* are available with these denotations. This result is ensured by the principle in (14).

(14) *Blocking Principle:* (Chierchia, 1998: 360)

For any type shifting operation  $\tau$  and any  $X$ :  $*\tau(X)$

if there is a determiner  $D$  such that for any set  $X$  in its domain,  $D(X) = \tau(X)$

The Blocking Principle ensures that bare nouns in English never receive definite interpretations; this is always blocked by *the*. It also ensures that singular count nouns never receive indefinite GQ interpretations; this is always blocked by *a*. Whether indefinite GQ interpretations are expected for bare plurals depends on the analysis accorded to plural determiner *some*: if treated as a pure existential quantifier, it is expected to block existential readings for bare plurals. Chierchia proposes that *some* not be treated in this way, and thus that existential GQ readings are in principle available to bare plurals. This allows him to explain why the bare plural is associated with an existential quantifier scoping over negation in examples like (15). That example demonstrates a scope pattern which is unavailable in simpler cases like (16).

(15) John didn't fix parts of this machine.  $\exists x[\text{parts-of-this-machine}(x) \wedge \neg \text{fix}(j, x)]$

(16) John didn't fix coffee machines.  $\neg \exists x[\text{coffee-machines}(x) \wedge \text{fix}(j, x)]$   
( $= \neg \exists x[\cup \text{COFFEE-MACHINE}(x) \wedge \text{fix}(j, x)]$ )

<sup>6</sup>On the singular definite generic, see section 4.

Table 1: Interpretations of English bare nouns (after Chierchia 1998)

|                                                                  | Bare mass noun                                                                       | Bare plural                                                                          | Bare singular                                |
|------------------------------------------------------------------|--------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|----------------------------------------------|
| a) Kind-level reading                                            | Available<br>N is kind-denoting                                                      | Available<br>$\cap$ type shift                                                       | Unavailable<br>$\cap$ undefined              |
| b) Narrow scope existential reading                              | Available<br>N denotation + DKP                                                      | Available<br>$\cap$ type shift + DKP                                                 | Unavailable<br>$\cap$ undefined              |
| c) Definite reading                                              | Unavailable<br>$\iota$ blocked by <i>the</i> and outranked by $\cap$                 | Unavailable<br>$\iota$ blocked by <i>the</i> and outranked by $\cap$                 | Unavailable<br>$\iota$ blocked by <i>the</i> |
| d) Wide scope existential reading ( $\exists$ GQ interpretation) | Unavailable<br>$\exists$ outranked by $\cap$ ; available only if $\cap$ is undefined | Unavailable<br>$\exists$ outranked by $\cap$ ; available only if $\cap$ is undefined | Unavailable<br>$\exists$ blocked by <i>a</i> |

Why is a wide scope existential reading available in (15) but not in (16)? Chierchia builds on Carlson's intuition that the crucial factor is that not every plural property corresponds to a kind. Notably, *coffee machines* is considerably more amenable to a kind-level analysis than is *parts of this machine*. Suppose, therefore, that *parts of this machine* is undefined in combination with  $\cap$ , as the sum of the machine's parts is not a kind. This means that the default  $\cap$  type shift for the bare plural cannot be applied, and an alternative option must be chosen. Chierchia proposes that the availability of alternatives is regulated by a hierarchical ranking as in (17).

(17) *Ranking of Type Shifts (to be revised):*

$$\cap > \{\iota, \exists\}$$

Because *coffee machines* is capable of shifting via  $\cap$ , this is the only possibility. The result is a kind-level denotation which may lead to an existential reading only via DKP. For *parts of this machine*, by contrast, the kind-level reading is off the table and the lower ranked  $\exists$  type shift may be used. This makes *parts of this machine* a quantificational expression which is capable of scoping over negation in (15).

The overall view of English bare nouns is summarized in Table 1; note that here and elsewhere, we set aside the generic reading.<sup>7</sup> With that proviso, the only available readings of bare nouns are in the unshaded cells of rows (a) and (b). The unattested readings in rows (c) and (d) are absent due to the combination of the Blocking Principle and the Ranking of type shifts (in some cases redundantly), as discussed above for count nouns. The same logic may be applied to mass nouns if these nouns can shift to properties, via  $\cup$ , from their basic kind-level denotations.

<sup>7</sup>This omission is due both to the relatively minor role of the generic reading in the Chierchia/Dayal system and to the well-known interaction between generic readings and verbal morphology. This interaction means that significant further work on the tense/aspect/mood system of TdVZ will be necessary before major claims about generic sentences are made.

Bare singulars turn out not to make viable arguments in English in view of two factors working together. On one hand, the undefinedness of  $\cap$  in combination with a singular prevents kind-level readings; this prevents narrow scope existential readings by blocking the proper setup for DKP. On the other hand, the lexical determiners *the* and *a* block the application of the other two type shifts,  $\iota$  and  $\exists$ , which otherwise would be available to the bare singular.

## 2.2. Predictions for languages lacking a definite article

Several regions of Table 1 deserve special attention in connection with languages lacking definite articles. In this section, we focus on those that concern plurals and mass terms. We return to special issues in the analysis of bare singulars in section 4.

The first point of interest concerns row (c), the definite reading. On Chierchia's approach, the absence of a definite reading for English mass nouns and bare plurals is redundantly ruled out by blocking and by ranking of type shifts. Since the  $\iota$  operator is ranked below  $\cap$ , a definite reading is not expected for bare mass nouns and bare plurals even in a language lacking definite articles, so long as  $\cap$  is defined. Dayal (2004) proposes a modification to the ranking of type shifts which speaks to this point. The proper ranking, she proposes, is not (17) but (18).<sup>8</sup>

(18) *Revised Ranking of Type Shifts:*

$$\{\iota, \cap\} > \exists$$

With this revision, the absence of definite readings for bare nouns in English is entirely due to the presence of a definite article in the lexicon. A language lacking a definite article is expected to allow its bare nouns to type shift via  $\iota$  as well as via  $\cap$ . Bare nouns in such a language should allow a definite reading in general, alongside the kind-level and narrow scope existential readings available for bare plurals and bare mass nouns.

Dayal's revision to the ranking of type shifts has an additional consequence in row (d), the wide scope existential reading. In a language which uses an  $\iota$  type shift instead of a definite article, the  $\iota$  shift, which is always defined, will always outrank  $\exists$ . This means that bare plurals and mass terms should never allow wide scope existential readings.

Finally, a comment is in order on row (b), the narrow scope existential reading, for reasons external to the system itself. Many languages have some variety of incorporation construction available to objects and sometimes to unaccusative subjects. Incorporated nominals standardly receive narrow scope existential readings, just like English bare mass nouns and bare plurals.<sup>9</sup> In languages with 'pseudo-incorporation' (Massam, 2001), incorporated nominals may look morphosyntactically quite similar to their non-incorporated counterparts. In such languages,

<sup>8</sup>Dayal (2013) takes another step in this direction by proposing that  $\exists$  type shifts are in fact not available in natural language and not implicated in examples like (15). This proposal leads to the view that  $\iota$  and  $\cap$  are freely available, unranked options available to bare nouns, making (18) unnecessary as part of the theoretical machinery. The reader is referred to Dayal's paper for full details. Note that nothing in the present analysis depends on the decision between this view and the view discussed in the text.

<sup>9</sup>Indeed, this similarity is at the heart of work by van Geenhoven (1998).

Table 2: Expectations for bare mass and plural nouns in languages lacking definite articles

|                                                                  | Bare mass noun                               | Bare plural                                  |
|------------------------------------------------------------------|----------------------------------------------|----------------------------------------------|
| a) Kind-level reading                                            | Expected<br>N is kind-denoting               | Expected<br>$\cap$ type shift                |
| b) Narrow scope existential reading                              | Expected<br>N denotation + DKP               | Expected<br>$\cap$ type shift + DKP          |
| c) Definite reading                                              | Expected<br>$\cup$ + $\iota$ type shift      | Expected<br>$\iota$ type shift               |
| d) Wide scope existential reading ( $\exists$ GQ interpretation) | Unexpected<br>$\exists$ outranked by $\iota$ | Unexpected<br>$\exists$ outranked by $\iota$ |

care must be taken to tell apart those narrow scope existential readings produced by DKP versus those produced by incorporation. This may be done by consideration of the argument-structural role of the bare nominal. Crosslinguistically, incorporation does not apply to external arguments (Mithun 1984, Baker 1988); no such restriction is placed on DKP. Therefore, a narrow scope existential reading for an external argument must be due to DKP.

The main predictions discussed in this section are summarized in (19), and the overall range of interpretations expected for bare mass nouns and bare plurals in languages without definite articles is schematized in Table 2. The next section shows that the pattern in Table 2 correctly describes the behavior of bare mass and plural nouns in TdVZ.

- (19) A language lacking definite articles should ...
- allow bare plurals and bare mass nouns to have definite, kind-level, and narrow scope existential interpretations.
  - not allow bare nouns to have wide scope existential interpretations.
  - allow bare plurals and bare mass nouns to have narrow scope existential readings both as internal arguments and as external arguments.

### 3. TdVZ bare mass nouns and plurals

Mass nouns<sup>10</sup> and plural count nouns in TdVZ present a proper superset of the readings available to their counterparts in English. In both languages, these nouns function freely as arguments to kind-level predicates. Various such predicates in TdVZ are Spanish borrowings.

- (20) a. *Komuun na niis.*  
common COP water  
Water is common.
- b. *Raar-te na or.*  
rare-EMPH COP gold  
Gold is rare.

<sup>10</sup>The mass-count distinction in TdVZ appears to function in a way quite similar to English and Spanish. Mass nouns require measure phrases to combine with numerals, and show sorting/packaging coercions if pluralized. We have found one pair of quantifiers that distinguishes mass vs. count, viz. *suskatih* ‘how much’ vs. *bel* ‘how many’.

- (21) a. *Komuun-te na d-beez.*  
 common-EMPH COP PL-frog  
 Frogs are common.
- b. *Guk d-beez ekstingir.*  
 become PL-frog extinct  
 Frogs went extinct.

Because mass nouns and plurals may serve as kind terms, they are expected to allow existential readings via DKP. We see an existential reading of a mass term in (22) as well as in (23), where the bare noun is an external argument (ruling out an incorporation analysis).

- (22) Context: You notice a water leak on the sidewalk.

*Ka-zhi'i niis lo neez.*  
 PROG-spill water on road  
 Water is spilling on the road.

- (23) *La b-ain za manch tuwai?*  
 Y.N PERF-make butter stain towel  
 Did butter stain the towel?

The existential quantifier associated with the mass noun may only have narrow scope. This is readily seen for negation, where the two scope patterns are contrasted in (24) versus (25). Example (24) presents a negative answer to an existential question. Only the  $\neg > \exists$  scope pattern constitutes an appropriate answer, and the bare mass noun subject is felicitously used.

- (24) Context: Question (23)

*A'a', kedih b-ain-di za manch tuwai.*  
 no, NEG PERF-make-NEG butter stain towel  
 No, butter didn't stain the towel. [ $\neg > \exists$ ]

Example (25) presents a context where only a wide scope existential reading is appropriate; the narrow scope reading contradicts the previous discourse. The  $\exists > \neg$  pattern is not possible for a simple negated sentence with a mass subject, as (25a) makes clear. Instead, an apparently biclausal sentence with negation in the lower clause must be used, as in (25b).<sup>11</sup>

- (25) Previous discourse:

*Bi-la'a te tank chikru bi-zhi'i setih.*  
 PERF-crash one tanker and PERF-spill oil  
 A tanker crashed and oil spilled out.

- a. *# Per kedih bi-zhi'i-di setih.*  
 But NEG PERF-spill-NEG oil  
 But oil didn't spill out. [Consultant: "It's a contradiction."]
- b. *Per y-u'u tubru' setih kedih bi-zhi'i-di.*  
 but NEUT-be a.little.bit oil NEG PERF-spill-NEG  
 But some oil didn't spill out.

<sup>11</sup>This example instantiates a pattern of subordination without overt markers of embedded structure, which seems to be widespread both in TdVZ and in nearby Zapotecan languages.

The same range of facts holds of bare plurals. The existential reading of a bare plural and its narrow scope with respect to negation are seen in the question-answer pair in (26). (Further examples of the bare plural scoping under negation are seen in (40a) and (41a) below.)

- (26) Q: La ka-yoo d-beni gushadih?  
 Y.N PROG-eat PL-person grasshopper  
 Are people eating grasshopper?  
 A: Kedih ka-yoo-di d-tourist gushadih.  
 NEG PROG-eat-NEG PL-tourist grasshopper  
 No tourists are eating grasshopper. [ $\neg > \exists$ ]

Once again, narrow scope existential readings are conveyed with simple bare noun constructions, whereas wide scope constructions use a biclausal alternative, (27b).

- (27) a. # Ka-sia d-bekuh, per kedih ka-sia-di d-bekuh.  
 PROG-howl PL-dog but NEG PROG-howl-NEG PL-dog  
 Dogs are howling, but dogs aren't howling.  
 Consultant: "It's contradicting each other."  
 b. Ka-sia d-bekuh, per y-u'u d-bekuh kedih ka-sia-di.  
 PROG-howl PL-dog but NEUT-be PL-dog NEG PROG-howl-NEG  
 Dogs are howling, but there are dogs not howling.

In the facts reviewed thus far, TdVZ mass nouns and plurals match the range of interpretations of their English counterparts. Where the languages diverge is in the availability of the definite reading. In TdVZ, bare mass nouns and plurals freely allow definite readings. Definite readings of both plurals and mass nouns are seen in the short discourse in (28); bare nouns occur here first with existential readings, italicized, and subsequently as anaphoric definites, bolded. Examples (29) and (30) provide similar examples collected via the act-out (29) and storytelling (30) tasks.

- (28) Context: I am narrating what is happening in a cooking show I am watching.  
 a. Raate d-kosiner ri-beki *d-paap* kun za le'n perolih.  
 every PL-chef HAB-put PL-potato and butter in pot  
 Every chef puts potatoes and butter in a pot.  
 b. **D-paap** g-ai lo za.  
 PL-potato FUT-cook in butter  
 The potatoes will cook in the butter.  
 (29) Y-u'u jug, y-u'u *niis*. Naa gu-da'-a **niis** le'n vas.  
 NEUT-be juice, NEUT-be water. I PERF-pour-1SG water in cup  
 I have some juice and some water. I pour the water into a cup.

- (30) Context: A boy and his dog are walking through the park, carrying a frog and a turtle in a bucket. [Excerpt from *Frog on his own*]

- a. Mientr ri-zaa-d-an, gu-na-d-an *d-maripoos*.  
 while HAB-walk-PL-HUMAN PERF-see-PL-HUMAN PL-butterfly  
 While they walked, they saw butterflies.
- b. Beez siemprte ri-zhulazu-m r-idie-m. Gu-asia-m.  
 frog always HAB-like-ANIM HAB-go.out-ANIM PERF-jump-ANIM  
 B-idie-m le'n kubet.  
 PERF-go.out-ANIM from bucket  
 The frog always liked to go out. It jumped. It went out from the bucket.
- c. Mientr bekuh kin ka-ye-m **d-maripoos**.  
 while dog DEM PROG-look-ANIM PL-butterfly  
 Meanwhile that dog was looking at the butterflies.

In summary, bare mass nouns and plurals in TdVZ allow kind-level readings, narrow scope existential readings, and definite readings; wide scope existential readings are absent. This means that these nouns behave in precisely the way predicted by the Chierchia/Dayal system. They may function as kind terms, giving rise to kind-level and narrow scope existential readings (the latter by DKP). Alternatively, they may type shift via  $\iota$ , producing definite readings. But they may not type shift into generalized quantifiers with  $\exists$ , given that  $\iota$  is higher than  $\exists$  on the ranking of type shifts. This reveals an important sense in which the definite/indefinite distinction is not fully neutralized in this language. An important class of indefinite interpretations remains unavailable to bare plurals and bare mass nouns.

#### 4. Interpreting bare singulars

In this section we turn to the predictions of the Chierchia/Dayal system for bare singulars. This case deserves special attention in view of the fact that many languages are able to use singular arguments with kind reference. In English, this is seen as the singular definite generic:

- (31) a. The gopher is widespread. b. Babbage invented the computer.

This construction has received a good amount of theoretical and empirical scrutiny.<sup>12</sup> One central puzzle, originally noted by Lawler (1973), is that singular definite generics diverge from bare plurals in their allowance for existential readings. The existential reading of singular definite generics is possible only in cases where the predicate describes “something momentous or significant about the species as a whole” (Carlson, 1977); it is absent in examples like (32b), in contrast to bare plural counterpart (32a).

- (32) a. Gophers are eating my tomatoes.  
 b. The gopher is eating my tomatoes.

<sup>12</sup>See, i.a., Carlson 1977, Ojeda 1991, Wilkinson 1991, Krifka et al. 1995, Chierchia 1998, and Dayal 2004.

A number of different approaches to this puzzle have been explored. On a view like Wilkinson's (1991), where bare plurals are ambiguous between kind-level and indefinite readings, the facts simply show that definite singulars are not similarly ambiguous; they lack indefinite interpretations. On Carlson's (1977) view, adopted and adapted by Chierchia (1998) and Dayal (2004), this explanation is not available; bare plurals always denote kinds. Examples like (31) show that singular definites can denote kinds, too, but (32b) seems to show that this kind-level interpretation is not always available.

The approach taken by Chierchia (1998) responds to the challenge of (31)-(32) by essentially reversing Wilkinson's explanation – treating singular definites, rather than bare plurals, as subject to an ambiguity. The core approach to singular definites is as referential expressions denoting singular collectives. To combine with a kind-level predicate, the singular definite must be mapped to the associated individual concept via abstraction over the world/situation variable. This operation is forced in examples like (31) by sortal restrictions of the predicate. When a singular definite combines with an object-level predicate, as in (32b), however, there is no sortal mismatch to be repaired by intensionalization. This leaves the singular definite without a true kind-level interpretation. It may combine with the predicate only via simple function application, not in the way mediated by DKP.<sup>13</sup>

These considerations lead to the following predictions for singular count nouns in languages lacking definite articles. We saw above that languages lacking definite articles are expected to allow all nouns to type shift via  $\iota$ , given that this type shift is not lexically blocked. (See (19a).) Bare singulars should thus allow definite readings. If intensionalization is universally available as a type adjustment, then bare singulars should also allow kind-level readings. In contrast, existential readings of bare singulars are expected to be significantly limited. Wide scope existential readings are predicted to be absent, given (at least) that the  $\exists$  type shift is outranked by  $\iota$ .<sup>14</sup> (See (19b).) Furthermore, bare singulars are expected to diverge from bare plurals in the availability of the narrow scope existential reading. Bare singulars cannot obtain narrow scope existential readings by DKP. Narrow scope existential readings for bare singulars could only arise via an independent mechanism, such as incorporation. This means that narrow scope existential readings should always be absent for singulars when they serve as external arguments, given that incorporation is not possible in this argument-structural configuration. The two predictions specific to bare singulars are summarized in (33), and the overall range of expected interpretations for bare singulars is schematized in Table 3.

- (33) A language lacking definite articles...
- a. should allow bare singulars to have kind-level or definite interpretations.

<sup>13</sup>An alternative route is explored by Dayal (2004), who posits that singular definites do indeed have true kind-level interpretations without the help of a special abstraction operation. What is key is that singular kind terms block access to their instantiation sets: “the singular kind term is an atomic entity which does not allow distributive predication to entities we intuitively associate with it. That is, it is an atomic term whose only instantiation set, when available, includes perhaps a representative or prototypical object.” This means that DKP is unavailable for singular kind terms, blocking the missing reading of (32b). As far as we can tell, this approach is equal in empirical coverage to the Chierchia 1998 view; we adopt the latter for simplicity of exposition only.

<sup>14</sup>See section 6 for additional discussion.

- b. should not allow bare singulars to have narrow scope existential interpretations, except via incorporation (if the language makes use of this option); narrow scope existential interpretations should always be absent for singular external arguments, which cannot incorporate.

Table 3: Expectations for bare singulars in languages lacking definite articles

|                                                                     | Bare singular                                |
|---------------------------------------------------------------------|----------------------------------------------|
| a) Kind-level reading                                               | Expected<br>$\iota$ + intensionalization     |
| b) Narrow scope existential reading                                 | Unexpected<br>(modulo incorporation)         |
| c) Definite reading                                                 | Expected<br>$\iota$ type shift               |
| d) Wide scope existential reading<br>( $\exists$ GQ interpretation) | Unexpected<br>$\exists$ outranked by $\iota$ |

The next section shows that this rather complex set of expectations is again borne out for TdVZ.

## 5. TdVZ bare singulars

There are three respects in which bare singulars are expected to behave like bare plurals: in allowing kind-level readings, in allowing definite readings, and in disallowing wide scope existential readings. We begin this section with the evidence that these expectations are met.

As expected, kind-level predication may be carried out in TdVZ either via the bare plural or via the bare singular.

- (34) a. Guk (d-)beez ekstingir.      b. Komuun-te na (d-)beez lo geu.  
       become (PL-)frog extinct      common-EMPH be (PL-)frog in river  
       Frogs/the frog went extinct.      Frogs are / the frog is common in the river.

Also as expected, bare singulars are amenable to definite readings just as their plural counterparts are. Anaphoric singular reference is accomplished with bare singulars in examples like (35) and (36); the relevant definite terms are bolded.

- (35) Rap-a te manzan, kon te manguh, per gu-zuub-an **manguh** lo yagzhilih.  
       have-1SG a apple and a mango but NEUT-sit-3SG mango on chair  
       I have an apple and a mango but the mango is on the chair.

- (36) Context: A boy and his dog are walking through the park with a net, looking to see if they can catch an animal. They come across a frog sitting on a lily pad in a pond.
- a. “N-iu’!” n-e-m. “A te beez zu lo nis!”  
 NEUT-look NEUT-say-ANIM PRT one frog stand on water  
 “Look!” it [the dog] said. “There’s a frog on the water!”
- b. Xila’azga, xila’azga, ka-zaa-d-an te neez-d-an **beez**.  
 slowly slowly PROG-walk-PL-3 PRT catch-PL-3 frog  
 Slowly, slowly, they walked to catch the frog.

Examples (37) show that bare singulars are also readily used to describe referents that are unique, whether absolutely or relatively.

- (37) a. Ziit-te zuub **gubiizh**. b. Rom zu-gua **Paap**.  
 far-EMPH sit sun Rome PROG-be.located pope  
 The sun is very far away. The pope lives in Rome.

Finally, bare singulars behave like bare plurals, and as expected, in disallowing wide scope existential readings. Examples (38) and (39) show that bare singulars are rejected in a context calling for the wide scope existential reading; the consultant corrects the sentences to include the word *te* ‘one’ (discussed in section 6).

- (38) Context: there’s six frogs and five of them are in the basket. We want to say there’s one that’s not, so we say:

# Kedih y-u’u-di beez le’n kanast.  
 NEG NEUT-be-NEG frog in basket

Speaker’s correction:

Kedih y-u’u-di te beez le’n kanast.  
 NEG NEUT-be-NEG one frog in basket  
 One frog isn’t in the basket.

- (39) Context: I’m editing a paper for someone else, and fixing mistakes. I’m expressing my regret because I realize I’ve sent the paper off and there is a mistake I didn’t fix.

- a. Kedih b-ain sru-di-a te eror.  
 NEG PERF-make good-NEG-1 one mistake  
 I didn’t fix a mistake.
- b. # Kedih b-ain sru-di-a eror.  
 NEG PERF-make good-NEG-1 mistake  
 Consultant: “It’s more normal if you say *te eror*.”

Discussion of example (39b) revealed that the bare singular object would be improved in this context if modified by a relative clause or a sequence of other modifiers. This additional material presumably rescues the example by improving the felicity of a definite reading, which requires a single salient referent for the object.

This brings us to the point where bare singulars and bare plurals are expected to diverge, namely

the possibility of the narrow scope existential reading. Let us begin with those bare arguments not amenable to incorporation. Example (40) contrasts a bare singular and a bare plural subject for the unergative verb *zhiiz* ‘laugh’. As we saw above, the bare plural is freely able to show a narrow scope existential reading in this environment; the bare singular, however, is not.

- (40) Context: my husband has shared a joke with me and I told it to my class. When I get home, he asks if anyone laughed. I have to report the sad news: no laughing.
- a. Kedih ba-zhiiz-di d-bi’in xkuilih.  
 NEG PERF-laugh-NEG PL-student  
 No students laughed.
- b. # Kedih ba-zhiiz-di bi’in xkuilih.  
 NEG PERF-laugh-NEG student  
 Intended: No student laughed. Only possible reading: one student didn’t laugh.

Example (40b) is acceptable only on an interpretation where the bare singular picks out a single individual – just what is expected, if it is forced to be definite when serving as an external argument of a non-kind-level predicate. Example (41) shows a similar contrast for transitive subjects. The bare plural is readily able to show the narrow scope existential reading; the bare singular has only a single-individual reading.

- (41) The mail carrier is often chased by dogs. Today he comes home and says: *Sru guk nazhi* ... [It was a good day...]
- a. ... kedih bi-dieno-di d-bekuh naa.  
 NEG PERF-chase-NEG PL-dog me  
 No dogs chased me.
- b. # ... kedih bi-dieno-di bekuh naa.  
 NEG PERF-chase-NEG dog me  
 Intended: no dog chased me. [Consultant: “This sounds like a specific dog.”]

It is quite striking that this contrast between singulars and plurals comes out precisely as expected and essentially in parallel with the English facts in (32). The result is even more remarkable if we consider that the contrast collapses for internal arguments – a fact which we propose to attribute to (pseudo)-incorporation. The prototypical incorporated arguments are direct objects, and in TdVZ, narrow scope existential readings are freely available in this case. Example (42) shows that both singular and plural direct objects may scope under a higher intensional operator and quantificational subject. Example (43) provides an additional case of a singular direct object showing a narrow scope existential reading.

- (42) Context: Tourists going to Hollywood have a general desire to meet celebrities.
- a. Kadga tourist ri-kas gu-mbe beni famos.  
 every tourist HAB-want SBJ-meet person famous  
 Every tourist wants to meet a famous person.
- b. Kadga tourist ri-kas gu-mbe d-beni famos.  
 every tourist HAB-want SBJ-meet PL-person famous  
 Every tourist wants to meet famous people.

- (43) Context: I'm going to meet somebody and I want to describe to them what I look like.

Kedih kaa-di                      zhumbrel kiye-'.  
 NEG PROG.wear-NEG hat              head-1

I'm not wearing a hat.

Subjects of certain intransitive verbs may also show narrow scope existential readings; these verbs are plausibly analyzed as unaccusative. One of these is the (locative) copula *u'u*.

- (44) Kedih y-u'u-di              beez le'n kanast.

NEG NEUT-be-NEG frog in basket

There's no frog in the basket.

Finally, prepositional objects may show narrow scope existential readings in examples like (28a) above, where pots covary with chefs. This range of facts shows that bare singulars may in principle have narrow scope existential readings, but only by a mechanism that does not apply to subjects of unergative intransitives (40) or to transitive subjects (41). Incorporation is a mechanism that is argument-structure sensitive in precisely this way, and thus, these facts suggest that TdVZ is a language making use of some type of incorporation construction.

These facts are of special interest for the study of incorporation constructions because there is no obvious morphosyntactic difference in TdVZ between clauses with incorporated objects versus those with non-incorporated objects. There is, for instance, no difference in object marking or object agreement (by contrast to Hindi (Dayal, 2011) or Nez Perce (Deal, 2010)), no overt compounding of the verb and the object (by contrast to West Greenlandic (van Geenhoven, 1998)) and no switch from VSO to VOS (by contrast to Niuean (Massam, 2001) or Chol Mayan (Coon, 2010)). This suggests that TdVZ may be a language with *purely* semantic incorporation: the object composes with the verb in a way that facilitates extraordinary narrow scope (perhaps among other semantic effects; see Dayal 2011), but without any special consequence for word order or morphosyntactic marking.

## 6. Does TdVZ have an indefinite determiner?

The theory presented thus far makes use of two central tools in regulating the interpretation of bare nouns: the Blocking Principle (14) and Ranking of Type Shifts (18). In this section, we consider and reject the possibility that Ranking may be removed from the theory by means of an analysis that reassigns some of its work to Blocking. In particular, we argue that TdVZ does not have indefinite articles (i.e. items that lexicalize the  $\exists$  type shift) available for all types of NPs. The best candidate for such an item is *te* 'one', and we argue that this lexical item does indeed create existential GQs; however, it is restricted to singulars or partitive structures. The absence of a wide scope existential reading for mass and plural bare nouns therefore cannot be attributed to Blocking by *te*.

The behavior of *te* 'one' with singulars is in several ways reminiscent of English indefinite article *a*. Like *a*, *te* gives rise to antifamiliarity and antiuniqueness implications, showing effects of Maximize Presupposition (Heim, 1991).

- (45) Nau-te        te    bekuh bedih    lele'e. Cha-rilian    (#te) bekuh.  
 chase-EMPH one dog    rooster patio. PROG-hungry one dog  
 A dog is chasing a rooster on the patio. The dog looks hungry. [Consultant: With *te*, it means another dog.]
- (46) Rom    zu-gua                    (#te) Paap.  
 Rome PROG-be.located one    pope  
 The pope lives in Rome [Consultant: with *te*, there is more than one pope.]

*Te*-phrases are also similar to English *a*-phrases in allowing variable scope with respect to clausemate negation. We have seen *te*-phrases with scope over negation in (38)-(39) above. An example with scope under clausemate negation is shown in (47).

- (47) Q: Did Maria buy a chicken?  
 A: Ketih guzi-di    Lie    te    bedih.  
       NEG buy-NEG Maria one chicken  
       Maria didn't buy a chicken. ( $\neg > \exists$ )

Overall, these facts suggest that singular *te* phrases, like their English *a*-phrase counterparts, are existential GQs. This has the consequence that the absence of a wide scope indefinite reading for TdVZ bare singulars could be attributed to Blocking, rather than Ranking, just like in English. Can the absence of the  $\exists$  type shift in TdVZ *in general* be attributed to Blocking, then? No: while *te* can occur in plural DPs (unlike English *a*), *te PL-N* does not behave as an ordinary existential GQ. Rather, plural DPs containing *te* seem to be partitives, often also containing a demonstrative and presupposing the existence of an element in  $[[PL-N]]$  (e.g., in (48), a plurality of tortillas). Also notably, *te PL-N* is never used for an ordinary narrow scope existential reading, unlike in singular examples like (47); bare plurals are used instead.

- (48) Bell (lee) ri-ki'ini-u    **te d-get    kan**, guni-naa.  
       If (you) HAB-need-2S one PL-tortilla DEM, tell-1SG  
       If you need some of the tortillas, let me know.  
       Consultant: This is what you say if you've already made the tortillas.

The interaction with number suggests that *te* is a existential GQ only with a singular complement. Apparent plural complements, like in (48), reflect hidden partitive structure: *If you need one portion of the/those tortillas*.<sup>15</sup> We conclude that blocking by *te* does some, but not all, of the work of ruling out wide scope existential readings for bare nouns. Both Blocking and Ranking are needed in order to fully constrain the interpretation of bare nouns in TdVZ.

## 7. Conclusions

In this paper, we have demonstrated that TdVZ, while it may lack definite articles, is not a language where definite and indefinite readings are freely available for bare nouns. Rather,

<sup>15</sup>The absence of an overt noun 'portion' here recalls Nez Perce and Yudja, on the analysis of Deal (2017).

(in)definiteness in TdVZ bare nouns is constrained by number and by argument-structural position, and this in precisely the way predicted by the neo-Carlsonian approach to bare noun meaning (Chierchia 1998, Dayal 2004). In corroborating this approach with evidence from Zapotecan, our results lend new support for the neo-Carlsonian theory as a characterization not of an accident of (Indo-)European heritage or history, but rather of Universal Grammar mechanisms at work in number-marking languages.

## Clefts: Quite the contrary!<sup>1</sup>

Emilie DESTRUEL — *University of Iowa*

David BEAVER — *University of Texas at Austin*

Elizabeth COPPOCK — *University of Gothenburg and Swedish Collegium for Advanced Study*

### Abstract.

Much of the previous literature on English it-clefts—sentences of the form ‘It is X that Z’—concentrates on the nature and status of the exhaustivity inference (‘nobody/nothing other than X Z’). This paper concerns the way in which it-clefts signal contrast. We argue that it-clefts signal a type of contrast that does not merely involve a salient antecedent, as on more traditional characterizations of contrast such as those of e.g. Kiss (1998) and Rooth (1992), but also involves a conflict between the speaker’s and the hearer’s beliefs, as under the characterization of contrast given by Zimmermann (2008, 2011), which we term *contrariness*. Results of a felicity judgment experiment suggest that clefts do have a preference for contrariness, and one which has a gradient effect on felicity judgments: the more strongly interlocutors appear committed to an apparently false notion, the better it is to repudiate them with a cleft.

**Keywords:** English it-clefts, contrast, interlocutors’ expectations, existential inference.

### 1. Introduction

As discussed by Horn (1981: 127), Halvorsen (1978) identified three meaning components for English it-clefts of the form “It is X that V-ed”. Consider the following example:

- (1) It’s David who smiled.
  - a. David smiled.
  - b. Someone smiled.
  - c. No one other than David smiled.

The cleft sentence (1) gives rise to the three implications in (1a)-(1c): the PREJACENT INFERENCE (1a), i.e. the proposition expressed by the canonical form ‘X V-ed’, an EXISTENTIAL INFERENCE (1b) such that there exists an X who V-ed, and an EXHAUSTIVITY INFERENCE (1c), such that X identifies the sole (or maximal) entity of which V holds.

A great deal of the subsequent work on clefts has been dedicated to the exhaustivity implication, aiming both to give a precise characterization of its content and to identify its discourse status, i.e. whether it is conventionally encoded within the cleft itself, or arises from pragmatic reasoning on the discourse context (e.g. Halvorsen 1978, Atlas and Levinson 1981, Wedgwood 2007, Velleman et al. 2012, Buring and Kriz 2013, Destruel et al. 2015).

But clefts have also been posited to express a *contrast*, and indeed this tradition dates back to the work in which the term “cleft” was first introduced. Thus we find in Jespersen (1927),

---

<sup>1</sup>We would like to thank the audience of the SuB 2016 conference for their helpful comments on this work.

which is perhaps the first general treatment of clefts, “A cleaving of a sentence by means of *it is* (often followed by a relative pronoun or connective) serves to single out one particular element of the sentence and very often, by directing attention to it and bringing it, as it were, into focus, to mark a contrast.” (Jespersen 1927: 147f.). Later work discussing clefts’ contrastive function includes É. Kiss 1998, Patten 2012: 85ff, Destruel and Velleman 2014, and Umbach 2004, p. 4 who follows É. Kiss.

In the literature, the notion of *contrast* is often discussed in relation to two other primitives of information structure, topic and focus. Since clefts are known to be focus-marking devices, we will be interested in contrast in focus-related contexts. We take focus to be the part of the sentence that evokes a set of alternatives relevant for the interpretation of that sentence, and which is taken to be salient by the speaker (Rooth, 1985, 1992; Krifka, 2007). Now, turning to contrastive focus, several definitions have been offered. É. Kiss (1998: 267), takes an *identificational focus* to have the feature [+contrastive] “if it operates on a closed set of entities whose members are known to the participants of the discourse [...] In this case, the identification of a subset of the given set also identifies the contrasting complementary subset.” Rooth (1992) defines contrast as a subcase of a more general notion of focus; for Rooth, a phrase  $\alpha$  should be taken as contrasting with a phrase  $\beta$  if the ordinary semantic value of  $\beta$  is a subset of the focus semantic value of  $\alpha$ .

But, as Zimmerman (2008) points out, the two approaches described above do not fully predict when contrast-marking constructions such as clefts will be used. In languages as diverse as Finnish and Hausa, which are argued to use clefts to indicate exhaustivity or the presence of an antecedent, canonical sentences can sometimes be used when an exhaustive or a contrastive meaning is intended, and an explicit antecedent is present. This is illustrated in Hausa in example (2) (taken from Zimmerman 2008: 351), where Speaker B uttering (2b) corrects Speaker A uttering (2a). This suggests that there may not be a strict one-to-one correspondence between a certain focus interpretation, i.e. here contrastive, and the way in which it is realized grammatically.

- (2) a. You will pay 20 naira.  
 b. A’a zâ-n biyaa shâ bìyāñ nèe.  
     no, FUT-1SG pay fifteen PRT  
     ‘No, I will pay [fifteen.]<sub>f</sub>’

As opposed to Kiss and Rooth, Zimmerman (2008) argues for a notion of contrast that calls on *hearer expectation*, i.e. whereby a focused constituent  $\alpha$  is a contrastive focus whenever the speaker assumes that “the hearer will not consider the content of  $\alpha$  or the speech act containing  $\alpha$  likely to be(come) common ground” (Zimmerman, 2008: 9). Since it relates to speaker and hearer belief, it can be thought of as *doxastic contrast*, but to avoid confusion with existing notions of contrast, we will use the term *contrariness*.

With these distinctions in mind, let us distinguish among three imaginable hypotheses:

- Hypothesis A: The meaning components identified by Halvorsen (1978) (the Halvorsen components) are sufficient to capture the significance of a cleft construction.

- Hypothesis B: In addition to the Halvorsen components, clefts signal a non-doxastic type of contrast, of the type characterized by É. Kiss (1998) or Rooth (1992).
- Hypothesis C: In addition to the Halvorsen components, clefts signal a doxastic type of contrast, i.e. contrariness.

Hypothesis B is appealing, at least at first sight, because it accounts for some important judgments such as the observation that, while it-clefts often sound odd as direct answers to overt questions, as in (4) (see also results from Destruel and Velleman 2014 who find this context to lead to the lowest naturalness ratings for clefts), they often sound much better as corrections, as in (3).<sup>2</sup> In this case, the previous utterance being corrected provides exactly the kind of antecedent that Rooth mentions for a contrastive focus.

- (3) A: I wonder why Alex cooked so much beans.  
B: Actually, it was John who cooked the beans.

- (4) A: Who cooked the beans?  
B: #It was John who cooked the beans.<sup>3</sup>

However, Hypothesis B is not without limitations. There are certain observations that it cannot explain. For instance, in contexts in which an antecedent *is* available, speakers may nevertheless choose not to use a cleft. Indeed, in some such contexts, clefts seem actively dispreferred, and their use sounds stilted and odd. For instance, (5b) does not strike us as good idiomatic English. This is confirmed in the rating experiment conducted by Destruel and Velleman (2014) where this particular sentence was actually given a lower naturalness rating than (6b), despite the fact that (5b) has an antecedent available (viz. Canada) and (6b) does not.

- (5) A: Darren sounded really excited about his vacation. I think he might be going to Canada.  
a. B: Actually, he's going to Mexico.  
b. B: ? Actually, it's Mexico that he's going to.
- (6) A: We were planning Amy's surprise party for weeks. I can't believe she found out about it. Who told her about it?  
a. B: Ken told her about it.  
b. B: It was Ken who told her about it.

So, we are still left with the question: If the mere presence of an antecedent is not “enough” to drive the naturalness ratings of a cleft up, what else is needed to make it-clefts good? In this paper, we will follow Zimmerman's (2008) notion of contrast and set out to test Hypothesis

<sup>2</sup>Indeed, our invocation of *contrariness* could be seen as an implementation of the notion of *corrective focus*: see e.g. Gussenhoven 2008. However, there are some cases where contrariness could be argued to be at play that do not involve what one would be inclined to call corrections, including “Either Mary ate the beans, or it was John who ate them.” For this reason, we take it that correction, although it is a possible use of clefts, is not what clefts mark.

<sup>3</sup>Throughout the paper, we will indicate ungrammaticality with an asterisk (\*) and infelicity with a hash (#).

C. We will give experimental evidence showing that *contrariness* has a positive and gradient effect on the felicity of clefts: The more there is a contrast in expectation between the speaker and the hearer, the better clefts are.

## 2. Experiments

The core idea behind the set of experiments presented hereafter (two pre-tests and one main study) is to test Hypothesis C described in the introduction: the more strongly an interlocutor appears committed to a (false) proposition, the better it is to repudiate them with a cleft. This means that the presence of a focal antecedent in the discourse, although maybe necessary, is not a sufficient use-condition for it-clefts. Rather, it is when they are used as a response to an (explicit) contrary claim that clefts are most felicitous.

### 2.1. Design and Material

In all experiments below, the same source sentences were used to generate the stimuli that were provided to subjects, and the stimuli were always presented in written form. In the main study, the stimuli consisted of a short dialogue between Speaker A who provided the context, and Speaker B who provided the contrary comment. A's part, as illustrated in (7), always contained three sentences, the first two establishing the context and the last one containing the information on which B's comment was based. Experimental items varied depending on the form of the last sentence in A's discourse across six possible contexts. The six different contexts were designed to vary along three dimensions: (i) CONTRADICTION, i.e. whether or not the information in B's sentence contradicted the information stated in the last sentence uttered by A, (ii) COMMITMENT, i.e. the strength with which A was committed to their statement (as measured in a pre-test), and (iii) AT-ISSUENESS, i.e. whether or not the relevant proposition in A's speech commented on by B was at-issue. B's part was always either in a canonical form or a cleft form. When A's context was non-contradictory (context 1), B's sentence was always introduced by "Yeah,...", while in the other contexts (contexts 2 through 6), B's sentence was introduced by "Actually,...". The different conditions are summarized in Table 1, and an illustrative sample is given in (7)–(8).

|                        | Contradiction | Strength of Commitment | At-issueness |
|------------------------|---------------|------------------------|--------------|
| 1- Non-contradictory   | no            | +                      | no           |
| 2- Weak at-issue       | yes           | ++                     | yes          |
| 3- Weak non-at-issue   | yes           | +++                    | no           |
| 4- Strong at-issue     | yes           | ++++                   | yes          |
| 5- Strong non-at-issue | yes           | +++++                  | no           |
| 6- Presuppositional    | yes           | ++++++                 | no           |

Table 1: Conditions for A's last sentence.

#### (7) Contexts (sample lexicalization)

Speaker A: We were planning Amy's surprise party for weeks. I can't believe she found out about it. [...]

a. Context 1: ... I guess someone from the staff told her.

- b. Context 2: ... I guess Alice must have told her.
- c. Context 3: ... And Alice—who I think, probably went and told her about it—just laughed and said it was no big deal!
- d. Context 4: ... Alice told her about it, you know.
- e. Context 5: ... And Alice—who went and told her about it—just laughed and said it was no big deal!
- f. Context 6: ... I'm annoyed that Alice told her about it!

(8) **Sentences to rate (sample lexicalization)**

Speaker B: (Yeah/ Actually,) [...]

- a. Ken told her about it.
- b. it's Ken who told her about it.

Finally, we also controlled for the GRAMMATICAL FUNCTION of the element that B commented on, i.e. a grammatical subject or an object. Example (7) above illustrates the subject condition. An example of the object condition for context 1, i.e. the non-contradictory context, is given below in (9):

- (9) a. Speaker A: Look at John this evening! He's all dressed up. [...] I guess he's going out with someone from the marketing team.
- b. Speaker B: Yeah, he's going out with Karen/ Yeah, it's Karen he's going out with.

We created a total of 12 lexicalizations for each contexts, thus 72 experimental dialogues per grammatical function (or 144 total). Three groups of participants were recruited. Participants in the main study were asked to judge the naturalness of B's part based on A's. In pre-test 1 and pre-test 2, the two different groups of participants only saw and rated A's part. The specifics of each task are discussed in more details hereafter in subsections 2.2-2.4.

## 2.2. Pre-test 1: Strength of existential inference

*Motivation:* It is important for our argument that any effect we find of doxastic contrast is not an artifact of variation among items with respect to the strength of the existential inference that they give rise to. We therefore carried out a pre-test in order to measure the strength of the existential inference in A's part, in other words, how strongly A believes that someone V-ed.

*Procedure:* In this task, participants only saw and judged A's discourse. A total of 65 participants, all undergraduates at the University of Iowa, were recruited from a first-year language class and given extra-credit for their participation. The test was delivered via the web-based survey site Qualtrics. Participants sat in front of a computer screen and read a total of 24 contexts (A's part) pseudo-randomized among 24 fillers. On each trial, they saw Speaker A's sentences and were asked to judge, on a scale from 1–7, how likely it is that the speaker thinks that somebody V-ed. So for instance, given context 1 in (7a) above, participants would be asked how likely is it that someone told Amy about her surprise party (1 corresponding to extremely unlikely, and 7 to extremely likely).

*Results:* Mean naturalness ratings for the strength of the existential inference in A's sentence are presented in Table 2. Overall, we observe that participants deem the likelihood of speaker thinking that someone V-ed lower for the context that lacks a contrast between A's sentence and B's response (i.e. context 1), versus other contexts. The data were analyzed using a mixed effect linear regression model to predict ratings with by-participant and by-item random intercept, and contrast as a factor (sum-coded as -1/1 for context 1 vs. others, respectively). Results reveal a significant effect of CONTRAST on existential ratings ( $\beta = 2.043$ ,  $SE = 0.091$ ,  $t = 22.24$ ,  $p < .001$ ), suggesting that, indeed, there was a significant difference in ratings between context 1 and the others where a conjecture was present.

| Context                | Mean ratings (Subject) | Mean ratings (Object) | Overall ratings |
|------------------------|------------------------|-----------------------|-----------------|
| 1- Non-contradictory   | 4.6                    | 4.4                   | 4.5             |
| 2- Weak at-issue       | 6.5                    | 6.3                   | 6.4             |
| 3- Weak non-at-issue   | 6.5                    | 6.5                   | 6.5             |
| 4- Strong at-issue     | 6.6                    | 6.7                   | 6.7             |
| 5- Strong non-at-issue | 6.4                    | 6.4                   | 6.4             |
| 6- Presuppositional    | 6.7                    | 6.7                   | 6.7             |

Table 2: Mean naturalness ratings for Pre-test 1.

Crucially though, focusing on the contradictory data set, we see that contexts 2-6 do not significantly differ from each other with respect to A's commitment to existence. This is good news: If we further find that these contexts differ in the strength of A's commitment to a statement that B will contradict (as they were designed to do and tested in pre-test 2), then we will be able to test our prediction as stated in Hypothesis C.

### 2.3. Pre-test 2: Strength of commitment

*Motivation:* Recall that we designed for four levels of commitment strength, namely *non-contradictory*, *weak*, *strong* and *presuppositional*, with the underlying assumption that commitment would get increasingly stronger in these contexts. In pre-test 2 we measured commitment strength (how strongly committed A is to 'X V-ed') directly. This gave us a more accurate measure of this factor to use, and allowed us to confirm that the contexts we created were indeed, as they were designed to be, different from each other with respect to the strength of commitment of Speaker A to the prejacent proposition in their last utterance (the target proposition).

*Procedure:* A total of 65 participants were recruited, different from those who took part in pre-test 1. They were all undergraduates at the University of Iowa. They were enrolled in a first-year language class and were given extra credit for their participation. The test was delivered via Qualtrics. Participants sat in front of a computer screen and read a total of 24 contexts (A's part) pseudo-randomized among 24 fillers. On each trial, they saw Speaker A's sentences and were asked to judge, on a scale from 1–7, how strongly Speaker A is committed to the fact that X V-ed. So for instance, given context 1 in (7a) above, participants would be asked how strongly is Speaker A committed to the proposition that someone from the staff told Amy about her surprise party (with 1 corresponding to extremely uncommitted and 7 to extremely committed).

*Results:* Mean naturalness ratings are reported in Table 3. Overall, we observe that the context with the lowest rating, as predicted, is the one where there is no contradiction (context 1). We then observe a strengthening trend, with contexts 4–6—which we designed as containing a stronger commitment of A to the prejacent proposition—being rated higher than contexts 2–3, which were meant to weakly commit A to the prejacent. This result is welcome and suggests that there is indeed a difference between contexts in A’s degree of commitment to the prejacent.

| Context                | Mean ratings (Subject) | Mean ratings (Object) | Overall ratings |
|------------------------|------------------------|-----------------------|-----------------|
| 1- Non-contradictory   | 2.2                    | 2                     | 2.1             |
| 2- Weak at-issue       | 3.6                    | 3.9                   | 3.8             |
| 3- Weak non-at-issue   | 2.7                    | 2.6                   | 2.7             |
| 4- Strong at-issue     | 6.1                    | 6.1                   | 6.1             |
| 5- Strong non-at-issue | 5.5                    | 5.3                   | 5.4             |
| 6- Presuppositional    | 5.3                    | 5.6                   | 5.5             |

Table 3: Mean naturalness ratings for Pre-test 2.

The results from the two pre-tests are illustrated in relation to each other in Figure 1. Recall that contradictory contexts (2–6) all provide an antecedent and commit Speaker A to existence (illustrated by the fact that ratings on the x-axis are homogeneously high). But, importantly, we observe that they differ in the strength of A’s commitment to a statement that B will contradict, which allows us to test Hypothesis C.

Figure 1: Existential \* Strength of commitment.

## 2.4. Main study

*Goal:* The overarching goal of the main study is to test Hypothesis C. We investigated the effect of four factors on participants' naturalness ratings of clefts and canonicals: (i) EXISTENCE (results from strength of existence as reported in pre-test 1), (ii) GRAMMATICAL FUNCTION, i.e. whether the focus was a subject or an object, (iii) AT-ISSUENESS, i.e. whether or not the element in A's speech commented on by B was at-issue and (iv) CONTRARINESS.

The motivation behind including AT-ISSUENESS as a factor comes from Destruel and Velleman (2014), who also argue for the relevance of *contrast in expectation* in the interpretation of clefts, and argue that two types of expectations may be at play; not just expectations about the state of the world but also expectations about the shape and direction of discourse. The latter type is directly relevant here since it may involve beliefs about the direction in which the discourse is going, expressed, among other ways, by marking content as at-issue or not-at-issue. We assume that interlocutors taking part in a discourse will generally address the propositions that are currently at-issue. Thus, a move which addresses a previously not-at-issue proposition is an *unexpected* discourse move. Consequently, if it-clefts are more natural when there is a conflict in expectations, we expect clefts to be judged more acceptable if Speaker B is commenting on content which had previously been marked as not-at-issue (in A's speech), thereby violating the expectation that such content will not need to be discussed further.

The factor CONTRARINESS was measured as follows: In non-contradictory contexts, items were attributed a contrariness value of 0, because Speaker B does not say anything that conflicts with what Speaker A says. In contradictory contexts, the contrariness value for an item is the strength of Speaker A's commitment to the conflicting proposition (as measured in pre-test 2). Thus, contrariness was operationalized as the product of commitment and contradiction, i.e.  $\text{Contrariness} = \text{Commitment} * \text{Contradiction}$ . If Hypothesis C turns out to be borne out, we expect that clefts will be judged as more natural in contexts where contrariness is higher.

*Procedure:* For this study, we counterbalanced the experimental dialogues across 12 lists so that each participant saw 24 items (12 subjects and 12 objects). The order of the items was pseudo-randomized among 24 fillers. A total of 64 participants were recruited on Amazon's Mechanical Turk and paid for their participation. On each trial, participants saw a written context (Speaker A's part), followed by Speaker B's sentence in either a cleft or a canonical form. Participants were asked to rate "How natural is Speaker B's sentence given A's" on a seven point Likert scale, with endpoints labeled as "extremely natural" and "extremely unnatural".

*Results:* We present results by sentence form, for clefts first, then for canonicals. Visual inspection of Figure 2 suggests that clefts were overall rated as more natural when the context contains a stronger degree of contrariness (as illustrated by the upward trend in the position of the red dots) than when the context does not include a contrast at all (blue dots). We analyzed the cleft data by fitting a series of mixed effect models predicting naturalness ratings from the fixed effects of interest and random effect structures that included random by-participant and by-item intercepts. Results were obtained using the *lme4* package (Bates et al., 2015) in R (R Core team 2016). We found no main effect of GRAMMATICAL FUNCTION ( $\beta = 0.376$ , SE =

0.114,  $t = 1.64$ ), suggesting that whether the focus is a subject or an object, the naturalness ratings for the cleft are not influenced. Surprisingly, we also found no effect of AT-ISSUENESS ( $\beta = -0.518$ ,  $SE = 0.113$ ,  $t = -1.55$ ); when clefts were used to signal an unexpected discourse move, i.e. to contrast with an element that was part of the non-at-issue content of A's speech, they were not drastically better than when commenting on an at-issue part of discourse.

There was, however, a main effect of EXISTENCE ( $\beta = 0.91$ ,  $SE = 0.061$ ,  $t = 14.8$ ), suggesting that clefts are rated significantly better in contexts where the existence of the element to be contrasted is assumed, and an effect of CONTRARINESS ( $\beta = 0.383$ ,  $SE = 0.022$ ,  $t = 17.36$ ), which supports Hypothesis C. Among models that contain subsets of these factors, the model that gave the best fit to the data was one that included both factors (i.e. Judgment  $\sim$  Existence + Contrariness,  $\chi^2 = 69.5$ ,  $p < .001$ )

Figure 3 combines the results for clefts and canonicals, with the lighter-colored dots representing the naturalness ratings of clefts (light red) and of canonicals (light blue) in the one experimental context where there is no contradiction present. Darker-colored dots represent the naturalness ratings for both sentence forms in other contexts, plotted by the strength of contrariness attributed to these contexts (i.e. commitment results from pre-test 1 \* contradiction).

Figure 2: Mean naturalness ratings for clefts by ratings for contrariness.

Visual inspection of Figure 3 suggests that, for canonical sentences, the trend is quite different. As opposed to clefts, when the context does not include a contradiction, canonical sentences are rated as very natural. This should come to no surprise since, in English, canonical sentences constitute an unmarked sentence form, and are commonly used to answer an explicit wh-question. The trend for canonicals is also different from clefts when looking at contexts that *do* include a contradiction: the felicity of canonicals does not significantly improve as the level of contrariness increases, but in fact decreases. These observations are reflected in the results of our statistical analysis: Fitting a series of mixed-effect linear regression models to the

Figure 3: Mean naturalness ratings for canonicals vs. clefts by ratings for contrariness.

subset of data for canonicals only reveals a main effect of CONTRARINESS ( $\beta = -0.092$ ,  $SE = 0.017$ ,  $t = -5.24$ ), but no effect of the other predictors (GRAMMATICAL FUNCTION,  $t = 1.43$ ; AT-ISSUENESS,  $t = -1.28$  and EXISTENCE,  $t = 1.19$ ). Here, a model that includes both Existence and Contrariness does not give a better fit to the data than the two models with each single predictors ( $\chi^2 = 1.39$ ,  $p = 0.23$ ;  $\chi^2 = 2.75$ ,  $p = 0.19$ , respectively).

One thing to note is that, in our experiment, sentences were delivered in written form, therefore without prosodic marking. It is possible that naturalness ratings could have been higher for contexts with a high level of contrariness if the stimuli had been heard with (the appropriate) pitch accent. Indeed, English commonly resorts to prosody to signal information structure, and contrastive focus is known to have a particular prosodic contour (Selkirk, 2002; Katz and Selkirk, 2011).

### 3. Closing Discussion

Our experimental results provide clear evidence in favor of the hypothesis that the felicity of clefts is related to the presence of *doxastic contrast* (Hypothesis C).

The goal of the present paper was to test prior hypotheses concerning clefts' standard components of meaning. We hypothesized that the mere presence of an antecedent in discourse which the clefted element would pick up and comment on (i.e. simple contrast) would not suffice to fully explain the felicity pattern of English it-clefts. Instead, we set out to test the hypothesis that something more refined is needed, namely a notion of contrast that includes a conflict between interlocutors' expectations. We followed Zimmermann's notion of contrast, which relates to how strongly the addressee believes the contrary, and experimentally operationalized it. So what have we learned?

We have shown that the presence of an explicit alternative—or in other words of a contrast, as defined in semantic terms by the previous literature (Rooth, 1992)—does increase the naturalness of clefts. This suggests that the presence of an antecedent is a necessary condition for clefts to be felicitous. But our study shows that it is not sufficient. Instead, we have shown that the factor which leads clefts to be significantly preferred (in contrast to canonicals and controlling for other factors known to influence the acceptability of clefts such as existence) is that of contrariness as defined along the lines of Zimmermann: Clefts are more natural when there exists a metalinguistic contrast. Additionally, we have seen that one type of expectation is most relevant for this metalinguistic contrast—expectations involving interlocutors' beliefs about the world (i.e. expectations about what content is likely to be added in the common-ground). On the other hand, our study showed that a conflict with respect to the direction in which the discourse is heading, operationalized as the conflicting element being (non)-at-issue, was not relevant, as this factor did not influence naturalness ratings. In sum, our main finding is that clefts are better not only when there is an antecedent to contradict in the preceding discourse context, but crucially when this antecedent is not the one expected by the listener. This result is not captured by any existing model of clefts.

Another interesting point concerns the felicity of canonical sentences, and their relation to clefts. Indeed, in many languages, clefts and canonicals are considered to be in competition in focus-related contexts. This means that, in theory, when canonicals are “bad”, clefts take over as the preferred strategy and are more felicitous. Put slightly differently, clefts' emergence in discourse can depend on canonicals' availability and naturalness. But this is not the case in English. Indeed, our results do not show a complete reversal in trend, whereby canonicals become drastically unnatural in contexts where clefts increase in felicity. This is not surprising given that in English, focus (including contrastive focus) is typically marked via prosodic means. Thus, canonicals are never truly bad. Clefts simply represent an additional option the language has to signal a (even more) marked interpretation, e.g. doxastic contrast, unambiguously. On the other hand, in languages where canonicals are less (or not) available, like in French, we expect clefts to be judged more natural in non-contradictory contexts, but still expect an effect of contrariness on their felicity. We leave this as an issue to be investigated in future work.

Finally, the results of the present study have implications for current theories of focus. Much prior work on focus has emphasized properties that relate to the presence of some prior structure in discourse, for example the presence of a question, of an element of the same type as the target, or of a clause which exhibits structural parallelism. A quite different line of work was initiated by Pierrehumbert and Hirschberg (1990), who analyze various types of intonational contour in terms of speaker and hearer expectations. Our experiments and analysis imply that clefts have an intrinsically doxastic function. At the very least, this suggests that something like the Pierrehumbert and Hirschberg approach is the right one for analyzing the marking of information structure more generally. Our conclusion is that approaches which limit themselves to the occurrence or non-occurrence of particular words or structures in a text are inherently insufficient to explain the distribution and interpretation of information-structural devices in English, and that a full theory of information structural marking must refer to doxastic notions such as the speaker's expectation as to what the hearer believes.

# An experimental investigation of (non-)exhaustivity in *es*-clefts<sup>1</sup>

Joseph P. DE VEAUGH-GEISS — *Universität Potsdam*

Swantje TÖNNIS — *Universität Graz*

Edgar ONEA — *Universität Graz*

Malte ZIMMERMANN — *Universität Potsdam*

**Abstract.** We present an empirical study on exhaustivity inferences in German *es*-clefts compared to definite descriptions (pseudoclefts with an identity statement), exclusives, and focus constructions. Our study uses a novel mouse-driven picture-verification task in which the incremental updating of the context allows one to determine at which point participants take exhaustivity into consideration. Our results are compatible with a parallel analysis of clefts and definite pseudoclefts (see Percus 1997; Büring and Križ 2013; cf. DeVaugh-Geiss et al. 2015), in so far as both structures are indeed interpreted on a par. In striking contrast to these analyses, however, we found that clefts do not systematically receive exhaustive interpretations, nor do definite pseudoclefts. We conclude that exhaustivity is not conventionally coded in either clefts nor definite pseudoclefts but rather arises through the anaphoric existence presupposition in both constructions together with a number-based implicature.

**Keywords:** *es*-clefts, definite pseudoclefts, exhaustivity, number-based pragmatic implicature, experimental study

## 1. Introduction

It has long been discussed in the literature that focus-background *it*-clefts (in German, *es*-clefts) give rise to both an existence as well as an exhaustivity inference, illustrated in (1). (For existence see Horn 1981; Delin 1992; Dryer 1996; Rooth 1999; Abrusán 2016; and for exhaustivity Halvorsen 1976, 1978; Atlas and Levinson 1981; Percus 1997; É. Kiss 1998; Velleman et al. 2012; Büring and Križ 2013, among others.)

- (1) Es ist MAX, der einen Cocktail gemischt hat.  
it is M. who a cocktail mixed has  
'It is MAX who mixed a cocktail.' (it-cleft)  
Max mixed a cocktail. (canonical meaning)  
→ Someone mixed a cocktail. (existence presupposition)  
→ No one except Max mixed a cocktail. (exhaustivity inference)

While there is general consensus that the existence inference is a presupposition (although see the remarks in Büring and Križ 2013: Sec. 6 for arguments to the contrary), there is a long-standing debate on the semantic-pragmatic source of exhaustivity in clefts. On the one hand,

We would also like to thank (in alphabetical order) David Beaver, Judith Degen, Emilie Destruel, Agata Renans, and Maribel Romero for the insightful and critical comments at various stages in this research, as well as the participants at Sinn und Bedeutung 21 and the XPrag.de annual meeting for their feedback. Anna-Christina Boell, Julia Bauermann, and Mareike Philipp were essential in preparing and running the experiments at the Universität Potsdam and Universität Göttingen. All errors are our own.

there are accounts which take exhaustivity to be conventionally-coded and context-independent, which we will refer to as the semantic accounts. In this camp are: (a) the Definite-Semantic analyses that claim *it*-clefts share the presuppositional semantics of definite descriptions (Percus, 1997; Büring and Križ, 2013); and (b) the Inquiry-Terminating account, which takes clefts to encode the same discourse-semantic operators as exclusives, differing only in what is at-issue and what is not-at-issue (Velleman et al., 2012). On the other hand there are the non-conventionally-coded and context-dependent exhaustivity analyses, which we refer to as the pragmatic accounts, that take the exhaustive inference to be a generalized conversational implicature (Horn, 1981, 2014) or a focus-triggered scalar implicature (DeVeagh-Geiss et al., 2015).<sup>2</sup>

One of the crucial ways in which the two camps differ is in the predictions regarding the robustness and systematicity of the exhaustive inference. With *robustness* we are referring to the strength of exhaustivity in terms of its obligatoriness and cancellability; by contrast, *systematicity* refers to the regularity of the exhaustive inference within and across both experimental settings and participants. In short, a robust inference is context-independent and non-negotiable, and a systematic inference will show up using various experimental methods and not just for a subset of the participants. Semantic analyses predict cleft exhaustivity will be robust and systematic; pragmatic analyses generally make the opposite prediction.

Another crucial way in which the theories differ is in their predictions in terms of *parallelism* with other exhaustivity effects, in particular for our study here, definite pseudoclefts. The definite semantic accounts of Percus 1997 and Büring and Križ 2013 make the clearest of all predictions in this respect, namely that clefts and definite pseudoclefts will pattern alike. The presuppositional account in Velleman et al. 2012, however, does not make any particular predictions regarding parallel behavior of clefts and definites. The pragmatic accounts, by contrast, predict clefts and definite pseudoclefts to elicit different response patterns, but plain focus and clefts may show comparable behavior.<sup>3</sup>

The goal of the two experimental studies presented here is to evaluate cleft exhaustivity along these three parameters, that is, robustness, systematicity, and parallelism. This paper will proceed as follows: In Section 2 we provide the theoretical and empirical background to cleft exhaustivity, and in Section 3 we describe the methods, design, and results of two joint experiments conducted on German *es*-clefts. Anticipating the results a bit, we find that clefts and definite pseudoclefts elicit nearly perfectly-parallel behavior, although neither showed robust nor systematic response patterns, results which no existing theory in the literature predict. In Section 4 we present two proposals which take advantage of the anaphoricity of clefts and definite pseudoclefts in order to account for the (non-)exhaustivity found in both constructions. Section 5 concludes.

<sup>2</sup>See, however, Pollard and Yasavul 2016 for the argument that clefts do not encode exhaustivity *per se*.

<sup>3</sup>However, see DeVeagh-Geiss et al. 2015, in which clefts are predicted to show stronger exhaustivity effects than plain focus—even in subject position—given unambiguous focus-marking in the former but not in the latter. See also Horn 1981 for the claim that cleft exhaustivity is strengthened by the speaker going “out of her way” by using the cleft construction.

## 2. Background

Here we provide an overview of the theoretical and experimental work on cleft exhaustivity in the literature. We first take a closer look at the semantic approaches, which we divide into two groups: (a) the Definite-Semantic approaches, in particular Percus 1997 and Büring and Križ 2013, and (b) the Inquiry-Terminating (IT) approach, namely Velleman et al. 2012. Following this we discuss the pragmatic accounts in Horn 1981, 2014, and DeVeugh-Geiss et al. 2015.

**Theoretical approaches** Starting with the semantic approaches, Percus (1997) proposed that *it*-clefts of the form *It is X who P* and definite descriptions of the form *The one who P is X* are parallel in their underlying syntax, with the former being derived from the latter syntactically through a process of extraposition (see Percus 1997 for details). Accordingly, the semantics for both constructions are claimed to be identical, with exhaustivity in clefts being equal to the uniqueness/maximality presupposition of the definite. Büring and Križ (2013), by contrast, make no claims regarding the syntax of the two constructions; rather, they employ algebraic semantics (Link, 1983) to model the exhaustivity effect for clefts as a homogeneity presupposition, which they argue accounts for the uniformity presupposition of definite descriptions as well. In this account, a cleft as in (1)—and the definite description counterpart—presupposes that Max is not one of a plurality of cocktail-mixers; i.e., either Max was the only cocktail-mixer, or he did not mix a cocktail at all. Since in both of these analyses cleft exhaustivity is conventionally-coded and context-independent, they make a clear and direct prediction that exhaustivity effects will be robust and systematic, with parallel behavior predicted for their definite description counterparts.

For the IT-construction approach, Velleman et al. (2012) make no particular claim about the parallelism between clefts and definites, instead taking clefts to share the same discourse-semantics with exclusives, namely by encoding the operators MIN and MAX. In particular, exhaustivity is encoded with MAX, which necessitates that no answer to the Current Question be above a certain upper bound. Thus, the answer terminates an inquiry by marking it as maximal. In exclusives MAX is at-issue, whereas in clefts it is not-at-issue. Similar to the semantic definite accounts, the IT-construction account would predict robust and systematic exhaustivity effects, given that the MAX operator is coded in the cleft-structure, but says nothing about parallel behavior between clefts and definites. Nevertheless, one problem with this approach—as pointed out by Pollard and Yasavul (2016)—is that clefts do not always provide a maximal answer, as illustrated in the following:

- (2) Q: Who took the last cookie?  
A: It was John or Mary, but I don't remember which.

Turning now to the pragmatic approaches, since exhaustivity in clefts does not appear to be as obligatory as semantic accounts might predict, Horn (1981) argued that exhaustivity in clefts is a (generalized conversational) implicature. This analysis is supported in part by data such as the following, in which—unlike the existence presupposition—the exhaustivity inference does not project out of the embedding environment, illustrated in (3).

- (3) It isn't Max who mixed a cocktail.  
       → Someone mixed a cocktail. (existence)  
       ↗ No one except Max mixed a cocktail. (exhaustivity)

Furthermore, cleft exhaustivity appears to be easily violable, illustrated in (4).

- (4) “Yes, it is bread we fight for—but we fight for roses too!”  
       (in a poem by James Oppenheim in 1911,<sup>4</sup> cited by Horn 2014)

Horn (1981, 2014) proposes that the exhaustivity inference in clefts has parallels to exhaustivity inferences in other focus constructions, which is argued to be strengthened for clefts by the fact that the speaker has chosen the more marked structure over the canonical word order. This additional strengthening is necessary to account for differences in acceptability for cancellation of plain focus and clefts, illustrated in the following contrast.

- (5) a. Max has three children; indeed, he has four.  
       b. #It was a pizza that Mary ate; indeed, it was a pizza and a calzone.  
           (examples (18c)–(18d), pg. 133, Horn, 1981)

Although DeVeauigh-Geiss et al. (2015) similarly argue exhaustivity is focus-derived, they take a different pragmatic approach from Horn 1981. In their analysis, clefts are a structural device for marking focus unambiguously, and exhaustivity is a focus-triggered scalar implicature derived from Grice's Maxim of Quantity: that is, “[t]he focal alternatives build scales, and the quantity maxim conversationally implicates the exclusion of alternatives higher on the scale” (DeVeauigh-Geiss et al., 2015: 387). The weaker exhaustivity for plain focus is argued to be due to focus projection, since projection to a higher constituent makes the focal alternatives ambiguous. By contrast, projection out of the cleft pivot appears not to be possible, and thus *it*-clefts provide optimal environments for further pragmatic enrichment. These pragmatic accounts both predict that exhaustivity in clefts is context-dependent and neither robust nor systematic; furthermore, there are no predicted parallels to definite descriptions. A summary of the semantic and pragmatic approaches to cleft exhaustivity and their predictions is found in Table 1. It is worth noting that there are no accounts which predict exhaustivity to be *–robust/systematic* and *+parallel* to definites.

|                                     | <i>±robust/systematic</i> | <i>±parallel definite descriptions</i> |
|-------------------------------------|---------------------------|----------------------------------------|
| (A) <i>Semantic Definite</i>        | +                         | +                                      |
| (B) <i>Semantic IT-Construction</i> | +                         | +/-                                    |
| (C) <i>Pragmatic Accounts</i>       | –                         | –                                      |
| ?                                   | –                         | +                                      |

Table 1: Predictions of three theoretical approaches to cleft exhaustivity.

<sup>4</sup> [https://web.archive.org/web/20160216133611/https://en.wikipedia.org/wiki/Bread\\_and\\_Roses#Words](https://web.archive.org/web/20160216133611/https://en.wikipedia.org/wiki/Bread_and_Roses#Words)

**Experimental work** While the theoretical literature tends to bias toward semantic accounts of cleft exhaustivity, experimental work rather supports a pragmatic account, since cleft exhaustivity has been shown to be less robust and less systematic than would be predicted for an inference which is conventionally-coded and context-independent. Prior studies have typically taken exhaustivity in exclusives as a baseline comparison for cleft exhaustivity. One such example is Onea and Beaver (2009), who tested exhaustivity effects in Hungarian preverbal focus using the “*Yes, but...*” test, and the subsequent studies on clefts by Destruel et al. (2015). In this paradigm, participants are presented with question-answer pairs in which, given a visual stimulus with or without an exhaustivity violation, they had to choose between three possible continuations corresponding to different exhaustivity strengths: (i) strictly exhaustive (*No. ...*), (ii) slightly exhaustive (*Yes, but...*), and (iii) non-exhaustive (*Yes, and...*). While exclusives elicited a majority of strictly exhaustive responses (i) in contexts depicting an exhaustivity violation, clefts in English and French elicited a majority of slightly exhaustive (ii) and non-exhaustive (iii) responses. Destruel et al. (2015) argue that the *Yes, but...* paradigm is a test of the at-issue status of an inference, and given their results, that exhaustivity in clefts is not-at-issue while in exclusives it is at-issue.

However, not-at-issue inferences can have either a semantic or a pragmatic source (Horn, 2014). One diagnostic for the source of an inference traditionally found in the literature is to test whether or not an inference is defeasible: whereas semantic inferences are truth-conditional and cannot be cancelled in unembedded environments,<sup>5</sup> pragmatic inferences are non-truth-conditional and thus typically more easily cancellable, as illustrated in (5a). The cancellation diagnostic is the basis for the experimental studies in Saur 2013 and DeVeugh-Geiss et al. 2015 on German *es*-clefts. In both studies, the exhaustivity inference from a cleft was followed by a violation (e.g., *Es ist X, der P. Außerdem, Y P.* ‘It was X that P. Furthermore, Y P,’ Saur 2013). In comparison to exclusives, clefts showed weaker exhaustivity effects when the exhaustive inference was violated: that is, participants more readily accepted cleft sentences despite the violation, which was not the case for sentences with *nur* ‘only.’ Based on the relative acceptability found in both studies, exhaustivity is argued not to be conventionally coded in clefts, but rather derived as a pragmatic implicature.

Although most studies on exhaustivity compare clefts directly to exclusives, not all have. One such study is Byram-Washburn et al. 2013, in which the acceptability of clefts was tested using written dialogues across various conditions. They find that conditions with violations of contrastiveness led to much lower acceptability ratings than conditions with violations of exhaustivity (see also Destruel and Velleman 2014 for experimental studies on contrastiveness inferences in clefts). Based on these findings, they conclude that exhaustivity is not conventionally-coded but a conversational implicature (in line with Horn 1981). However, it is not clear that the target stimuli were in fact violating exhaustivity, since there is a possible domain narrowing given the temporal adverb *yesterday* found in the target but not in the context. A direct comparison to exclusives could have, in fact, served as a useful control.

<sup>5</sup>Compare to embedded environments, in which semantic inferences, i.e., assertions and presuppositions, are (potentially) interpreted under the embedding operator, and thus cancellable; for presupposition cancellation, see, e.g., Karttunen 1971; Stalnaker 1974; Chierchia and McConnell-Ginet 1996; Abbott 2006; Abrusán 2016, among others.

To sum up, the experimental literature has found that the at-issue status of cleft exhaustivity is different from that of exclusives, with exhaustivity in clefts being not-at-issue and that of exclusives at-issue (in line with previous claims in the theoretical literature, e.g., Horn 1981). Moreover, the results from a growing number of studies are more compatible with a pragmatic approach than a hardwired semantic approach to cleft exhaustivity, given that exhaustivity violations are generally found to be more acceptable for clefts than might be expected for a context-independent and truth-conditional inference. Cancellation of exhaustivity is nonetheless not as acceptable as might be expected for a pragmatic analysis (DeVeagh-Geiss et al., 2015), and no study to date—as far as the authors are aware of—have directly compared cleft exhaustivity to the maximality inference of definite descriptions, a notable gap between the theoretical and experimental literature.

### 3. Methods & results

We conducted two joint-studies on German *es*-clefts in order to test the robustness, systematicity, and parallelism of cleft exhaustivity when compared to exclusives, focus, and definite pseudoclefts using a mouse-guided incremental information paradigm written in Python (GNU/Linux v.3.4.2; Windows v.3.3.5) with the PyGame module (v.1.9.2a0, LGPL, Shinnars 2011). Participants were presented with contextual information one box at a time in order to measure which truth-value judgment was made ('true' or 'false') as well as at which point there was enough information for participants to make their judgment. The design of both experiments was the same and will be presented together here.

At the beginning of the experiment participants were introduced to four roommates, Jens, Max, Tom, and Ben, who they were told undertook various activities together. Participants were informed that only these four roommates would appear throughout the entire experiment. After a brief introduction to the experiment including three practice trials, the experiment started. At the beginning of each trial, participants heard the audio stimuli in their headphones, after which they uncovered up to four boxes revealing the various activities of the four roommates. Their task was to uncover only as many boxes as necessary to make a judgment whether the sentence they heard was true or false. An example of the four target auditory stimuli is presented in (6)–(9). Pitch accent was always on the subject, illustrated by capital letters in the example stimulus.

- (6) EXCLUSIVE  
 Nur MAX hat einen Cocktail gemischt.  
 only M. has a cocktail mixed.  
 'Only Max mixed a cocktail.'

- (7) PLAIN FOCUS  
 MAX hat einen Cocktail gemischt.  
 M. has a cocktail mixed  
 'Max mixed a cocktail.'

## (8) DEFINITE PSEUDOCLEFT

Derjenige, der einen Cocktail gemischt hat, ist MAX.  
 the.one who a cocktail mixed has is M.  
 ‘The one who mixed a cocktail is Max.’

## (9) CLEFT

Es ist MAX, der einen Cocktail gemischt hat.  
 it is M. who a cocktail mixed has  
 ‘It is Max that mixed a cocktail.’

Note that in the definite pseudocleft sentences, the complex definite forms *derjenige*, *diejenige*, and *dasjenige* are compounds of the singular determiner elements *der*- ‘the.MASC,’ *die*- ‘the.FEM,’ or *das*- ‘the.NEUT’ plus *-jenige*, the latter derived etymologically from the demonstrative marker *jene/jener/jenes* meaning ‘that one (over there).’ We will argue that this inherent deictic or context-anaphoric meaning component will prove to be crucial for the interpretation of definite pseudoclefts in our experiments. For all stimuli in the definite pseudocleft condition, the complex-definite subject was singular and masculine, and it displayed singular nominative marking and gender agreement with the masculine proper name in predicative position.

The boxes were manipulated to present information in such a way as to be informative about the source and status of the exhaustivity inference. That is, whereas Box 1 was always irrelevant to the purposes of the experiments, the two experiments differed in a critical way at Box 2.

- Experiment I tested the at-issue status of exhaustivity by verifying in Box 2 the canonical meaning or prejacent of the target sentences. For example, for sentences (6)–(9) Max says: ‘*I mixed a cocktail.*’ If exhaustivity is at-issue, we predict that after revealing the second box participants must continue uncovering Box 3 and Box 4 in order to check that exhaustivity holds.
- Experiment II tested the semantic-pragmatic source by falsifying exhaustivity in Box 2. For example, for sentences (6)–(9) someone other than Max, e.g., Ben, says: ‘*I mixed a cocktail.*’ We predict that if exhaustivity is semantic (asserted or presupposed), falsifying exhaustivity should be enough to judge the target sentence as false; by contrast, if it is pragmatic the exhaustivity implicature is defeasible and thus participants can continue to uncover Box 3 and Box 4 in order to check the as-yet-unverified prejacent.

Although participants were free to choose which box to uncover next, we programmed the experiment such that the order was pre-determined. Moreover, once inside a box the cursor could not exit the box for at least 2000ms. This was done to keep participants from unnecessarily uncovering too many boxes, such as, e.g., by automatically mousing over all four boxes and then making a judgment. Further details of the individual experiments will be presented below.

Our experiments exhibit the following important design features that will allow for a controlled and systematic study of exhaustivity inferences in clefts and definite pseudoclefts.

1. The experiments explicitly control for at-issue semantic exhaustivity triggered by exclusive particles, on the one hand, and for bona fide pragmatic exhaustivity, as triggered by instances of in situ prosodic focus in auditory stimuli.
2. The experiments explicitly control for domain restriction in order to rule out any attempts at explaining exhaustivity violations away in terms of a subsequent enlargement of the quantificational domain.
3. The experiments involve no scalar ordering of alternatives in order to rule out attempts at explaining exhaustivity effects away by recourse to ordering on a contextually-supplied scale.

In both experiments there were two dependent variables: *Early Judgment* and *Late Judgment*. The first dependent variable was measured at Box 2 and had three values: *richtig* ‘correct,’ *falsch* ‘false,’ or ‘continue’ by uncovering Box 3. The second dependent variable was the final evaluation of the stimuli once all relevant information at the third or fourth box had been revealed. Clearly there was data for the *Late Judgment* only when participants chose to continue in the *Early Judgment* measure.

There was a 1:1 target-to-filler ratio. Filler items consisted of sentences with universal quantifiers (*jeder* ‘everyone’), expletive constructions (*es ist klar, dass ...* ‘it is clear that ...’), plural conjunctions (e.g., *Ben und Max haben ...* ‘Ben and Max have ...’), and scalar constructions (*weniger als drei Leute* ‘fewer than three people’). There were 32 target items and 32 filler items for a total of 64 sentences.

For Experiment I, we tested 32 German native speakers (24 female, 8 male), all students in Potsdam and Berlin, Germany (average age: 25.6).<sup>6</sup> For Experiment II we tested 32 German native speakers (20 female, 12 male), most of them students in Göttingen, Germany (average age: 27.8). The experiments took part in a laboratory environment, and participants were compensated for their time. We now turn to the individual experiments and their results.

**Factorial design of Experiment I** Experiment I involved a 4\*2 factorial design, the two factors being *Sentence Type* (EXCLUSIVE, FOCUS, DEFINITE PSEUDOCLEFT, CLEFT) and *Exhaustivity* (±EXHAUSTIVE). Recall that the early judgment was at Box 2, which verified the canonical meaning or prejacent, whereas the factor *Exhaustivity* was measured as a late judgment in Box 3 and Box 4. For the condition +EXHAUSTIVE, exhaustivity holds. For instance, given a target sentence as in (6)–(9), in Box 2 Max says he mixed a cocktail, and in the other boxes none of the remaining roommates had the property of mixing a cocktail, as illustrated below. For the condition –EXHAUSTIVE, by contrast, one of the roommates in Box 3 or Box 4 also has the relevant property. For example, in Box 3 Jens says ‘I mixed a cocktail,’ which, for the sake of space, is not illustrated here.

BOX 1: Tom    ‘*I fetched a straw.*’  
BOX 2: Max    ‘*I mixed a cocktail.*’

BOX 3: Jens    ‘*I opened a bottle.*’  
BOX 4: Ben    ‘*I provided a schnaps.*’

<sup>6</sup>There were 33 participants in Experiment I, but one participant was removed since judgments were erratic on the controls.

Figure 1: Proportion of early judgments (judgment = 1, continue = 0) for Experiment I (left) and Experiment II (right).

**Experiment I results** For data preparation of the target items, 1 response out of the 1024 potential responses at Box 1 was treated as an error and removed. All data at Box 2 were coded with 1 for judgment made and 0 for continue. Note that in Experiment I when a participant made a judgment at Box 2, the sentence was always judged ‘correct’; that is, no participant selected ‘false’ at this point. Exclusives elicited a judgment at Box 2 only 1% of the time (2/256 responses): most participants chose to continue uncovering Boxes 3 and 4, as expected. By contrast, clefts and definite descriptions elicited a ‘correct’ judgment 43% (110/255 responses and 41% of the time (105/256 responses), respectively, and focus 74% of the time (189/256 responses). See the left graph in Figure 1 for the proportion of judgments made per sentence type in Experiment I. Note that when participants continued and exhaustivity was violated in Box 3 or Box 4, the sentence was consistently judged ‘false,’ suggesting that the experiment was indeed sensitive to exhaustivity.

We conducted a generalized linear mixed effects model (binomial family) in R with the dependent variable being the early response at Box 2 and the independent variable the sentence type (i.e.,  $glmer(Judgment.Box2 \sim SentType + (1|Item) + (1|Participant), family = binomial, data = ExpI)$ ).<sup>7</sup> Contrast coding was non-orthogonal: clefts were the baseline comparison for each of the other sentence types. There was no significant difference found between clefts and definite descriptions (SE = 0.286,  $p = 0.392$ ); by contrast, there was a highly significant difference found between clefts and exclusives, and clefts and focus ( $p < 0.001$  in all cases).

**Factorial design of Experiment II** Experiment II again had a 4\*2 factorial design, as in Experiment I, the two factors being *Sentence Type* (EXCLUSIVE, FOCUS, DEFINITE PSEUDO-CLEFT, CLEFT) and *Canonical* ( $\pm$ CANONICAL). Recall that the early response was at Box 2, which falsified the exhaustive inference. The factor *Canonical* was measured as a late response in Box 3 and Box 4. The condition +CANONICAL means the canonical meaning or prejacent holds. For instance, for the sentences in (6)–(9) Max says in Box 3 that he in fact mixed a

<sup>7</sup>We ignore the late response in our computation, because in this early stage of evaluation it plays no role.

cocktail, as illustrated below. For the condition –CANONICAL, by contrast, Max in Box 3 or Box 4 says he did something other than mix a cocktail. For example, in Box 3 Max says ‘I provided a schnaps,’ which, for the sake of space, is not illustrated here.

BOX 1: Jens ‘*I opened a bottle.*’  
BOX 2: **Ben** ‘*I mixed a cocktail.*’

BOX 3: Max ‘*I mixed a cocktail.*’  
BOX 4: Tom ‘*I fetched a straw.*’

**Experiment II results** For data preparation of the target items, there were 3/1024 ‘correct’ judgments for the falsifier at Box 2, which were treated as errors. The remaining data at Box 2 were coded with 1 for judgment made and 0 for continue. As predicted, exclusives elicited ‘false’ judgments 92% of the time (236/256 responses): most participants chose not to continue uncovering contextual information, even though the prejacent had not yet been verified. By contrast, focus elicited judgments only 15% of the time (38/256 responses): that is, most participants continued to uncover the remaining boxes to see if the canonical meaning held. Definite descriptions elicited ‘false’ judgments 50% of the time (128/255 responses), and clefts were similar in eliciting judgments 47% of the time (120/254 responses). Note that for participants who continued uncovering and found that the prejacent did not hold, they consistently judged the sentence as ‘false’; furthermore, when they found that the prejacent was verified, they consistently judged the sentence as ‘true.’ See the right graph in Figure 1 (on page 355) for the proportion of judgments made per sentence type for Experiment II.

Again, we conducted a generalized linear mixed effects model in R with the dependent variable being the early response at Box 2 and the independent variable the sentence type (i.e., *glmer(Judgment.Box2 ~ SentType + (1|Item) + (1|Participant), family = binomial, data = ExpII)*). Contrast coding was non-orthogonal: clefts were the baseline comparison for each of the other sentence types. Again, there was no significant difference found between clefts and definite descriptions (SE = 0.2223,  $p = 0.403$ ). By contrast, there was a highly significant difference found between clefts and exclusives, and clefts and focus ( $p < 0.001$  in all cases).

**Post hoc analysis** In both experiments we measured whether and at which point participants made a truth-value judgment given the incremental evidence provided. Crucially, we were interested in participant response behavior at Box 2, which differed between the two experiments: in Experiment I the exhaustive inference was verified at Box 2, whereas in Experiment II the exhaustive inference was falsified at Box 2. The questions associated with the early evaluation variable are as follows. In Experiment I we established whether verifying at Box 2 that the canonical meaning holds was sufficient to make a judgment, or whether the exhaustivity inference was taken into consideration by further uncovering Boxes 3 and 4. That is, if a participant judged the sentence they heard as ‘true’ upon revealing the information at Box 2, exhaustivity did not matter (enough) to justify further investigation. By contrast, if a participant continued this means that exhaustivity was significant enough to warrant checking the upcoming information. In this case we predict participants will judge the sentence as ‘true’ in the +EXHAUSTIVE late response condition and ‘false’ in the –EXHAUSTIVE late response condition. This is precisely what we found, confirming that participants understood the logic of the experiment.

Figure 2: Proportion of early judgments (judgment = 1, continue = 0) for Experiment I for non-exhaustive group (left) and exhaustive group (right).

When analyzing participant behavior individually we found two main groups for definite pseudoclefts and clefts: either participants treated definite pseudoclefts and clefts as exhaustively as exclusives (Exp. I: 20 participants; Exp. II: 16 participants) or as non-exhaustively as focus (Exp. I: 12 participants; Exp. II: 16 participants). These categories were calculated like so: In Experiment I, if they chose ‘continue’ for definite pseudoclefts 5/8 or more times they fell into the exhaustive interpretation group, since exhaustivity was significant enough to warrant further uncovering a majority of the time; otherwise, they were in the non-exhaustive interpretation group (i.e., 4/8 or less times they chose ‘correct’ when the canonical meaning of the sentence was verified without checking the remaining boxes). In Experiment II, if they made a ‘false’ judgment for definite pseudoclefts 5/8 or more times they again fell into the exhaustive interpretation group, since falsifying exhaustivity at Box 2 was enough to judge the auditory stimuli as false; otherwise, they were in the non-exhaustive interpretation group (i.e., 4/8 or less times they chose ‘continue’ to check that the canonical meaning holds despite exhaustivity having been falsified).

Again, the post hoc analysis, illustrated in Figure 2 for Experiment I (on this page) and Figure 3 for Experiment II (on page 358), shows quite clearly that definite pseudoclefts were indeed interpreted in full parallel to clefts in both the participant groups as well as in the experiments, albeit in two different ways, either entirely exhaustively or entirely non-exhaustively. It is therefore reasonable to assume that the source of the exhaustivity inference is identical, or at least very similar, in both clefts and definite pseudoclefts.

#### 4. Analysis

The experimental data are not in line with any of the major theories of cleft exhaustivity. As pointed out in connection with Table 1 on page 350, neither semantic nor pragmatic analyses would predict exhaustivity in clefts to be non-robust/unsystematic and parallel to definite pseudoclefts at the same time. The post-hoc analysis in particular indicated that our results are incompatible with semantic analyses of cleft exhaustivity (the effect being non-robust and unsystematic across speakers and experiments). Finally, it seems unlikely that the existence of

Figure 3: Proportion of early judgments (judgment = 1, continue = 0) for Experiment II for non-exhaustive group (left) and exhaustive group (right).

(unambiguously) marked focal alternatives is responsible for triggering the pragmatic exhaustivity implicature, given that there is weak exhaustivity in the plain focus conditions. In light of all this, we propose an alternative pragmatic analysis of the exhaustivity effect in clefts and definite pseudoclefts. In particular, we argue that our participants systematically differed in their assumptions regarding the potential linguistic contexts required for licensing the critical audio stimulus, in particular its existence presupposition.

**Anaphoric presupposition of clefts** It is standardly assumed in the literature that clefts have anaphoric potential (Prince 1978; Horn 1981; Soames 1989; Delin 1992; Hedberg 2000; and many others). They introduce as part of their constructional meaning a presupposition that marks the information conveyed by the cleft as known-fact (Prince, 1978) or, simply, as anaphoric (Delin, 1992). The anaphoric potential of clefts can be formally expressed in the form of an existence presupposition, following van der Sandt 1989 and Rooth 1996.

Turning next to the experimental setting of our experiments, there is no linguistic context against which to evaluate the audio stimulus. As a result, the existential presupposition of the cleft condition must be accommodated. This amounts to saying that the hearer will integrate into her discourse model some discourse referent with the relevant property described by the cleft relative that she takes the experimental speaker to (anaphorically) refer to. Crucially, we do not adopt claims in Szabolcsi 1994 (on pre-verbal focus in Hungarian) and Percus 1997 (on English *it*-clefts) that the existential presupposition of cleft sentences comes with an obligatory maximality effect. Instead we propose that part of what the experiment participants did was to reason about the anaphoric antecedent of the existential presupposition. On this proposal, the exhaustive group would take the presupposed discourse referent *x* to refer to an accommodated maximal discourse referent with property *P* denoted by the cleft relative.

One way of constructing a suitable discourse referent *x* would consist in assuming the denotation of an implicit question, as provided in Pollard and Yasavul 2016. That is, participants could have assumed that the cleft addresses the issue “who *P*?,” thus resolving the existence

presupposition to a maximal discourse referent  $x$  with property  $P$ . Linking this with an identificational at-issue semantics for clefts, namely  $x = \text{Pivot}$ , the result will be that the maximal individual  $x$  with property  $P$  equals the pivot, which comes down to an exhaustivity claim. By contrast, the non-exhaustive group would accommodate a non-maximal discourse referent, as suggested by Pollard and Yasavul 2016 for indefinite antecedents. For this group the interpretation is then simply that there is some  $x$  with property  $P$ , and  $x = \text{Pivot}$ , which does not trigger an exhaustivity inference.

The foregoing assumptions would, in principle, suffice in order to explain our experimental findings in terms of differences in the way in which the experimental subjects accommodated the anaphoric existence presupposition of clefts. On this analysis, the exhaustivity inference is a pragmatic effect that can be reliably predicted in a number of explicit contexts, but which leads to ambiguity in the absence of overt linguistic context. Still, an analysis along these lines is not without problems. A potential issue is that the proposed analysis relies explicitly on an identificational, as opposed to, e.g., a predicational, semantic analysis of clefts, working in tandem with the presupposed anaphoric content.

Nevertheless, we do not want to dismiss the above sketch of an analysis altogether. At present, though, our experimental data do not provide sufficient and conclusive evidence in favor of this particular spell-out. Fortunately, there is no need for basing the pragmatic analysis of cleft exhaustivity on the semantic assumption that clefts are identificational. In particular, there is an additional implicature giving rise to exhaustivity even on a predicational semantics for clefts. This second implicature interacts with the existence presupposition and is triggered by the choice between singular and plural clefts. The fact that German clefts show consistent and transparent semantic marking of number is assumed to make the effect even stronger.

**Number implicature of German clefts** As discussed in Büring and Križ 2013, there are plural and singular clefts, as shown in (10).

- (10) a. Es waren Georg und Friedrich, die Wilhelm verprügelt haben.  
           it COP.PL Georg and Friedrich REL.MASC.PL Wilhelm beaten have  
           ‘It was George and Frederick that beat William.’  
       b. Es war Georg, der Wilhelm und Friedrich verprügelt hat.  
           it COP.SG Georg REL.MASC.SG Wilhelm and Friedrich beaten has  
           ‘It was George that beat William and Frederick.’

It is reasonable to assume that the presupposed discourse referent inherits the singular or plural feature from the cleft sentence. Put differently, plural clefts presuppose the existence of a non-atomic sum-individual, while singular clefts at least give rise to the implicature that the anaphoric antecedent is not a sum individual, but rather an atomic individual.

Especially in situations with zero context, as found in our experiments, we expect this implicature to give rise to an exhaustivity inference along the following lines of reasoning: By using the singular cleft, the experimental speaker implicates that there is no sum-individual antecedent with the cleft relative property  $P$ . If there actually were sum-individuals with the cleft

relative property *P*, and the speaker were aware of that fact, the listener would be in no position to identify the singular discourse referent the speaker meant to refer to, given the absence of further linguistic context. This in turn would make it impossible to assign the cleft sentence a proper interpretation, as it remains unclear which individual the cleft sentence is about. Hence, being cooperative, the speaker must have meant to convey that there are no potential plural antecedents at all. Hence, we are safe to assume that there is exactly one individual with property *P* in the context, which is then identified by the pivot. The core ingredients of the number-based analysis are summed up in (11):

- (11) Components of number-based pragmatic analysis of cleft exhaustivity:
- a. Asserted content:  $P(\text{focus})$  or  $\text{focus} = x$
  - b. Existence presupposition:  $\exists x[P(x)], \text{atomic}(x)$
  - c. Singular-based implicature:  $\neg \exists Y[\text{sum}(Y) \wedge P(Y)]$

Note that participants have the option to reason that the speaker is not committed to exhaustivity to a degree that is sufficient to judge the cleft sentence as true or false based on the truth or falsity of this implicature. This can happen, for instance, if a speaker has no relevant knowledge concerning the other individuals under consideration, thereby restricting the scope of the existence presupposition to the singular individual she is certain about. This explains the behavior of the non-exhaustive group.

We would like to stress that the analysis sketched in the previous subsection and the number-based analysis presented here are by no means mutually exclusive. It may very well be possible that both interpretive processes are simultaneously active: The number-contrast would create an exhaustivity implicature based on the anaphoric existential presupposition plus some reasoning over the speaker's intention in choosing a singular over a plural cleft. And, additionally, it would also be possible to maximize the anaphoric antecedent.

**Definite pseudoclefts** What remains to be done is to show how the pragmatic analysis developed for clefts can be extended in order to capture the parallel interpretive properties of definite pseudoclefts in our experiments. Following a long list of scholars ranging from Frege (1892) to Coppock and Beaver (2015), definite descriptions in general are commonly treated as triggering a uniqueness presupposition. However, at least for the particular definite expressions found in definite pseudoclefts in German, we argue that deriving exhaustivity in an anaphoric familiarity-based analysis à la Heim 1982 better captures the results reported here.

We argue that definite pseudoclefts in German cannot be analyzed as run of the mill definite descriptions, given our experimental findings. Instead, we would like to propose that definite pseudoclefts express anaphoric reference as part of their conventional meaning, as evidenced by their discourse-semantic behavior and by their morpholexical make-up. First, note that the form *-jenige* shows the weak inflectional properties of prenominal modifying elements in definite contexts, but, more importantly, as a deictic expression it must anaphorically relate to a salient discourse referent in the preceding context (or at least to a perceptually salient individual in the utterance situation). We therefore propose that the strong bias for interpreting definite

pseudoclefts as anaphoric expressions, rather than as referentially unique expressions, follows from the explicit presence of the demonstrative (anaphoric) element as part of the complex definite determiner.

Second, observe that definite pseudoclefts are deviant as discourse openers, especially in comparison to their plain definite description counterparts, even if the two types of definite expressions have the same descriptive content. The relevant contrast is illustrated in (12). Example (12b) allows for easy accommodation of the fact that the lord, whoever that may be, has been murdered by someone, thereby triggering the interpretation that the gardener was the murderer. Example (12a), in contrast, resists such an interpretation. The most natural interpretation for (12a) is that it presupposes that the murder of the lord has already been the topic of discussion in the preceding discourse, either explicitly or implicitly. This being a condition on discourse structure, and not on the external world as such, it is very hard to accommodate, especially at the beginning of a story.

(12) Out Of The Blue

- a. #Derjenige, der den Lord umgebracht hat, war der Gärtner.  
the.one who the lord murdered has was the gardener  
'The one who murdered the lord was the gardener.'
- b. Der Mörder des Lords war der Gärtner.  
'The murderer of the lord was the gardener.'

Having established that definite pseudoclefts express an anaphoric relationship in the form of an existence presupposition rather than uniqueness in the utterance situation, we can apply the same reasoning as for the cleft-case, which gives us precisely the same predictions: With uniqueness no longer part of the semantic meaning of the definite pseudocleft expressions, we do not expect systematic or robust uniqueness or exhaustivity effects to show up with this construction. Furthermore, the singular-plural contrast is also observed with definite pseudoclefts, although oddly only in the masculine and feminine paradigm. The masculine and feminine forms *derjenige* and *diejenige* are morphosyntactically and semantically marked for singular, as opposed to their plural counterpart *die-jenigen* 'the.PL-ones.' This accounts for the parallel behavior of clefts and definite pseudoclefts in our experiments. Since we only referred to masculine referents in the experiments, the use of the singular form of the definite pseudocleft should give rise to the same number-based pragmatic reasoning procedure as laid out for the case of clefts above.

By contrast, the neuter form *dasjenige* resembles the neuter determiner/relative form *das* 'the/which' and the neuter *wh*-expression *was* 'what' in being semantically number-neutral (Zimmermann, 2011; Bayer, 2002). As a result, the neuter forms can refer to singular and plural forms alike, as illustrated in (13a), unlike their masculine and feminine counterparts, as in (13b):

- (13) a. Dasjenige, was Peter gekauft hat, ist Brot und Rosen.  
DEF.NEUT WH.NEUT Peter bought has COP.SG [bread and roses]<sub>PL</sub>  
'What Peter bought is bread and roses.'

- b. \*Derjenige, den Peter eingeladen hat, ist Klaus und Peter.  
 DEF.MASC.SG REL.MASC.SG Peter invited has COP.SG [Klaus and Peter]<sub>PL</sub>  
 (lit.) ‘The one that Peter invited is Klaus and Peter.’

The difference between masculine/feminine and neuter forms in terms of semantic number marking gives rise to another interesting prediction to be checked in future research: If the number-based pragmatic analysis of pseudoclefts is on the right track, we predict neuter definite pseudoclefts in German to be less exhaustive than their masculine or feminine counterparts. Given that the neuter singular form can refer to both singularities and sum individuals, there is no comparable contrast in the semantic number paradigm, and singular-based implicatures should be much weaker, or altogether absent.

## 5. Conclusion

We reported the results of two offline experiments on cleft exhaustivity in the incremental information-retrieval paradigm. It was shown that clefts and definite pseudoclefts are treated on a par by the participants of a verification and a falsification experiment, in contrast to sentences with plain intonation foci and to sentences with exclusive particles. In particular, the exhaustivity inference in clefts and definite pseudoclefts is more pronounced than with plain focus, while being less systematic and less robust than with exclusive particles. We have argued that the non-systematic and non-robust nature of the exhaustivity effect is not accounted for by existing theoretical accounts, be they semantic or pragmatic. Moreover, a post hoc analysis further unveiled that about half of the participants treated both clefts and pseudoclefts systematically as exhaustive, while the other half treated both as non-exhaustive. Again, this finding poses a challenge to semantic theories of cleft exhaustivity.

In response to the novel data, we argue that there must be some pragmatic component in the derivation of cleft exhaustivity. We then sketched a pragmatic analysis of cleft exhaustivity in clefts and definite pseudoclefts, which is based on two central assumptions: Both sentence types are anaphoric and introduce an existence presupposition. The choice of singular or plural in clefts and definite pseudoclefts triggers a pragmatic implicature, which is further supported by a systematic contrast in the marking of semantic singular and plural in German. The proposed analysis makes a number of interesting predictions to be investigated in future research, such as crosslinguistic differences or the special case of neuter definite pseudoclefts in German. At the same time, in its present form the proposed analysis is only a sketch, and more theoretical, experimental, and crosslinguistic work needs to be done before a fully detailed compositional analysis of exhaustivity in clefts and definite pseudoclefts is in reach.

# Cognitive vs. emotive factives: An experimental differentiation<sup>1</sup>

Kajsa DJÄRV — *University of Pennsylvania*

Jérémy ZEHR — *University of Pennsylvania*

Florian SCHWARZ — *University of Pennsylvania*

**Abstract.** A central question in current presupposition theory is what (sub-)classes of triggers there are and how they differ from one another (Abusch 2002; Sudo 2012; Tonhauser et al. 2013; Romoli 2012; Abrusán 2016). Factives have traditionally been thought to presuppose the truth of their complements, but the potential need for further differentiation was present from the start, beginning with the distinction between semi-factives (e.g. *discover*) and ‘full’ factives (e.g. *regret*) by Karttunen (1971). However, the precise nature of the differences involved has remained elusive in theoretical terms, and key empirical properties have been difficult to pin down experimentally (e.g. Jayez et al. 2015). We present new experimental evidence confirming specific differences between emotive factives (*be happy*, *appreciate*) and cognitive factives (*be aware*, *realize*) using a yes/no-continuation acceptability rating task (Cummins et al., 2013). We spell out an analysis of the demonstrated contrast in terms of a distinction between triggers based on whether or not their presupposed content is encoded as part of the conventionally entailed content (Sudo, 2012; Klinedinst, 2010), and also discuss the broader theoretical implications of our experimental results.

**Keywords:** semantics, experimental pragmatics, presupposition, factivity, entailment.

## 1. Introduction

### 1.1. Theoretical background

A central question in current presupposition theory concerns whether and how expressions that trigger presuppositions can be classified in different categories according to their semantic and pragmatic properties (cf. Abusch 2002; Simons 2007; Simons et al. 2010; Sudo 2012; Tonhauser et al. 2013; Romoli 2012; Abrusán 2016). We investigate this question with regards to *factive* presupposition triggers, i.e. expressions that presuppose the truth of their complement clause. (1)-(2) illustrate that the truth of the embedded clause – that the proposal offended them – remains part of what is conveyed even under negation.

- (1) a. I had discovered that the proposal offended them.  
b. I had not discovered that the proposal offended them.
- (2) a. I regretted that the proposal offended them.  
b. I did not regret that the proposal offended them.

We present new experimental data pertaining to the difference between two types of factives: cognitive factives like *discover* and *find out* on the one hand, which convey a relation between a

---

<sup>1</sup>We would like to thank the audiences at SuB21, as well as various Schwarz Lab meetings for useful comments and discussion. Work on this project has been supported by NSF-grant BCS-1349009 to Florian Schwarz.

proposition and states or events relating to the subject's doxastic state, and emotive factives like *regret* and *be happy* on the other hand, which communicate a relation between a proposition and the subject's emotive affect towards it.

### 1.1.1. Empirical contrasts between cognitive and emotive factives

It was already noted by Karttunen (1971) that what he called “semi-factives” (such as *discover* and *find out*) can easily lose their presuppositional status. For example, they do not necessarily project from the antecedents of conditionals, in contrast to other factives such as *regret*, as illustrated in (3).

- (3) a. If I discover later that the proposal offended them, I will apologize.  
*does NOT presuppose* the proposal offended them.  
 b. If I regret later that the proposal offended them, I will apologize.  
*presupposes* the proposal offended them.

(3a) conveys no commitment on part of the speaker to the proposition ‘the proposal offended them’, despite the fact that *discover* typically conveys the truth of its complement at a global level. Furthermore, cognitive factives can be used ‘parenthetically’ (e.g. Hooper and Thompson 1973; Simons 2007) by having the embedded clause answer a question, as shown in (4) from Simons (2007: p. 1035), whereas emotive factives typically cannot be used this way (5).

- (4) A: Where was Harriet yesterday?  
B: Henry discovered that **she had a job interview at Princeton.**
- (5) A: Where was Harriet yesterday?  
B: ?? Henry is happy that **she had a job interview at Princeton.**

In (4), B introduces *she had a job interview at Princeton* as the embedded clause of the cognitive factive *discovered* and uses it to introduce new, non-presupposed information to answer the question, which can certainly not be taken for granted. By contrast, in (5) it is introduced as the embedded clause of the emotive factive *is happy*, and here it seems to retain its presuppositional status: B's response is intuitively inappropriate, presumably because information that has the status of a presupposition is not suitable for addressing A's inquiry for new information about Harriet.

### 1.1.2. Theoretical approaches to the contrast

While the contrasts illustrated above go back to the beginnings of the linguistic literature on presuppositions, extensive discussion of explicit theoretical proposals for differentiating types of triggers only began in the early 2000's. One prominent proposal by Dorit Abusch (2002; 2010) distinguishes between 'soft' and 'hard' triggers, and assigns cognitives to the former category and emotives like *regret* to the latter.<sup>2</sup> The contrast above can then be seen as an

<sup>2</sup>Abusch never employs the terms *cognitive* and *emotive*, but mentions Karttunen's discussion of *discover* as a case of soft trigger.

instance of a more general pattern, as the presuppositions of soft, but not hard triggers, are thought to be easily suspendable. For example, it is seen as parallel to the contrast between the soft trigger *win* and the hard trigger *too* illustrated in (6), from Jayez et al. (2015: p. 174; but note that these authors propose their own terminology and distinction in terms of ‘strong’ vs. ‘weak’ triggers).

- (6) a. I don’t know whether Paul participated in the race, but if he **won**, he must be very proud.  
 b. ?? I don’t know whether Paul participated in the race, but if Mary participated **too**, they probably had a drink together just after.

The context in both cases establishes that the speaker is agnostic about Paul’s participation in the race. In (6a), this does not seem to create a critical conflict with the notion of participation conveyed by *win*, which typically projects (from antecedents of conditionals and other standard projection environments) and is thus taken to be a presupposition. In contrast, in (6b), the agnostic preface seems to clash with the projecting presupposition that someone else (salient in the context, with Paul as the only feasible candidate) participated in the race.

Generally speaking, Abusch’s analysis follows influential work by Stalnaker (1974) in assuming that (at least) certain presuppositions can be derived pragmatically, i.e., as a general conversational inference that is not conventionally encoded at the level of lexical meaning. In particular, Abusch puts forth an account based on lexical alternatives. Under this view, soft triggers are associated with a set of lexical alternatives (e.g. *win* is associated with the alternative *lose*). In addition, a context-sensitive pragmatic principle imposes that one member from the set of sentences where the alternatives are substituted in fact holds. In the case of soft triggers, the idea is that all the alternatives share an entailment (e.g., *win* and *lose* both entail participation), which results in the entailment being true regardless of which alternative turns out to be true. The suspendability of the presuppositions of soft triggers is then explained by the context-sensitivity of this pragmatic principle: given that the content that traditionally is seen as presupposed starts off as a simple conventional entailment of the trigger, the effect of the pragmatic principle can effectively lose its force, e.g., when this entailment is locally relevant. This is what happens in (6a) where Abusch’s analysis represents the meaning of the conditional as *if Paul both participated and won*, and the effect of considering alternatives in the provided context does not give rise to a global notion that Paul participated.

In addition to Abusch, there are several other proposals taking a conversational approach to deriving presuppositions which differ in the details. For example, Romoli (2012) proposes an alternative-based pragmatic account of presuppositions, where soft presupposition triggers are assimilated to indirect scalar implicatures. A different type of pragmatic account has grown out of work by Mandy Simons and colleagues (Simons, 2007; Simons et al., 2010; Tonhauser et al., 2013). For these authors, the presuppositional status of a trigger depends crucially on the Question Under Discussion (QUD). I.e., whether or not part of the content introduced by an expression is treated as presupposed or backgrounded is determined relative to the conversational goals and issues at stake. Like Abusch and Romoli, they assume that factives entail the truth of their complement clause. For example, if the QUD is ‘What happened?’, then the content of

the matrix clause (*Henry discovered that p*) constitutes the ‘at-issue’ part of the utterance, and *Harriet had a job interview at Princeton* is backgrounded and treated as part of the common ground, i.e., presupposed. If the QUD is ‘Where was Harriet yesterday?’, as in (4) and (5), then the content of the embedded clause *Harriet had a job interview at Princeton* is treated as new, at-issue information, which updates the common ground, i.e., it is not presupposed. The contrast between the cognitive and the emotive factives with respect to their ability to suspend their presupposition on this account then, would presumably need to be linked to a difference in their abilities to function parenthetically (see (4) and (5)).<sup>3</sup>

Taking a more general perspective, what’s crucial for current purposes is that all of these pragmatic approaches involve the assumption that presupposition triggers lexically entail the content that eventually gets projected as a presupposition (that the embedded clause is true), for both cognitive and emotive factives. In contrast, we argue that the experimental data presented below suggests that this only holds for cognitive factives, and that the presupposition of emotive factives is not part of what is conventionally entailed. Such a distinction between triggers has been advanced by previous authors for other triggers, in particular Sudo (2012); Dahlman (2016).

## 1.2. Experimental background

While experimental work on presuppositions has only recently become a research area with significant growth, the aim of substantiating differences between different types of triggers has been a key driving force in it. For reasons of space, we will not attempt anything close to comprehensive coverage of this literature, but merely highlight a couple of especially relevant examples of prior research (for a recent review of experimental work on presuppositions more generally, see Schwarz 2016).

One of the early studies finding differences between triggers is Tiemann et al. (2011), who detect variation in acceptability judgments in contexts that do not explicitly support the trigger’s presupposition, but are consistent with it. Similarly, Domaneschi et al. (2014) find that while some presupposition triggers leave a lasting impact – suggesting their presupposition is accommodated – others essentially seem to be ignored: after reading short texts containing various triggers followed by a distractor task, subjects are more likely to answer questions based on the contribution of triggers like *stop*, compared to a greater likelihood of failing to consider the presupposition such as that of the prefix *re-* (as in *reintroduce*). Tiemann (2014) and Tiemann et al. (2015) report a similar lack of consideration of the presupposition of *again* when answering questions, even without a delay in the task.

The just mentioned studies confirm some of the differences between triggers, in that the patterns of variation across triggers at least roughly match one of the theoretical divisions between types of triggers. But other studies that are more narrowly targeted at comparisons between specific triggers falling on opposite sides of a given proposal for a theoretical divide have failed to

<sup>3</sup>Note that while the QUD-based account certainly leaves room for differentiating triggers, it is not obvious what precisely it would say about the contrast between different types of factives.

yield clear confirmation of expected contrasts. For example, Schwarz (2014) compares the presumed ‘soft’ trigger *stop* with the ‘hard’ trigger *again* in terms of their processing time course. The results from visual world eye tracking suggest that both soft and hard triggers are processed rapidly, contrary to what might be expected based on (one line of) results on processing conversational implicatures, which can be presumed to share crucial features with soft triggers on certain pragmatic accounts. Furthermore, various attempts at comparing soft triggers to implicatures suggest that they differ in their processing profile, providing evidence against analyses that assimilate them (Chemla and Bott, 2013; Kennedy et al., 2015: among others). Yet another attempt at assessing a key part of the empirical claim with regards to the distinction between hard and soft triggers illustrated in (6) was made by Jayez et al. (2015). Their acceptability judgment study focusing on the hard triggers *too* and *regret* suggests that these, too, can fail to project from antecedents of conditionals in contexts that globally establish ignorance with respect to the truth of the presupposition, at least with sufficient contextual support.

Most relatedly to the experiments reported below, Cummins et al. (2013) and Amaral and Cummins (2015) investigate various triggers in English and Spanish and test the acceptability of *Yes*, *although* and *No*, *because* continuations, as illustrated for *again* and *stop* below:<sup>4</sup>

- (7) Q: Did Brian lose his wallet again?  
 A: Yes, although he never lost it before.  
 A': No, because he never lost it before.
- (8) Q: Did John stop smoking?  
 A: Yes, although he never smoked before.<sup>5</sup>  
 A': No, because he never smoked before.

Across all triggers that they looked at, both *yes* and *no* responses of this sort are degraded relative to controls, suggesting that contradicting the presupposition comes with a cost no matter what. But interestingly, the triggers in their results seem to be grouped into two classes with regards to the extent to which *yes*,... and *no*,... responses differ from one another: for expressions such as *stop* and *still*, there is a fairly substantial, statistically significant difference in acceptability between the response options, with higher ratings for *no* than for *yes*. In contrast, expressions such as *again* and *too* yield comparable acceptability ratings for both continuations.<sup>6</sup> Cummins et al. (2013) relate their results to the distinction between lexical and resolution triggers (Zeevat, 1992), but they broadly align with the soft-hard distinction as well. And in line with common claims about this distinction, the interpretation offered by these authors is indeed that the first set of triggers more easily allows for ‘local accommodation’ (Heim, 1983: i.e., an interpretation where presupposed content acts as if it were run-of-the-

<sup>4</sup>Similar tasks involving the selection of the best answer from a set of options had previously been used to investigate clefts and focus (Onea and Beaver, 2011; Velleman et al., 2012; Destruel et al., 2015).

<sup>5</sup>Note that Cummins et al. (2013) do not explicitly provide the continuations they used for *stop*, so this is our best guess at what they looked like for this question, which is listed in the materials in their appendix.

<sup>6</sup>Note that they also found *regret* to pattern with the first set of triggers, exhibiting a significant difference between continuations. This is directly relevant to our findings below, and at first sight may seem incompatible with them; see footnote 12 for our take on this.

mill entailed content), leading to relatively greater acceptability of the *no*-responses for these triggers. But there is a potential additional dimension to the variation as well, which can be related to Zeevat's notion of lexical triggers, which constitute cases where the presupposition is a requirement that comes with the asserted component of the trigger. As Amaral and Cummins (2015: p. 169) put it, in these cases 'the responses in condition [A; *yes*-continuation] appear self-contradictory, if we assume that the presupposition is a logical prerequisite for the at-issue content of the trigger.' In other words, the content introduced in the question cannot be affirmed independently of the presupposition. Our experiments below build on essentially this notion, though we couch it in a slightly different theoretical context.<sup>7</sup>

## 2. Experiments

The starting point for our investigation is the hypothesis that we find different relationships between different subcomponents of meaning for emotive and cognitive factives. Generally speaking, both types of factives contribute (at least) two meaning components, that of the ATTITUDE involved (which relates the matrix subject's mental state to the embedded proposition), and that of the (EMBEDDED) proposition P (conveying that P is true). We propose that these two components stand in a different relationship to each other for the two types of factives, such that for emotive factives, P can be disentangled from the subject's ATTITUDE in a way that it cannot for cognitive factives. The basic intuition is that it is quite easy to imagine that one is *happy* about a certain state of affairs, but is simultaneously wrong about it. It is harder to see how one can *discover* something which is not true. Relatedly, (9a) is a coherent statement, whereas (9b) gives rise to contradiction:<sup>8</sup>

- (9) a. John was happy that his parents are coming to town, although it turned out that he was in fact mistaken/although it turned out that they had to cancel.
- b. ?? John discovered that his parents are coming to town, although it turned out that he was in fact mistaken/although it turned out that they had to cancel.

More specifically, we build on the proposal by Sudo (2012) that certain triggers (e.g., change of state verbs like *stop*) have their presupposition represented as part of the entailment at the lexical level, whereas others (such as gender features on pronoun or the additive presupposition of *also*) do not. Adapting this general approach, we hypothesize that cognitive and emotive factives differ in terms of their entailment properties — specifically, that P, while generally surfacing as projective content for both types of factives, is also part of the conventionally entailed content of cognitive factives, whereas it is not for emotive factives (Table 1).

<sup>7</sup>Note that a further directly related notion, that of certain triggers exhibiting 'Obligatory Local Effects,' has been introduced in recent work by Tonhauser et al. (2013).

<sup>8</sup>On this point, Egré (2008: p. 103) also observes that the emotive *regret* behaves differently from the cognitive *know* in false-belief environments.

| Factive Type                   | COGNITIVE that P | EMOTIVE that P |
|--------------------------------|------------------|----------------|
| <b>Conventional Entailment</b> | P & ATTITUDE     | ATTITUDE       |

Table 1: Our hypothesis. Cognitives, but not factives, conventionally encode their embedded proposition P as part of their entailment.

We test this hypothesis using a yes/no-continuation task, similar to the above-mentioned one employed by Cummins et al. (2013) to explore differences between a range of triggers such as *stop* and *again*. The task pairs a factive question with a response of the form *yes, although...* or *no, because...*, followed by a denial of the content of the embedded proposition, as illustrated in (10).

- (10) Q. Is Anna **aware/happy** that [<sub>P</sub> Ryan is coming to the wedding]? /  
 Does Anna **realize/appreciate** that [<sub>P</sub> Ryan is coming to the wedding]?  
 A1. Yes, although he isn't.  
 A2. No, because he isn't.

While the overall approach taken here is quite similar to that of Cummins et al., our hypothesis provides a slightly different angle on the expected outcomes by focusing on whether or not an affirmative answer is possible when the presupposition is explicitly denied at the same time. Our basic assumption is that a *yes*-response necessarily commits the speaker to the entailed content introduced by the question. However, it may in principle be possible to deny a presupposition, to the extent that it is introduced entirely at a separate level and not part of the conventionally entailed content. This leads to diverging predictions based on our hypothesis: if the content of the embedded proposition is entailed, as we propose is the case for the cognitive factives, saying *yes* and then denying the content of the embedded proposition should be contradictory, and thus only *no* will be a viable response. But for the emotive factives, where we hypothesize that the content of the embedded proposition is not part of what is entailed, it should in principle be possible to just endorse the (emotive) ATTITUDE by responding *yes*, even if qualifying immediately by noting that the embedded proposition is false – i.e. singling out one aspect of the meaning (the entailed content: ATTITUDE) while contesting another aspect (P). Note that homing in on one particular aspect of meaning in your affirmation may still come at a cost, i.e., it is indeed plausible that the default impact of an affirmation involves endorsing both entailed and presupposed content, wholesale, as it were. What's crucial for our approach is that in principle it may be possible that non-entailed presuppositions can be denied along with a *yes*-response, while entailed ones cannot. If so, that leads to a prediction for our hypothesized difference between cognitive and emotive factives, namely that the latter should yield a greater acceptance of *yes*-responses than the former. Note that the hypothesis makes no specific prediction for the relative acceptability of denials of presupposed content with *no*-continuations, which require targeting the presupposed content with negation (commonly analyzed as involving local accommodation). It's possible that the different relationship between presuppositions and entailments has a reflex here, too, but this does not necessarily follow from our hypothesis. In the following, we report on two experiments to test these predictions: Experiment 1, where the participants were asked to choose which of the *yes* vs. *no* answer-options they preferred, and

Experiment 2, which uses acceptability ratings to home in on the acceptability of *yes*-responses more directly.

## 2.1. Experiment 1

### 2.1.1. Design

In Experiment 1, participants were presented with questions containing a cognitive or an emotive factive and had to indicate their preference with respect to *yes* and *no*-answer options. There were additional response options to express that ‘Both options are equally good.’ or ‘Both options are equally bad.’

- (11) Q. {Did Mark **find out**/Was Mark **surprised**} that [<sub>PS</sub> his parents are visiting]?
- A1. Yes, although they had to cancel because of the weather.
  - A2. No, because they had to cancel because of the weather.
  - A3. Both options are equally good.
  - A4. Both options are equally bad.

If, as hypothesized, cognitives but not emotives entail the content of the proposition they embed, we expect that the *yes*-responses should be more readily available for the questions with an emotive factive, compared to those with a cognitive one. That is, for the emotive factives, we expect both the *yes* and the *no*-responses to be in principle available. Assuming more or less comparable availability of the *yes* and *no*-responses, the *both good* and *both bad* responses should be chosen more frequently for emotive factives (depending on how the potential cost of local accommodation (for *no*) or targeting only one aspect of meaning (for *yes*) affects acceptability judgments). For the cognitive factives on the other hand, we expect these to allow only the *no*-responses, as these should be clearly better than *yes*-responses (even if involving some cost for local accommodation). Hence, *both good* should be impossible with the cognitive factives, given the unacceptability of the *yes*-response. The *both bad* option might get chosen for the cognitive factives, if subjects dislike both local accommodation and cancellation/suspension. However, this is likely to be the dispreferred choice, assuming that local accommodation does make *no*-responses available.

### 2.1.2. Participants

Thirty-six native speakers of English participated in the study. The participants were recruited on Prolific.ac, a crowd-sourcing tool for recruiting participants to participate in scientific studies online. Participants were paid at rate of 5.20 GBP per hour for their participation. The task took approximately 10 minutes to complete. No participant was excluded from the analyses.

### 2.1.3. Materials

All items presented short written dialogues between two speakers. There were two variations of twenty-four experimental items, corresponding to the two predicate types: COGNITIVE (*re-*

*alize, find out*) and EMOTIVE (*be disappointed, be surprised*) factives, as illustrated in (11) above. Each subject only saw a given item in one version, with item-condition pairings counterbalanced across subjects. In addition, there were twenty-four filler items where factives were paired with different continuations. Given the prediction for the critical part of the experiment, that the *yes*-responses should be endorsed to a greater extent in the EMOTIVE condition than in the COGNITIVE condition, the fillers were designed to yield the opposite preference. Hence, among the fillers, the emotive factives favoured a *no*-response, and the cognitive factive favoured a *yes*-response, as illustrated in (12) and (13), in order to counteract the potential risk of introducing an overall bias against the *yes*-responses. The *both good* and *both bad* options in (A3) and (A4) were available for the fillers, too.

(12) Emotive filler:

- Q. Was Mike disappointed that John decided to quit football?  
 A1. Yes, although he didn't think John was a very good player.  
 A2. No, because he didn't think John was a very good player.

(13) Cognitive filler:

- Q. Was Mary surprised that Bill got the grant?  
 A1. Yes, although she was on the grant committee.  
 A2. No, because she was on the grant committee.

The participants were given the following instructions: "In this experiment you will read short questions. You will then be asked to choose which answer you prefer, given a choice of two answers. You also have the opportunity to say that you think that both answers are equally good or equally bad. There is not a right or a wrong answer. Simply choose the answer that you prefer, given the preceding question." In order to control for variability stemming from the two predicate types influencing the answers across conditions, we used a block design. Thus, half of the participants saw the emotive factives in a randomized order first, and the cognitive factives in a randomized order last, and vice versa for the other half of the participants. Each block contained both fillers and critical items. Additionally, the items were divided into two groups, in order for each specific predicate to be evenly distributed across participants, thus creating a two-by-two Latin square design.<sup>9</sup>

#### 2.1.4. Analysis

The results were analyzed as logistic mixed effects regression models in R (version 3.1.2) using the *glmer* function of the *lme4* package (version 1.1-11) and its *bobyqa* optimizer. Results from maximally complex converging models are reported here (Barr et al., 2013). We ran four types of models regarding the predicted outcomes: models predicting the observation of a *yes*-response (to the exclusion of all the others), of a *no*-response (to the exclusion of all the others), of a *both good*-response (to the exclusion of all the others) and of a *both bad*-response (to the exclusion of all the others). They tested for a fixed effect of predicate type (EMOTIVE, COGNITIVE). For each of these simple-effect models, we also ran a version testing for an

<sup>9</sup>The experiment is available at: <http://spellout.net/ibexexps/SchwarzLabArchive/YesNoFact/experiment.html>

effect of block order (EMOTIVE-COGNITIVE, COGNITIVE-EMOTIVE) and its interaction with predicate type. Participants and items were added as random effects, with a random slope for predicate type per participant, and a random slope for predicate type and block order (in the relevant models) per item. Our different baselines exhausted the logical space of effects and interactions. The models did not include data-points for the filler items, and no other data-point was excluded.

### 2.1.5. Results

The results are summarized in Figure 1. The response patterns for the first block showed a clear contrast between the cognitive and the emotive factives. There was a main effect of predicate type on the observation of *no*- and *both bad*-responses in the first block (resp.  $p = 0.00247$ ,  $\beta = 1.2433$ ,  $SE = 0.4107$  and  $p = 0.024687$ ,  $\beta = 1.6566$ ,  $SE = 0.7375$ ), with *no*-responses being more frequent for the cognitive factives and *both bad*-responses being more frequent for the emotive factives. There was also a significant interaction with block order for the *no*-responses ( $p = 0.02423$ ,  $\beta = 1.3729$ ,  $SE = 0.6092$ ) but not for the *both bad*-responses; the significant main effects between the two types of factives disappeared in the second block (predicate type for *no*  $p = 0.7260$ ,  $\beta = 0.12959$ ,  $SE = 0.36983$ ; predicate type for *both bad*  $p = 0.678$ ,  $\beta = 0.3225$ ,  $SE = 0.7768$ ), suggesting that exposure to one type of factive predicate had a strong effect on the participants' responses, potentially through priming one type of interpretation, or through adjusting the participants' standards for evaluation. There was no such significant main effect on the observation of *yes*- and *both good*-responses (all  $p > 0.17$ ,  $\beta \leq 0.5$ ). We observed the same results in simple models, excluding block order as a predictor: *no*- and *both bad*-responses were more frequent with cognitives than with emotives (*no*:  $p = 0.0222$ ,  $\beta = 0.5266$ ,  $SE = 0.2303$ ; *both bad*:  $p = 0.0223$ ,  $\beta = 0.7232$ ,  $SE = 0.3165$ ) but there was no significant effect of predicate type for *yes*- and *both good*-responses (*yes*:  $p = 0.737$ ,  $\beta = 0.08468$ ,  $SE = 0.25253$ ; *both good*:  $p = 0.809$ ,  $\beta = 0.07354$ ,  $SE = 0.30382$ ).

Figure 1: **Left:** proportion of responses for the two types of factives in block 1, where the contrast between the cognitive and the emotive factives is significant for the *no* and the *both bad*-responses. **Center and right:** responses for the four response types (*yes*, *no*, *both good*, *both bad*), by block. The contrast between the two types of factives is neutralized in block 2.

To summarize, even though the contrasts between the two verbs are subtle, and subject to influencing each other across blocks, there is nonetheless a clear contrast between the two types of factives with respect to the availability of *no*-responses. Even though there was no direct, visible contrast in the availability of *yes*-responses and *both good*-responses, the contrast in *both bad*-responses is in line with our hypothesis, according to which the two aspects of meaning identified as part of the semantics of the two types of factives (the ATTITUDE and the (EMBEDDED) P components) contribute to the overall semantic properties in different ways for the emotive and the cognitive factives — specifically in terms of the truth of the embedded clause being part of the conventional entailment in the case of cognitive factives, but not for the emotive factives. Under this view, participants were not sufficiently inclined to consider an interpretation where either negation targeted P directly or where an affirmative response selectively endorsed the conventionally entailed content (for emotive factives). At the same time, participants did display a sensitivity to the contrast in entailment in that they were more amenable to accepting a *no*-response for cognitive factives, because it should be easier to target the embedded proposition P with negation when it is conventionally entailed.

However, there is at least one alternative interpretation of the results which basically attributes the contrast in *no*-responses to varying availability of local accommodation, and does not posit a difference between factives in terms of whether or not P is part of the conventionally entailed content. To spell out a specific version of this alternative, it might be that only emotives are lexically associated with a conventional presupposition that P (which at the same time is part of the entailed content as well). In contrast, the presuppositional status of P would result from a pragmatic derivation in the case of cognitive factives, in line with the proposals by Simons, Romoli and others. Based on these assumptions, *no*-responses for cognitives are expected to be easily acceptable, to the extent that the pragmatic derivation does not (or at least not necessarily) take place under negation.<sup>10</sup> For emotives on the other hand, both a *yes* and a *no*-response would require cancellation of a hard-coded, conventional presupposition, which would lead participants to generally prefer the *both bad* response to indicate a presupposition failure.

In order to disambiguate between these two interpretations of the results, Experiment 2 used an acceptability rating task where subjects were only presented with one answer option at a time. This allowed us to test for a contrast in the acceptability of *yes*-responses between the two types of factives more directly. As discussed above, our hypothesis predicts that *yes*-responses paired with denials of P will be more readily available for emotive factives than for cognitive factives. In contrast, the alternative interpretation we just considered does *not* predict such a contrast in the *yes*-responses, as both types of factives should yield low ratings for *yes*-responses, based on the crucial assumption that factives uniformly include a conventional entailment that P.

<sup>10</sup>For Romoli in particular, the justification after *no* would block or cancel this derivation, in the same way that the *sometimes* implicature normally associated with *not always* does not arise in *I don't always curse because I never curse*).

## 2.2. Experiment 2

### 2.2.1. Design

Experiment 2 used an acceptability rating task to provide an independent assessment of the acceptability of *yes* and *no* continuations. Participants saw only one response at a time (*yes*, *although...* or *no*, *because...*), as shown in (14) and (15).

(14) Q. {Is Maria **aware** /**happy**} that [<sub>P</sub> Mike is moving back to Chicago]?

A1. Yes, although he isn't.

(15) Q. {Is Maria **aware**/Is Maria **happy**} that [<sub>P</sub> Mike is moving back to Chicago]?

A2. No, because he isn't.

Specifically, the participants were asked to rate to what extent the answer sounds natural to them, in light of the question, by choosing a value between 1 ('completely unnatural') to 7 ('completely natural') by clicking the number or pressing the corresponding key. They were instructed that there was no right or wrong answer. If cognitive, but not emotive factives conventionally entail P, then we expect to see a contrast between the cognitive and the emotive factives in the *yes*-responses, such that *yes* is rated significantly lower for the cognitives than for the emotives. Again, no specific predictions were made for the *no*-responses. In addition to the slight change in the nature of the task, the stimuli were refined from Experiment 1 to be more uniform, in particular by consistently using future-oriented progressive forms (e.g., *is moving to Chicago*) in the embedded clause and expressing denial in the response-continuation via VP-ellipsis. This was done to avoid potential other pragmatic strategies of reconciling the denial with the initial affirmative or negative response, which may have given rise to additional variation in response patterns for the original set of materials.

### 2.2.2. Participants

Sixty-two undergraduate students at the University of Pennsylvania, all native speakers of English, participated in the study for course credit through the Psychology department's subject pool. The experiment took approximately 15 minutes, and was carried out on lab computers.

### 2.2.3. Materials

As illustrated above, the items consisted of short dialogues between two speakers, as in (14), (15). Versions of the twenty-four critical items were created in four conditions, corresponding to the two predicate types—cognitive and emotive, and the two answer types—*yes*, *although* and *no*, *because*. We also included a between item adjective-verb manipulation, such that half of the items contained verbal factives (*appreciate*, *realize*), and half of them, adjectival factives (*happy*, *aware*). Forty-eight filler items were also included. These were designed with two purposes in mind: first, to provide a floor and a ceiling baseline for the *yes*- and *no*-responses; and second, to counterbalance the number of good and bad *yes*- and *no*-responses. Half of the fillers were therefore constructed using a non-factive matrix predicate (*think*), where the *no*-

answers would be infelicitous, and the *yes*-answers would be fully acceptable, as in (16). The other half of the fillers involved a question with two conjuncts, as in (17). Here, it would be the *yes*-answers that were infelicitous, while *no* would be an acceptable response.

- (16) Q. Does Sue think that Bill's parents are going to the wedding?  
 A1. #No, because they are. ('Bad Control')  
 A2. ✓Yes, although they aren't. ('Good Control')
- (17) Q. Is John going to Paris and Rome this summer?  
 A1. ✓No, he's not. ('Good Control')  
 A2. #Yes, although he isn't going to Rome. ('Bad Control')

The participants were given the following instructions: "In this experiment you will read short dialogues between two people in the form of a question and an answer. You will then be asked to rate to what extent the answer sounds natural to you in light of the question, by choosing a value between 'completely unnatural' (1) to 'completely natural' (7). There is not a right or a wrong answer. Simply make the choice based on how well you feel the answer works for the preceding question." In contrast to Experiment 1, the factive and emotive items were randomly mixed, but answer type (*yes* vs. *no*) was separated by blocks, with order counter-balanced across groups.<sup>11</sup>

#### 2.2.4. Analysis

The ratings were analyzed using linear mixed effects regression models in R (version 3.1.2), using the *lmer* function of the *lme4* package (version 1.1-11). All our models included predicate type (EMOTIVE, COGNITIVE) and answer type (YES, NO) as fixed effects. Given that we didn't make predictions regarding syntactic category (ADJECTIVE, VERB) nor block order (YES-NO, NO-YES), we fitted models excluding them both (simple models) and models including either one of them as predictors (models including both of them would not converge). We tested for the maximally complex models, including all possible interactions of predictors and all random slopes for participants and items as random effects, and our different baselines exhausted the logical space of effects and interactions. The models only included the data points of the experimental items.

#### 2.2.5. Results

The results are presented in Figure 2. Responses were similar in the first and second block (main effects  $t \leq 1.35$ ,  $\beta \leq 0.45$ ; two-way interactions  $t \leq 0.3$ ,  $\beta \leq 0.15$ ; three-way interaction  $t = 0.302$ ,  $\beta = 0.13988$ ,  $SE = 0.43359$ ) and for adjectives and verbs (main effects  $t \leq 1.5$ ,  $\beta \leq 0.35$ ; two-way interactions  $t \leq 1.63$ ,  $\beta \leq 0.44$ ; three-way interaction  $t = 1.216$ ,  $\beta = 0.37898$ ,  $SE = 0.31167$ ). As predicted, the response patterns showed the *yes*-ratings to be significantly higher for the emotive than for the cognitive factives (simple model:  $t = 4.954$ ,  $\beta = 0.76$ ,  $SE = 0.1534$ ;  $t \geq 3.1$  and  $\beta \geq 0.59$  otherwise), with no difference in the *no*-ratings (simple

<sup>11</sup>The experiment is available at:  
<http://spellout.net/ibexexps/SchwarzLabArchive/YesNoRating/experiment.html?Home=true>

model:  $t = 0.625$ ,  $\beta = 0.1005$ ,  $SE = 0.1607$ ;  $t \leq 0.785$  and  $\beta \leq 0.1683$  otherwise). There was also an interaction between predicate type and answer type (simple model:  $t = 4.083$ ,  $\beta = 0.8605$ ,  $SE = 0.2108$ ;  $t \geq 2.61$  and  $\beta \geq 0.67$  otherwise).

Figure 2: Mean ratings by answer type and predicate type (merged blocks).

With this experiment, we replicated the main conceptual result from Experiment 1, in that we elicited a contrast between emotive and cognitive factives. The contrast no longer consists in participants endorsing *no*-answers more readily as responses to cognitives than to emotives; rather, we now see that participants deem *yes*-answers relatively more natural as responses to emotives than to cognitives.<sup>12</sup> Importantly, the results from Experiment 1 were not only compatible with our hypothesis, but also with an alternative hypothesis based on potential differences in the availability of local accommodation. However, the results from Experiment 2 are not in line with the predictions of such an alternative view: that view assumes that *P* is conventionally entailed both by cognitive and emotive factives, therefore *yes*-answers should be rated as low for emotive as for cognitive factive questions (under the assumption that *yes* commits the speaker to all the entailed content). On the other hand, our hypothesis is well in line with the results: participants were able to understand the affirmative reply as singling out the entailed content to the exclusion of the embedded proposition *P* to some extent for emotives. This led to an increase in acceptability of *yes*-continuations, in contrast to cognitives, which were visibly as low as the baseline controls in this regard. This is consistent with the idea that emotives do not, but cognitives do, conventionally entail *P*, given the assumption that it is in principle possible to selectively affirm the conventionally entailed content with a *yes*-response.

### 3. Discussion

Taken together, the results from Experiment 1 and Experiment 2 support the hypothesis we advance, that cognitive and emotive factives differ in terms of whether the truth of the embedded

<sup>12</sup>Cummins et al. (2013) report results for *regret*, which look similar to other triggers that we would see as candidates for entailing their presupposition. However, there is no direct point of comparison to other types of factives, and furthermore, their materials seem pragmatically skewed by using embedded clauses that the matrix subject is virtually guaranteed to be an informed authority on, such as *Did Fiona regret buying the house?*.

clause is part of what is conventionally entailed (in addition to being presupposed). While the first experiment did not support that notion directly, the results were perfectly consistent with this notion, but they also could be explained by an alternative hypothesis that locates the difference entirely in terms of the interaction of negation (and more generally, *no*-answers) with different triggers. Experiment 2 sought to get a more direct comparison of the acceptability of *yes*-responses paired with a denial of the presupposition, and found a significant difference (and corresponding interactions) between the two types of factives. This showed that an explanation of the contrast has to extend beyond negation, which our hypothesis does but the alternative one does not provide. That said, there are various aspects of the results as well as the broader theoretical discussion that merit further consideration.

The first issue to raise here is the absence of a contrast in ratings for the *no*-answers in Experiment 2, which contrasts with what we observed in Experiment 1. We suggested that *no*-responses were more likely to be selected with the cognitive factives because it is easier for negation to target the embedded proposition *P* when it is part of the conventionally entailed content. In the case of the emotives, this requires allowing negation to target purely presuppositional content, which may come with some cost (e.g., through local accommodation). But based on this interpretation, it may seem a bit surprising that we did not find parallel results for Experiment 2, where no difference in acceptability between *no*-answers for emotive and cognitive factives emerged. While we can't offer a full-fledged explanation for this, there are a number of tentative points to offer that suggests that this need not undermine our proposal. To begin with, the two experiments differed not only in the explicit task, but also in several other details of implementation. While the choice of an appropriate response in Experiment 1 could be seen as closer to a production situation, the acceptability rating task in Experiment 2 primarily involved comprehension (plus assessment of an observed dialogue). It is at least possible that this introduces an asymmetry in terms of how likely people are to call upon a mechanism such as local accommodation: in Experiment 1, it was easy to avoid such a move by choosing a different response choice, whereas in Experiment 2, it may have offered itself as the last resort for taking the presented dialogue to be plausible. Furthermore, the block manipulations in the two experiments were different: Experiment 1 separated the two types of factives into separate blocks, whereas Experiment two had different blocks for *yes* and *no*-continuations, with factive types mixed with blocks. Thus the lack of an effect for negation in the latter may simply parallel the block order effect in Experiment 1, where no differences emerged between factive types in the second block. Finally, it is worth noting that the issue we're addressing effectively is based on a null effect, and the absence of evidence in this regard should not be mistaken as evidence against our hypothesis. The core of our line of argument is that there is a difference between emotive and cognitive factives in terms of conventional entailment, and that we can find *positive* evidence for *non-entailment*, which we did.

We should also address why no difference between types of factives in the acceptability of the *yes*-responses emerged in Experiment 1: both *yes* and *both good* choices were equally low there for cognitives and emotives, whereas in Experiment 2, *yes*-answers were judged to be more natural for emotives. As already noted in connection with the preceding point, the two experiments differed in various relevant respects, in particular with regards to choosing an appropriate response vs. providing a graded assessment of the acceptability of a fixed response. While the

contrast between the different types of factives had an impact in both tasks, the persistent global presence of the truth of the embedded proposition for emotives seems to have decreased selection of either response in Experiment 1, suggesting that participants were reluctant to select a response with an unsupported presupposition from an emotive factive. That *no*-responses were much more readily selected and clearly preferred, for cognitives, fits the notion that their presuppositions are less persistent than those of emotives, echoing the claim that presuppositions of soft triggers are more easily suspendable than those of hard triggers (Abusch, 2002). As discussed earlier, expressions that have been claimed to project part of their conventionally entailed content (as we claim is the case for cognitive factives) tend to fall in the category of soft triggers, whereas expressions that have been claimed to trigger a presupposition independent from their conventionally entailed content (as we claim for emotive factives) generally fall in the category of hard triggers. Note that we here have tried to remain neutral as to the source of the projective content of factives, leaving open the possibility that in the case of cognitive factives, it could be derived as a type of implicature *à la* Romoli (2012) or a conversational inference more generally, based on the presence of the relevant proposition at the level of the conventionally entailed content. In contrast, this type of analysis is not available for the emotives, given our interpretation of the data. One obvious remaining option then is to posit that in the case of emotive factives, we are dealing with a conventionally encoded presupposition that is NOT simultaneously present at the level of conventionally entailed content.

However, there is at least one further alternative, which relates to the question of what exactly is involved in the ATTITUDE component, in particular in the case of emotive factives.<sup>13</sup> To spell out this option, let us first step back and return to the possibility of deriving the factive inference for cognitive factives: the original source of this content is in the conventional entailments at the lexical level, on this view. Its special status, leading to projection behavior is derived in one way or another based on the notion that one can distinguish between different pieces of meaning at this level namely i. that the subject believes (or has come to believe, etc.) that P, and ii. that P holds. In contrast, the information conveyed by an emotive factive expression like *be happy that P* seems to ultimately involve at least three pieces: i. that the subject has an emotionally positive attitude towards P, ii. that P holds, and iii. that the subject believes that P holds. So while there clearly is only one ingredient to the ATTITUDE component of cognitives (i), there could be any combination of (i) and (iii) that is lexically encoded to form the ATTITUDE component of emotives. Relating this to our experimental results, note that any of these options would be compatible with our interpretation of the experimental results above, given that none of the considered ATTITUDE components entail P. Once we incorporate all three pieces of information into our considerations, further candidates for a conventionally encoded *presupposition* of emotives enter the picture. In addition to the option noted above that P (ii) be treated as a hard-coded presupposition, one could well imagine that emotives conventionally encode the subject's belief that P (iii) as a presupposition and derive the stronger inference that P in fact holds conversationally, based on assumptions about the well-informedness and authority of the attitude holder. Alternatively, the 'belief-presupposition' (iii) could also be part of what is conventionally entailed, and emotive factives would then entail this presupposition. This would still be consistent with our interpretation of the experimental results, since neither the presuppositional nor the conventionally entailed content of emotive factives would

<sup>13</sup>Thanks to Valentine Hacquard for discussion leading to our consideration of this possibility.

then contribute that P holds: this would only emerge as a possibly defeasible inference from the presupposition that the subject believes P. In summary, once we think more broadly about precisely what ingredients there are to the meaning of emotive factives, more options open up, including one where a belief-presupposition of emotives is represented at the level of conventional entailments. While this would make cognitive and emotive factives more similar again on an abstract level, there would still be a substantive difference with regards to the role of the embedded proposition P (which would still be entailed for cognitives but not for emotives on the view under consideration).

Regardless of where one comes down on these more intricate issues, the interpretation of our data is as follows: Our starting point was the long-standing observation that i. the complements of factives in general (i.e., both cognitive and emotive) are typically projected as true or impose restriction on the context of utterance, but ii. they differ in the extent to which they do so. Our proposal is that the content of the proposition that factives embed is also part of what is conventionally entailed in the case of cognitives, but not in the case of emotives. The experimental results we obtained and presented here support this proposal, and even the final alternative analysis we just discussed would wind up embracing it by assuming that emotives neither presuppose nor conventionally entail the truth of the proposition they embed, as it maintains that the truth of the embedded proposition could be derived from other conventionally encoded content. In the end, the various analyses that we discussed share precisely this property, while crucially differing on how the truth of the embedded proposition ends up as part of the conveyed content, with behavior that suggests it is (generally) projective and imposes constraints on the context of utterance, as presuppositions are traditionally thought to do.

#### 4. Conclusion

We presented two experiments investigating the role of the embedded proposition of both cognitive and emotive factives, using a *yes/no*-continuation task. Taken together, the experiments suggest that while the embedded proposition of cognitives inevitably gets embraced by affirmative responses to questions, this is not necessarily so for emotives. We interpret these results in terms of a more general distinction between presupposition triggers, where some – like cognitives – entail their presupposition, whereas others – like emotives – do not. This interpretation rules out certain pragmatic accounts of emotives, but leaves open at least two theoretical paths for introducing their factive presupposition, either in terms of conventionally encoding them at the presuppositional level (and only at the presuppositional level), or by deriving them from other ingredients, such as the belief-component that seems to be involved in emotives as well.

## When is not-believing believing that not?<sup>1</sup>

Mojmír DOČEKAL — *Masaryk University, CZ*

Jakub DOTLAČIL — *University of Amsterdam, NL*

**Abstract.** We present two experiments that studied the licensing conditions of two Czech expressions in neg-raising and non-neg-raising environments: *ani jeden* ‘even one’ and *až do* ‘until’. English counterparts of these expressions are often treated as belonging to the same class, that of strict NPIs. However, our experiments revealed subtle differences between the two expressions, which we argue could be explained if we assume that only *ani jeden* ‘even one’ is a strict NPI, while *až do* ‘until’ is an expression sensitive to durativity of the predicate it modifies. The experiments furthermore showed that mood affects licensing of both *ani jeden* ‘even one’ and *až do* ‘until’ under neg-raising predicates. The role of mood on licensing is explained in Romoli’s theory of neg-raising.

**Keywords:** Neg-raising, NPIs, mood, experimental semantics, Czech

### 1. Introduction

In this article we focus on an interaction of two phenomena: Neg-raising (NR) and Negative Polarity Items (NPIs) licensing. The phenomena have been treated as connected since the first formal approaches to NR. In particular, strict NPI licensing is standardly taken as a test of NR-hood (see Lakoff 1969 and Horn 1989, among others). NR is exemplified with (1): (1a) is in most contexts understood as (1b) – and this interpretation is the so-called NR reading of (1a).

- (1) a. John doesn’t believe that Mary was here.  
b.  $\neg$  John believes that Mary wasn’t here.

The article has two aims: an empirical and a theoretical one. In the empirical part, we present new experimental data from Czech on NR and NPIs. The data show that the choice of mood (indicative vs. subjunctive) has an effect on licensing expressions sensitive to negation (NPIs being one main representative of such a category). Second, the data also show that not all expressions sensitive to negation are equal: in particular, we will observe that expressions like ‘even’ have a very different behavior from expressions like ‘until’ when interacting with negation. The theoretical point of the article is the argument that the effect of mood can be captured in Romoli’s theory of NR-hood (Romoli, 2013), and that ‘until’ should not be classified in Czech as a strict NPI, in contrast to English.

The main part of the article discusses two experiments on NR, NPIs and mood, and the theoretical consequences of the experimental results. Before turning to the experiments and the theory, we need to prepare the ground. We begin so by giving a necessary background on Czech expressions sensitive to negation.

## 2. Czech expressions sensitive to negation

In Czech, there are at least three groups of expressions sensitive to negation.

First, there is a class of weak NPIs, which is represented by the NP *sebemenší tušení* ‘slightest suspicion’. We can see that it is a weak NPI since it requires a downward entailing (DE) environment in the at-issue meaning – see (2) – a standard condition for weak NPIs. There doesn’t seem to be any locality constraint between this NPI and its licenser.

- (2) Nikdo/málo lidí/\*někdo o tom (ne)-měl-o/-0 sebemenší tušení.  
 nobody/few people/\*somebody about that had slightest suspicion  
 ‘Nobody/few people/\*somebody had slightest suspicion about that.’

In this article we stay agnostic as to the exact mechanism of weak NPI licensing (see, e.g., Gajewski 2011 and Crnič 2014 for two recent proposals). In fact, weak NPIs will not play any role in the following sections.

The second class consists of strict NPIs. These can be represented by NPs such as *ani jeden článek* ‘not even one article’. Currently, several theoretical approaches to strict NPIs co-exist (see Zwarts 1998, Giannakidou 2006, Gajewski 2011, Collins et al. 2014). Here, we will use that of Zwarts (1998): strict NPIs are licensed by anti-additive functions. Anti-additive functions are defined in (3).

- (3) A downward-entailing function  $f$  is anti-additive iff for any  $a$  and  $b$  in the domain of  $f$ ,  $f(a)$  and  $f(b) \leftrightarrow f(a \text{ or } b)$ .

The condition of anti-additivity can explain why we observe the difference between (2) where the DE quantifier *málo lidí* ‘few people’ licensed the weak NPI and (4) where the licensing of the strict NPI is invalid:

- (4) Nikdo/\*málo lidí/\*někdo (ne)-přečetl ani jeden článek.  
 nobody/\*few people/\*somebody read even one article  
 ‘Nobody/\*few people/\*somebody read even one article.’

On Zwarts’ account, the explanation lies in the fact that the quantifier *málo lidí* is not anti-additive. To see this, consider a situation with six students, 3 of them dancing and (other) 3 of them singing. Assuming that 3 but not 6 is seen as a small number, the sentence *Few students were dancing and few students were singing* is true but the sentence *Few students were dancing or singing* is not – that is, the anti-additive condition is not satisfied by the DE quantifier *few people*). In general, since anti-additive licensors are a proper subset of DE licensors (see, e.g., Gajewski 2011) strict NPIs appear in some, but not all, environments that license weak NPIs.

A third class of expressions sensitive to negation are expressions of the type *až do* ‘until + time expression’, see (5).<sup>2</sup>

- (5) Vojáci se \*(ne)vystřídali až do půlnoci.  
 soldiers SE neg-change till to midnight  
 ‘The soldiers will not change until midnight.’

The English counterpart of *až do* is often taken as a good candidate for strict NPIs (when combining with predicates denoting episodic events). It is also widely used in testing NR properties of predicates (cf. Gajewski 2011, Romoli 2013). Nevertheless, we treat the Czech expression as a separate type. In particular, we assume it is an expression sensitive to durativity of the modified predicate (ESD), as can be seen by the fact that the Czech *až do* can appear with stative predicates, (6). The negative version of (5) is possible because negation changes a punctual predicate into a durative one (Krifka 1989, a.o.). We are not the first to take this position. In particular, *until* in English has been analyzed along this line by Smith (1974) and Mittwoch (1977). However, at least since Karttunen (1974), this type of analysis has been often challenged/substituted by an approach that postulates two types of *until*, one of which is sensitive to durativity and another one that appears with episodic predicates and is a strict NPI (see De Swart 1996 for a detailed discussion).

- (6) Vojáci zůstanou až do půlnoci.  
 soldiers stay till to midnight  
 ‘The soldiers will stay until midnight.’

While we have nothing to say about the English case, we do have a novel argument that the Czech *až do* should not be analyzed this way. As we will demonstrate in the following part of the article, Czech examples containing *až do* ‘until’ with punctual predicates like (5) are very different from parallel cases of strict NPIs.

### 3. Experiments

In this section we describe the design of two experiments pertinent to the topic of the article. Both experiments targeted NR, NPI licensing and various factors influencing the licensing.

#### 3.1. Experiment 1

The first experiment tested whether expressions sensitive to negation are accepted in clauses embedded under negated NR and non-NR predicates and how mood of the embedded predicate

<sup>2</sup>Apart from these three groups, Czech also has n-words (expressions requiring clause-mate negation):

- (i) Nikdo \*(ne)spal.  
 Nobody not-slept.  
 ‘Nobody slept.’

This class of negative expressions will not play any role in the rest of the article.

influences the acceptability. The experiment was a 3x2x2 design.

Three types of predicates were used (Condition: PREDICATE):

1. opinion class of NRs – see (7) for an item with a strict NPI;
2. probability class of NRs – see (8) for an item with a strict NPI;
3. non-NR predicates (mostly communication and causative verbs) – see (9) for an item with a strict NPI

All predicates embedded either indicative or subjunctive mood (Condition: MOOD). Finally, two types of expressions sensitive to negation were tested: either the strict NPI *ani jeden* ... ‘not even one’ or the ESD *až do* ‘until’ (Condition: NEGATIVE EXPRESSION). While the first two conditions were tested within items, the last one was a between-item condition. This was so because it would be hard, if not impossible, to have sentences that could be fully parallel up to the NPI/ESD difference.

An example with strict NPIs for opinion, probability and non-NR predicates are given here.

- (7) Nemyslím, že 0/by ani jeden z běžců může/mohl ten závod vyhrát.  
do-not-think-I that IND/SUBJ even one of runners can/could the race win  
‘I don’t think that even one of the runners can/could win the race.’
- (8) Není možné, že 0/by ani jeden z běžců může/mohl ten závod vyhrát.  
it’s-not possible that IND/SUBJ even one of runners can/could the race win  
‘It’s not possible that even one of the runners can/could win the race.’
- (9) Netvrdím, že 0/by ani jeden z běžců může/mohl ten závod vyhrát.  
do-not-say-I that IND/SUBJ even one of runners can/could the race win  
‘I don’t say that even one of the runners can/could win the race.’

The example items with ESDs *až do* ‘until’ are shown below for the same three predicate classes.

- (10) Majitel toho hotelu neví, že 0/by kuchaři odjeli až do konce měsíce.  
owner this hotel not-knows that IND/SUBJ cooks left up to end month  
‘The owner of this hotel doesn’t know that cooks would leave/left until the end of the month.’
- (11) Podle majitele toho hotelu není možné, že 0/by kuchaři odjeli až do konce měsíce.  
according owner this hotel not possible that IND/SUBJ cooks left up to end month  
‘According to the new owner of the hotel it’s not possible for the cooks to leave until the end of the month.’

- (12) Majitel toho hotelu se nedoslechl, že 0/by kuchaři odjeli až do  
 owner this hotel not-hear that IND/SUBJ cooks left up to end  
 konce měsíce.  
 month  
 ‘The owner of this hotel doesn’t hear that cooks would leave/left until the end of the month.’

The participants in this experiment judged acceptability of the items on 5-point Likert scale (5=best, 1=worst).

There were 36 experimental items. 18 experimental items were constructed with the ESD *až do* ‘until’, 18 experimental items appeared with the strict NPI *ani jeden* ‘even one’. Furthermore, the experiment included 36 fillers, each of them an uncontroversially grammatical or ungrammatical sentence. All the fillers had their complexity comparable to the items.

60 Czech native speakers took part in the experiment which was run online on IBEX. 3 participants were excluded from the analysis due to their unreliable behavior in distinguishing good and bad fillers.<sup>3</sup>

### 3.2. Experiment 2

The second experiment also tested NR and NPI licensing in Czech. It consisted of two experimental methods – an acceptability and an inference task. For the topic of the current paper only the data from the acceptability part matter (for details of the whole Experiment 2 see Dočekal and Dotlačil 2016). In the acceptability test participants judged acceptability of *ani jeden* ‘even one’ and *až do* ‘until’. The acceptability was judged on the 5-point Likert scale (5=best, 1=worst), as in the other experiment. 5 different environments were used in the experiment (Condition: ENVIRONMENT):

- (a) simple positive sentences;
- (b) simple negative sentences;
- (c) clauses embedded under negated NR predicates of intention and judgment/obligation;
- (d) clauses embedded under negated NR predicates of opinion;
- (e) clauses embedded under negated non-NR predicates.

<sup>3</sup>On average, participants judged grammatical fillers as better than ungrammatical ones by more than 2 points difference on the 5-point scale (the mean of the difference between judgements on good and bad fillers was 2.21) and every participant (apart from the three excluded ones) showed at least a 1-point difference. The mean difference between good and bad fillers for the three excluded participants was smaller than 1 point (0.62, 0.37 and 0.15). Since they reported much weaker sensitivity to grammatical/ungrammatical sentences, they were not used for further analyses.

In the conditions (c), (d) and (e) strict NPIs and ESDs were placed in embedded clauses. One item for all conditions is shown in (13).

- (13)
- a. Ztratila se ani jedna ovce.  
lost SE even one sheep  
'A single sheep is missing.'
  - b. Neztratila se ani jedna ovce.  
neg-lost SE even one sheep  
'Not a single sheep is missing.'
  - c. Nový bača v Tatrách nechce, aby se ztratila ani jedna ovce.  
new shepherd in Tatra neg-wants C-SUBJ SE lost even one sheep.  
'The new shepherd in the Tatra mountains does not want a single sheep to be missing.'
  - d. Nový bača v Tatrách si nemyslí, že se ztratila ani jedna ovce.  
new shepherd in Tatra SI neg-think C-IND SE lost even one sheep  
'The new shepherd in the Tatra mountains does not think that a single sheep is missing.'
  - e. Nový bača v Tatrách neříká, že-IND se ztratila ani jedna ovce.  
new shepherd in Tatra neg-say C SE lost even one sheep  
'The new shepherd in the Tatra mountains does not say that a single sheep is missing.'

The second manipulation was the type of negative expression. As in Experiment 1, either the strict NPI *ani jeden* 'even one' or *až do* 'until' was used. There were 40 items in total: 20 items appeared with the strict NPI 'even one' and other 20 items used the ESD 'until'. The experiment also included 30 fillers. The experiment was run on IBEX and 60 Czech native speakers participated in it.

Both experiments were filled out by students of Masaryk University and volunteers. While we do not know whether there were people participating in both experiments, we note that there was more than half a year break between the two experiments. Furthermore, different university classes were asked to participate in the two experiments, making it unlikely that the same participant was tested more than once.

#### 4. Results

The results of Experiment 1, revealing the effect of mood and predicate type, are visualized in Figure 1.<sup>4</sup>

We analyzed the Experiment 1 using mixed-effects ordered probit models with two fixed effects: MOOD (indicative vs. subjunctive, the former being the reference level), PREDICATE (opinion (NR), probability (NR) and communication/causative (non-NR), the first one being the reference level), and their interaction. The model furthermore included intercept-only subject and item random effects. We found the following:

<sup>4</sup>Notice that the graph focuses on just a slice of the response scale (from 2.0 to 2.7), to make the contrast more transparent.

Figure 1: Experiment 1, means and standard errors for three predicates crossed by the subjunctive/indicative mood manipulation

1. NR predicates were judged as significantly better than non-NR predicates ( $\beta = -0.22, z = -2.51, p = 0.012$ ). Recall that the acceptability was mostly influenced by the ESDs/NPIs and their licensing by the three types of predicates interacting with the mood.
2. There was no difference between the opinion and probability class of NR predicates.
3. The subjunctive mood acted as a facilitating factor in the acceptability: ESDs/NPIs embedded in subjunctive clauses were more acceptable than the ones embedded in indicative clauses:  $\beta = 0.2, z = 2.39, p = 0.017$ .

To study the effect of NPI type, we considered a second model, which added another fixed effect: NEGATIVE EXPRESSION ('even one' and 'until', the former being the reference level) and the interaction of this factor with MOOD and PREDICATE. The new model had a significantly better fit than the previous one (Likelihood ratio test,  $p < .001$ ). The model revealed that ESDs 'until' were generally more acceptable than strict NPIs 'even one' ( $\beta = 0.4, z = 2.65, p = .008$ ). The improvement was further strengthened in the case of probability predicates (there was a significant probability  $\times$  'until' interaction in the positive direction,  $\beta = 0.48, z = 2.79, p = 0.005$ ).

Figure 2: Experiment 2

The graphical summary of the second experiment is presented in Figure 2.<sup>5</sup> Recall that there were 5 environments tested in Experiment 2: NPIs/ESDs in simple positive clauses, in simple negative clauses, in clauses embedded under negated intention/judgment NR predicates, in clauses embedded under negated opinion NR predicates and in clauses embedded under negated non-NR predicates. To study the effect of these environments, we considered a mixed-effects ordered probit model with one factor, ENVIRONMENT (NR predicates of intention/judgment type were the reference level). The model also had the intercept+slope subjects and items random effects. The model showed that intention/judgement NR predicates were significantly worse than simple negative sentences ( $\beta = 3.2, z = 7.3, p < .001$ ), and significantly better than positive sentences ( $\beta = -1.5, z = -9.2, p < .001$ ). They were also significantly better than NPIs/ESDs embedded under non-NR predicates ( $\beta = -0.8, z = -5.6, p < .001$ ), while there was no difference between two types of NR predicates (intention/judgement vs. opinion) ( $p > .1$ ). The difference between NR and non-NR predicates seems stable – it was significant in both experiments, and we interpret it as showing that Czech has a class of neg-raising predicates, contra Bošković and Gajewski (2009) (see Dočekal and Dotlačil 2016 for the same point and more details).

To study the difference between the NPI ‘even one’ and the ESD ‘until’, we ran a second model, which consisted of the factor ENVIRONMENT, the factor NEGATIVE EXPRESSION (NPI or ESD, the former being the reference level) and their interaction. The model also included the full random structure for subjects and items.

<sup>5</sup>We did not use boxplots to summarize the results of Experiment 1 since the effects of mood are smaller than effects of NPIs and would be almost impossible to observe in such a graphical summary.

Replicating the results of the first experiment, the model yielded a significant effect for ESDs ( $\beta = 0.45, z = 2.3, p = 0.02$ ), showing that ‘until’ was judged as better than ‘even one’ in the intention/judgement NR class. The positive effect was even stronger in the opinion class of NR predicates (opinion  $\times$  ESD interaction –  $\beta = 0.6, z = 2.43, p = 0.02$ ), as well as in non-NR sentences and positive sentences (non-NR  $\times$  ESD interaction –  $\beta = 0.6, z = 2.17, p = 0.03$ ; positive sentences  $\times$  ESD interaction –  $\beta = 0.89, z = 2.61, p = 0.009$ ). In our understanding, the positive interaction of ‘until’ with non-NR predicates and positive sentences shows that ESDs lead to less severe degradation than strict NPIs when appearing outside of their licensing environment. However, this would not explain why ‘until’ is better than ‘even one’ when embedded under NR predicates, since NR predicates should license both (cf., Gajewski 2005). It would also not explain the following finding: ESDs were *less* acceptable than NPIs when appearing in simple negative clauses (negative sentence  $\times$  ESD interaction –  $\beta = -3.92, z = -4.14, p < .001$ ). The last effect can be also observed in Fig. 2: while ‘until’ improves acceptability ratings in non-NR, NR and positive sentences compared to ‘even one’, it is clearly judged as worse than ‘even one’ in simple negative sentences.

## 5. Analysis and discussion

There are two main points of the results we want to address:

1. Why does subjunctive mood improve the acceptability of NPIs/ESDs?
2. Why is the ESD ‘until’ less acceptable than the NPI ‘even one’ in negative sentences, but more acceptable under NR predicates?

Let’s start with the first question.

We rely on Romoli (2013) and its scalar approach to NR: NR predicates contribute the at-issue meaning (universal quantification over possible worlds) and an excluded middle alternative (EM) implicature – formalized as the second alternative in (14a). Let’s illustrate its working on an example: for a NR verb like *believe* EM is intuitively equivalent to subject’s opinionatedness – a well-informed experiencer of the verb believes either the embedded proposition  $p$  (e.g. that it is raining) or its negation (that it is not raining). Consider now what happens when we interpret the sentence *John does not believe that it is raining*. Romoli, following Chierchia (2013), assumes that sentences come with an exhaustivity operator, EXH, that affirms the proposition and negates the alternatives that do not contradict the proposition (this is a slight simplification – see Romoli 2013 for the full account). Thus, when we combine the EXH operator with the sentence, the resulting meaning is as in (14b). This can be simplified into (14c). Intuitively: if John doesn’t believe that it’s raining and he’s opinionated w.r.t. raining, then he believes it is not raining.

- (14) a.  $Alt(NR) = \{\lambda p \lambda x. \Box_x[p], \lambda p \lambda x. [\Box_x[p] \vee \Box_x[\neg p]]\}$   
 b.  $EXH(\text{John does not believe that it is raining}) = \neg \Box_j p \wedge \neg \neg [\Box_j p \vee \Box_j \neg p]$   
 where  $p = \text{it is raining}$   
 c.  $\Box_j \neg p$

The scalar theory of NR explains the acceptability of both ESDs and strict NPIs under negated NR predicates. For the former, it is crucial that negation creates a durative predicate (see, for example, Krifka 1989, a.o.). Given that it does and that the negation is interpreted on the embedded predicate, it suffices for the ESD ‘until’ to modify such a negated predicate to be licensed. For the latter, assume that strict NPIs are licensed in anti-additive environments (Zwarts, 1998). Then, they will be licensed when embedded under NR predicates. Somewhat more technically, since (15) is valid, strict NPIs are licensed under NR predicates. For more details, see Gajewski (2005).

$$(15) \quad \Box_x \neg p \wedge \Box_x \neg q \Leftrightarrow \Box_x \neg (p \vee q)$$

But why would subjunctives facilitate licensing of strict NPIs/ESDs? We follow Villalta (2008) in her description of the subjunctive mood in embedded sentences as a transferer of alternatives into matrix clauses. According to Villalta, indicative mood, unlike subjunctive, stops such a transfer.

The observed effect of subjunctive follows from this approach. If alternatives can be transferred to the NR predicate, they can be computed. However, if they are not transferred (because they are stopped at the left periphery of the embedded sentence by the indicative mood), the exhaustification of the EM alternatives cannot proceed and the scope of the negation remains high. In this respect, Slavic languages reveal the dependency of NR interpretation on the availability of alternatives, which in turn supports the implicature approach to NR. The presuppositional approach (Gajewski, 2005) to NR would have to make some further assumptions to describe this type of dependency. The effect of mood could also be captured by syntactic accounts of NR (Collins et al., 2014), as subjunctives are generally more transparent for movement (Progovac, 1993).

We now turn to the second question: why do the ESD ‘until’ and strict NPI ‘even one’ differ from each other? First, notice that ‘until’ in Czech shows different scopal behavior than NPIs. NPIs generally cannot c-command their licensors (De Swart, 1998), see (16). Surprisingly, the reverse is true for the ESD ‘until’: while it is degraded in (17a) it improves when *až do půlnoci* ‘until midnight’ precedes/outscopes negation, (17b).

- (16) a. Phil would not give me anything.  
 b. \*Anything Phil would not give me.  
 (from De Swart 1998, ex. 8)

- (17) a. ??Petr neusnul až do půlnoci.  
 Petr neg-fell-asleep up to midnight  
 ‘Petr didn’t fall asleep until midnight.’  
 b. Až do půlnoci Petr neusnul.  
 up to midnight Petr neg-fell-asleep  
 ‘Until midnight Petr didn’t fall asleep.’

In our experiment we used items with ESDs linearized after negated verbs (which is the default adverb placement), as illustrated in (18) (the simple negative condition).

- (18) Vojáci se nevystřídají až do půlnoci.  
 soldiers SE neg-exchange up to midnight  
 ‘The soldiers will be not exchanged until midnight.’

Remember, that in such sentences ESDs were considered worse than strict NPIs. Changing the linearization seems to improve the acceptability of (18) considerably (although we lack a proper experimental support for our intuitions in this case). But recall that if *až do* ‘until’ would be an NPI, this effect would be totally unexpected. If anything, we would expect an opposite effect. This strongly suggests to us that *až do* ‘until’ is *not* a strict NPI (in contrast to what is commonly assumed about its English counterpart). More concretely, since Czech is a language in which arguments/adjuncts are often interpreted in their surface position (i.e., QR is much less common than in English), the ESD ‘until’ is interpreted as a modifier of the (non-negative) VP when appearing after the verb. This VP is punctual and thus, it cannot satisfy the requirement of ‘until’. The change in linearization as in (17b) allows a different parse, one in which ‘until’ modifies the negated event, hence the improved acceptability of the ESD in this case.

But why would ‘until’ be more acceptable (as compared to the strict NPI ‘even one’) when modifying punctual predicates embedded under NR predicates? One explanation could go as follows. Negation is interpreted in the embedded clause at the logical form via pragmatic mechanisms. Since it is not syntactically present there, there is no signal from syntax whether the ‘until’ modifier should be interpreted in its scope or above it. In other words, there is no evidence from syntax that would support either interpretation. Given that, readers are free to pick the interpretation that is more suitable – and that is the one in which the ESD is interpreted above negation and the condition of the ESD is satisfied. Notice that this does not predict that ESDs should be better under NR predicates than in simple negative clauses. If the strengthening to EM is marginal to begin with (as Dočekal and Dotlačil 2016 argue), ESDs might be still less acceptable in this case than in simple negative clauses. What is (correctly) predicted is a relative difference: ESDs should be less acceptable than strict NPIs in simple negative clauses, but this difference should disappear in clauses embedded under NR predicates. Since ESDs are generally less degraded when lacking their licenser, compared to strict NPIs (as witnessed by the fact that ESDs are more acceptable than strict NPIs in positive sentences and clauses embedded under non-NR predicates), we furthermore expect that under NR predicates, ESDs should not just be as good as strict NPIs, but in fact, even more acceptable than strict NPIs – and this is correct.

## 6. Conclusion

We discussed two experiments that studied the licensing conditions of two expressions in Czech: *ani jeden* ‘even one’ and *až do* ‘until’. English counterparts of these expressions are often treated as belonging to the same class, that of strict NPIs (Gajewski 2005 and references there). However, our experiments revealed subtle differences between the two expressions, which we argued could be explained if we assume that only *ani jeden* ‘even one’ is a strict NPI, while *až do* ‘until’ is an expression sensitive to durativity of the predicate it modifies. Aside from that, we also saw that Czech reveals effects of mood in licensing both *ani jeden* ‘even one’ and *až do* ‘until’ under NR predicates. The role of mood on licensing was explained in Romoli’s theory of NR. Both points show that experimental work on languages less often stud-

ied (from the perspective of formal semantics) can clearly enrich our current understanding of language variation and interpretation.

# Focus association by movement: Evidence from binding and parasitic gaps<sup>1</sup>

Michael Yoshitaka ERLEWINE — *National University of Singapore*

Hadas KOTEK — *Yale University*

**Abstract.** Under the influential Roothian proposal for focus association, focused phrases remain in-situ at LF (Rooth, 1985, 1992). However, a recent line of work has resurrected the idea that focus association involves covert movement: specifically, the associate of English sentential *only* must covertly move to *only*, with the possibility of covert pied-piping (Drubig, 1994; Krifka, 1996, 2006; Tancredi, 1997, 2004; Wagner, 2006; Erlewine and Kotek, 2014, 2018). In this paper we contribute to this emerging consensus view with additional evidence from reflexive binding and parasitic gap licensing.

**Keywords:** focus association, *only*, covert movement, binding, parasitic gaps

## 1. Two approaches to focus association

The problem of focus association concerns the relationship between focus-sensitive operators such as *only* and focused constituents such as *Fridays* or *chocolate* in (1). The semantics of *only* quantifies over the focused constituent and its contextual alternatives: for example, (1a) asserts that there is no day other than Friday where John eats chocolate, whereas (1b) asserts that John eats nothing other than chocolate on Fridays (see e.g. Horn, 1969).

- (1) a. John only eats chocolate on [Fridays]<sub>F</sub>.  
b. John only eats [chocolate]<sub>F</sub> on Fridays.

How does *only*'s semantics make reference to this focused constituent? One family of approaches posits the existence of *covert focus movement* so that the focused constituent becomes a local argument of the *only* operator at LF. A sample LF for example (1b) under the covert focus movement view is given in (2) below. Here we illustrate the non-quantificational subject *John* in its VP-internal base position. The movement in (2) makes the focus *chocolate* a local argument of a two-place *only* operator.<sup>2</sup>

- (2) **Covert movement LF for (1b):**  
only ([chocolate]<sub>F</sub>) ( $\lambda x$  . John eats  $x$  on Fridays)  
           $\uparrow$ ----- $\downarrow$

The alternative approach — popularized by Rooth (1985, 1992) and adopted in much contemporary work on focus semantics — assumes that focused constituents remain in-situ at LF. The operator (*only*) makes indirect reference to the choice of focus and its alternatives through a process of *alternative computation*. Each syntactic node  $\alpha$  is associated not only with its ordinary semantic denotation  $\llbracket \alpha \rrbracket^o$  but also with a set of alternatives,  $\llbracket \alpha \rrbracket^f$ , defined recursively as in (3) below. Focused (F-marked) constituents introduce non-trivial alternatives into their focus-

<sup>1</sup>We thank Aron Hirsch and anonymous reviewers for comments on the material here. Errors are each other's.

<sup>2</sup>The precise geometry of this movement could vary. See footnotes 7 and 8 in Erlewine and Kotek (2018) for detailed discussion of this movement and alternative formulations.

alternative denotations (3c), which are then propagated up through the process of *pointwise composition* (3b).

(3) **Focus alternative computation:**

- a. For non-focused terminal nodes:

$$\llbracket \alpha \rrbracket^f = \{ \llbracket \alpha \rrbracket^o \}$$

- b. For non-focused branching nodes (pointwise composition):

$$\llbracket [\alpha \beta] \rrbracket^f = \left\{ a \circ b \mid a \in \llbracket \alpha \rrbracket^f, b \in \llbracket \beta \rrbracket^f \right\}$$

where  $\circ$  is the appropriate composition operation for  $\llbracket \alpha \rrbracket^o$  and  $\llbracket \beta \rrbracket^o$ .

- c. For focused nodes:

$\llbracket \alpha \rrbracket^f$  is a contextually-determined subset of  $D_\tau$  where  $\tau$  is the type of  $\llbracket \alpha \rrbracket^o$

The result of this procedure is that the contextual alternatives to *chocolate* in (4b) will be reflected indirectly in the set of alternatives at VP (4c), which is a local argument of *only*.

(4) **Interpreting (1b) with focus in-situ:**

- a. only [<sub>VP</sub> John eats [chocolate]<sub>F</sub> on Fridays ]

- b.  $\llbracket [\text{chocolate}]_F \rrbracket^f = \{ \text{chocolate, fish, pizza, ...} \}$

- c.  $\llbracket \text{VP} \rrbracket^f = \left\{ \begin{array}{l} \text{John eats chocolate on Fridays,} \\ \text{John eats fish on Fridays,} \\ \text{John eats pizza on Fridays, ...} \end{array} \right\}$

- d. [only VP]  $\Rightarrow$  John doesn't eat fish on Fridays,  
John doesn't eat pizza on Fridays, ...

As an empirical argument for the in-situ view, Rooth (1985) following Anderson (1972) notes that focus association is apparently insensitive to syntactic islands. For example, in (5) based on an example from Kratzer (1991), *only* successfully associates narrowly with the focused constituent *the Zoning Board* inside a relative clause island. Under the covert movement approach — so the argument goes — covert movement of *the Zoning Board* should be impossible, just as the corresponding overt focus movement in (6) is ungrammatical.<sup>3</sup>

(5) **Focus association is apparently island-insensitive:**

I only contacted [<sub>island</sub> the person who chairs [the Zoning Board]<sub>F</sub>].

(6) **Corresponding overt focus movement of *the Zoning Board*:** (Kratzer, 1991: 831)

\* It was [the Zoning Board]<sub>F</sub> that I contacted [<sub>island</sub> the person who chairs \_\_\_\_].

Drubig (1994) however notes that this island-sensitivity problem can be avoided if covert focus movement can trigger *pied-piping*. That is, instead of the logically focused constituent moving alone to become a local argument of *only*, a *focus-containing phrase* can instead move to *only*. This possibility is illustrated schematically for the case of example (5) in (7) below.

<sup>3</sup>A possible response may be to say that covert (focus) movement is not sensitive to the same island constraints as overt movement, but this is ultimately incorrect. See Wagner (2006) and Erlewine and Kotek (2016, 2018) for evidence that covert focus movement *is* sensitive to syntactic islands.

- The interpretation of the pied-piped constituent in (7) then must utilize Rooth's mechanism of in-situ alternative computation in order to yield the observed sensitivity to the position of focus within the pied-piped phrase. Pied-piping of the constituent in (7) is also independently observed in overt focus movement, as in example (8):<sup>4</sup>

- This hypothetical possibility of pied-piping in covert focus movement thus defuses Rooth's argument from island-insensitivity for the in-situ approach to focus association. Independent evidence is then necessary to adjudicate between these two possible options. A series of works in the past decade have introduced new arguments for the idea that focus association with English *only* necessarily involves covert focus movement with the possibility of covert pied-piping.<sup>5</sup> The gist of each of these arguments is summarized here in (9).

- In this paper, we contribute two new arguments to this growing body of evidence. Following related diagnostics for covert *wh* movement by Nissenbaum (2000a, b), we will show that covert focus movement in English can feed reflexive binding and the licensing of parasitic gaps. These effects too are unexplained by the in-situ approach to focus association.

<sup>5</sup>All of these works in (9) look exclusively at focus association with English sentential *only*. A significant open question is whether this claimed necessity of covert movement in focus association extends to other focus-sensitive operators or languages.

Nissenbaum (2000b: pp. 124ff) shows that covert *wh*-movement in English allows reflexives to be bound by an antecedent outside of their surface local binding domain: that is, covert phrasal movement feeds reflexive binding. Consider the contrast in (10):

- The masculine reflexive *himself* does not have a local antecedent within the embedded clause, as the ungrammaticality of the baseline (10a) indicates. However, when this reflexive is contained within an in-situ *wh*-phrase, it can be bound by a higher antecedent, as long as the containing *wh*-phrase takes scope under the antecedent. In this case, assuming that movements triggered by the same head (here: matrix C) will “tuck in” (see also Richards, 1997; Pesetsky, 2000), (10) will have a LF representation as in (11).<sup>6</sup>

- In this higher LF position, *himself* is close enough to the intended antecedent, *who*. We therefore conclude that Binding Condition A is evaluated at LF.

Now consider example (13), which differs minimally from (12) in the addition of *only* above *want*, associating with the F-marked *picture*. The reflexive *myself* is now successfully bound by its intended antecedent, which is outside of *myself*'s surface local binding domain (cf (12)).

- The grammaticality of the reflexive binding in (13) is explained by the availability of covert focus movement with pied-piping. The proposed LF for (13) is given in (14). Here the overt

Proceedings of *Sinn und Bedeutung* 21  
 Edited by Robert Truswell, Chris Cummins, Caroline Heycock, Brian Rabern, and Hannah Rohde

A-movement of the subject from its predicate-internal position to its surface position, above *only*, is critical and therefore illustrated.

(14) **LF for (13) using covert focus movement with pied-piping:**

$I_i \lambda y . \text{only} ([a [\text{picture}]_F \text{ of myself}_i]) (\lambda x . y \text{ want } [\text{BD the museum to display } x])$

If a different constituent is focused which will not trigger covert movement of the reflexive, the long-distance binding in (13) is not licensed:

(15) \* I only want [BD the [museum]<sub>F</sub> to display a picture of myself].

Notice that the solution here is not to simply say that focused constituents themselves can violate locality in reflexive binding: what is focused in (13) is *picture*, not *myself*. It is necessary for covert focus movement of the F-marked constituent, *picture*, to trigger pied-piping of the whole reflexive-containing DP, *a picture of myself*.

Note too that it is not simply the case that focus on the head noun *picture* in (13) somehow allows *myself* to be bound long-distance, by an antecedent outside of the surface binding domain (BD). This long-distance binding facilitated in (13) is limited to the scope of *only*. If we attach *only* lower, within the surface binding domain of the reflexive, the long-distance antecedent option disappears:

(16) \* I want [BD the museum to only display a [picture]<sub>F</sub> of myself].

To summarize, we find that association with *only* feeds reflexive binding, as would be predicted by a theory of covert movement with pied-piping: the F-marked constituent moves (possibly with pied-piping) to become the first argument of *only*. This movement can put this constituent in a local relationship with a binder that is otherwise absent, licensing a binding relation. This result is unexpected under an in-situ account of Association with Focus, which predicts no difference between (12) and (13).

### 3. Parasitic gap licensing

The literature on parasitic gaps has largely followed Engdahl (1983) in assuming that *wh*-in-situ never licenses parasitic gaps. Engdahl's examples are reproduced in (17) below. Assuming that in-situ *wh*-phrases must or can move covertly (Karttunen, 1977; Huang, 1982; Pesetsky, 2000; Kotek, 2016; a.o.), this claim is commonly (re)interpreted as a claim that covert movements cannot license parasitic gaps.

(17) **Wh-in-situ does not license parasitic gaps:** (Engdahl, 1983: p. 14)

- a. \* John filed *which articles* without reading pg?
- b. \* Who filed *which articles* without reading pg?

Nissenbaum (2000a, b) shows that Engdahl's generalization is not exceptionless: although it is true that covert movement *alone* does not license parasitic gaps, overt movement together

with covert movement through the same  $\nu P$  edge can together license *two* parasitic gaps. An in-situ *wh*-phrase can license a *secondary parasitic gap* (18), which is not simply licensed by the presence of a non-*wh* phrase in the same position (19).

- (18) **Wh-in-situ licenses a secondary parasitic gap:** (Nissenbaum, 2000a: p. 542)

*Which senator<sub>i</sub>* did you persuade    <sub>i</sub> to borrow *which car<sub>j</sub>*  
[after getting an opponent of pg<sub>i</sub> to put a bomb in pg<sub>j</sub>]?

- (19) \* *Which senator<sub>i</sub>* did you persuade    <sub>i</sub> to borrow a Prius<sub>j</sub>  
[after getting an opponent of pg<sub>i</sub> to put a bomb in pg<sub>j</sub>]?

It is also possible to license an adjunct with just one parasitic gap bound by the overtly-moved *wh*-phrase (20a), but not with one corresponding to the in-situ *wh*-phrase (20b). The main clauses in both examples here are identical to that in (18). The secondary parasitic gap *pg<sub>j</sub>* as in (18) is, then, itself parasitic on the first parasitic gap *pg<sub>i</sub>* which corresponds to the overtly moved *wh*-phrase.

- (20) **Secondary parasitic gap is parasitic on the first parasitic gap:**

- a. *Which senator<sub>i</sub>* did you persuade    <sub>i</sub> to borrow *which car<sub>j</sub>* (Ibid. p. 552)  
[after talking to pg<sub>i</sub> for an hour]?  
b. \* *Which senator<sub>i</sub>* did you persuade    <sub>i</sub> to borrow *which car<sub>j</sub>*  
[after putting a bomb in pg<sub>j</sub>]?

To license the adjunct with two parasitic gaps, both the overt and covert  $\bar{A}$ -movement steps must cross the same  $\nu P$  edge. This is accomplished in (18) at the  $\nu P$  edge associated with *persuade*, as *which senator* is overtly  $\bar{A}$ -moved from within it. Subjects which are first  $\bar{A}$ -moved out of  $\nu P$  do not license their own parasitic gaps (Engdahl, 1983; a.o.) and similarly do not license secondary parasitic gaps:

- (21) \* *Which terrorist<sub>i</sub>*    <sub>i</sub> persuaded the senator to borrow *which car<sub>j</sub>*  
[after getting a friend of pg<sub>i</sub> to put a bomb in pg<sub>j</sub>]?

The correct generalization regarding the licensing of parasitic gaps by covert movement is then as in (22). Nissenbaum (2000a, b) gives an explanation for this generalization in terms of the derivational timing of overt vs covert movement and adjunction of the parasitic-gap-containing adjunct. We refer interested readers to those works.

- (22) **The Engdahl/Nissenbaum generalization:**

Covert  $\bar{A}$ -movement by itself does not license parasitic gaps. However, covert  $\bar{A}$ -movement does license a secondary parasitic gap when it crosses a  $\nu P$  edge that is also crossed by an overt  $\bar{A}$ -movement step.

We now show that focus association with *only* also licenses secondary parasitic gaps, as predicted by the covert focus movement approach to Association with Focus. Example (23) below is based on the ungrammatical baseline (19) above, but with the addition of an *only* associating

with the object of *drive* — here, *a Jaguar*:

(23) **The focus associate of *only* licenses a secondary parasitic gap:**

- ✓ *Which senator<sub>i</sub>* could you only persuade \_\_\_<sub>i</sub> to drive [a [Jaguar]<sub>F</sub>]<sub>j</sub>  
[after getting an opponent of pg<sub>i</sub> to put a bomb in pg<sub>j</sub>]?

Both the overt movement of *which senator* and the covert movement of *a Jaguar* to *only* in (23) will cross through the *vP* edge associated with *persuade*, to which the *after*-adjunct adjoins. If *only* is introduced lower so that the path of covert focus movement does not overlap with the overt *wh*-movement path, as in (24), the secondary parasitic gap becomes ungrammatical, as also predicted by the generalization in (22).

(24) **The position of *only* marks the height of covert focus movement:**

- \* *Which senator<sub>i</sub>* could you persuade \_\_\_<sub>i</sub> to only drive [a [Prius]<sub>F</sub>]<sub>j</sub>  
[after getting an opponent of pg<sub>i</sub> to put a bomb in pg<sub>j</sub>]?

Just as we saw with *wh*-movement, parasitic gap licensing by covert focus movement is only possible when crossing a *vP* edge that is also crossed by overt  $\bar{A}$ -movement, as per the Engdahl/Nissenbaum generalization (22). The generalization also predicts that a single parasitic gap is not licensed by the covertly moved focus of *only* alone. This prediction is borne out in (25):

(25) **Covert focus movement alone does not license parasitic gaps, as predicted by (22):**

- a. \* I only criticized [[this]<sub>F</sub> book] without reading pg.  
b. \* I only want to read [[this]<sub>F</sub> book] without buying pg.

We include another set of secondary parasitic gap contrasts, similar to the examples above. Example (26a) shows the ungrammaticality of a secondary parasitic gap with a referential DP, *the placebo*; example (26b) shows the availability of a secondary parasitic gap with a *wh*-phrase in that position; and (26c) shows the parallel licensing of a secondary parasitic gap with an *only* associating with a focused *placebo*.

- (26) a. \* *Which patients<sub>i</sub>* did the doctors assign \_\_\_<sub>i</sub> to the placebo<sub>j</sub>  
[after showing the families of pg<sub>i</sub> how to administer pg<sub>j</sub>]?  
b. *Which patients<sub>i</sub>* did the doctors assign \_\_\_<sub>i</sub> to *which drug<sub>j</sub>*  
[after showing the families of pg<sub>i</sub> how to administer pg<sub>j</sub>]?  
c. Context: Following FDA regulations, patients' families were shown how to administer all the drugs that might be associated with the trial. After some patients began exhibiting unexpected symptoms, the families wrote the FDA and demanded to know:  
*Which patients<sub>i</sub>* did the doctors only assign \_\_\_<sub>i</sub> to [the [placebo]<sub>F</sub>]<sub>j</sub>  
[after showing the families of pg<sub>i</sub> how to administer pg<sub>j</sub>]?

In examples (19) and (26a), the secondary parasitic gap is not licensed. The presence of the secondary parasitic gap is not by itself able to force the covert movement necessary to license

the gap. Instead, this movement must be independently licensed — covert *wh*-movement in (18) and (26b) and covert focus movement in (23) and (26c).

We conclude that — like in the case of covert *wh*-movement — parasitic gaps on F-marked material are licensed in Association with Focus constructions. This is predicted if association with *only* requires covert focus movement but is unexplained by the common, in-situ association approach of Rooth (1985) and others.

#### 4. Conclusion

Evidence from reflexive binding and parasitic gap licensing shows that the focus associate of *only* is interpreted in a higher position at LF through covert movement. This is predicted under the covert movement theory of *only*, where the F-marked constituent moves (possibly with pied-piping) to become the first argument of a two-place *only* (Drubig, 1994; Krifka, 1996, 2006; Tancredi, 1997, 2004; Wagner, 2006; Erlewine and Kotek, 2014, 2018). It is inconsistent with the influential in-situ analysis of association with *only* (Rooth, 1985, 1992), and hence serves as an argument against this view.

# Subjective standard-setting in gradable predicates: On the Mandarin *hen* structure<sup>1</sup>

Huilin FANG — *University of Southern California*

**Abstract.** Canonical positive degree sentences in Mandarin Chinese are formed with a morpheme *hen*. In the literature, this morpheme is regarded as the positive degree morpheme *pos* (Kennedy, 1999; Liu, 2010; Grano, 2012; Zhang, 2015) that introduces a contextually given norm, as well as binding the degree argument. However, the traditional *pos* analysis cannot fully account for some behaviors of *hen*. First, *hen* sentences share several characteristics of subjective predicates like Predicates of Personal Tastes (PPTs). These features include the triggering of faultless disagreement and embedding under perceptual verb *ganjue* and *ganjue-dao* ‘feel/find’. Furthermore, when compared with other adjectival expressions, the *hen* form makes a weaker statement, which is related to the speaker’s subjective belief. To account for these two characteristics, I propose that *hen* introduces a subjective standard determined by a judge that is based on a subjective epistemic knowledge state.

**Keywords:** degree semantics, gradable adjectives, positive degree sentences, subjectivity, Mandarin Chinese

## 1. Introduction

This work focuses on a type of Mandarin adjectival sentence, the *hen* sentence, which has the basic structure like (1). It is unique in that there is an obligatory morpheme *hen* that appears before the adjective.

- (1) Afu hen gao  
Afu HEN tall  
‘Afu is tall.’

It is hard to pinpoint the meaning of *hen*. By some native speakers’ intuition, this particle is a dummy marker in the sentence. Yet other speakers might think that it also means *very*, which indicates that the degree is high. Because of these features, *hen* is often regarded as the overt realization of positive degree morpheme, *pos* (see von Stechow, 1984; Kennedy, 1999, 2005, 2007, among many others, on *pos*). *Pos* has two functions. It introduces a contextually given standard, and the degree of the sentence exceeds this standard significantly. Second, gradable adjectives take a degree argument, *pos* binds this argument to avoid type mismatches when combined with the subject. The lexical entry of *pos* is given in (2). The function *s* here is a contextually sensitive function that takes a gradable adjective *g* and returns a corresponding standard. An example of the derivation is given in (3).

- (2)  $\llbracket pos \rrbracket = \lambda g \lambda x. g(x) > s(g)$  (Kennedy, 2007)

---

<sup>1</sup> I would like to thank Roumyana Pancheva, Barry Schein, Andrew Simpson, Audrey Li, Robin Jesheon, who gave me valuable comments on an early version of this work. I’d also like to thank Thomas Grano, Alexis Wellwood, and the audience at Sinn und Bedeutung 21, and also the audience from WCCFL 34, who helped me to develop my work from my previous presentation there. All remaining errors are my own responsibility.

- (3)  $\llbracket pos \text{ expensive} \rrbracket = \lambda d \lambda x. \text{expensive}(x) \geq s(g)$

Meaning: the degree of expensiveness exceeds a contextually given degree.

Implication: The degree of expensiveness stands out among a comparison class.

The advantage of this analysis is straightforward. It explains why *hen* is obligatory with gradable adjectives, and it also accounts for certain parallels of *hen* sentences with positive degree sentences in English. For example, the degree of the sentence should not only exceed the standard, but it should be significant enough for the subject to stand out among the objects in a comparison class. Therefore, *John is tall* implies that John's height not only exceeds a certain norm for tall people, but it also is significant enough to 'stand out' among them. As a support for the *pos* analysis of *hen*, this feature might be able to explain why some native speakers have an intuition that *hen* is similar to *very*, which also implies the degree to be significant.

However, there are several features of *hen* that cannot be accounted for directly by viewing it as *pos*. The first one is related to the subtypes of gradable adjectives that *hen* can occur with, and the different meanings they trigger, followed by problems that emerge when compared with another adjectival form, the *shi...-de* form. Second, contrary to previous analyses, *hen* is only obligatory when the sentence is uttered out of the blue. When there is an existing standard from the context, it can be dropped. The *hen* form is also weaker than the expression where *hen* is dropped. Third, *hen* predicates are licensed by a negation form *mei* that only selects eventive predicates. Finally, *hen* shows certain features that are parallel to subjective predicates, such as *Predicates of Personal Tastes* (PPTs). These properties can be accounted for if one sees *hen* as related to a subjective standard determined by a judge's knowledge state. In the following sections, I start by discussing the first three problems in section 2, and then move on to discuss the subjective features of *hen* predicates in section 3. In section 4, I discuss the characteristics of the subjectivity of *hen*. In section 5, I provide an analysis for the *hen* sentences, which is similar to Fernald's view on verbs like *appear* and *seem* (Fernald, 2000). Section 6 concludes this work.

## 2. Problems with the *pos* analysis

### 2.1. *Hen* with absolute adjectives

Gradable adjectives can be classified into two major classes, *relative adjectives* and *absolute adjectives* (Kennedy and McNally 2005). They are distinguished according to whether the scales they correspond to are bounded or open. As scales are set of ordered degrees, if a scale has no minimal or maximal degrees, it is an open scale. If it has maximal or minimal degrees, it is a closed scale. For example, the adjective *tall* corresponds to a scale of height, and there is no maximal or minimal degree for height. Adjectives with an open scale are relative adjectives. Some examples are given in (4).

#### Relative adjectives:

- (4) Open scales: the standard is contextually restricted  
*Gao*, 'tall', *pang* 'fat', *chang* 'long', *kuan* 'wide', *shuai* 'handsome'

In contrast, adjectives corresponding to closed scales are absolute adjectives. They can be further classified into three types, upper-closed scales, which have a maximal degree but no minimal degree, lower-closed scales, which have only a minimal degree, and totally closed scales, which have both minimal and maximal degrees. The examples are given in (5). I assume that the same categorization works for Mandarin as well.<sup>2</sup>

### Absolute adjectives:

- (5) a. Upper-closed scales: **standard=degree<sub>max</sub>**  
       *gan* ‘dry’, *ganjin* ‘clean’, *ping* ‘flat’, *zhi* ‘straight’  
       b. Lower-closed scales: **standard=degree<sub>min</sub>**  
       *shi* ‘wet’, *zan* ‘dirty’  
       c. Totally-closed scales: **standard=degree<sub>max</sub>**  
       *man* ‘full’, *xing* ‘awake’, *touming* ‘transparent’, *kai* ‘opened’, *kandejian* ‘visible’

In English, when an absolute adjective has a maximal degree, which include upper-closed scale and totally-closed scale adjectives, the standard is set at the maximal degree. A lower-closed scale has only a minimal degree, and the standard is set at this degree.

While both positive degree sentences with absolute and relative adjectives in English use the same form, Mandarin Chinese actually grammaticalizes this distinction. The *hen* form is only the default form for relative adjectives, as shown in (1), while the canonical positive form for absolute adjectives is the *shi...-de* form. *Shi* is the main copula in Mandarin Chinese, and *-de* is a modifier marker. The *shi...-de* form is also the predicative form for non-gradable adjectives, as in (9).

### Upper-closed scales: **standard=d<sub>max</sub>**

- (6) Wazi shi gan-de  
       sock COP dry-DE  
       ‘The sock is dry.’  
       Implication: The dryness of the sock reaches d<sub>max</sub>

### Lower-closed scales: **standard=d<sub>min</sub>**

- (7) Wazi shi shi-de  
       sock COP wet-DE  
       ‘The sock is wet.’  
       Implication: The sock has at least minimal wetness

### Totally-closed scales: **standard=d<sub>max</sub>**

- (8) Beizi shi man-de  
       cup COP full-DE  
       ‘The cup is full.’

<sup>2</sup> The major piece of evidence for this categorization, according to Kennedy and McNally (2005), is from modification by certain degree modifiers. An adjective like *slightly* modifies adjectives with lower bounds. *Completely* takes adjectives with upper bounds. Proportional adjectives, such as *half*, modify adjectives with totally-closed scales. Adjectives in Mandarin Chinese have similar properties. Due to limitations of space, I will not include the examples here.

**Non-gradable adjectives**

- (9) Diqui shi yuen-xing-de  
 Earth COP round-shape-de  
 ‘The Earth is round.’

The *shi...-de* form can also occur with relative adjectives, but only when there is a known standard given in the context, which sets things into categorical distinctions. Take (10) for example. When the *shi...-de* form is used with *gao* ‘tall’, it implies that there is an absolute degree that separates objects into those that are tall and those that are not. If being 6 feet tall count as tall, as long as Afu reaches this degree of height, he is a tall person. Afu does not need to ‘stand out’ in a comparison class, which is distinct from English positive degree sentences.

- (10) Afu shi gao-de, Ali bu-shi.  
 Afu COP tall-DE Ali NEG-COP  
 ‘Afu belongs to the category of tall people, while Ali doesn’t.’

Quite unexpectedly, *hen* can also co-occur with absolute adjectives. Yet it only means that the degree is rather high, and it does not necessarily reach the absolute standard. It can be anywhere on the scale, as long as it is regarded as high. The sentences in (11) are examples of upper-closed scale adjectives. As shown in (11b), a *hen* sentence does not entail the *shi...-de* form, of which the standard is the maximal degree.

- (11) a. Wazi hen shi  
 sock HEN wet  
 ‘The sock is very wet.’  
 b. Wazi hen gan, dan bu-shi (wanquan) gan-de  
 sock HEN dry but NEG-COP totally dry-DE  
 ‘The sock is very dry, but it is not (completely) dry.’

Likewise, with lower-closed adjectives, the sentence asserts that the degree is significantly high, not just reaching the minimal degree.

- (12) Wazi hen shi  
 sock HEN wet  
 ‘The sock is very wet.’  
 Implication: the reference value is significantly high.

As for adjectives with totally-closed scales, the standard does not need to reach the upper bound, but it is significantly high.

- (13) a. Beizi hen man  
 cup HEN full  
 ‘The cup is very full.’  
 b. Beizi hen man, dan bu-shi (wanquan) man-de  
 cup HEN full but NEG-COP totally full-DE  
 ‘The cup is very full, but it’s not totally full.’

What is the difference between the *shi...-de* form and the *hen* form when it comes to absolute adjectives? A possible analysis is that the *shi...-de* form introduces what is known as a *conventional standard* (Kennedy, 2007), while *hen* introduces a contextually given standard, functioning just like *pos*. In English, the traditional analysis of *pos* cannot directly account for why standards for absolute adjectives are set at the bounds. Kennedy (2007) proposes an economy principle, *Interpretive Economy*, which requires the interpretations of a sentence to be based on conventional understanding as much as possible. Since the standards of absolute adjectives are conventionally on the natural bounds, their standards are interpreted on these bounds, unless such interpretations are unavailable.

Take *wet* for example. *Wet* has a lower-closed scale. For an expression *the sock is wet*, it only requires minimal wetness for things to count as wet. As a result, context-dependent standards become last resort, which emerges only when conventional standards are unavailable. It is possible that Mandarin has both types of standards irrespective of the categories of the gradable adjectives. Therefore, the *hen* form derives a standard from a comparison class even with absolute adjectives. Take (13) for example. It would mean that the cup's fullness exceeds a contextually given standard of being full, which is derived from comparing the fullness of this specific cup with other objects filled to different degrees. It does not entail that it reaches the conventional standard, which is the maximal degree. In other words, absolute adjectives now behave just like relative adjectives in standard setting when *hen* is added. This explains why (13b) is not contradictory under the traditional *pos* analysis.

The above analysis, however, faces a problem. If what *hen* introduces is a contextual standard for a thing *x* to count as having a property *P*, it would be nearly equivalent to, when expressed under that same context, that *x* is a *P* thing. This works for relative adjectives in English. In (14), once the standard for being tall is set through the context, and the girl exceeds that height, she is a girl that has the property of being tall.

(14) That girl is tall.  $\approx$  That girl is a tall girl.

This is not borne out for *hen* sentences with absolute adjectives, as shown in (15). For the sock to be *hen*-dry, it does not need to be dry at all, whether the standard is given contextually or stipulated conventionally. It only implies that the dryness of the sock is significantly high.

(15) Zhe wazi hen gan  $\approx$  zhe wazi shi yi-zhi gan-de wazi.  
 this sock HEN dry this sock COP one-CL dry-DE sock  
 'This sock is very dry.'  $\approx$  'This sock is a dry sock.'

The data presented here seems to suggest that the *hen* form is a weaker statement than the attributive form in (15). Similarly, it is weaker than the *shi...-de* form in (13). In conclusion, the *hen* form is not simply the *pos* counterpart of English, or at least this is not the full picture.

## 2.2. Comparison with the ‘bare’ form

A second problem with the *pos* analysis is that *hen* is not obligatory in some marked environments.<sup>3</sup> When a simple sentence is uttered out of the blue, it is infelicitous without *hen*, as in (16).

### Out of the blue context:

- (16) A: #Afu congming.  
           Afu smart  
           ‘Afu is smart.’

However, *hen* can be omitted when the property denoted by the gradable adjective is regarded as a known fact.

- (17) Women dou zhidao, Afu gao.  
       we      all know Afu tall  
       ‘We all know, that Afu is tall.’

Furthermore, as pointed out by Liu (2010), *hen* can be omitted under some modals, including factive verbs such as *aonao* ‘regret/annoyed’ and *zhidao* ‘know’, and epistemic modals like *renwei*, as shown in (18) and (19).

### Factive verbs:

- (18) a. Wo aonao ta (hen) wuzhi.  
           I feel-annoyed s/he HEN ignorant  
           ‘I feel annoyed at her/his being ignorant.’  
       b. Wo zhidao ta (hen) wusi.  
           I know s/he HEN altruistic  
           ‘I know that he is altruistic.’ (Liu, 2010)

### Epistemic modal *renwei* ‘think’:

- (19) Wo renwei ta (hen) wuli.  
       I think s/he HEN unreasonable  
       ‘I think s/he is unreasonable.’ (Liu, 2010)

Based on the analysis that *hen* is the realization of *pos*, Liu proposes that modals, as well as several other structures (see footnote 3), carry an operator that licenses a covert form of *hen*.

However, Liu does not mention a common feature when *hen* is dropped in these sentences. In the bare form, there is always a strong implication that the property denoted by the adjective is already an accepted fact. This explains why the bare form is compatible with factive verbs, which trigger the presupposition that the complement proposition is true. Similarly, with

<sup>3</sup> Liu (2010) points out that there are several structures in which *hen* is not obligatory, which include questions, embedding under certain modals, and in the predicative position of contrastive focus forms. He proposes that these syntactic structures license a covert counterpart of *pos*, and the restriction is syntactic. However, the data given in this section are not syntactically unique. A thorough study on these structures is beyond the scope of this article. I leave it for future research.

epistemic modal like (19), the bare form implies that the speaker is emphasizing a statement that is acknowledged in the context, while when *hen* is present, there is no such implication.

In conclusion, although *hen* can be absent, it implies that the statement is about a given standard, or a known fact. This feature cannot be explained directly by the *pos* analysis.

### 2.3. The puzzle of negation

A third puzzle regarding *hen* is related to negation. In Mandarin Chinese, there are two negation markers, *bu* and *mei*. *Bu* negates generic or habitual predicates, as in (20), and states, as shown in (21).

#### Generic and habitual readings:

- (20) Wo bu chi mugua.  
 I NEG eat papaya  
 'I don't (generally) eat papayas.' (Ernst, 1995: 1)

#### States:

- (21) Wo bu shi laoshi.  
 I NEG COP teacher  
 'I'm not a teacher.'

*Mei* negates eventive predicates and non-states (*a la* Lin, 2003; also see Huang, 1988; Ernst, 1995; Lee and Pan, 2001; Hsieh, 2001; a.m.o.). According to Lin, a predicate negated by *mei* has an episodic meaning. Therefore, compared to (21), (22) denies that there was an episode of papaya eating. Generally speaking, *mei* cannot negate states, as shown in (23) and (24).

- (22) Wo mei chi mugua.  
 I NEG eat papaya  
 'I did not eat papayas.' (Ernst, 1995: 1)

- (23)\*Afu mei shi laoshi.  
 Afu NEG COP teacher  
 Intended: 'Afu is/was not a teacher.'

- (24)\*Afu mei gao.  
 Afu NEG tall  
 Intended: 'Afu is not tall.'

One would expect that a predicate with gradable adjectives to be negated by *bu* only, since it describes a state. An example is shown in (25).

#### *Hen* form under *bu*:

- (25) Afu bu hen gao.  
 Afu NEG HEN tall  
 'Afu is not tall.'

However, surprisingly, when *hen* is present, it can be negated by *mei*. This is shown in (26). When *hen* is absent, the sentence is ungrammatical, as shown in (24).

***Hen* form under *mei*:**

- (26) Afu mei hen gao.  
 Afu NEG HEN tall  
 ‘Afu is/was not very tall.’

In comparison, the *shi...-de* form can only be negated by *bu*, never by *mei*, as shown in (27) and (28). In fact, the copula *shi* only co-exist with negation marker *bu*.

***Shi...-de* form:**

- (27) Beizi bu shi man-de.  
 cup NEG COP full-DE  
 ‘The cup is not full.’

- (28)\*Beizi mei shi man-de  
 cup NEG COP full-DE

Table 1 is a summary of adjectival predicates in negation sentences. The major puzzle is that *hen* licenses the use of *mei*. It seems to imply that the *hen* form is more ‘eventive’ than the *shi...-de* form. This is the third phenomenon that the *pos* analysis cannot account for.

**Table 1**      **Types of adjectival predicates under negation**

|                                        | <i>Mei</i> | <i>Bu</i> |
|----------------------------------------|------------|-----------|
| <i>Hen</i>                             | Ok         | Ok        |
| <i>Shi...-de</i>                       | No         | No        |
| <b>Bare adjectives (no <i>hen</i>)</b> | No         | Ok        |

### 3. *Hen* sentences are subjective

#### 3.1. Subjectivity in adjectives

In this section I propose that *hen* is related to a subjective reading. Subjectivity is related to people’s opinions. It is well known that certain predicates are more subjective than others. One of the widely discussed topics on subjectivity in the domain of adjectives is on Predicates of Personal Tastes (PPTs) (See Kennedy, 2013; Lasersohn, 2005, 2009; Stephenson, 2007; Pearson, 2013; among others). Adjectives like *tasty* and *fun* have truth conditions relativized to a judge. In other words, a sentence like (29a) has the truth condition of (29b), in which *j* refers to the judge who makes the evaluation of what counts as tasty.

- (29) a. The cake is tasty.  
       b. The cake is tasty for *j*.

In comparison, adjectives that have objective dimensions, such as *tall*, *large*, *heavy*, *dry*, *full*, *long*, *empty*, are generally not regarded as subjective.

There are two commonly discussed diagnostics to identify subjective predicates. The first one is called *faultless disagreement* (Kölbel, 2002; Lasersohn, 2005, 2009; among many others). Faultless disagreement refers to the phenomenon that participants of a conversation can argue over whether a statement is true, without reaching a real conclusion, since both of them are entitled to their own opinions. This is shown in (30). None of them can be wrong with respect to whether chili is tasty.

- (30) *John*: The chili is tasty.  
       *Mary*: No! The chili is not tasty. (Lasersohn, 2005)

Lasersohn proposes that there should be an independent judge parameter, aside from the ordinary world and time parameters. He adopts a Kaplanian (Kaplan, 1989) approach in explaining faultless disagreement. Kaplan distinguishes between *characters* and *contents*. The character of a sentence is a function from context to the contents. When the indexicality of the character is resolved, the result is the content of the sentence. Faultless disagreement is the debate over the same content, but they are evaluated by different judge parameters. The case of PPTs contrasts with sentences with other indexical expressions, such as first person indexicals, as in (31). The expression *I'm a doctor* has different contents when uttered by different speakers. If what John says is true, Mary's objection here is infelicitous.

- (31) *John*: I'm a doctor.  
       *Mary*: #No, you're not a doctor! (Lasersohn, 2005)

Another feature of subjective predicates is the capability of embedding under perceptual attitude verb, such as *find* (Sæbø, 2009; Kennedy, 2013). The English *find* is a verb that expresses a person's personal perceptions. Non-subjective adjectives, such as *tall*, are not acceptable under *find*, as shown in (32) and (33).

- (32) John finds the cake tasty.

- (33) #John finds Mary tall.

The *hen* form shows both characteristics. This is explained in the following sections.

### 3.2. Faultless disagreement in Mandarin Chinese

Similar to the PPTs, the *hen* form triggers faultless disagreement. This is shown in (36). Imaging the two speakers are arguing about whether Afu is a tall person. When using the *hen* form, it is more likely to trigger faultless disagreement than the *shi...-de* form, as in (35). By a native speaker's intuition, while the *hen* form provides a certain vagueness related to how

the standard is set with respect to the speaker, the *shi...-de* form is related to a more absolute standard that is objective, without the need for assessment from the speaker.

- (34) A: Afu *hen* gao  
 Afu HEN tall  
 ‘Afu is tall.’  
 B: Cuo! Afu *bu* gao!  
 wrong Afu NEG tall  
 ‘Wrong! Afu is not tall.’

- (35) A: Afu *shi* gao-de  
 Afu COP tall-DE  
 ‘Afu is tall.’  
 B: Cuo! Afu *bu-shi*!  
 wrong Afu NEG-COP  
 ‘Wrong! Afu is not tall.’

This contrast is more obvious with absolute adjectives. When they appear with *hen*, there is vagueness with respect to what counts as significantly full for each individuals, which triggers faultless disagreement, as in (36). As for the *shi...-de* form, there is no faultless disagreement, as in (37).

- (36) A: Beizi *hen* man.  
 cup HEN full  
 ‘The cup is very full.’  
 B: Cuo! Beizi *bu* *hen* man!  
 wrong cup NEG HEN full  
 ‘Wrong! The cup is not very full!’

- (37) A: Beizi *shi* man-de  
 cup COP full-DE  
 ‘The cup is full.’  
 B: Cuo! Beizi *bu* *shi* man-de  
 wrong cup NEG COP full-DE  
 ‘Wrong! The cup is not full!’

In conclusion, there is a strong intuition that the *hen* form triggers faultless disagreement, and this contrast is particularly obvious when compared with the *shi...-de* counterpart.

### 3.3. Embedding under *ganjue* and *ganjue-dao* ‘find/feel’

PPTs can embed under attitude verb *find*. Kennedy (2013) points out that only subjective predicates like PPTs can embed under *find* with positive forms, while non-subjective adjectives, such as *big*, *large* or *small*, cannot.

- (38) a. Anna finds her bowl of pasta tasty/delicious. (Positive sentences)  
 b. ? Anna finds her bowl of pasta big/large/small.

Mandarin Chinese has two similar verbs, *ganjue* and *ganjue-dao* ‘find/feel’. They have the same verb root *ganjue*, which literally means ‘to feel.’ They are both related to a person’s gut feelings or judgment based on personal experiences. These two verbs are generally not completely acceptable to occur with non-subjective expressions, as shown in (39) and (40) respectively.

- (39)? Afu *ganjue/ganjue-dao* hua shi hong-se de  
 Afu find/feel flower COP red-color DE  
 Int. ‘Afu finds the flower red.’

- (40)?? Afu *ganjue/ganjue-dao* konglong miejue-le  
 Afu find/feel dinosaurs extinct-PERF  
 Int. ‘Afu find/feel that dinosaurs are extinct.’

A feature that *ganjue* and *ganjue-dao* have is that the judge often has low degree of certainty over his statements. Therefore, it is compatible with an expression in which the speaker second guesses himself.

- (41) Wo *ganjue/ganjue-dao* Lisi hen bukekao, dan ye nanshuo.  
 I find/feel Lisi HEN unreliable but still hard-to-say  
 ‘I have the feeling that Lisi isn’t reliable, but it’s hard to say.’

*Ganjue-dao* is often related to evaluation over a specific situation, and it entails an event of direct encounter of the object. *Dao* is a morpheme can be literally translated as ‘to’ or ‘reach’ (Chen and Tao, 2014). When attached to a verb, *dao* adds the meaning that the agent expresses heightened senses and a high degree of transitivity (Chen and Tao, 2014), which is often related to direct perceptual encounters. According to Maienborn (2005), there are several often used diagnostics that can identify an event argument in the predicate position, such as the plausibility of locative and temporal modifiers, and the existence of manner adverbs. *Ganjue-dao* can appear with these three, as shown in (42) to (44) respectively.

#### Locative modifiers:

- (42) Zai zheli Ali *ganjue-dao* ta hen congming.  
 at here Ali find/feel he HEN smart  
 ‘Here Ali had the feeling that he was smart.’

#### Temporal modifiers:

- (43) Xianzai Afu *ganjue-dao* Ali hen mei.  
 Now Afu find/feel Ali HEN beautiful  
 ‘Now Afu feels that Ali is beautiful.’

#### Manner adverbs:

- (44) Afu jianjian *ganjue-dao* Lisi hen congming.  
 Afu gradually feel/find Lisi HEN smart  
 ‘Afu gradually starts to feel that Lisi is smart.’

While *ganjue-dao* is related to direct perceptual experiences, *ganjue* allows guessing based on circumstantial or inferential evidence. Imagine a scenario where Afu has heard people's description of Lisi's build, and how he looks when he stands in a group, but Afu does not know Lisi's exact height, and he has never met him. It is felicitous to say (45) by using *ganjue*. On the contrary, *ganjue-dao* involves an event of actually observing or perceiving the object. Therefore, it is strange to use *ganjue-dao* in the same situation, as shown in (46).

(45) Afu ganjue Lisi hen congming, suiran mei gen ta peng-guo mien.  
 Afu find/feel Lisi HEN smart although NEG with him meet-EXP.PERF face  
 'Afu has a feeling that Lisi is smart, although he never met him face to face.'

(46) Afu ganjue-dao Lisi hen congming, #suiran mei gen ta peng-guo mien.  
 Afu find/feel Lisi HEN smart although NEG with he meet-EXP.PERF face  
 Int. 'Afu feels that Lisi is smart, although he never met him face to face.'

In conclusion, the *hen* sentences are licensed under both *ganjue* and *ganjue-dao*. The *hen* forms can be used to describe observations of direct perceptual encounters, as in the case of *ganjue-dao*, and also possible to have the reading based on inferential information, as shown in the sentences with *ganjue*.

#### 4. The type of subjectivity of *hen*

What kind of subjectivity do *hen* sentences have? I propose that what *hen* contributes to the meaning is a standard that is evaluated by the judge according to his epistemic knowledge. In a sense, it is similar to subjective epistemic modals, which are statements based on speaker's subjective view. Viewing *hen* as parallel to epistemic modals has a second advantage. It explains why *hen* makes a weaker claim than the bare form: sentences with epistemic modals are usually weaker claims than simple statements (Karttunen, 1972; Lyons, 1977; Kratzer, 1991; Groenendijk and Stokhof, 1975; von Stechow and Gillies, 2009; among others). Therefore, a sentence like (47b) is intuitively weaker than (47a), as pointed out by Karttunen (1972).

- (47) a. John left.  
 b. John must have left.

This type of subjectivity is distinct from what is widely discussed in the literature of PPTs. The subjectivity related to PPTs has two well-known features. First, the judge of PPTs should be the direct perceptual experiencer of the evaluated object. Second, a PPT sentence cannot really be denied. On the contrary, the judge of a *hen* sentence does not need to be the direct perceptual experiencer. A *hen* sentence can be denied, as long as there is further evidence to object to the judge's evaluation. These features make *hen* more similar to subjective epistemic modals than PPTs.

#### 4.1. Comparison between *hen* and PPTs

According to Pearson (2013), PPTs requires the judge to be the direct experiencer of the described (stative) event of the object having the property attributed to it. This is shown in the infelicitous sentence (48).

- (48) a. This cake is tasty to John. #But he hasn't tried it.  
 b. This cake is tasty to me. #But I haven't tried it.

However, *hen* does not have the same restriction. It is felicitous to say (49), where the judge does not have direct experiences towards Afu.

- (49) Afu *hen* gao, dan wo mei yu-guo ta.  
 Afu HEN tall but I NEG met-EXP.PERF him  
 'Afu is tall, but I've never met him.'

For the speaker, to know whether Afu is tall does not require him to have perceptual experiences of Afu. This is not surprising, considering that *hen* can appear with a variety of gradable adjectives, not just those related to perceptual experiences.

#### 4.2. Faultless disagreement of *hen* sentences

*Hen* sentences are not really subject to faultless disagreement. If enough information is provided with respect to how the standard is set, a *hen* statement can still be false. This is shown in the conversation in (50).

- (50) A: Afu *hen* gao.  
 Afu HEN tall  
 'Afu is tall.'  
 B: Bu jue-de. Afu bu gao.  
 NEG find Afu NEG tall  
 'I don't think so. Afu isn't tall.'  
 A: Zai san-nianji xiaohai limian, Afu *hen* gao  
 in third-grade children among Afu HEN tall  
 'Among the third grade children, Afu is tall.'  
 B: Cuo-le! Wo jiao-guo de yi-nianji dou bi ta gao.  
 wrong-PERF I teach-EXP.PERF DE first-grade even COMP he tall  
 'Wrong! Even the first grades I taught was taller than him.'  
 A: Na wo xian wo cuo-le  
 then I think I wrong-PERF  
 'Then I guess I was wrong.'

In (50), Speaker A makes a statement that Afu is tall, based on his own understanding. Since it is unclear what his criteria are, there seems to be faultless disagreement. However, when Speaker A further clarifies that he bases his judgment on a group of third graders, the

sentence can be denied by a more knowledgeable person like Speaker B. This is not the case in PPTs. It is infelicitous to negate speaker A's original statement.

- (51) A: Zhe dangao hen haochi.  
           this cake HEN tasty  
           'This cake is tasty.'  
       B: Cuo-le. Youde geng haochi  
           wrong-PERF some better tasty  
           'Wrong! Some are tastier.'  
       A: #Haoba wo jian cuo le  
           Okay I say wrong PERF  
           'Okay. What I said was wrong.'

#### 4.3. Similarity with subjective epistemic modality

Epistemic modals can be subcategorized into subjective and objective modals. According to Lyons (1977), subjective modals are related to personal and likely more incomplete evidence. This is illustrated by a sentence like (52).

- (52) It may rain tomorrow.

When *may* is interpreted subjectively, it is reasoned according to someone's personal experiences. When it is interpreted objectively, it can be based on more solid evidence, such as scientific data (see Lyons, 1977; Drubig, 2001; von Fintel and Iatridou, 2002; von Fintel, 2003; Papafragou 2006; among others). Specifically, Papafragou (2006) views subjective modals as the special cases such that the modal claim is based on the speaker's personal belief alone, as opposed to beliefs shared by both the speaker and the hearer, or by a subset of people.

Although subjective modals are related to the speaker's knowledge or evidence, the statement expressed with a subjective modal can be challenged by other people when new evidence is available (Papafragou, 2006; von Fintel and Gillies, 2009; MacFarlane 2003). This is shown in an example originally from MacFarlane (2003), which is also discussed in Papafragou (2006).

- (53) Sally: Joe might be in Boston.  
       George: He can't be in Boston. I just saw him in the hall five minutes ago.  
       (i) Sally: Oh, then I guess I was wrong.  
       (ii) Sally: Oh, OK. So he can't be in Boston. Nonetheless, when I said "Joe might be in Boston", what I said was true, and I stand by that claim.

The case of *hen* in (50) is similar. When speaker A first makes a *hen* statement, he is talking about evaluation based on his own knowledge. However, when new evidence is added by speaker B about the general height for first grade students, A's knowledge becomes irrelevant. Therefore, the *hen* sentence is parallel with epistemic modal *yiding* 'must', as in (54). Yet this distinction is not acceptable with PPTs, as in (51).

- (54) A: Afu yiding zai jia.  
 Afu must at home  
 ‘Afu must be at home.’  
 B: Cuo-le, Afu lian-fenzhong qian hai zai bangongshi.  
 wrong-PERF Afu two-minute ago still at office  
 ‘Wrong! He was in the office two minutes ago.’  
 A: Haoba wo cai cuo le.  
 Ok I guess wrong PERF  
 ‘Ok, I guess I was wrong.’

### 5. *Hen* and parallelism with *seem* and *appear*

So far, I’ve shown that the *hen* form has several features that need to be accounted for. First, *hen* shows features of subjective predicates, such as triggering faultless disagreement, or at least superficially. Second, it licenses an adjectival predicate to appear with *mei*. Third, it is a standard given by a judge’s knowledge state. Finally, in comparison with the bare form, the *hen* form makes a weaker assertion.

To account for these three features, I propose that *hen* is subjective in the sense that it introduces a standard based on a subjective knowledge state. *Hen* introduces an event of evaluation, in which the judge is the evaluator. As a result, it can be licensed under *mei*. *Hen* is similar to epistemic modality in making a weaker statement when compared with the bare form.

There is an interesting parallelism between *hen* and English verbs like *appear* and *seem*. According to Fernald (2000), these two verbs are related to speaker’s judgment over a situation in an evaluative event, and make a generalization based on his evaluation. This is shown in (55). Adopting Carlsonian sorted types, here *x* is a stage of John, *Q* is some property of John, *G* is the generic quantifier, *y* is a stage realized by *z*, and *z* are individuals that are intelligent in general.

- (55) a. John seems to be intelligent.  
 b.  $\exists Q, x^s [perceive'(Q(x)) \& R(x, j) \& Q(x) \& Gy^s, z^i (Q(y) \& R(y, z)) [intelligent'(z)]]$   
 (Modified from Fernald, 2000: 90)

The meaning of (55) is as follows. There exists some stage-level property *Q*, and a stage  $x^s$ , which refers to the sort of stage objects, such that John is realized as *x*, and there is a perceiving event of *x*, such that *x* has *Q*, and in general, for any stage *y* and any individual *z* such that *z* realizes as *y*, if *y* also has the property *Q*, then *z* is regarded as intelligent.

*Hen* can be analyzed in a similar manner. Here a judge is involved in an event of evaluation, and based on his knowledge, he could determine whether the object being evaluated possesses that property denoted by the gradable adjective.

- (56) a. Afu hen gao  
 Afu HEN tall  
 ‘Afu is tall.’

- b.  $\exists Q, x^s, v^i [R(x, Afu) \& Eval(Q(x))(v) \& Gy^s, z^i (Q(y) \& R(y, z)) [tall'(z)]]$

In (56), there is a property  $Q$ , a stage  $x^s$ , and a judge  $v^i$ , such that the subject  $Afu$  is realized as  $x$ , and there is an evaluation event in which the judge  $v$  evaluates the stage  $x$  of  $Afu$  as having the property of  $Q$ , and for any stage  $y$ , individual  $z$ , if  $z$  is realized as  $y$ , and  $y$  has the property of  $Q$ , then  $z$  is tall.

## 6. Concluding remarks

On the surface, the Mandarin *hen* sentences are just the counterpart of English positive degree sentences. Yet different from English, they show properties of subjectivity. This work try to account for this property by seeing *hen* as introducing subjectivity in a similar manner as subjective modals. What *hen* does is introducing a subjective standard based on a judge's knowledge.

Although viewing *hen* as introducing a subjective standard is different is the traditional view that *hen* is *pos*, my analysis does not refute the idea that *hen* has the same function of *pos* in terms of binding the degree argument and avoiding type mismatches, as well as introducing a standard. The major difference of this analysis only lies in what the standard is based on. While the traditional *pos* analysis only requires a norm function that takes a comparison class and derives a norm from it, what *hen* does is to provide a norm based on a judge's knowledge state. Syntax-wise, *hen* is similar to a copula for avoiding type mismatches. Some languages are known to have different copulas that contrast in terms of subjectivity (de Bruyne, and Pountain, 1995; Maienborn, 2005; Geist, 2005), and the same contrast may also lie in positive degree morphemes.

# Coordination and focus particles (re?)united<sup>1</sup>

Jovana GAJIĆ — *University of Goettingen*

**Abstract.** The aim of this paper is to sketch a unified semantics for coordination markers and focus particles. The main empirical motivation is found in the existence of some ‘multipractic’ particles in Serbian, *ni* and *i*, which serve as coordination markers, additive focus particles and scalar focus particles. A disjunction-based analysis can capture the polarity-sensitive behavior of *ni*, whereas *i* relies on a conjunction semantics. An approach that involves the exhaustification of alternatives is a crucial ingredient. Nonetheless, two types of exhaustification should be allowed — one corresponding to ‘only’ and the other one to ‘even’.

**Keywords:** Negative Polarity Items, coordination, additive focus particles, scalar focus particles, exhaustification.

## 1. Introduction

Most research on coordination examines different aspects of conjunction and disjunction markers, focusing on the problems of their syntactic representation and the possibilities for interpretations based on the logical properties of corresponding connectives (Rooth and Partee (1982); Partee and Rooth (1983); Progovac (1998a, b); Szabolcsi and Haddican (2004); Zamparelli (2011)). Both conjunctions and disjunctions are scope-taking elements, and it is important to determine which constituents they have in their scope, as well as how they scopally interact with other functional expressions in a sentence. Special coordination markers that emerge in negative contexts, such as English ‘neither... nor’ (in (1), Wurmbrand (2008)) or French (*ni... ni* (in (2), González and Demirdache (2015)), have sparked some interest (de Swart (2001); Doetjes (2005); Dagnac (2012); Paperno (2014)).

- (1) Leo ate neither the rice nor the carrots.
- (2) Zoé n’aime \*(pas) le thé ni le café.  
Zoé *NEG*.likes *NEG* the tea *ni* the coffee  
‘Zoé doesn’t like tea nor coffee.’

At the center of attention of the research on this topic is what the logical nature of such connectives is, as well as their (scope) relations with negation. In a similar way, the issue of scope relations with negation and the source of polarity sensitivity are debated for different focus particles, as well:

- (3) (Ian cooked the food.) He washed the dishes too/\*either.

---

<sup>1</sup>I would like to thank the Harvard Linguistics Department, where I spent one semester as a visiting fellow, and especially professor Gennaro Chierchia. I am also thankful to Dorothy Ahn for her inspiring work. In addition, I benefited from a number of interesting suggestions from the anonymous reviewers of SuB21, as well as the participants of the conference. All errors are mine.

- (4) (Ian didn't cook the food.) He didn't wash the dishes either/?\*too.

Among others, Rullmann (2003) and Ahn (2015) discuss the alternation between English 'too' and 'either'. An additive (existential) presupposition is identified as responsible for the contextual restrictions on the distribution of the focus particles in (3) and (4). In the case of scalar focus particles, such as English 'even' (in (5) and (6), Horn (1969)), there is an additional, scalar presupposition that the assertion is less likely than all of its alternatives (Karttunen and Peters (1979)).

- (5) Even Muriel voted for Hubert.

- (6) Not even Muriel voted for Hubert.

Are the three phenomena related in any way and do they have some features in common? What can be observed cross-linguistically is that, in certain cases, one item can perform all of these roles. Along with a 'plain' conjunction marker *i* (8), Serbian<sup>2</sup> disposes with a coordination marker that only surfaces in negative contexts — *ni* (7). Noting their apparent morphological kinship, a starting hypothesis could thus be that *ni* is the polarity sensitive counterpart of *i*.

- (7) Sofija \*(ne) piše (ni) pesme ni priče.  
Sofija<sub>NOM</sub> NEG writes (ni) poems<sub>ACC</sub> ni stories<sub>ACC</sub>  
'Sofija doesn't write poems or stories'

- (8) Sofija (ne) piše (i) pesme i priče.  
Sofija<sub>NOM</sub> NEG writes (and) poems<sub>ACC</sub> and stories<sub>ACC</sub>  
'Sofija (doesn't) write(s) poems and/or stories'

As shown below, the same items can also serve as focus particles (FP), with both additive and scalar interpretations available, depending on the context.

- (9) I Lea je uradila domaći.  
FP Lea<sub>NOM</sub> AUX3Sg do<sub>PART</sub> homework<sub>ACC</sub>  
a. 'Lea did the homework, **too**'  
b. '**Even** Lea did the homework'

- (10) Ni Lea nije uradila domaći.  
FP Lea<sub>NOM</sub> didn't do<sub>PART</sub> homework<sub>ACC</sub>  
a. 'Lea didn't do the homework, **either**'  
b. 'Not **even** Lea did the homework'

This calls for an investigation of the possibility for a unified analysis of all these different uses of *ni* and *i*. The present paper outlines such a unified analysis, where *i* is treated as a conjunc-

<sup>2</sup>The language whose official name I use here, calling it Serbian, corresponds to what is (also) known as Bosnian-Croatian-Montenegrin-Serbian or Serbo-Croatian in the linguistic literature.

tion, but *ni* is a polarity sensitive disjunction, and it is only the nature of the individual members of coordination that differs in different uses — pronounced or silent. First the coordination role of *ni* and *i* will be examined, followed by a proposal of an analysis for *ni*. Next, the focus particle uses of *ni* and *i* will be presented, starting with the additive interpretation and followed by the scalar one, along with the corresponding accounts. Finally, some conclusions about a unified analysis will be laid out.

## 2. Coordination

The present section examines the particle *ni* as a coordination marker, comparing it to *i*.<sup>3</sup>

### 2.1. Distribution

In Serbian, sentential negation is indicated by the preverbal marker *ne* (turning into *ni-* when merging with certain auxiliaries). Being a strict Negative Concord language, the presence of multiple negatively marked expressions in one clause does not yield double negation readings in Serbian (11).

- (11) Niko        nikad    ne jede ništa.  
       NEG-person NEG-time NEG eats NEG-thing  
       ‘Nobody ever eats anything’

The hallmark of the distribution of *ni*-coordination is the requirement for the presence of overt negation in the same clause. Different kinds of phrases can be coordinated by *ni*: DPs<sup>4</sup> (12), NPs (13), PPs (14), VPs (15). *Ni* can appear as a single marker, introducing only the last member of the coordination, but it can also be reiterated, thus one *ni* heading each member of the coordination. When coordinated constituents are preverbal, single *ni* is ungrammatical<sup>5</sup>. Even though single *ni* is acceptable post-verbally, reiterated *ni* is generally preferred in all positions.

- (12) a. \*(Ni) Sofija    ni Lea    ne ide/idu u školu.  
       ni        Sofija<sub>NOM</sub> ni Lea<sub>NOM</sub> NEG go<sub>sg</sub>/go<sub>pl</sub> to school<sub>ACC</sub>  
       ‘Neither Sofija nor Lea go to school’  
       b. Sofija    nije    upoznala ?(ni) mog brata        ni tvoju    sestru.  
       Sofija<sub>NOM</sub> didn’t meet<sub>PART</sub> ni        my<sub>ACC</sub> brother<sub>ACC</sub> ni your<sub>ACC</sub> sister<sub>ACC</sub>  
       ‘Sofija didn’t meet my brother or your sister’
- (13) a. \*(Ni) devojčice ni dečaci    ne vole španać.  
       ni        girls<sub>SNOM</sub>    ni boys<sub>SNOM</sub> NEG like<sub>CP</sub> spinach<sub>ACC</sub>  
       ‘Neither girls nor boys like spinach’

<sup>3</sup>A detailed discussion of the conjunction marker *i* is outside of the scope of the present paper; the reader is referred to Arsenijević (2011).

<sup>4</sup>Both singular and plural agreement on the verb are possible.

<sup>5</sup>Nonetheless, even postverbal subjects coordinated by single *ni* yield strongly degraded sentences.

- b. Sofija ne voli ni španać ni šargarepu.  
 Sofija<sub>NOM</sub> NEG likes ni spinach<sub>ACC</sub> ni carrots<sub>ACC</sub>  
 ‘Sofija doesn’t like spinach or carrots’

 who<sub>NOM AUX3Sg</sub> come<sub>PART</sub> and what<sub>ACC AUX2Sg</sub> see<sub>PART</sub>  
 ‘Who came and what did you see?’

Unlike *ni*, *i* doesn’t have a restricted distribution — it is grammatical in both positive and negative environments, as shown in the examples above. Like *ni*, *i* can also appear as a single or reiterated marker. Nonetheless, single *i* is fully grammatical in all positions, especially when no contrastive focalisation is involved.

Do the apparent morphological kinship between the two coordination markers and their similar distribution indicate that *ni* is to be analyzed as a conjunction? Arsenijević (2011) offers an analysis of Serbo-Croatian connectives (*i*, *a*, *ali*, *ili*, *ni*), focusing on their morphological make-up and the syntax and semantics that can be derived from it, as well as their information structural behavior. In his account, *ni* is described as a negative conjunction, but without weighing in on the possible consequences of such an analysis.

## 2.2. Conjunction or disjunction?

Out of these two coordination markers, *ni* is the one whose status is debatable. For a strict NC language, such as Serbian, two questions emerge:

- Is *ni* inherently negative or semantically non-negative?
- Is it a conjunction or a disjunction?

It has been proposed that *ni* is a negative conjunction (Arsenijević (2011)). Yet, this is only one of the four logical possibilities resulting from the combination of the two relevant questions:

1. If *ni* is an inherently negative disjunction, the presence of a negative operator in each disjunct would predict readings that are not attested for Serbian sentences with *ni* (such as: ‘Lea didn’t eat a sandwich or she didn’t drink yogurt’ for the example in (15a)).
2. If *ni* is a semantically non-negative conjunction, its dependence on the presence of a clausemate negative operator is problematic.
3. If *ni* is an inherently negative conjunction, each conjunct needs to introduce a negative operator of its own.
4. If *ni* is a non-negative disjunction, all disjuncts would have to be in the scope of one negative operator.

Maintaining only options (3.) and (4.), we establish that they are, in fact, predicted to yield logically equivalent interpretations, as stated by one of the de Morgan's equivalences (22):

$$(22) \quad [\neg p] \wedge [\neg q] = \neg[p \vee q]$$

This makes it impossible to tease apart an interpretation of the *ni*-coordination as a conjunction that has negative operators in its scope (23a) from the one where it is a disjunction in the scope of a negative operator (23b), in simple sentences like (23). At the same time, a reading available for negated 'plain' conjunction *i* (in (24)), but not for *ni* (in (23)), is the one where the conjunction is in the scope of sentential negation, as paraphrased in (24b),<sup>6</sup> cf. Arsenijević (2011).

(23) Sofija ne piše (ni) pesme ni priče.

Sofija<sub>NOM</sub> NEG writes (ni) poems<sub>ACC</sub> ni stories<sub>ACC</sub>

a. 'Sofija doesn't write poems and she doesn't write stories'  $[\neg p] \wedge [\neg q]$

b. 'Sofija doesn't write poems or stories'  $\neg[p \vee q]$

(24) Sofija ne piše (i) pesme i priče.

Sofija<sub>NOM</sub> NEG writes (and) poems<sub>ACC</sub> and stories<sub>ACC</sub>

a. 'Sofija doesn't write poems and she doesn't write stories'  $[\neg p] \wedge [\neg q]$

b. 'Sofija doesn't write (both) poems and stories (only one of the two)'  $\neg[p \wedge q]$

Thus, not only have *ni* and *i* a similar morphological make-up, they also have one interpretation in common, in negative sentences. In the case of *i*, there is no reason to doubt the conjunction status of the connective, as it displays both scope orderings with respect to sentential negation. But is there a way to disentangle the two interpretations of *ni* ((23a) vs. (23b)) and determine whether it is a conjunction or a disjunction?

### 2.3. Determining the scope of *ni*

In order to create a more transparent LF, an additional scope-taking element can be inserted in the structure. One possible way is to pick a necessity modal as a 'scope-intervener'. This diagnostic would be parallel to the so-called split-scope readings in Germanic languages (Penka (2010); Zeijlstra (2011)). A necessity modal that is interpreted in the scope of sentential negation allows to test whether *ni* is unambiguously a narrow scope disjunction (25). However, if the modal is outscoped by both the sentential negation and the *ni*-coordination, two equivalent interpretations (26) are again possible.

$$(25) \quad \neg > \Box > [p \vee q]$$

$$(26) \quad \text{a. } \neg [[\Box p] \vee [\Box q]] = \text{b. } [\neg \Box p] \wedge [\neg \Box q]$$

The corresponding readings available for the Serbian example in (27) are paraphrased below:

<sup>6</sup>When *i* is reiterated in the negated sentence in (24), only the reading (24b) is available.

- (27) (Sofija) ne mora ni da kuva ni da čisti.  
 Sofija<sub>NOM</sub> NEG has-to ni<sub>FIN</sub> cook ni<sub>FIN</sub> clean  
 a. (25): ‘it is not necessary that Sofija cooks or cleans’  
 b. i. (26a): ‘it is not the case that it is necessary for Sofija to cook or that it is necessary for Sofija to clean’  
 ii. (26b): ‘it is not necessary for Sofija to cook and it is not necessary for Sofija to clean’

These readings don’t appear to be very distinct from each other, and this is because there is an entailment relation between them: the scopal configuration in (25) entails the ones in (26). It thus needs to be verified whether the only possible reading is the one paraphrased in (27a) or whether the readings in (27b) are independently available. A potential disambiguating scenario would be the following one:

- (28) Sofija’s aunt owns a restaurant and she needs some extra workforce, namely for cooking and cleaning, so Sofija’s mother sends her over to help out during summer holidays. The mother thus obliged Sofija to help her aunt out in the restaurant, but without designating either of the two chores as a particular requirement.

The scenario in (28) renders only (26/27b) true. Importantly, the sentence in (27) is not accepted by native speakers in this scenario, which discards the reading in (27b). This provides evidence for a narrow-scope disjunction account of *ni*, since the only available reading is the one (27a) where *ni* cannot be reanalyzed as a wide scope conjunction.

Intervention with modals speaks in favor of analyzing *ni* as a disjunction in the scope of sentential negation. But is there any further evidence? A second test for teasing apart the two interpretations involves a quantificational adverb as the intervening element, inspired by Shimoyama (2011). An adverb that outscopes sentential negation allows to test whether *ni* is unambiguously a wide scope conjunction (29). Nonetheless, when the adverb outscopes both the sentential negation and the *ni*-coordination, two equivalent interpretations are possible (30).

- (29)  $(Q_{adv} \neg p) \wedge (Q_{adv} \neg q)$

- (30) a.  $Q_{adv} > (\neg p \wedge \neg q) = b. Q_{adv} > \neg(p \vee q)$

If *ni* is a conjunction that has the negative operators in its scope, the interpretation in (29) should be available for the sentence in (31). But the reading in (31b), which can be represented through two logically equivalent LFs, also seems to be available, at first glance.

- (31) Sofija obično nije (ni) kuvala ni čistila.  
 Sofija<sub>NOM</sub> usually didn’t ni<sub>FIN</sub> cook<sub>PART</sub> ni<sub>FIN</sub> clean<sub>PART</sub>  
 a. (29): ‘It was usually not the case that Sofija cooked and it was usually not the case that Sofija cleaned’  
 b. i. (30a): ‘It was usually the case that Sofija didn’t cook and that Sofija didn’t clean’

ii. (30b): ‘It was usually not the case that Sofija cooked or cleaned’

Again, there is an entailment relation between these readings: the one in (31b) entails the one in (31a). In order to check whether the configuration in which *ni* can only be interpreted as a conjunction scoping over negation (31a) is available independently from the other one (31b), a context incompatible with the latter needs to be construed. Such a disambiguating scenario is given in the table in (32) — this state of affairs is compatible only with the interpretation in (31a). The reading in (31b) does not correspond to the distribution given in (32) because there were only two out of six days in which Sofija neither cooked nor cleaned (namely Tuesday and Friday), and this is not the majority of days, thus insufficient for employing ‘usually’. When native speakers are asked to judge, the sentence in (31) turns out to be unacceptable in the distribution depicted in (32). This provides evidence against an analysis of *ni* as a conjunction that outscopes sentential negation.

|      |          |     |     |     |     |     |     |
|------|----------|-----|-----|-----|-----|-----|-----|
| (32) |          | Mon | Tue | Wed | Thu | Fri | Sat |
|      | cooking  | yes | no  | no  | no  | no  | yes |
|      | cleaning | no  | no  | yes | yes | no  | no  |

Tests that rely on more complex quantificational configurations, with necessity modals or quantificational adverbs as potential interveners, show that Serbian *ni* behaves as a disjunction in the scope of a negative operator and not as a conjunction that scopes over negative operators.

An additional argument against a conjunction-based analysis comes from the observation that (*ni...*) *ni* is incompatible with collective predicates, as shown in the examples (33, 34). Furthermore, a predicate of a sentence whose subjects are coordinated by *ni* cannot be overtly modified with ‘together’ (35).

- (33) \* Ni Sofija ni Lea (ni Marko) se nisu sreli u biblioteci.  
 ni Sofija<sub>NOM</sub> ni Lea<sub>NOM</sub> ni Marko<sub>NOM</sub> REFL didn’t meet<sub>PART</sub> in library<sub>LOC</sub>  
 ‘Sofija, Lea and Marko didn’t meet (each other) in the library.’

- (34) \* Ni Sofija ni Lea (ni Marko) nisu oformili tim.  
 ni Sofija<sub>NOM</sub> ni Lea<sub>NOM</sub> ni Marko<sub>NOM</sub> didn’t form<sub>PART</sub> team<sub>ACC</sub>  
 ‘Sofija, Lea and Marko didn’t form a team (together).’

- (35) \* Ni Sofija ni Lea (ni Marko) ne pišu projekte zajedno.  
 ni Sofija<sub>NOM</sub> ni Lea<sub>NOM</sub> ni Marko<sub>NOM</sub> NEG write<sub>PI</sub> projects<sub>ACC</sub> together  
 ‘Sofija, Lea and Marko don’t write projects together’

This would be unexpected for a conjunction-based connective, as they normally exhibit non-Boolean interpretations with coordinated subject NPs/DPs (Champollion (2016)). However, Sofija and Lea (and Marko) cannot be interpreted as a semantic plurality in the examples above.

## 2.4. Strong NPI *ni*

The previous section revealed empirical evidence for a narrow scope disjunction analysis of Serbian *ni*, where it has been shown that this coordination marker must remain in the scope of sentential negation. This finding makes *ni* a good candidate for an NPI<sup>7</sup> (Ladusaw (1979), Chierchia (2013), inter alia), as exemplified for English ‘anyone’ in (36). But NPIs are known to be grammatical in weaker, Downward Entailing (DE) environments,<sup>8</sup> such as the scope of ‘few’ in (37).

(36) Lea didn’t see anyone.

(37) Few students saw anyone.

*Ni*-coordination is ungrammatical in DE contexts, as shown in (38). But this only means that *ni* cannot be analyzed as a weak NPI (Zwarts (1998)).

(38) \*Malo dece voli (ni) španać ni šargarepu.  
 few children<sub>GEN</sub> likes ni spinach<sub>ACC</sub> ni carrot<sub>ACC</sub>  
 ‘Few children like spinach or carrots’

In fact, *ni*-coordination is grammatical only in anti-additive (39) contexts.<sup>9</sup> This makes it a suitable candidate for a strong NPI.

(39) Niko ne voli (ni) španać ni šargarepu.  
 ni-wh<sub>NOM</sub> NEG likes ni spinach<sub>ACC</sub> ni carrot<sub>ACC</sub>  
 ‘Nobody likes spinach or carrots’

What is the syntactic and semantic mechanism that is behind such polarity sensitivity of *ni*?

## 3. Proposal

Building on the work of his predecessors (Kadmon and Landman (1993), Krifka (1995), Gajewski (2002)), Chierchia (2013) argues that the source of polarity sensitivity of NPIs is a logical contradiction that arises when they appear in an upward or non-monotone environment. What distinguishes NPIs from expressions that are not polarity sensitive are the obligatory alterna-

<sup>7</sup>The unclear status of the *ni*-coordination in fragment answers makes an analysis in terms of a pure neg-word (Negative Concord Item) less appealing.

(i) A: Koga si pozvao? B: ??? Ni Lea ni Sofiju.  
 who<sub>ACC</sub> AUX<sub>2sg</sub> invite<sub>PART</sub> ni Lea<sub>ACC</sub> ni Sofija<sub>ACC</sub>  
 A: Who did you invite? B: ??? Neither Lea nor Sofija.

<sup>8</sup>These environments allow for inferences from sets to subsets: ‘Few girls wore dresses’ → ‘Few girls wore blue dresses’.

<sup>9</sup>Such environments satisfy the equivalence:  $f(X \cup Y) \Leftrightarrow f(X) \cap f(Y)$ ; for example — ‘No girls sang or danced’ is equivalent to ‘No girls sang and no girls danced’.

tives that NPIs introduce, as well as the presence of a covert exhaustifying operator. The null head that hosts this operator must be able to value the features present on the NPI, through a feature-checking operation under c-command. The role of the operator is then to negate all the alternatives activated by the NPI that are not entailed by the assertion. In a non-DE context such exhaustification will lead to a contradiction.

Understood through this framework, the polarity sensitive behavior of Serbian *ni* stems from the presence of two formal features  $[\sigma, D]$  which need to be valued by matching features present on a c-commanding operator  $O^S_{[+\sigma, +D]}$ . Once the agreement between  $ni_{[-\sigma, -D]}$  and  $O^S_{[+\sigma, +D]}$  is established, the scalar ( $\sigma$ ) and subdomain (D) alternatives are activated for the *ni*-coordination. The scalar ( $\sigma$ ) alternative for a disjunction is a conjunction (its stronger scalemate), whereas subdomain (D) alternatives are drawn from the individual members of the *ni*-coordination. The role of the  $O^S$  operator is to perform the exhaustification of both scalar and domain alternatives associated with the *ni*-coordination.<sup>10</sup> In other words, all alternatives that are not entailed by the assertion have to be negated. The  $O^S$  operator (40)<sup>11</sup> is thus similar in effect to the focus particle ‘only’.

$$(40) \quad \parallel O_{(\sigma, D)-ALT} \phi \parallel^{g, w} = \parallel \phi \parallel^{g, w} \wedge \forall p \in \parallel \phi \parallel^{(\sigma, D)-ALT} [p \rightarrow \lambda w' \parallel \phi \parallel^{g, w'} \subseteq p]$$

When (*ni*...) *ni* is found in a positive sentence (41), the exhaustified alternatives end up being incompatible with the assertion (42a). Namely, the result of the exhaustification performed by  $O^S$  (42e) states that neither of the individual disjuncts ( $p, q$ ) is true, but the assertion says that (at least) one of them must be true (due to the meaning of the disjunction). This yields a clear contradiction, as shown in (42e).

- (41) \*Sofija piše (ni) pesme ni priče.  
 Sofija<sub>NOM</sub> writes (ni) poems<sub>SACC</sub> ni stories<sub>SACC</sub>  
 ‘Sofija writes *ni* poems *ni* stories’

- (42) a. Assertion:  $O^S(p \vee q)$   
 b. where  $p$  = ‘Sofija writes poems’ and  $q$  = ‘Sofija writes stories’  
 c. Scalar ( $\sigma$ ) alternatives:  $p \wedge q$   
 d. Subdomain (D) alternatives:  $p, q$   
 e. After EXH:  $(p \vee q) \wedge \neg(p \wedge q) \wedge \neg p \wedge \neg q$

Sets of scalar and subdomain alternatives are posited for the ‘plain’ disjunction (such as English ‘or’), as well (Sauerland (2004); Fox (2007)). What makes the difference in the case of NPIs, such as *ni*, is that these alternatives are always present and must invoke the presence of an exhaustifying operator. This is due to the agreement operation between the covert ONLY-operator and *ni*, which is required for the syntactic grammaticality of the sentence. But this restricts a *ni*-coordination to anti-additive contexts, such as the sentential negation in (43), since it is logically sustainable only in such scale-reversing environments. Plain disjunction

<sup>10</sup>Arsenijević (2011) also mentions a ‘Domain-Broadening effect’, referring to Chierchia (2006), introduced by the combination of the negative marker component *n-* and the additive *i* in *ni*.

<sup>11</sup>Modified from Chierchia (2013), p.138.

‘or’, for example, does not have such a restricted distribution, since its sets of alternatives are not necessarily active.

- (43) Sofija ne piše (ni) pesme ni priče.  
 Sofija<sub>NOM</sub> NEG writes (ni) poems<sub>ACC</sub> ni stories<sub>ACC</sub>  
 ‘Sofija doesn’t write poems or stories’
- (44) a. Assertion:  $O^S \neg(p \vee q)$   
 b. where  $p$  = ‘Sofija writes poems’ and  $q$  = ‘Sofija writes stories’  
 c. Scalar ( $\sigma$ ) alternatives:  $\neg(p \wedge q)$   
 d. Subdomain (D) alternatives:  $\neg p, \neg q$   
 e. After EXH:  $\neg(p \vee q)$

In contrast, when a negative environment hosts *ni*-coordination (43), the exhaustification of alternatives turns out to be vacuous (44e). This time, the assertion (44a) is the strongest of all the alternatives, i.e. it entails all the other alternatives — scalar (44c), as well as subdomain (44d), so there is no alternative to be negated. Crucially, after the syntactic agreement is effectuated and the sets of alternatives activated, no logical contradiction arises.

### 3.1. Why ‘strong’?

If a scale-reversing context prevents the logical contradiction to arise due to the presence of an NPI, it is still unclear why *ni*-coordination needs an anti-additive environment and why it is not acceptable in a weaker DE context. Following Gajewski (2011), Chierchia (2013) argues that it is not the anti-additivity to be held responsible for this. He introduces a parametric switch manifested in the so-called strong exhaustification, performed by  $O^S$ . Instead of exhaustifying only subdomain alternatives,<sup>12</sup>  $O^S$  is sensitive to the scalar alternatives as well. But, once it is invoked, the  $O^S$  operator cannot remain blind to the potential alternatives of other scalar elements that can be found in the same sentence. As a result, when found in the scope of an alternative-sensitive operator at LF, even scalar items which do not obligatorily carry active sets of alternatives, such as the quantifier ‘few NP’, have their scalar alternatives activated, for example, ‘some NP’. For this reason, (*ni...*) *ni* is ungrammatical in DE contexts such as the scope of ‘few NP’ in (45) — ‘few children like *x*’ gives rise to an additional implicature that ‘some children like *x*’ and this positive implicature provokes a contradiction, as shown in (46e).<sup>13</sup>

- (45) \*Malo dece voli (ni) španać ni šargarepu.  
 few children<sub>GEN</sub> likes ni spinach<sub>ACC</sub> ni carrot<sub>ACC</sub>  
 ‘Few children like spinach or carrots’

<sup>12</sup>This would, in fact, be sufficient to account for weak NPIs, since negating their scalar alternative in a positive context wouldn’t lead to a contradiction — ‘It is not the case that Sofija writes poems and stories’ is not incompatible with ‘Sofija writes poems or stories’, it is merely an implicature that would arise obligatorily.

<sup>13</sup>Along with its scalar alternatives, subdomain alternatives are also triggered for FEW, however, this is not exemplified here, as scalar alternatives suffice to make the point.

- (46) a. Assertion:  $O^S \text{FEW}_{ch} (P \text{ OR } Q)$   
 b. where  $P$  = ‘like spinach’,  $Q$  = ‘like carrots’, and  $\text{FEW}_{ch}$  = ‘few children’  
 c. Scalar ( $\sigma$ ) alternatives:  $\text{FEW}_{ch} (P \text{ AND } Q)$ ;  $\text{NO}_{ch} (P \text{ OR } Q)$ ,  $\text{NOT-ALL}_{ch}(P \text{ OR } Q)$ ,...  
 d. Subdomain ( $D$ ) alternatives:  $\text{FEW}_{ch} P$ ,  $\text{FEW}_{ch} Q$   
 e. After EXH:  $\text{FEW}_{ch} (P \text{ OR } Q) \wedge \text{FEW}_{ch} (P \text{ AND } Q) \wedge \neg \text{NO}_{ch} (P \text{ OR } Q) \wedge \text{NOT-ALL}_{ch}(P \text{ OR } Q) = \text{FEW}_{ch} (P \text{ OR } Q) \wedge \text{FEW}_{ch} (P \text{ AND } Q) \wedge \text{SOME}_{ch} (P \text{ OR } Q) \wedge \text{NOT-ALL}_{ch} (P \text{ OR } Q)$

Strong exhaustification thus takes into account not only the truth-conditional component of the meaning, but also the presuppositions and the implicatures. This is why strong NPIs are not acceptable in DE contexts, since additional scalar implicatures may arise and yield a contradiction after exhaustification. In contrast, weak NPIs are not coupled with an operator that performs strong exhaustification  $O^S$ , but with a ‘plain’ operator  $O$ , which looks only at the truth-conditional component of meaning and neglects presuppositions and implicatures.

### 3.2. What about *i*?

The conjunction *i* does not carry obligatory sets of scalar and subdomain alternatives (for whose activation the formal features  $[\sigma]$  and  $[D]$  are in charge). Therefore, as a coordination marker, *i* does not depend on the presence of an exhaustification operator, nor a scale-reversing environment for that matter. Activation of these alternatives is, nonetheless, possible, the difference with respect to *ni* being that it is not obligatory for *i*.

## 4. Focus particles

As exemplified in the introduction of this paper, both *i* and *ni* can serve as focus particles. Depending on whether the set of focal alternatives entailed by the previous context is ordered on a likelihood scale or a simple unordered set, the contribution to the interpretation is, respectively, that of a scalar or an additive focus particle. The present section argues that an ‘even’-based exhaustification is thus needed for both particles in their scalar focus particle incarnation.

### 4.1. Additive focus particles *i* and *ni*

As an additive focus particle, *i* can associate with constituents of different kinds and activate the corresponding unordered sets of focus alternatives ((47a) for the example in (47b)).<sup>14</sup> Following Ahn (2015)’s analysis of English ‘too’, *i* is analyzed as a conjunction which, this time, takes as its arguments the host proposition  $p$  and a silent anaphor  $q$  (48), where  $q$  is a member of the focus value (Rooth (1992)) of  $p$ . This means that, when the conjunction *i* lacks overt multiple conjuncts, one of its members of coordination remains covert, and this is the null anaphor. Due to the presence of the anaphor, a salient antecedent must be available in the preceding context

<sup>14</sup>Serbian is a pro-drop language.

in order for the sentence with an additive *i* to be felicitous. The anaphor *q* thus must be entailed by a member of the set of alternatives in the focus value of *p* (Rullmann (2003)), and this alternative must be distinct from *p* (Kripke (2009)). No exhaustification takes place, since *i* does not carry any formal features in charge of activating scalar and subdomain alternatives.

- (47) a. ‘She washed the dishes’, ‘She fed the dog’, ‘She practised the piano’...  
 b. I domaći je uradila.  
 also homework<sub>ACC</sub> AUX3Sg do<sub>PART.F</sub>  
 ‘She also did the homework’

- (48) Assertion:  $p \wedge q$

*Ni* also serves as an additive focus particle, but one that only appears in anti-additive contexts, similar to English ‘either’. In this use, single *ni* attaches to a focalized constituent and activates the corresponding unordered set of alternatives ((49a) for (49b)). Additive focus particle *ni* is infelicitous in the absence of a negative contextual antecedent.

- (49) a. ‘She didn’t wash the dishes’, ‘She didn’t feed the dog’, ‘She didn’t practise the piano’...  
 b. Ni domaći nije uradila.  
 (n)either homework<sub>ACC</sub> didn’t do<sub>PART.F</sub>  
 ‘She didn’t do the homework, either’

This is due to the presence of a silent anaphor in the semantics of focus particle *ni*, which must be entailed by a member of the set of focus alternatives of the host proposition. *Ni* is analyzed as a disjunction which takes as its arguments the host proposition *p* and the silent anaphor *q* (following Ahn (2015)’s proposal for ‘either’ in English). The difference between *ni*-coordination and *ni* additive particle is that in the latter case one disjunct is covert.

The polarity sensitivity of the additive focus particle *ni* is predicted by its disjunctive nature. Even in the absence of overt multiple members of the coordination, *ni* carries the formal features  $[\sigma, D]$  in charge of activating scalar and subdomain alternatives. The same exhaustification mechanism is at work and it applies vacuously in a negative environment (50), such as in the example in (49b). This is due to the fact that the assertion (50a) is the strongest alternative (50e).

- (50) a. Assertion:  $O^S \neg(p \vee q)$   
 b. where  $p$  = ‘She did the homework’ and  $q \in [[p]]^F$   
 c. Scalar ( $\sigma$ ) alternatives:  $\neg(p \wedge q)$   
 d. Subdomain (D) alternatives:  $\neg p, \neg q$   
 e. After EXH:  $\neg(p \vee q)$

Additive focus particle *ni* is unacceptable in a positive sentence (51) for the same reason as the coordination marker *ni* — a contradiction arises between the assertion and the exhaustified

alternatives (52e).

- (51) \*Ni domaći je uradila.  
 (n)either homework<sub>ACC</sub> AUX3Sg do<sub>PART.F</sub>  
 ‘\*She did the homework, either’
- (52) a. Assertion:  $O^S(p \vee q)$   
 b. where  $p$  = ‘She did the homework’ and  $q \in [[p]]^F$   
 c. Scalar ( $\sigma$ ) alternatives:  $p \wedge q$   
 d. Subdomain (D) alternatives:  $p, q$   
 e. After EXH:  $(p \vee q) \wedge \neg(p \wedge q) \wedge \neg p \wedge \neg q$

It turns out that the coordination and the additive focus particle use of *(n)i* can be treated on a par, if the status of the arguments that they take as a conjunction or a disjunction is allowed to be different — either an overt member of the coordination or a silent anaphor.

#### 4.2. Scalar focus particles *i* and *ni*

When used as focus particles, *ni* and *i* can have either an additive or a scalar contribution to the meaning of the sentence. The flip from the former to the latter is made once the set of focus alternatives becomes ordered on a likelihood scale, as exemplified for *i* in (53) and for *ni* in (54).

- (53) a. ‘She did the homework’ < ‘She washed the dishes’ < ‘She fed the dog’...  
 b. (Čak) i domaći je uradila.  
 even even homework<sub>ACC</sub> AUX3Sg do<sub>PART.F</sub>  
 ‘She even did the homework’
- (54) a. ‘She didn’t do the homework’ < ‘She didn’t wash the dishes’ < ‘She didn’t feed the dog’...  
 b. (Čak) ni domaći nije uradila.  
 even even homework<sub>ACC</sub> didn’t do<sub>PART.F</sub>  
 ‘She didn’t even do the homework’

The importance of the context is essential — the distinction between an additive and a scalar use of these particles depends solely on whether the alternatives are ordered or not, and this information can be retrieved from the context. The interpretation of *ni* and *i* as scalar focus particles requires emphasis and heavy stress is needed on the associate of the particle. Some other circumstances that can enforce this are information structural effects and the addition of an ‘even’-like particle in Serbian — *čak*.<sup>15</sup> As for the latter, the presence of *čak* is possible, but

<sup>15</sup>In the case of the scalar focus particle *i*, the universal quantifier *sve* (= ‘everything’) can marginally be used instead of *čak*.

not necessary. As a rough generalization, this additional particle is needed when the constituent that  $(n)i$  is attached to is topicalized.<sup>16</sup>

Is there an account for the scalar uses of  $i$  and  $ni$  that would be parallel to the one proposed in the previous section for the additive uses? Recall that we made use of conjunctions and disjunctions of the assertions and some propositional anaphors, respectively. ONLY-exhaustification was then used to explain the restricted distribution of  $ni$ . The difference that exists between the additive and the scalar use of these focus particles requires a different operator, one that can capture the scalar ordering of alternatives. An operator modelled after ‘even’ has been proposed by Chierchia (2013):

- (55)  $E_{ALT}(p) = p \wedge \forall q \in ALT [p <_{\mu} q]$   
 where ‘ $p <_{\mu} q$ ’ says that  $p$  is less likely than  $q$  with respect to some contextually relevant probability measure  $\mu$

When applied to the examples above ((53) and (54)), such EVEN-exhaustification looks like (56) and (57), respectively.

- (56) Scalar focus particle  $i$
- Assertion:  $E(p \wedge q)$
  - where  $p =$  ‘She did the homework’ and  $q \in [[p]]^F$
  - After EXH:  $p \wedge q \wedge p <_{\mu} q$
- (57) Scalar focus particle  $ni$
- Assertion:  $\neg E^S(p \vee q)$
  - where  $p =$  ‘She did the homework’ and  $q \in [[p]]^F$
  - Scalar ( $\sigma$ ) alternatives:  $\neg(p \wedge q)$
  - Subdomain (D) alternatives:  $\neg p, \neg q$
  - After EXH:  $\neg(p \vee q \vee p <_{\mu} q) = \neg p \wedge \neg q \wedge \neg p <_{\mu} \neg q$

The  $E$  operator is invoked to signal that the assertion is the least likely among the relevant alternatives. Such a mechanism is needed both for the scalar focus particle  $i$  (56) and for the scalar focus particle  $ni$  (57). This is the first time that some sort of exhaustification is needed for both the polarity sensitive ( $ni$ ) and the ‘plain’ item ( $i$ ). Note that, distributionally, these two expressions obey the same restrictions when they are scalar focus particles, as when they are additive focus particles — that is,  $ni$  is only grammatical in anti-additive contexts.

As a disjunction bearing  $[-\sigma, -D]$  features,  $ni$  gets checked and valued by a c-commanding  $E_{[-\sigma, +D]}$  operator.  $E^S$  activates a set of parallel, focus alternatives, ordered with respect to some contextually salient probability measure  $\mu$ . In the case of the scalar use of  $i$ , the result of the exhaustification (56c) assures not just that both the assertion and the propositional anaphor hold (as with the additive use), but also that the former is less likely than the latter. As for the

<sup>16</sup>It feels more natural to have the word order used in the examples (53b) and (54b) when scalarity is invoked without the help of the ‘even’-like particle *čak*, although other word orders also seem to be possible.

scalar use of *ni*, after exhaustification we get that not only the assertion and the propositional anaphor do not hold, but also the assertion not holding is less likely than any focus alternative not holding.

This proposal would capture one of the two possible interpretations of (53b), namely the scalar one, where Lea did the homework, she did something else as well, and Lea doing the homework was the least likely thing she could do. As for (54b), its scalar interpretation corresponds to: it is not the case that Lea did the homework, it is not the case that she did something else, and Lea not doing the homework was the least expected thing.

What is the link between the ONLY and the EVEN-exhaustification? In other words, why are these two mechanisms united in different interpretations of the same expressions? At first glance, there is nothing connecting the two types of exhaustification or the natural language expressions they are modelled after ('only' and 'even'). But notice that 'only' can acquire emphasis and receive a richer meaning than the one that is canonically attributed to it:

(58) I can only imagine what it looked like!

(59) He managed to read only one book (out of 50 that were on the list)!

In the above examples we see that the focus particle 'only' can, in addition to its regular exceptive meaning, implicate that the alternative that constitutes the assertion is the most likely. It means that this focus particle is also capable of expressing scalar ordering between different alternatives, under heavy emphasis, although it represents the mirror image of 'even' in positive contexts ('least likely' vs. 'most likely'). However, in the case of additive focus particles *ni* ('either') and *i* ('also'), we are not dealing with an overt 'only' particle, but with an 'only'-like exhaustification whose mechanism is fixed (40). It is thus still unclear how the switch from ONLY to EVEN exhaustification happens in one and the same item, if their mechanisms are fixed and essentially different from each other (with or without a probability measure).

## 5. Conclusions

This paper tried to provide a unified analysis for *ni* as a coordination marker and *ni* as a focus particle, since the source of their polarity sensitivity is identified as the same — their disjunctive nature in combination with the sets of alternatives they obligatorily introduce. Serbian particle *ni* is analyzed as a strong NPI disjunction that is always found in the scope of a negative operator and whose alternatives must be exhaustified. Scope diagnostics with necessity modals and quantificational adverbs provide additional evidence for the disjunction-based analysis of *ni*. Its polarity sensitive behavior results from its lexical specification — the particle must agree with a c-commanding silent operator, which makes the subdomain and scalar alternatives active and subject to exhaustification. The present account of different roles in grammar performed by *ni* is related to the distributionally non-restricted conjunction *i*, which also acts as an additive and a scalar focus particle.

The paper shows, on the case of *ni*, that an alternatives and exhaustification approach can also

be useful for analyzing polarity sensitive coordination markers. Crucially, it fits with the rest of the framework, since the lowest scalar elements exhibit negative polarity in all described cases (indefinites, modals, and now a disjunction).

Diachronic studies in the field of coordination strategies cross-linguistically report a common additive origin for a number of Indo-European conjunctions and additive particles (Goldstein (2016)), Old Church Slavonic *i* being among them. The reasoning is the following: if the additive particle is indeed a binary operator, as soon as the antecedent of the silent anaphor is immediately preceding the host in the discourse, the additive particle is easily reanalyzed as a conjunction. However, the opposite reasoning could also hold — such particles are used as coordinators at first (as advanced by Szabolcsi (2016)), and once the structure is left with only one member of the coordination, another one must be understood as silent, in order to rescue the meaning of the sentence.

# A uniqueness puzzle: *How many*-questions and non-distributive predication<sup>1</sup>

Francesco Paolo GENTILE — *McGill University*

Bernhard SCHWARZ — *McGill University*

**Abstract.** We discuss a novel observation about the meaning of *how many*-questions, viz. a uniqueness implication that arises in cases that feature non-distributive predicates, such as *How many students solved this problem together?*. We attempt an analysis of this effect in terms of Dayal's (1996) *Maximal Informativity Presupposition* for questions. We observe that such an analysis must be reconciled with the unexpected absence of uniqueness implications in cases where the non-distributive predicate appears under a possibility modal. We explore two possible solutions: (i) the postulation of a scopally mobile maximality operator in degree questions of the sort proposed in Abrusán and Spector (2011); (ii) the proposal that the informativity to be maximized is based on pragmatic, contextual, entailment rather than semantic entailment. We explain why neither solution is satisfactory. We also observe that a Maximal Informativity Presupposition fails to capture uniqueness implications in *how many*-questions with predicates that are weakly distributive in the sense of Buccola and Spector (2016), such as *How many students in the seminar have the same first name?*. We conclude that uniqueness implications in *how many*-questions must have a source that is independent of Dayal's (1996) Maximal Informativity Presupposition.

**Keywords:** *how many*-questions, uniqueness presuppositions, non-distributive predication, Maximal Informativity Presupposition.

## 1. Introduction

Recent work posits that questions come with a *Maximal Informativity Presupposition* (MIP, Dayal 1996). The MIP is stated informally in (1), where an answer is to be understood as a member of the question extension under the Hamblin/Karttunen analysis of questions, the set of so-called Hamblin/Karttunen answers (Hamblin 1973, Karttunen 1977).

- (1)   Maximal Informativity Presupposition (MIP)  
      A question presupposes that it has a true answer that semantically entails any other true answer.

Dayal (1996) proposed the MIP in order to capture the uniqueness presupposition carried by singular *which* questions. It has since played a prominent role in the analysis of so-called weak islands (Fox and Hackl 2006, Schwarz and Shimoyama 2011, Abrusán and Spector 2011, Abrusán 2011, 2014).

---

<sup>1</sup>For comments and discussion, we would like to thank audiences at the 9th Toronto-Ottawa-Montreal Semantics Workshop, Sinn und Bedeutung 21, and Theoretical Linguistics at Keio (TaLK) 2016, especially Itai Bassi, Aron Hirsch, Manfred Krifka and Mats Rooth; the members of the Semantics Research Group at McGill, especially Junko Shimoyama and Michael Wagner; and Brian Buccola. This research was supported by the Social Sciences and Humanities Research Council of Canada (SSHRC, grants #435-2016-1448 and #435-2013-0592).

In this paper, we discuss a phenomenon which, at first sight, is naturally interpreted as another symptom of the MIP, viz. uniqueness presuppositions that arise from *how many*-questions with non-distributive predicates. The phenomenon is illustrated by (2).

(2) How many students solved this problem together?

A questioner who already assumes that two or more student groups of different sizes solved the problem will not consider (2) a fully appropriate vehicle for requesting information about the exact sizes of those groups; and an addressee who believes that two or more student groups of different sizes solved the problem will likewise judge (2) as not fully appropriate. In short, the question is judged to carry the presupposition that there is a unique size of student groups who solved this problem.<sup>2</sup>

Under familiar assumptions about *how many*-questions (Beck and Rullmann 1999), the set of Hamblin/Karttunen answers to (2) contains, for any cardinality  $n$ , the propositions that there is a group of  $n$  students who solved this problem together. We note that none of these Hamblin/Karttunen answers are related by semantic entailment. For different cardinalities  $n$  and  $m$ , the propositions that there is a group of  $n$  students who solved this problem together and the propositions that there is a group of  $m$  students who solved this problem together are semantically independent. As a consequence, the MIP is true if and only if exactly one of these Hamblin/Karttunen answers is true, hence if and only if there is exactly one cardinality  $n$  such that there is a group of  $n$  students who solved this problem together. This straightforwardly captures the uniqueness effect described above, which therefore appears to present a novel instantiation the MIP in (1).

A puzzle arises under this analysis from the study of examples that feature modal operators. In (3), example (1) is modified by embedding the *wh*-phrase's scope under the deontic possibility modal *allowed*. Clearly, this question does *not* presuppose that there is only one cardinality  $n$  such that it is allowed that a group of  $n$  students solves this problem.

(3) How many students are allowed to solve this problem together?

Yet this unattested uniqueness presupposition is precisely what the MIP derives. The reason is that in this case, too, the Hamblin/Karttunen answers are not related by entailment. For different cardinalities  $n$  and  $m$ , the propositions that it is allowed for  $n$  students to solved this problem together and the propositions that it is allowed for  $m$  students to solved this problem together are again semantically independent. What, then, accounts for the contrast between (2) and (3)?

In this paper, we explore two answers to this question. The first answer enriches the syntax-semantics of *how many* questions by positing a scopally mobile maximality operator of the

<sup>2</sup>We are not the first to study *how many*-questions with non-distributive predicates (Beck and Rullmann 1999, Abrusán 2014). However, to our knowledge previous work confined attention to examples with possibility modals, such as Beck and Rullmann's example *How many people can play this game?*. As we will discuss shortly, possibility modals obviate the uniqueness effect just described, which explains why no uniqueness effects were reported in those works.

sort posited in Abrusán and Spector (2011); the second answer proposes that for the purposes of the MIP, the proper notion of informativity is contextually supported entailment rather than semantic entailment. Unfortunately, however, we find that both solutions fall short of properly characterizing the relevant data, mischaracterizing the conditions under which the uniqueness effect arises in (2) or (3). In addition, we observe that a Maximal Informativity Presupposition fails to capture uniqueness implications in *how many*-questions with predicates that are weakly distributive in the sense of Buccola (2015) and Buccola and Spector (2016), such as *How many students in the seminar have the same first name?*. We conclude that, despite initial appearance, uniqueness implications in *how many*-questions must have a source that is independent of Dayal's (1996) Maximal Informativity Presupposition.

## 2. On the syntax-semantics of *how many*-questions

We adopt assumptions about the syntax and semantics of *how many*-questions familiar from, for example, Beck and Rullmann (1999). We assign to our running example (2) the logical form in (4), where *spt* abbreviates *solved this problem together*.

$$(4) \quad \text{how } \lambda n [ \exists [n \text{ many}] \text{ students} ] \text{ spt}$$

In (4), the *wh*-phrase *how* has extracted from the argument position of *many*; *wh*-movement leaves behind a trace *n* ranging over degrees or, more specifically, cardinalities; the phrase *n many students* is taken to form an existential generalized quantifier, headed by the silent existential determiner  $\exists$ ; finally, *wh*-movement of *how* creates a derived predicate of cardinalities.

Again following Beck and Rullmann (1999), we take *many* to denote a relation between cardinalities and individual sums in the sense of Link (1983), which for ease of exposition we also refer to as *groups*. (Note that a group may consist of just one atomic individual.) As shown in (5), we take *many* to relate a cardinality *n* to a group *x* just in case the cardinality of *x* (i.e., the number of atomic individuals in *x*) equals *n*.

$$(5) \quad \llbracket \text{many} \rrbracket = \lambda n_d. \lambda x_e. \lambda w_s. |x| = n$$

The lambda abstract in (4) will accordingly denote the property of cardinalities in (6), which maps any cardinality *n* to the proposition that there is a group of size *n* that solved this problem.

$$(6) \quad \lambda n_d. \lambda w_s. \exists x [\llbracket \text{students} \rrbracket (x)(w) \wedge \llbracket \text{spt} \rrbracket (x)(w) \wedge |x| = n]$$

For ease of exposition, we adopt the so-called functional approach to the semantics of questions (Krifka 2011), that is, we assume that the property in (6) is also the denotation of the question in (2) as a whole. Under this assumption, the set of Hamblin/Karttunen answers to a *how many*-question (or any *wh*-question) is the set of propositions that forms the range of the question's denotation.

### 3. The uniqueness effect

Before we turn to the analysis of the uniqueness effect described in section 1, we briefly elaborate on the nature of this effect. According to our description above, (2) presupposes that there is a *unique size* of student groups that solved the problem together. However, some speakers judge (2) to even carry the presupposition that there is a *unique group* of students who solved the problem together. We will refer to these two presuppositions as the *uniqueness of size* and the *uniqueness of group* presupposition, respectively. Note that the uniqueness of group presupposition is stronger than the uniqueness of size presupposition: if there is only one group who solved the problem, then there is a unique size of student groups who solved it, viz. the size of that unique group; however, the reverse entailment does not hold, as there could be several groups of the same size who solved the problem.

Whether or not (2) indeed carries an (obligatory) uniqueness of group presupposition, we will in this paper focus on the weaker uniqueness of size presupposition, whose existence we take not to be in doubt. However, we will briefly return to the potential uniqueness of group presupposition, and its significance for the puzzle we describe, in section 9 at the very end of this paper.

### 4. An account of the uniqueness effect

For any given question, the MIP stated in (1) requires that the question have a true Hamblin/Karttunen answer that entails any other true Hamblin/Karttunen answer. Under the functional question semantics that we have adopted, the MIP can be characterized as the proposition that there is a true proposition in the question denotation's range that entails any other true answer in the range. This is stated in (7), where the variable  $x$  ranges over members of the domain of the question denotation, which in the case of *how many*-questions is the set of cardinalities.

- (7) For any (functional) question denotation  $Q$ :
- $$\text{MIP}(Q) = \lambda w_s. \exists x[Q(x)(w) \wedge \forall y[Q(y)(w) \rightarrow Q(x) \subseteq Q(y)]]$$

We observed in section 1 that the Hamblin/Karttunen answers to (2) are not related by entailment. For the denotation in (6), this means that it is *non-ordering* in the sense of (8): no proposition in the question denotation's range entails any other proposition in that range.

- (8) Non-orderingness
- $$f \text{ is non-ordering} :\Leftrightarrow \forall x, y[f(x) \neq f(y) \rightarrow f(x) \not\subseteq f(y)]$$

The denotation in (6) is non-ordering because, as noted, for different cardinalities  $n$  and  $m$ , the proposition that there is a group of  $n$  students that jointly solved this problem and the proposition that there is a group of  $m$  students that jointly solved this problem are semantically independent.

The central observation, as stated in (9), is now that for a non-ordering question denotation, the MIP encodes a uniqueness presupposition: if all the propositions in the range of the question

denotation are unrelated by entailment, then the MIP requires that there be at most (and at least) one of them that is true.

- (9) For any non-ordering question denotation  $Q$ :  

$$\text{MIP}(Q) = \lambda w_s. \exists x[Q(x)(w) \wedge \forall y[Q(y)(w) \rightarrow Q(x) = Q(y)] ]$$

For (2), the MIP therefore yields the proposition that exactly one proposition in the range of (6) is true, which we can describe as in (10), as the proposition that there is exactly one cardinality  $n$  such that a group of  $n$  students solved this problem together. In other words, the MIP delivers the uniqueness of size presupposition described above.

- (10)  $\lambda w_s. \exists! n[\exists x[\llbracket \text{students} \rrbracket(x)(w) \wedge \llbracket \text{spt} \rrbracket(x)(w) \wedge |x|=n] ]$

Note that the non-orderingness of the denotation of (2) is due to the semantic behaviour of the predicate *solved this problem together*. The property expressed by this predicate is itself non-ordering: for any two distinct groups  $x$  and  $y$ , the proposition that the members of  $x$  solved the problem together fails to entail the proposition that the members of  $y$  solved the problem together.

Of course, not all predicates are non-ordering. To illustrate, we contrast (2) with (11), where *solved this problem together* is replaced by *laughed*.

- (11) How many students laughed?

The properties expressed by *laugh* and *students* are distributive in the sense of (12), where  $\sqsubseteq$  is the mereological part-of relation between groups of individuals. For any two groups of individuals  $x$  and  $y$  such that  $x$  is included in  $y$ , the proposition that  $y$  are students (or is a student) who laughed entails the proposition that  $x$  are students (or is a student) who laughed. This keeps the denotation of the logical form (13a), shown in (13b), from being non-ordering. In fact, distributivity ensures that (13b) is *downward scalar* in the sense of (14) (Beck and Rullmann 1999).<sup>3</sup>

- (12) Distributivity  

$$f \text{ is distributive} : \Leftrightarrow \forall x,y[x \sqsubseteq y \rightarrow f(y) \subseteq f(x)]$$
- (13) a. how  $\lambda n[ \exists [n \text{ many}] \text{ students}] \text{ laughed}$   
 b.  $\lambda n_d. \lambda w_s. \exists x[\llbracket \text{students} \rrbracket(x)(w) \wedge \llbracket \text{laughed} \rrbracket(x)(w) \wedge |x| = n]$
- (14) Downward scalarity  

$$f \text{ is downward scalar} : \Leftrightarrow \forall n,m[m \leq n \rightarrow f(n) \subseteq f(m)]$$

<sup>3</sup>Since it presupposes reference to the intrinsic ordering of cardinalities or other degrees, the notion of downward scalarity selectively applies to the denotations *how many*-questions and other degree questions, not to question in general.

The denotation in (13b) is downward scalar because, given distributivity of *students* and *laughed*, the existence of a group of  $n$  students who laughed guarantees the existence of a group of  $m$  students who laughed, for any  $m \leq n$ ; hence for any such  $n$  and  $m$ , the proposition that there is a group of  $n$  students who laughed semantically entails the proposition that there is a group of  $m$  students who laughed. Consider now the set of cardinalities that a given downward scalar question denotation maps to a true proposition. Suppose that this set has a (unique) maximal element. The downward scalar function will map that maximal element to a proposition that entails all the other true propositions in its range, and hence the MIP will be met; so, as stated in (15), the MIP will merely require that the set of cardinalities that the question denotation maps to a true proposition have a maximal member in terms of the intrinsic ordering of cardinalities.

- (15) For any downward scalar question denotation  $Q$ :  

$$\text{MIP}(Q) = \lambda w_s. \exists n[Q(n)(w) \wedge \forall m[Q(m)(w) \rightarrow m \leq n] ]$$

But in order for a set of cardinalities to have a (unique) maximal member, all it takes is for that set to be non-empty and finite. Applied to the downward scalar denotation of (11) in (13b), the MIP therefore yields the proposition stated in (16), the presupposition that there is a group of students of some (finite) size who solved this problem together.

- (16)  $\lambda w_s. \exists n[\exists x[\llbracket \text{students} \rrbracket(x)(w) \wedge \llbracket \text{laugh} \rrbracket(x)(w) \wedge |x|=n] ]$

So in this case, the MIP amounts to a mere existence presupposition. The content of the MIP is predicted to be more obvious, however, in cases that feature non-ordering properties, as illustrated by the correctly predicted uniqueness of size presupposition for (2).

## 5. The puzzle: modal obviation of the uniqueness effect

Under the MIP-based account for the uniqueness of size presupposition in *how many*-questions, an interesting puzzle emerges from examples that feature modal expressions such as deontic *required* and *allowed*. Consider the pair of questions in (17), where (17b) repeats (3). Extrapolating from our analysis of (2), we arrive at assigning to these questions the logical forms in (18a) and (19a) and the denotations in (18b) and (19b).<sup>4</sup>

- (17) a. How many students are required to solve this problem together?  
 b. How many students are allowed to solve this problem together?
- (18) a.  $\text{how } \lambda n[ \text{required} [ \exists [n \text{ many}] \text{ students} ] \text{ spt} ] ]$   
 b.  $\lambda n_d. \lambda w_s. \forall v[v \in \text{ACC}(w) \rightarrow \exists x[\llbracket \text{students} \rrbracket(x)(v) \wedge \llbracket \text{spt} \rrbracket(x)(v) \wedge |x|=n] ]$
- (19) a.  $\text{how } \lambda n[ \text{allowed} [ \exists [n \text{ many}] \text{ students} ] \text{ spt} ] ]$   
 b.  $\lambda n_d. \lambda w_s. \exists v[v \in \text{ACC}(w) \wedge \exists x[\llbracket \text{students} \rrbracket(x)(v) \wedge \llbracket \text{spt} \rrbracket(x)(v) \wedge |x|=n] ]$

<sup>4</sup>We only consider the “de dicto” readings of the relevant questions (Cinque 1990), where the existential generalized quantifier containing *many* plus modified noun is interpreted within the scope of the modal.

So, the denotation assigned to (17a), shown in (18b), maps any cardinality  $n$  to the proposition that in every permissible world, there is a group of students of size  $n$  who solved the problem together; likewise the denotation of (17b), shown in (19b), maps any cardinality  $n$  to the proposition that there is a permissible world in which there is a group of students of size  $n$  who solved the problem together. Note that the non-orderingness of the denotation of *solve this problem together* ensures that the question denotations in (18b) and (19b), too, are once again non-ordering. For any distinct cardinalities  $n$  and  $m$ , the proposition that in every permissible world there is a group of  $n$  students who solved the problem together does not entail the proposition that in every permissible world there is a group of  $m$  students who solved the problem together; likewise the proposition that there is a permissible world where a group of  $n$  students solved the problem together does not entail the proposition that there is a permissible world where a group of  $m$  students solved the problem together. This means that for both of those cases the MIP once again delivers a uniqueness presupposition. Given (18b), the MIP assigned to (17a), shown in (20a), is the proposition that that there is a unique cardinality such that a student group of that cardinality is required to solve the problem; and given (19b), the MIP assigned to (17b), shown in (20b), is the proposition that there is a unique cardinality such that a student group of that cardinality is allowed to solve the problem.

- (20)    a.  $\lambda w_s. \exists!n[\forall v[v \in \text{ACC}(w) \rightarrow \exists x[\llbracket \text{students} \rrbracket(x)(v) \wedge \llbracket \text{spt} \rrbracket(x)(v) \wedge |x|=n]]]$   
           b.  $\lambda w_s. \exists!n[\exists v[v \in \text{ACC}(w) \wedge \exists x[\llbracket \text{students} \rrbracket(x)(v) \wedge \llbracket \text{spt} \rrbracket(x)(v) \wedge |x|=n]]]$

For the question in (17a), this prediction appears adequate, supported by intuitions similar to those about the non-modal example in (2). A speaker using (17a) indeed seems to exclude the possibility of there being more than one cardinality such that it is required for a student group of that cardinality to solve the problem. However, for the question in (17b), the predicted uniqueness of size presupposition is clearly incorrect. The question can be used very naturally in contexts where there is assumed to be a range of permissible group sizes. For example, the interlocutors' common knowledge might entail that there is an upper bound on the permissible sizes, that this upper bound is between five and ten, and that there are no further constraints on permissible group sizes. In this case, common knowledge is consistent with there being between five and ten permissible sizes, and the speaker may use (17b) to obtain further information.

So the uniqueness effect is expectedly preserved under the addition of the necessity modal, but it is unexpectedly obviated by the addition of the possibility modal. How can this obviation effect of possibility modals be accounted for? In sections 6 and 7, we examine two different conceivable strategies to answer this question that preserve the idea that the uniqueness effect is due to a maximal informativity presupposition.

## 6. First try: a maximality operator

We are not the first to encounter a problem of unwanted uniqueness presuppositions derived by the MIP. Abrusán and Spector (2011) describe much the same problem as they develop an analysis of degree questions that lets gradable predicates denote relations between individuals and intervals of degrees. Abrusán and Spector report that such an interval semantics comes

into conflict with the assumption that questions carry a maximal informativity presupposition. For example, they report that under their interval-based analysis, a degree question like (21) is incorrectly assigned the MIP that there is only one length that the paper is allowed to have.

(21) How long is the paper allowed to be?

This presupposition is inconsistent with intuitions about (21), which clearly indicate that the question can be used in contexts where the paper is permitted to have a range of different lengths. For example, (21) can be used in a context where the interlocutors's common knowledge entails that there is an upper bound on the paper's permitted lengths, that this upper bound is somewhere between 10 and 20 pages, that there is a lower bound of 6 pages, and that there are no further constraints on the on permissible lengths. In such a scenario, common knowledge is consistent with there being between 5 and 15 different permitted paper lengths (measured in terms of numbers of pages). The speaker might then use (21) to obtain further information.

The problem that Abrusán and Spector (2011) describe is transparently analogous to our puzzle of modal obviation of the uniqueness of size effect in *how many*-questions. Therefore, since Abrusán and Spector offer a solution to the problem that arises in their interval semantics, one might hope that this solution is transferrable to our puzzle. That is the line of attack that we explore below.

Abrusán and Spector propose that gradable predicates (such as *long* or *many*) introduce a scopally mobile operator  $\Pi$  (first defined in Heim 2006) that creates derived properties of degrees. Here we minimally adapt Abrusán and Spector's semantics for  $\Pi$  to ensure consistency with our assumptions. We take  $\Pi$  to denote a Curried version of a function from properties of cardinalities to properties of cardinalities, which relates any set of cardinalities that has a unique maximal member to the singleton set containing that maximal member. This denotation is spelled out in (22) (where *max* maps a set of cardinalities to its unique maximal member). We note that a nearly identical maximality operator has been employed for somewhat different purposes in Buccola and Spector (2016).

(22)  $[\Pi] = \lambda m_d. \lambda P_{d(st)}. \lambda w_s. \max\{n: P(n)(w)\} = m$

To illustrate the syntax and the semantic effect of  $\Pi$ , we return to the question in (11), repeated below in (23). As shown in (24a), we assume that  $\Pi$  enters the syntactic derivation as part of a phrase, the  $\Pi$ -phrase, that also includes the *wh*-phrase *how* and that sits in the argument position of *many*; in (24b), the  $\Pi$ -phrase has extracted from its base position to the edge of the sentence, forming a derived predicate of cardinalities in its scope; and in (24c), *how* has subextracted from the  $\Pi$ -phrase, once again forming a predicate of cardinalities in its scope.

(23) How many students laughed?

(24) a.  $[\exists [ [\Pi \text{ how}] \text{ many}] \text{ students}] \text{ laughed}$   
 b.  $[\Pi \text{ how}] \lambda n [ [\exists [n \text{ many}] \text{ students}] \text{ laughed}]$   
 c.  $\text{how } \lambda m [ [\Pi m] \lambda n [ [\exists [n \text{ many}] \text{ students}] \text{ laughed}] ]$

Given the denotation of  $\Pi$  shown in (22), the logical form in (24c) receives the denotation in (25). This question denotation maps any cardinality  $m$  to the proposition that  $m$  is the largest cardinality  $n$  such that there is a group of  $n$  students who laughed. More transparently, (25) maps any cardinality to the proposition that the set of all students who laughed has that cardinality.

$$(25) \quad \lambda m_d. \lambda w_s. \max\{n: \exists x[\llbracket \text{students} \rrbracket(x)(w) \wedge \llbracket \text{laughed} \rrbracket(x)(w) \wedge |x| = n]\} = m$$

The propositions in the range of this function are mutually incompatible. For any distinct cardinalities  $n$  and  $m$ , the proposition that  $n$  is the number of all students who laughed contradicts the proposition that  $m$  is the number of all students who laughed. Therefore, the MIP derived from (25) is satisfied as long as there are (finitely many) students who laughed. Therefore, just like under the analysis in section 4 (where we appealed to the distributivity of the meaning of *laugh*) the MIP for (23) amounts to a mere existence presupposition.

For completeness, we note that (23) may well be considered ambiguous between the meaning in (25) and the meaning we derived in section 3, shown in (13b). Repurposing related hypotheses entertained in Buccola and Spector (2016), we can see two possible ways of recovering (13b). One way is to assume that the presence of  $\Pi$  is optional and that (13a), too, is a well-formed logical form for (23). Another option is to assume that the  $\Pi$ -phrase can scope within the containing noun phrase, below the existential determiner  $\exists$ . As readers are invited to verify, with such narrow scope, the presence of  $\Pi$  winds up having no effect on the question denotation as a whole, replicating the meaning assigned to the logical form (13a), where  $\Pi$  is not present in the first place.

We are now ready to return to our problematic example (3), repeated again below in (26). We are focusing on a logical form for this question where the  $\Pi$ -phrase has moved past *allowed* to again take widest scope, turning (27a) into (27b), followed by short subextraction of *how*, yielding (27c). The denotation assigned to (27c) is shown in (28).

(26) How many students are allowed to solve this problem together?

- (27) a. allowed [  $\exists$  [  $\Pi$  how ] many ] students ] spt]  
 b. [  $\Pi$  how ]  $\lambda n$ [allowed [  $\exists$  [  $n$  many ] students ] spt] ]  
 c. how  $\lambda m$ [  $\Pi$  m ]  $\lambda n$ [allowed [  $\exists$  [  $n$  many ] students ] spt] ] ]

$$(28) \quad \lambda m_d. \lambda w_s. \max\{n: \exists v[v \in \text{ACC}(w) \wedge \exists x[\llbracket st \rrbracket(x)(v) \wedge \llbracket spt \rrbracket(x)(v) \wedge |x|=n] ] \} = m$$

This denotation maps any cardinality  $m$  to the proposition that  $m$  is the largest cardinality  $n$  such that in some permissible world, there is a group of  $n$  students who solved this problem together. More transparently, (28) maps any cardinality  $m$  to the proposition that  $m$  is the largest permitted size of groups of students that solve this problem. Since there can be at most one such largest permitted group size, the propositions in the range of (28) are again pairwise incompatible. Therefore, the MIP once again yields a mere existence presupposition, though in

this case the presupposition that there is a *largest* permitted size of student groups solving the problem.

So the  $\Pi$ -phrase scoping over the possibility modal in (26) has the welcome effect of preempting the derivation of the unattested uniqueness of size presupposition, that is, the presupposition that there is a *unique* permitted size of student groups solving the problem. Moreover, the weaker MIP now derived for (26) appears weak enough to be consistent with intuitions about the meaning of the question.

This might be an encouraging finding, especially since the  $\Pi$  operator employed here, or some version of it, may have independent support from domains other than *how many*-questions (Heim 2006, Buccola and Spector 2016, Abrusán and Spector 2011, Kennedy 2015). However, there remains an obvious open question that the proposal as stated fails to answer. Why is the obviation of the uniqueness effect tied to the presence of a possibility modal? After all, one might expect that the questions in (2) and (17a), repeated below in (29a) and (29b), also allow for logical forms where the  $\Pi$ -phrase takes wide scope, that is, the logical forms in (30).

- (29) a. How many students solved this problem together?  
 b. How many students are required to solve this problem together?
- (30) a.  $\text{how } \lambda m [ \Pi m ] \lambda n [ \exists [n \text{ many}] \text{ students} ] \text{ spt} ]$   
 b.  $\text{how } \lambda m [ \Pi m ] \lambda n [\text{required } [ \exists [n \text{ many}] \text{ students} ] \text{ spt} ] ]$

These logical forms, too, would preempt the uniqueness of size presuppositions described in sections 1, 3, and 5. The MIP that the logical form in (30a) would give rise to is the proposition that there is a *largest* size of student groups who solved the problem. But once again, this proposition amounts to a mere existence presupposition. Whenever there is at least one student group (of finite size) who solved the problem, there is guaranteed to be exactly one that is as large as any of the others. Hence the  $\Pi$ -phrase in (30a) incorrectly obviates the very uniqueness of size presupposition that served as the starting point of our investigation. Similarly, the MIP based on (30b) is the proposition that there is a *largest* cardinality such that it is required for there to be a student group of that cardinality that solves the problem. Once again, this is weaker than the uniqueness presupposition described above, namely the proposition that there is a unique required cardinality of student groups solving the problem.

Therefore, if a MIP-based account of the uniqueness effects in (29a) and (29b) is to be preserved, logical forms like those in (30) must be excluded as well-formed inputs to semantic interpretation. Unfortunately, however, there appears to be no independent rationale for such exclusion. In particular, it is not promising to explore the hypothesis that there is something wrong with the syntactic distance that the moving  $\Pi$ -phrase has travelled in the logical forms in (30), since an equal or greater distance is covered by the  $\Pi$ -phrase movement posited in the logical form in (27c). We conclude that, as long as the uniqueness of size effect is sought to be accounted for in terms of the MIP, the obviation of this effect by a scopally mobile  $\Pi$ -phrase must be excluded, which presumably requires excluding the logical form in (27c) along with

those in (30). We then require a different account of the puzzling obviation of the uniqueness of size effect by possibility modals.

## 7. Second try: contextual entailment

Having reverted to the position that the relevant question denotations are as initially presented in sections 2 and 5, we now target the MIP itself for revision. Our formulation of the MIP in (7) above follows Dayal (1996) and subsequent literature in that it construes the relevant notion of informativity as semantic entailment. We will now explore the consequences of instead construing informativity for the purposes of the MIP as pragmatic, contextual, entailment. Let  $c$  be the context set in the sense of Stalnaker (1978). As stated in symbols in (31), we say that a proposition  $p$  contextually entails a proposition  $q$  in context set  $c$  just in case  $q$  is semantically entailed by  $p$  in conjunction with  $c$ .

$$(31) \quad \text{Contextual Entailment} \\ p \subseteq_c q : \Leftrightarrow p \cap c \subseteq q$$

We use this definition to minimally revise the statement of the MIP in (7) as shown in (32), relativizing it to the context set and substituting contextual entailment for semantic entailment.

$$(32) \quad \text{For any (functional) question denotation } Q \text{ and context set } c: \\ \text{MIP}_c(Q) = \lambda w_s. \exists x[Q(x)(w) \wedge \forall y[Q(y)(w) \rightarrow Q(x) \subseteq_c Q(y)]]$$

The immediate benefit of this revision is that the problematic modal obviation example in (3), repeated once more in (33), is no longer predicted to carry a uniqueness of size presupposition in all contexts.

$$(33) \quad \text{How many students are allowed to solve this problem together?}$$

Under (32), the felicity of (33) is expected to be consistent with the existence of multiple true Hamblin/Karttunen answers, as long as there is one among them that contextually entails all the others. The most natural contexts of this sort are contexts that ensure that the denotation of (33) in (19b), repeated in (34), is *contextually scalar*.

$$(34) \quad \lambda n_d. \lambda w_s. \exists v[v \in \text{ACC}(w) \wedge \exists x[\llbracket \text{students} \rrbracket(x)(v) \wedge \llbracket \text{spt} \rrbracket(x)(v) \wedge |x|=n]]$$

The denotation in (34) is contextually scalar in the intended sense in contexts where the relative contextual strength of any two Hamblin/Karttunen answers is predictable from the intrinsic ordering of the two cardinalities that (34) maps to these propositions. In particular, (34) might be *contextually downward scalar* in the sense defined in (35).

$$(35) \quad \text{Contextual downward scalarity} \\ f \text{ is contextually downward scalar in } c : \Leftrightarrow \forall n, m[m \leq n \rightarrow f(n) \subseteq_c f(m)]$$

According to (35), the denotation (34) is contextually downward scalar in contexts where for any cardinalities  $n$  and  $m$  such that  $m \leq n$ , the proposition that there are permissible worlds where a group of  $n$  students solves the problem contextually entails the proposition that there are permissible worlds where a group of  $m$  students solves the problem. In such a context, the truth of the contextual MIP for (33) merely requires that the set of permissible student group sizes have a unique maximal member. Assuming contextual downward scalarity, the proposition that (34) maps that maximal member to will be true and will contextually entail all the other true propositions in the range of (34).

We submit that contexts that make (34) contextually downward scalar are rather natural. Such a context could arise in a scenario where, for some cardinality  $n$ , the relevant authority, say, a university teacher, is known to have stated that groups of no more than  $n$  students may be formed to collaborate on solving this problem, and where it is moreover understood that there are no further restrictions on permitted group sizes. In such a scenario, the contextual downward scalarity of (34) is common knowledge: if it were to emerge, for example, that groups of five students are permitted, an interlocutor could justifiably infer that groups of four or less are permitted as well. A speaker who lacks complete information about the identity of  $n$  might appropriately use (33) in the hope of acquiring such information.

Once again, the obvious question is whether the approach under consideration captures our finding that the obviation of the uniqueness of size presupposition is only observed with possibility modals. The non-modal example (2) and the case with a necessity modal in (17a) are repeated again in (36), together with their denotations in (37), repeated from (6) and (18b).

- (36) a. How many students solved this problem together?  
 b. How many students are required to solve this problem together?
- (37) a.  $\lambda n_d. \lambda w_s. \exists x[\llbracket students \rrbracket(x)(w) \wedge \llbracket spt \rrbracket(x)(w) \wedge |x| = n]$   
 b.  $\lambda n_d. \lambda w_s. \forall v[v \in ACC(w) \rightarrow \exists x[\llbracket students \rrbracket(x)(v) \wedge \llbracket spt \rrbracket(x)(v) \wedge |x| = n]]$

The expectation is, of course, that in the examples in (36), the uniqueness effect might disappear in suitable scenarios. The most plausible conceivable cases of this sort would again be scenarios that render the denotations in (37) contextually scalar. But now, again focusing on contextual downward scalarity, let us consider what such scenarios would be like.

For (37a), contextual downward scalarity would require a scenario where for any cardinalities  $n$  and  $m$  such that  $m \leq n$ , the existence of a student group of size  $n$  who solved the problem contextually guarantees the existence of a student group of size  $m$  who solved the problem. In such a scenario, upon learning that there was a group of, say, six students who solved the problem together, one would be able to infer that there was also a group of five that did so, as well as a group of four, and so on. So in scenarios of this type, the existence of a group of  $n$  students who solved the problem would allow one to infer that there are at least  $n-1$  other groups who did so as well, whose cardinalities moreover cover the entire range from 1 to  $n-1$ . We suggest that such a scenario is outlandish enough to not readily come to mind to speakers that interpret sentence (36a). The robustness of the uniqueness of size presupposition carried by

(36a) would then not be a matter of linguistic structure, but of the complexity and implausibility of the type of scenario under which that uniqueness presupposition would be weakened in the way it can be weakened in cases with possibility modals.

This line of analysis arguably accommodates the case of (36b), as well. For the denotation in (37b), contextual downward scalarity would require a scenario where for any cardinalities  $n$  and  $m$  such that  $m \leq n$ , the proposition that a group of  $n$  students solved the problem in every permissible world contextually entails the proposition that a group of  $m$  students solved the problem in every permissible world. In such a scenario, upon learning that it is required for a group of  $n$  students to solve the problem, one would be justified in drawing the inference that it is also required that  $n-1$  other groups of students solve the problem, whose cardinalities moreover must cover the entire range from 1 to  $n-1$ . Once again, we submit that such a scenario is sufficiently implausible to not readily come to mind to speakers judging the question in (36b), which serves to account for the robustness of the uniqueness effect in that example.

Thus, unlike our attempted account in terms of the  $\Pi$ -operator, the move to a revised MIP based on contextual entailment promises to capture the fact that the obviation of the uniqueness of size effect is limited to cases with a possibility modal.

Even so, we must report that, unfortunately, this account does not seem to fully capture the conditions on the use of the case with the possibility modal. While it affords a welcome weakening of the conditions on the use of (33), we can observe that this weakening does not go far enough. Consider a scenario where a teacher is known to have stipulated, for two different cardinalities  $n$  and  $m$ , that students must form groups to solve the problem together and that each group must have one of the sizes  $n$  and  $m$ . In this scenario, without having any further beliefs about the permitted group sizes, a speaker may felicitously use (33) to learn about the identity of  $n$  and  $m$ . Yet in this scenario, no contextual entailment holds between the proposition that a group of  $n$  students solves the problem in some permissible world and the proposition that a group of  $m$  students solves the problem in some permissible world. This scenario not only conflicts with the presupposition given by the original MIP in (7) but likewise with the weaker presupposition given by the revised MIP, based on contextual entailment.

So we are still left without a solution to the puzzle of modal obviation of the uniqueness of size effect. If we were to insist that this effect is a symptom of the MIP, we would still need to find a different way of understanding why the relevant *how many*-questions with possibility modals do not carry the expected presuppositions. In the next section, we present a type of *how many*-question that raises the reverse problem, by virtue of carrying a uniqueness of size presupposition that the MIP fails to derive.

## 8. Another problem: weak distributivity and weak downward scalarity

The *how many*-question in (38) gives rise to a similar observation as the question in (2) that we presented as our first illustration of the uniqueness of size presupposition. That is, (38) suggests that there is only one size of groups of students in the seminar that have the same first name.

(38) How many students in the seminar have the same first name?

In support of this assessment, we present two concrete scenarios in the form of the class rosters in (39). Imagine that (39a) is the roster for the seminar and that an addressee who has access to this information is presented with the question in (38). It seems clear that the addressee's cooperative response would be *three*, given that the class roster in (39a) shows a group of students with the same first name (viz. Ann), which has cardinality 3, and given that it does not show any other group of students that share their first name.

- |      |    |              |              |
|------|----|--------------|--------------|
| (39) | a. | Adams, Ann   | Durant, Bill |
|      |    | Baker, Ann   | Ellis, Chris |
|      |    | Collins, Ann | Foster, Dan  |
|      | b. | Adams, Ann   | Durant, Bill |
|      |    | Baker, Ann   | Ellis, Bill  |
|      |    | Collins, Ann | Foster, Dan  |

In contrast, the class roster in (39b) shows a second group of students with the same first name (viz. Bill), which has cardinality 2. We submit that an addressee who has this information would be hard pressed to answer the question in (38). While such an addressee could truthfully assert that there are groups of two and three students with the same first name, the question in (38) does not appear to be a suitable vehicle for eliciting this information. Accordingly, a speaker who takes a class roster like (39b) to be a good possibility would presumably refrain from using (38) as a request for information. These observations confirm that (38) indeed carries a uniqueness of size presupposition.

Interestingly, however, this uniqueness of size presupposition cannot be understood as an instantiation of the MIP. This is a consequence of the semantic behaviour of the denotation of *have the same first name* and the denotation of the question in (38) as a whole. In contrast to the property expressed by *solve this problem together*, the property expressed by *have the same first name* is not non-ordering. For example, it is clear that the proposition that Adams, Baker, and Collins have the same first name semantically entails the proposition that Adams and Baker have the same first name. In fact, this example illustrates that the property expressed by *have the same first name* is weakly distributive in the sense of definition (40). That is, the property is distributive down to groups of at least two individuals: for any groups  $x$  and  $y$  such that  $x$  is included in  $y$  and  $x$  has cardinality 2 or more, the proposition that the individuals in  $y$  have the same first name semantically entails the proposition that the individuals in  $x$  have the same first name.<sup>5</sup>

(40) Weak distributivity

$f$  is *weakly distributive*  $:\Leftrightarrow \forall x,y[x \subseteq y \wedge 2 \leq |x| \rightarrow f(y) \subseteq f(x)]$

<sup>5</sup>What keeps the property from being distributive simpliciter is that it does not apply to any atomic individuals. Setting aside the so-called discourse anaphoric reading of *same* (Beck 2000), the statement that, say, Adams has the same first name is not meaningful. That some collective predicates are weakly distributive in this way was observed in, e.g., Champollion (2010), Buccola (2015), and Buccola and Spector (2016), who illustrate the phenomenon with the verb *gather*. We borrow the term *weak distributivity* from Buccola and Spector (2016) (although in a slightly different meaning).

Under our current assumptions about the syntax and semantic of *how many*-questions, (38) has the logical form in (41a) and the denotation in (41b), where *hsfn* abbreviates *have the same first name*.

- (41) a. how  $\lambda n[ \exists [n \text{ many}] \text{ students}] \text{hsfn}$   
 b.  $\lambda n_d. \lambda w_s. \exists x[ \llbracket \text{students} \rrbracket(x)(w) \wedge \llbracket \text{hsfn} \rrbracket(x)(w) \wedge |x| = n]$

The weak distributivity of the denotation of *have the same first name* (together with the distributivity of the denotation of *students*) guarantees that the question denotation in (41b) is *weakly downward scalar* in the sense of definition (42).

- (42) Weak downward scalarity  
 $f \text{ is weakly downward scalar} : \Leftrightarrow \forall n, m [m \leq n \wedge 2 \leq m \rightarrow f(n) \subseteq f(m)]$

That is, for any cardinalities  $n$  and  $m$  such that  $m \leq n$  and  $2 \leq m$ , the proposition that a group of  $n$  students have the same first name semantically entails the proposition that a group of  $m$  students have the same first name.

For an argument that will be familiar from section 4, consider now the set of cardinalities (greater than 1) that a given weakly downward scalar question denotation maps to a true proposition. Suppose that this set has a (unique) maximal element. The weakly downward scalar function will map that maximal element to a proposition that entails all the other true propositions in its range, and hence the MIP will be met; so, as stated in (43), the MIP will merely require that the set of cardinalities that the question denotation maps to a true proposition have a (unique) maximal member in terms of the intrinsic ordering of cardinalities.

- (43) For any weakly downward scalar question denotation  $Q$ :  
 $\text{MIP}(Q) = \lambda w_s. \exists n[Q(n)(w) \wedge \forall m[Q(m)(w) \rightarrow m \leq n]]$

But, again, in order for any set of cardinalities to have a maximal member, all it takes is for that set to be non-empty and finite. Applied to the weakly downward scalar denotation of (38) in (41b), the MIP therefore yields the proposition stated in (44), the presupposition that there is a group of students in the seminar of some size (greater than 1 and finite) who have the same first name. So, just like questions with (strongly) downward scalar denotations, (38) winds up with a mere existential presupposition.

- (44)  $\lambda w_s. \exists n[ \exists x[ \llbracket \text{students} \rrbracket(x)(w) \wedge \llbracket \text{hsfn} \rrbracket(x)(w) \wedge |x| = n]]$

This result entails that the MIP does not capture the uniqueness of size presupposition of (38), identified above. In the scenario (39b), for example, the MIP of (38) would be satisfied. In this scenario, the question has two true Hamblin/Karttunen answers, viz. the proposition that there is a group of two students who have the same first name and the proposition that there is a group of three students who have the same first name. MIP is satisfied in this scenario because, due to the weak distributivity of the property of having the same first name, the latter proposition semantically entails the former.

We conclude that for *how many*-questions with weakly distributive predicates, a MIP-based account delivers a presupposition that is too weak to capture the attested uniqueness effect.

## 9. Conclusion

To recap, we described a uniqueness presupposition carried by certain *how many*-questions with non-distributive predicates, such as *solve this problem together*. We explored an approach to this uniqueness effect that credits it to (a version of) Dayal's (1996) Maximal Informativity Presupposition (MIP). However, we found two symmetric problems for this approach. (i) The MIP derives an overly strong presupposition for *how many*-questions where a non-distributive predicate is embedded under a possibility modal. For such cases, the MIP is very obviously inadequate when informativity is construed as semantic entailment, and substituting contextual entailment for semantic entailment does not go far enough in weakening the MIP. We saw that a  $\Pi$ -operator which can outscope the possibility modal would weaken the MIP sufficiently to be consistent with intuitions; but such a  $\Pi$ -operator would be expected to incorrectly remove the uniqueness effect across the board, and leave one without an explanation for why the effect is ever observed to begin with. (ii) The MIP derives a presupposition that is too weak for *how many*-questions with a weakly distributive predicate.

Our finding about *how many*-questions with a weakly distributive predicate brings us back to our discussion of the uniqueness effect in section 3. There we noted that some speakers report that the question in (2), repeated one more time in (45a), does not merely carry a uniqueness of size presupposition, but a stronger uniqueness of group presupposition. That is, the relevant speakers take (45a) to presuppose that there is a unique group of students who solved the problem together. We suspect that this observation extends to (38), repeated in (45b), that is, that (45b) is naturally read as presupposing that there is only one group of students in the seminar that have the same first name.

- (45) a. How many students solved this problem together?  
b. How many students in this seminar have the same first name?

So, at least for some speakers, the MIP-based approach delivers presuppositions that are overly weak in two different ways. It fails to derive attested uniqueness of size presuppositions in *how many*-questions with certain collective predicates, and it fails to derive uniqueness of group presuppositions across the board.

The problem of predicted presuppositions being too weak becomes even more pronounced under a recent proposal in Fox (2013). In the context of analyzing so-called mention-some readings of questions, Fox proposes a revision of Dayal's (1996) definition of the MIP. Translated into our format, Fox proposes to replace Dayal's MIP in (7), repeated in (46), with the weaker version in (47).

- (46) For any (functional) question denotation  $Q$ :  
MIP( $Q$ ) =  $\lambda w_s. \exists x[Q(x)(w) \wedge \forall y[Q(y)(w) \rightarrow Q(x) \subseteq Q(y)] ]$

- (47) For any (functional) question denotation  $Q$ :  

$$\text{MIP}(Q) = \lambda w_s. \exists x[Q(x)(w) \wedge \neg \exists y[Q(y)(w) \wedge Q(x) \supset Q(y)] ]$$

The MIP as defined in (46) requires that the set of true Hamblin/Karttunen answers have a member that is maximal in terms of the ordering given by semantic entailment, that is, a member that entails any other member. This maximal member is necessarily unique. Hence according to (46) the MIP excludes the existence of two true Hamblin/Karttunen answers that are not related by entailment. In contrast, the MIP defined in (47) merely requires that the set of true Hamblin/Karttunen answers have *at least one* maximal element in terms of the ordering given by semantic entailment, that is, at least one member that is not entailed by any other member. This allows for the existence of two true Hamblin/Karttunen answers that are not related by entailment.

Recall now that in all of the *how many*-questions with a non-distributive predicate like *solve this problem together*, the Hamblin/Karttunen answers are semantically unrelated. But that means that for those questions, the MIP as defined in (47) will amount to a mere existence presupposition, requiring that the question have at least one true Hamblin/Karttunen answer. Hence the weak MIP does not derive a uniqueness of size presupposition, let alone a uniqueness of group presupposition, for any of the questions we have studied in this paper.

In all, the negative results that we have reported suggest that the uniqueness of size effect we set out to understand is after all not a symptom of the MIP, and that an alternative account of this effect is to be sought, one that also captures uniqueness of group presuppositions and that extends to *how many*-questions with weakly distributive predicates. We must leave the development of such an alternative account to future work. But we will conclude by pointing to one possible approach that may have some promise: We have analyzed *many* as a relational adjective, which combines with a cardinality denoting expression to form an intersective modifier. In contrast, Hackl (2000) proposes that *many* is a so-called parametrized determiner. Hackl takes this determiner to have existential quantificational force. Adapting Hackl's proposal, one could think of *many* as being more similar to a singular definite article in that it triggers a presupposition of uniqueness. Uniqueness presuppositions would then be contributed by conventional lexical meaning, and would not be tied to the interpretation of questions in the way they are under the approach explored in this paper. We hope to spell out and evaluate this idea in future work.

Julian HOUGH — *Bielefeld University*

David SCHLANGEN — *Bielefeld University*

**Abstract.** Incremental processing at least as fine grained as word-by-word has long been accepted as a basic feature of human processing of speech (see e.g., Schlesewsky and Bornkessel (2004)) and as an important feature for design of spoken dialogue systems (see e.g., Schlangen and Skantze (2009); Hough et al. (2015)). Nonetheless, with a few important exceptions (see e.g., Kempson et al. (2016)), incrementality is viewed as an aspect of performance, not semantic meaning. Moreover, it seems to entail giving up on compositionality as a constraining principle on denotations. In this paper, we point to a variety of dialogical phenomena whose analysis incontrovertibly requires a semantics formulated in incremental terms. These include cases, above all with sluicing, that call into question existing assumptions about ellipsis resolution and argue for incremental updating of QUD. The incremental semantic framework we sketch improves on existing such accounts (reviewed in Peldszus and Schlangen (2012); Hough et al. (2015)) on both denotational and contextual fronts: the contents we posit are in fact tightly constrained by a methodological principle more restrictive than traditional compositionality, namely the Reprise Content Hypothesis (Purver and Ginzburg (2004); Ginzburg and Purver (2012); Cooper (2013a)), embedded within independently motivated dialogue states (Ginzburg (2012)).

**Keywords:** Incremental processing, dialogue, clarification potential, sluicing

### 1. Introduction

Incremental processing at least as fine grained as word-by-word has long been accepted as a basic feature of human processing of speech (see e.g., Schlesewsky and Bornkessel (2004)) and as an important feature for design of spoken dialogue systems (see e.g., Schlangen and Skantze (2009); Hough et al. (2015)). Nonetheless, with a few important exceptions (see e.g., Kempson et al. (2016)), incrementality is viewed as an aspect of performance, not semantic meaning. Moreover, it seems to entail giving up on compositionality as a constraining principle on denotations. In this paper, we point to a variety of dialogical phenomena whose analysis incontrovertibly requires a semantics formulated in incremental terms. These include cases, above all with sluicing, that call into question existing assumptions about ellipsis resolution and argue for incremental updating of QUD. The incremental semantic framework we sketch improves on existing such accounts (reviewed in Peldszus and Schlangen (2012); Hough et al.

<sup>1</sup>Many thanks to the insightful comments of three *Sinn und Bedeutung* reviewers, as well as to the audience at *Sinn und Bedeutung*, 2016. We acknowledge support by the French Investissements d'Avenir–Labex EFL program (ANR-10-LABX-0083) and by the Disfluences, Exclamations, and Laughter in Dialogue (DUEL) project within the Projets Franco-Allemand en sciences humaines et sociales of the Agence Nationale de Recherche (ANR) and the Deutsche Forschungsgemeinschaft (DFG). For Hough and Schlangen: this work was supported by the Cluster of Excellence Cognitive Interaction Technology 'CITEC' (EXC 277) at Bielefeld University, which is funded by the German Research Foundation (DFG).

(2015)) on both denotational and contextual fronts: the contents we posit are in fact tightly constrained by a methodological principle more restrictive than traditional compositionality, namely the Reprise Content Hypothesis (Purver and Ginzburg (2004); Ginzburg and Purver (2012); Cooper (2013a)), embedded within independently motivated dialogue states (Ginzburg (2012)).

The structure of the paper is as follows: in section 2 we introduce the data and draw from it basic specifications for incremental semantics. In section 3 we present the necessary background concerning KOS and Type Theory with Records, the frameworks we employ for representing dialogue, grammar, and semantics. In section 4, we sketch an account of dialogical incremental processing, which we apply to the data from section 2 in section 5. We end with some brief conclusions.

## 2. Why Semantics needs Incrementality : the Data and Initial specification

(1) exemplifies the fact that at any point in the speech stream of A's utterance B can interject with an acknowledgement whose force amounts to B understanding the initial segment of the utterance (Clark (1996)):

- (1) A: Move the train ... B: Aha A: ... from Avon ... B: Right A: ... to Danville. (Trains corpus)

(1) requires us to be able to write a lexical entry for 'aha' and 'yeah' (and their counterparts cross linguistically, e.g., French: 'ouais', 'mmh', ...) whose context is/includes "an incomplete utterance". (2a,b,c) exemplify a contrast between three reactions to an 'abandoned' utterance: in (2a) B asks A to elaborate, whereas in (2b) she asks him to complete her unfinished utterance; in (2c) B indicates that A's content is evident and he need not spell it out:

- (2) a. A(i): John ... Oh never mind. B(ii): What about John/What happened to John? A: He's a lovely chap but a bit disconnected. / # burnt himself while cooking last night.  
b. A(i): John ... Oh never mind. B(ii): John what? A: # He's a lovely chap but a bit disconnected. / burnt himself while cooking last night.  
c. A: Bill is ... B: Yeah don't say it, we know.

(2a,b,c) requires us to associate a content with A's incomplete utterance which can either trigger an elaboration query (2a), a query about utterance completion (2b), or an acknowledgement of understanding (2c). (3) is an attested example of an abandoned utterance in mid-word:

- (3) [Context: A is in the kitchen searching for the always disappearing scissors. As he walks towards the cutlery drawer he begins to make his utterance, before discovering the scissors once the drawer is opened.] A: Who took the sci-...

(3) requires us to integrate within-utterance and (in this case, visual) dialogue context processing.

(4) exemplifies two types of expressions—filled pauses and exclamative interjections—that can in principle, be inserted at any point in the speech stream of A’s utterance; the interjection ‘Oh God’ here reacts to the utterance situation conveyed incrementally.

- (4) Audrey: Well it’s like th- it’s like the erm (pause) oh God! I’ve forgotten what it’s bloody called now? (British National Corpus)

(4) requires us to enable the coherence of a question about what word/phrase will follow, essentially at any point in the speech stream; It also requires us to enable the coherence of an utterance expressing negative evaluation of the current incomplete utterance. (5a-e) illustrate that an incomplete clause can serve as an antecedent for a sluice, thereby going against the commonly held assumption that sluicing is an instance of ‘S-ellipsis’ (Merchant (2001)):

- (5) a. The translation is by—who else?—Doris Silverstein (The TLS, Feb 2016)  
 b. He saw—can you guess who?—The Dude;  
 c. Queen Rhonda is dead. Long live . . . who? (New York Times, Nov 2015);  
 d. A: A really annoying incident. Some idiot, B: Who? A: Not clear. B: OK A: has taken the kitchen scissors.  
 e. A: Someone I’m not saying who / B: No, do say/Who?

(5) requires us to enable either incomplete argument frames or QNPs immediately after their utterance to trigger sluices.

### 3. Background

#### 3.1. KoS

For our dialogical framework we use KoS (Ginzburg (1994); Larsson (2002); Purver (2006); Ginzburg (2012). KoS provides a cognitive architecture in which there is no single common ground, but distinct yet coupled Dialogue GameBoards, one per conversationalist. The structure of the dialogue gameboard (DGB) is given in table 1. The *Spkr* and *Addr* fields allow one to track turn ownership; *Facts* represents conversationally shared assumptions; *VisualSit* represents the dialogue participant’s view of the visual situation and attended entities; *Pending*, the nature of which we explicate in more detail below, represents moves that are in the process of being grounded and *Moves* represents moves that have been grounded; *QUD* tracks the questions currently under discussion, though not simply questions *qua* semantic objects, but pairs of entities which we call *InfoStrucs*: a question and an antecedent sub-utterance.<sup>2</sup> This latter entity provides a partial specification of the focal (sub)utterance, and hence it is dubbed the *focus establishing constituent* (FEC). This is similar to the *parallel element* in higher order unification-based approaches to ellipsis resolution e.g. Gardent and Kohlhase (1997); and to Vallduví (2015), who relates the focus establishing constituent with a notion needed to capture *contrast*.

<sup>2</sup>Extensive motivation for this view of QUD can be found in (Fernández, 2006; Ginzburg, 2012), based primarily on semantic and syntactic parallelism in non-sentential utterances such as short answers, sluicing, and various other non-sentential utterances.

| Dialogue Gameboard |                                                               |                              |
|--------------------|---------------------------------------------------------------|------------------------------|
| <i>component</i>   | <i>type</i>                                                   |                              |
| Spkr               | Individual                                                    | <i>keeps track of</i>        |
| Addr               | Individual                                                    | <i>Turn</i>                  |
| utt-time           | Time                                                          | <i>ownership</i>             |
| Facts              | Set(propositions)                                             | <i>Shared assumptions</i>    |
| VisualSit          | Situation                                                     | <i>Visual scene</i>          |

Table 1: Dialogue Gameboard

### 3.2. TTR

The logical underpinnings of KoS is Type Theory with Records (TTR) (Cooper (2012); Cooper and Ginzburg (2015)). TTR is a framework that draws its inspirations from two quite distinct sources. One source is Constructive Type Theory for the repertory of type constructors, and in particular records and record types, and the notion of witnessing conditions. The second source is situation semantics (Barwise (1989)) which TTR follows in viewing *semantics as ontology construction*. This is what underlies the emphasis on specifying structures in a model theoretic way, introducing structured objects for explicating properties, propositions, questions etc. It also takes from situation semantics an emphasis on *partiality* as a key feature of information processing. This aspect is exemplified in a key assumption of TTR—the witnessing relation between records and record types: the basic relationship between the two is that a record  $r$  is of type  $RT$  if each value in  $r$  assigned to a given label  $l_i$  satisfies the typing constraints imposed by  $RT$  on  $l_i$ :

#### (6) record witnessing

The record:

$$\left[ \begin{array}{l} l_1 = a_1 \\ l_2 = a_2 \\ \dots \\ l_n = a_n \end{array} \right] \text{ is of type: } \left[ \begin{array}{l} l_1 : T_1 \\ l_2 : T_2(l_1) \\ \dots \\ l_n : T_n(l_1, l_2, \dots, l_{n-1}) \end{array} \right] \text{ iff } a_1 : T_1, a_2 : T_2(a_1), \dots, a_n : T_n(a_1, a_2, \dots, a_{n-1})$$

This allows for cases where there are fields in the record with labels not mentioned in the record type. This is important when e.g., records are used to model contexts and record types model rules about context change—we do not want to have to predict in advance all information that could be in a context when writing such rules.

For what follows, we require use of an analog to priority unification for record types in *asymmetric merge* (Cooper, 2012; Hough, 2015) defined as: given two record types  $R1$  and  $R2$ ,

$R1 \sqcup R2$  will yield a record type which is the union of all fields with labels not shared by  $R1$  and  $R2$  and the asymmetric merge of the remaining fields with the same labels, whereby  $R2$ 's type values take priority over  $R1$ 's fields, yielding a resulting record type with  $R2$ 's fields only in those cases.

$$(7) \quad \text{Asymmetric Merge} \quad \begin{bmatrix} a:T_1 \\ b:T_2 \\ c:T_3 \end{bmatrix} \sqcup \begin{bmatrix} b:T_2 \\ c:T_4 \end{bmatrix} = \begin{bmatrix} a:T_1 \\ b:T_2 \\ c:T_4 \end{bmatrix}$$

### 3.2.1. Conversational Rules

Context change is specified in terms of *conversational rules*, rules that specify the *effects* applicable to a DGB that satisfies certain *preconditions*. This allows both illocutionary effects to be modelled (preconditions for and effects of greeting, querying, assertion, parting etc.), interleaved with *locutionary effects*. We mention here three rules used subsequently. The first two concern the incrementation of QUD. (8a)<sup>3</sup> specifies that given the LatestMove being  $q$ ,  $q$  becomes maximal in QUD, whereas (8b) concerns the effect of A asserting  $p$ : this raises the issue  $p?$ —the responder can then either decide to discuss this issue (as a consequence of the rule QSPEC introduced below as (9)) or accept it as positively resolved (as a consequence of a rule we do not mention here):

(8) a. Ask QUD-incrementation

b. Assertion QUD-incrementation

$$\left[ \begin{array}{l} \text{pre} = \left[ \begin{array}{l} q : \text{Question} \\ \text{LatestMove} = \text{Ask}(\text{spkr}, \text{addr}, q) : \text{IllocProp} \end{array} \right] \\ \text{effects} = \left[ \text{qud} = \langle q, r^*. \text{qud} \rangle : \text{poset}(\text{Question}) \right] \end{array} \right] \quad \left[ \begin{array}{l} \text{pre} = \left[ \begin{array}{l} p : \text{Prop} \\ \text{LatestMove} = \text{Assertion}(\text{spkr}, \text{addr}, p) : \text{IllocProp} \end{array} \right] \\ \text{effects} = \left[ \text{qud} = \langle p?, r^*. \text{qud} \rangle : \text{poset}(\text{Question}) \right] \end{array} \right]$$

QSPEC is KoS' version of Gricean Relevance—it characterizes the contextual background of reactive queries and assertions. QSPEC says that if  $q$  is QUD-maximal, then subsequent to this either conversational participant may make a move constrained to be  $q$ -specific (i.e. either a partial answer or sub-question of  $q$ ).<sup>4</sup>

<sup>3</sup>Throughout in update rules we will use  $r^*$  to refer to the immediately preceding information state which is required to be of the type in the field labelled by 'pre' or 'preconditions'.

<sup>4</sup>We notate the underspecification of the turn holder as *TurnUnderspec*, an abbreviation for the following specification which gets unified together with the rest of the rule:

$$\left[ \begin{array}{ll} \text{PrevAud} = \{ \text{pre.spkr}, \text{pre.addr} \} & : \text{Set}(\text{Ind}) \\ \text{spkr} & : \text{Ind} \\ \text{c1} & : \text{member}(\text{spkr}, \text{PrevAud}) \\ \text{addr} & : \text{Ind} \\ \text{c2} & : \text{member}(\text{addr}, \text{PrevAud}) \\ & \wedge \text{addr} \neq \text{spkr} \end{array} \right]$$

$$(9) \quad \text{QSPEC} \left[ \begin{array}{l} \text{pre} = \left[ \text{qud} = \langle i, I \rangle : \text{poset}(\text{InfoStruc}) \right] \\ \text{effects} = \text{TurnUnderspec} \\ \left[ \begin{array}{l} r : \text{AbSemObj} \\ R : \text{IllocRel} \\ \boxed{\bigwedge} \text{LatestMove} = \\ R(\text{spkr}, \text{addr}, r) : \text{IllocProp} \\ c1 : \text{Qspecific}(r, i, q) \end{array} \right] \end{array} \right]$$

**Update procedure:** Using asymmetric merge, we employ the following update process for a dialogue context  $C$  and for some rule  $R$ , a record of type (10).

$$(10) \quad \left[ \begin{array}{ll} \text{pre} & : \text{RecType} \\ \text{effects} & : \text{RecType} \end{array} \right]$$

When updating from one context  $C_i$  to the next  $C_{i+1}$  with rule  $R$ :

$$(11) \quad \begin{array}{l} \text{If } C_i : T_{C_i} \text{ and } T_{C_i} \text{ is a subtype of } R.\text{pre}, \\ \text{then } R \text{ licenses the conclusion that:} \\ C_{i+1} : T_{C_i} \boxed{\bigwedge} R.\text{effects} \end{array}$$

The updates operate on various levels of information which can be arbitrarily fine-grained (even phonetic). This gives us the requisite apparatus for the incrementality discussed in section 2.

### 3.3. The Reprise Content Hypothesis and Generalized Quantifiers

As a means of tightly constraining semantic denotations, we adopt the Reprise Content Hypothesis (RCH, Purver and Ginzburg, 2004; Ginzburg and Purver, 2012; Cooper, 2013a):

$$(12) \quad \text{A fragment reprise question queries exactly the standard semantic content of the fragment being reprised.}$$

This uses the data from responses to clarification questions about a constituent as indicative of its content (e.g., *A: Most students object to the proposal. B: Most students? A: Carl, Max, and Minnie.*). Purver and Ginzburg (2004) and Ginzburg and Purver (2012) use such data to argue in favour of witness sets rather than higher order entities as denotations of QNPs, whereas Cooper (2013a) refines Purver and Ginzburg's account and shows how the RCH can be maintained using a GQ-based perspective. Using the RCH as a methodological principle for positing denotations can be applied straightforwardly in an incremental setting. It offers a stronger constraint than Fregean/Montogovian compositionality which leaves underdetermined which part contributes what—it fulfills the criteria of what Milward (1991) calls *incremental representation* and *strongly incremental interpretation*.

### 3.4. Grounding/Clarification interaction Conditions

Much recent work in dialogue has emphasized two essential branches that can ensue in the aftermath of an utterance:

- **Grounding:** the utterance is understood, its content is added to common ground, uptake occurs.
- **Clarification Interaction:** some aspect of the utterance causes a problem; this triggers exchange to repair problem.

KoS's treatment of repair involves two aspects. One is straightforward, drawing on an early insight of Conversation Analysis (Schegloff (2007)), namely that repair can involve 'putting aside' an utterance for a while, a while during which the utterance is repaired. That in itself can be effected without further ado by adding further structure to the DGB, specifically the field introduced above called *Pending*. 'Putting the utterance aside' raises the issue of *what is it that we are 'putting aside?'*. In other words, how do we represent the utterance? The requisite information needs to be such that it enables the original speaker to interpret and recognize the coherence of the range of possible clarification queries that the original addressee might make. Ginzburg (2012) offers detailed arguments on this issue, including considerations of the phonological/syntactic parallelism exhibited between CRs and their antecedents and the existence of CRs whose function is to request repetition of (parts of) an utterance. Taken together with the obvious need for *Pending* to include values for the contextual parameters specified by the utterance type, Ginzburg concludes that the type of *Pending* combines tokens of the utterance, its parts, and of the constituents of the content with the utterance type associated with the utterance. An entity that fits this specification is the *locutionary proposition* defined by the utterance. A locutionary proposition is a proposition whose situational component is an utterance situation, typed as in (13a) and will have the form of record (13b):

$$(13) \quad \text{a. } LocProp =_{def} \left[ \begin{array}{l} \text{sit} : Sign \\ \text{sit-type} : RecType \end{array} \right] \quad \text{b. } \left[ \begin{array}{l} \text{sit} = u \\ \text{sit-type} = T_u \end{array} \right]$$

Here  $T_u$  is a grammatical type for classifying  $u$  that emerges during the process of parsing  $u$ . It can be identified with a *sign* in the sense of Head Driven Phrase Structure Grammar (HPSG, Pollard and Sag, 1994). This is operationalized as follows: given a presupposition that  $u$  is the most recent speech event and that  $T_u$  is a grammatical type that classifies  $u$ , a record  $p_u$  of the form (13b), gets added to *Pending*. The two branches lead to the following alternative updates:

- Grounding, utterance  $u$  understood: update MOVES with  $p_u$  and respond appropriately (with the second half of an adjacency pair etc.)
- Clarification Interaction:
  1.  $p_u$  remains for future processing in PENDING;
  2.  $CQ(u)$ , a clarification question calculated from  $p_u$ , updates QUD and  $CQ(u)$  becomes a discourse topic.

## 4. An incremental perspective on grounding and clarification

### 4.1. Incrementalizing dialogue processing

The account in section 3.4 was extended to self-repair in Ginzburg et al. (2014): the basic idea is simply to incrementalize the perspective from the turn level to the word level: as the utterance unfolds incrementally there potentially arise questions about what has happened so far (e.g. *what did the speaker mean with sub-utterance u1?*) or what is still to come (e.g. *what word does the speaker mean to utter after sub-utterance u2?*). These can be accommodated into the context if either uncertainty about the correctness of a sub-utterance arises or the speaker has planning or realizational problems. Overt examples for such accommodation are provided by self-addressed questions (*She saw the ... what's the word?*, *Je suis comment dire?*), as explained below.

The account of Ginzburg et al. (2014) exemplified some incremental contents and explained a significant conceptual change that would need to be assumed—that *Pending* would have incremental utterance representations. It did not, however, begin to spell out concretely the nature of such representations, which are crucial in a third option a speaker has apart from grounding and (self)clarifying, namely *prediction* (see examples (2) and (3) above).

We can summarize this picture of processing as in (14), the monitoring and update/clarification cycle is modified to happen *at the end of each word utterance event*, and in case of the need for repair, a repair question gets accommodated into QUD.

- (14) a. Ground: continue (Levelt (1983)).
- b. Predict: stop, since content is predictable.
- c. (Self)Clarify: generate CR given lack of expected utterance.

In the rest of this section we sketch an account of incremental utterance representations, including in particular incremental semantic contents.

### 4.2. Update Rules for specifying syntax

An essential presupposition of our approach (already in its non-incremental version, see above) is a view of syntax as speech event classification by an agent. For a very detailed exposition of such a view see Cooper (2016), a précis of which can be found in Cooper (2013b). Starting at the word level—if  $\text{Lex}(T_w, C)$  is one of the lexical resources available to an agent  $A$  (e.g.,  $\text{Lex}(\text{'Beethoven'}, \text{NP})$  or  $\text{Lex}(\text{'a'}, \text{Det})$ ) and  $A$  judges an event  $e$  to be of type  $T_w$ , then  $A$  is licensed to update their DGB with the type  $\text{Lex}(T_w, C)$ . Intuitively, this means that if the agent hears an utterance of the word “composer”, then they can conclude that they have heard a sign which has the category noun. This is the beginning of *parsing*, which Cooper shows how to assimilate to a kind of update akin to that involved in non-linguistic event perception such as route finding. The licensing condition corresponding to lexical resources like (14) is given in (15). We will return below to how this relates to gameboard update. (15) says that an agent

with lexical resource  $\text{Lex}(T, C)$  who judges a speech event,  $u$ , to be of type  $T$  is licensed to judge that there is a sign of type  $\text{Lex}(T, C)$  whose ‘s-event.e’-field contains  $u$ .

- (15) If  $\text{Lex}(T, C)$  is a resource available to agent  $A$ , then for any  $u$ ,  $u :_A T$  licenses  $:_A \text{Lex}(T, C) \left[ \bigwedge \right] [\text{s-event}: [e=u:T]]$

Strings of utterances of words can be classified as utterances of phrases. That is, speech events are hierarchically organized into types of speech events in a way akin to the complex event structures needed to model activities such as route finding. Agents have resources which allow them to reclassify a string of signs of certain types (“the daughters”) into a single sign of another type (“the mother”). For instance, a string of type  $\text{Det} \cap N$  (that is, a concatenation of an event of type  $\text{Det}$  and an event of type  $N$ ) can lead us to the conclusion that we have observed a sign of type  $NP$  whose daughters are of the type  $\text{Det} \cap N$ .

The resource that licences this is a rule which modelled as the function in (16a) which we represent as (16b).

- (16) a.  $\lambda u : \text{Det} \cap N . NP \left[ \bigwedge \right] [\text{syn}: [\text{daughters}=u:\text{Det} \cap N]]$   
 b.  $\text{RuleDaughters}(NP, \text{Det} \cap N)$

‘RuleDaughters’ is to be the function in (17). Thus ‘RuleDaughters’, if provided with a subtype of  $\text{Sign}^+$  and a subtype of  $\text{Sign}$  as arguments, will return a function which maps a string of signs of the first type to the second type with the restriction that the daughters field is filled by the string of signs:

- (17)  $\lambda T_1 : \text{Type} .$   
 $\lambda T_2 : \text{Type} .$   
 $\lambda u : T_1 . T_2 \left[ \bigwedge \right] [\text{syn}: [\text{daughters}=u:T_1]]$

#### 4.3. Semantic Composition using asymmetric merge

As we mentioned in section 3.2.1, we use asymmetric merge to integrate utterances into the DGB. We postulate as the denotation associated with the root of the tree the type *illocutionary proposition*, which is hence compatible with declarative, interrogative and imperative utterances. This gets refined as each word gets introduced using asymmetric merge, which enables us to effect a combinatory operation that synthesises function application and unification.

We exemplify how this works in explicating the evolution of the speaker’s information state in example (3), repeated here as (18).

- (18) [Context: J is in the kitchen searching for the always disappearing scissors. As he walks towards the cutlery drawer he begins to make his utterance, before discovering the scissors once the drawer is opened.] J: Who took the sci-...

Before the first word we assume that the speaker has the question ‘who took the scissors’ (which we denote here with  $q_0$ ) on his agenda, in the private part of his information state;<sup>5</sup> in his visual field he can see no scissors:<sup>6</sup>

$$(19) \quad \text{InfState}_0 : T_0 \text{ where } T_0 \text{ is } \left[ \begin{array}{l} \text{private.agenda} = \langle \text{ask}(s, q_0) \rangle : \langle \text{Type} \rangle \\ \text{DGB.FACTS} = \{ \dots \neg \exists x \text{In}(\text{Vis} - \text{sit}, x.\text{scissors}(x)) \dots \} : \{ \text{Type} \} \end{array} \right]$$

We assume that an utterance,  $u_1$ , of an interrogative NP such as *who* results in the update in (20). The content associated with the utterance involves *projection* in a sense we explicate shortly. Here it is projected to be a question of type *WhPQ* as in (20), a function from records that include a person  $x$  into propositions involving a predication  $P(x)$ .

$$(20) \quad \left( \begin{array}{l} x:\text{Ind} \\ c:\text{person}(x) \end{array} \right) \rightarrow \text{RecType}$$

$P$  is of type *Pred*, that is  $(\text{Ind} \rightarrow \text{RecType})$ , the type of functions from individuals to record types. The function,  $w$ , which serves as the incremental content (cf. Milward and Cooper, 1994) of *who* is given in (21).<sup>7</sup>

$$(21) \quad w = \lambda P:\text{Pred} . \lambda r: \left( \begin{array}{l} x:\text{Ind} \\ c:\text{person}(x) \end{array} \right) . P(r.x)$$

Now the updated information state is characterized in (22).

$$(22) \quad \text{InfState}_1 : T_0 \left[ \begin{array}{l} \bigwedge \\ \cdot \end{array} \right] \left[ \begin{array}{l} \text{sit} = u_1 : \text{Sit} \\ \text{DGB.Pending} = \left[ \begin{array}{l} \text{sit-type} = \left[ \begin{array}{l} \text{phon} : \text{who} \\ \text{cont} = w : (\text{Pred} \rightarrow \text{WhPQ}) \end{array} \right] : \text{RecType} \end{array} \right] : \text{RecType} \end{array} \right]$$

We denote the type computed in (22) by  $T_1$ . We take content of the verb *took* to be (23a) (ignoring tense) of type (23b). We represent this content as ‘take’.

$$(23) \quad \text{a. take}' = \lambda y:\text{Ind} . \lambda x:\text{Ind} . [e:\text{take}(x,y)] \quad \text{b. } (\text{Ind} \rightarrow \text{Pred})$$

Thus the incremental content of *who took* can be computed in line with Milward and Cooper (1994) as (24a) which can be expressed with reference to  $\text{InfState}_1$  as (24b).

<sup>5</sup>This is not a necessary assumption—presumably many utterances are partially planned as their generation starts, hence the occurrence of some filled pauses to buy the speaker planning time.

<sup>6</sup>We assume this visual field is part of the speaker’s DGB, which is again a simplification, since it need not be (quasi)-shared.

<sup>7</sup>Milward and Cooper (1994) offer an explicit procedure that converts such lambda terms to existentially quantified propositions. Their fragment considered only declarative utterances. In the current work we could adapt their procedure to yield existentially quantified *illocutionary* propositions.

$$(24) \quad \text{a. } \lambda y:Ind . w(\text{take}'(y)) \quad \text{b. } \lambda y:Ind . \text{InfoState}_1.\text{DGB.Pending.sit-type.cont}(\text{take}'(y))$$

We abbreviate (24b) as *wt*. We can compute a type for  $\text{InfState}_2$  as in (25).

$$(25) \quad \text{InfState}_2 : T_1 \left[ \begin{array}{c} \wedge \\ \cdot \end{array} \right] \left[ \text{DGB.Pending} = \left[ \begin{array}{c} \text{sit} = u_2:\text{Sit} \\ \text{sit-type} = \left[ \begin{array}{c} \text{phon} : \text{who took} \\ \text{cont} = wt : (Ind \rightarrow WhPQ) \end{array} \right] : \text{RecType} \end{array} \right] : \text{RecType} \right]$$

We use  $T_2$  to represent the type computed in (25). J opens the drawer and sees the scissors there. This updates the DGB facts with a fact that the scissors are in the visual field. This, in turn, implies that no one took the scissors, and hence, given the existence of a resolving answer to the question, the original motivation for asking it is eliminated. We can now compute a type for the next information state,  $\text{InfState}_3$ , as in (26).

$$(26) \quad \text{InfState}_3 = T_2 \left[ \begin{array}{c} \wedge \\ \cdot \end{array} \right] \left[ \begin{array}{c} \text{private.agenda} = \langle \rangle : \langle \text{Type} \rangle \\ \text{DGB.FACTS} = \left\{ \dots \left[ \begin{array}{c} x:Ind \\ c:\text{scissors}(x) \\ \text{In}(\text{VisSit}, x) \end{array} \right] \dots \right\} : \{ \text{Type} \} \end{array} \right]$$

#### 4.4. Pending and charts

Information included in the ‘Pending’-field of the dialogue gameboard includes a type that represents the agent’s view of the ongoing parse as the utterance unfolds. We call this type a *chart-type* because we appeal to a notion of chart parsing for this purpose, though as will become clear our approach is compatible with various other approaches for such representations, for instance Hough’s graph-based representation (Hough (2015)) which synthesizes a graph-based Dynamic Syntax view of parsing (Sato (2011)) with the Incremental Unit (IU) framework of Schlangen and Skantze (2011) for incremental processing.

The type of Pending remains *LocProp*, as in (27). The issues that remains is how to explicate  $T_{\text{chart}}$  in order to understand how incremental content arises.

$$(27) \quad \left[ \begin{array}{c} \text{sit} = s \\ \text{sit-type} = T_{\text{chart}} \end{array} \right]$$

We present here the briefest sketch of chart parsing as it is used in computational linguistics; for a recent textbook introduction to chart parsing see Jurafsky and Martin (2009), Chap. 13, whereas for its implementation in TTR see Cooper (2016). The idea of a chart is that it should store all the hypotheses made during the processing of an utterance which in turn allow us to compute new hypotheses to be added to the chart. Charts can be updated incrementally for

each word and they can represent several live possibilities in a single data structure. We will say that a chart is a record and we will use our resources to compute a chart type on the basis of utterance events.

#### 4.5. Charts: a simplified example

Suppose that we have so far heard an utterance of the word *Dudamel*. At this point we will say that the type of the chart is (28)

$$(28) \quad \left[ \begin{array}{ll} e_1 & : \text{“Dudamel”} \\ e & : [e_1:\text{start}(e_1)] \cap [e_1:\text{end}(e_1)] \end{array} \right]$$

The main event of the chart type (represented by the  $e$ -field) breaks the phonological event of type “Dudamel” down into a string of two events, the start and the end of the “Dudamel”-event.<sup>8</sup> Thus (28) records that we have observed an event of the phonological type “Dudamel” and an event consisting of the start of that event followed by the end of that event. Given that we have the resource  $\text{Lex}_{\text{PropName}}(\text{“Dudamel”}, d)$  available, we can update (28) to (29):

$$(29) \quad \left[ \begin{array}{ll} e_1 & : \text{“Dudamel”} \\ e_2 & : \text{Lex}_{\text{PropName}}(\text{“Dudamel”}, d) \boxed{\wedge} [\text{s-event}: [e=e_1:\text{Phon}]] \\ e & : [e_1:\text{start}(e_1)] \cap [e_1:\text{end}(e_1)] \cap [e_2:\text{start}(e_2)] \cap [e_2:\text{end}(e_2)] \end{array} \right]$$

That is, we add the information to the chart that there is an event (labelled ‘ $e_2$ ’) of the type which is the sign type corresponding to “Dudamel” and that the event which is the speech event referred to in that sign type is the utterance event, labelled by ‘ $e_1$ ’. Furthermore the duration of the event labelled ‘ $e_2$ ’ is the same as that labelled ‘ $e_1$ ’.

The type  $\text{Lex}_{\text{PropName}}(\text{“Dudamel”}, d)$  is a subtype of  $NP$ . Thus the event labelled ‘ $e_2$ ’ could be the first item in a string that would be appropriate for the function which we have abbreviated as (30a), which has the type (30b).

$$(30) \quad \text{a. } S \longrightarrow NP \ VP \mid NP'(VP') \quad \text{b. } (NP \cap VP \rightarrow \text{Type})$$

Cooper (2016) argues for an analogy between non-linguistic event prediction and the prediction that occurs in parsing.<sup>9</sup> So on observing a noun-phrase event one can predict that it might be followed by a verb phrase event thus creating a sentence event. We add a hypothesis event to our chart which takes place at the end of the noun-phrase event as in (31).<sup>10</sup>

<sup>8</sup>These starting and ending events correspond to what are standardly called *vertices* in the chart parsing literature.

<sup>9</sup>Indeed he suggests that this might extend to non-linguistic event prediction among non-humans, e.g., the prediction by a dog playing Fetch that it should run after a stick which is held up.

<sup>10</sup>In terms of the traditional chart parsing terminology this corresponds to an *active edge* involving a *dotted rule*. The fact that the addition of this type to the chart type is triggered by finding something of an appropriate type to be the leftmost element in a string that would be an appropriate argument to the rule corresponds to what is called a *left-corner* parsing strategy.

$$(31) \left[ \begin{array}{lcl} e_1 & : & \text{"Dudamel"} \\ e_2 & : & \text{LexPropName}(\text{"Dudamel"}, d) \left[ \bigwedge \right] [\text{s-event}: [e=e_1: \text{Phon}]] \\ e_3 & : & \left[ \begin{array}{l} \text{rule} = S \longrightarrow NP \ VP \mid NP' (VP') : (NP \frown VP \rightarrow \text{Type}) \\ \text{fnd} = e_2 : \text{Sign} \\ \text{req} = VP : \text{Type} \\ e : \text{required}(\text{req}, \text{rule}) \end{array} \right] \\ e & : & \left[ \begin{array}{l} [e_1 : \text{start}(e_1)] \frown [e_1 : \text{end}(e_1) \\ [e_2 : \text{start}(e_2)] \frown [e_2 : \text{end}(e_2) \\ [e_3 : \text{start}(e_3)] \frown [e_3 : \text{end}(e_3)] \end{array} \right] \end{array} \right]$$

In the  $e_3$ -field the ‘rule’-field is for a syntactic rule, that is, a function from a string of signs of a given type to a type. The ‘fnd’-field is for a sign or string of signs so far found which match an initial segment of a string of the type required by the rule. The ‘req’-field is the type of the remaining string required to satisfy the rule as expressed in the ‘e’-field. This hypothesis event both starts and ends at the end of the event of the noun-phrase event  $e_2$ .

In what follows, we will adopt a simplified version of (31), exemplified in (32). We will omit the ‘e field’.

$$(32) \left[ \begin{array}{lcl} e_1 & : & \text{"Dudamel"} \\ e_2 & : & \text{Lex}_{NP}(\text{"Dudamel"}) \left[ \bigwedge \right] [\text{s-event}: [e = e_1 : \text{Phon}]] \\ e_3 & : & \left[ \begin{array}{l} \text{fnd} = e_2 : \text{Sign} \\ \text{req} = \left[ \begin{array}{l} \text{cat} = VP : \text{Syncat} \\ \text{cont} : (\text{Ind} \rightarrow \text{Prop}) \end{array} \right] : \text{Type} \\ \text{proj} = \left[ \begin{array}{l} \text{s-event} : \text{fnd.phon} \frown \text{req.phon} \\ \text{cat} = S \\ \text{cont} = \text{req.cont}(\text{fnd.cont}) : \text{Prop} \end{array} \right] : \text{Type} \end{array} \right] \end{array} \right]$$

## 5. Incremental Dialogue Processing: principles and examples

With a basic means of representing utterances in progress, we can now formulate certain principles which will serve to help explicate the phenomena discussed in section 2.

### 5.1. Utterance Projection

The first principle we introduce corresponds to the ‘stop option’ in our utterance protocol (14b)—it says that if one projects that an utterance will continue in a certain way, then one can actually use this prediction to update one’s DGB. This is of course a dangerous principle to apply in an unconstrained fashion, and would ideally be formulated using probabilities about the projection, for instance using the framework of Cooper et al. (2015), though we do not do so here. (33) is an update rule which moves a locutionary proposition from pending to Latest-Move. ( $r^*$  represents the previous information state which is required to be of the type labelled ‘preconds’.)

(33) **Utterance Projection**

$$\left[ \begin{array}{l} \text{preconds} = \left[ \begin{array}{l} \text{pending.sit} : \text{Sign} \\ \text{pending.sit-type.proj} : \text{Type} \end{array} \right] \\ \text{effects} = \text{TurnUnderspec} \left[ \bigwedge \right] \left[ \text{LatestMove} = r^* : \text{LocProp} \right] \end{array} \right]$$

We exemplify an incremental view of the latest move that is being moved in (33) with a word-by-word evolution of the latest move, analogous to that in section 4.3, but this time for an initial segment of a declarative utterance: *Jo...saw...*

$$\begin{array}{ll} (34) \text{ a.} & \left[ \begin{array}{l} \text{sit} = u_1 \\ \text{sit-type} = \left[ \begin{array}{l} \text{phon} : \text{"Jo"} \\ \text{dgb-params} : \left[ \begin{array}{l} j : \text{Ind} \\ s_0 : \text{Rec} \end{array} \right] \\ \text{cont} = \lambda P : \text{Pred} . \left[ \begin{array}{l} \text{sit} = s_0 \\ \text{sit-type} = [c_1 : P(j)] \end{array} \right] : (\text{Pred} \rightarrow \text{Prop}) \end{array} \right] \end{array} \right] \\ \text{b.} & \left[ \begin{array}{l} \text{sit} = u_2 \\ \text{sit-type} = \left[ \begin{array}{l} \text{phon} : \text{"Jo saw"} \\ \text{dgb-params} : \left[ \begin{array}{l} j : \text{Ind} \\ s_0 : \text{Rec} \end{array} \right] \\ \text{cont} = \lambda x : \text{Ind} . \left[ \begin{array}{l} \text{sit} = s_0 \\ \text{sit-type} = [c_1 : \text{Saw}(j, x)] \end{array} \right] : (\text{Ind} \rightarrow \text{Prop}) \end{array} \right] \end{array} \right] \end{array}$$

## 5.2. Forward-Looking Disfluencies

*Forward-looking* disfluencies are disfluencies where the moment of interruption is followed not by an alteration, but just by a completion of the utterance which is delayed by a filled or unfilled pause (hesitation) or a repetition of a previously uttered part of the utterance (repetitions). As we mentioned with respect to example (4) and in our discussion in section 4.1, we need a means of enabling at any point in the speech stream the emergence of a question about what is still to come in the current utterance. Forward Looking Disfluencies involve the update rule in (35)—given a context where an initial segment of utterance by A has taken place, the next speaker—underspecified between the current one and the addressee—may address the issue of what A intended to say next by providing a co-propositional utterance:

(35) Forward Looking Utterance Rule:

$$\left[ \begin{array}{l} \text{preconds} = \left[ \begin{array}{l} \text{spkr} : \text{Ind} \\ \text{addr} : \text{Ind} \\ \text{pending.sit-type} : \left[ \begin{array}{l} \text{fnd} : \text{Sign} \\ \text{req} : \text{Sign} \end{array} \right] \end{array} \right] \\ \text{effects} = \text{TurnUnderspec} \left[ \begin{array}{l} \text{MaxQud} = \left[ \begin{array}{l} \text{q} = \lambda x : \text{Ind} . \text{MeanNextUtt}(r^*.\text{spkr}, r^*.\text{fnd}, x) \\ \text{fec} = \{ \} \end{array} \right] : \text{InfoStruc} \\ \text{LatestMove} : \text{LocProp} \\ \text{c2} : \text{Copropositional}(\text{LatestMove}^{\text{content}}, \text{MaxQud}) \end{array} \right] \end{array} \right]$$

A consequence of (35), is that it offers the potential to explain cases like (36). In the aftermath of a filled pause an issue along the lines of the one we have *posited* as the *effect* of the conversational rule (35) actually gets uttered:

- (36) a. Carol 133 Well it's (pause) it's (pause) er (pause) what's his name? Bernard Matthews' turkey roast. (BNC, KBJ)  
 b. They're pretty ... um, how can I describe the Finns? They're quite an unusual crowd actually.  
<http://www.guardian.co.uk/sport/2010/sep/10/small-talk-steve-backley-interview>

On our account such utterances are licensed because these questions are co-propositional with the issue 'what did A mean to say after u0?'. This suggests that a different range of such questions will occur depending on the identity of (the syntactic/semantic type of) u0. This expectation is met, as discussed in Tian et al. (2016), who also discuss cross-linguistic variation with SAQs in English, Chinese, and Japanese.

### 5.3. Prediction and Clarification for incomplete utterances

We return now to (2a,b), repeated here as (37):

- (37) a. A(i): John . . . Oh never mind. B(ii): What about John? A: He's a lovely chap but a bit disconnected. / # burnt himself while cooking last night.  
 b. A(i): John . . . Oh never mind. B(ii): John what? A: burnt himself while cooking last night. / # He's a lovely chap but a bit disconnected.

Whether (2a) or (2b) arise depends on whether one uses utterance projection or the forward looking utterance rule. For the former, as we showed in (34), an initial referential NP when prediction is applied results in (roughly) the projected content in (38). Thus, given the conversational rule *QSPEC* (the rule (9) above), B's follow up questions are justified as seeking elaboration of the existentially quantified proposition  $\exists P \text{ IllocRel}(\text{spkr}, P(j))$ :

$$(38) \quad \text{LatestMove} = \left[ \begin{array}{l} \text{sit} = u_1 \\ \text{sit-type} = \left[ \begin{array}{l} \text{phon} : \text{"John"} \\ \text{dgb-params} : \left[ \begin{array}{l} j : \text{Ind} \\ s0 : \text{Rec} \end{array} \right] \\ \text{cont} = \lambda P : \text{Pred} . \left[ \begin{array}{l} \text{sit} = s0 \\ \text{sit-type} = [c1 : P(j)] \end{array} \right] : (\text{Pred} \rightarrow \text{Prop}) \end{array} \right] \end{array} \right]$$

As for (2b), this follows by applying the forward looking utterance rule, where the addressee takes over.

#### 5.4. Sluicing, incrementally

We assume, following Cooper (2013a) that a QNP such as ‘someone’ has a content of the form (39), where *q-params* constitute descriptive content that, in contrast to the *dgb-params*, does not require instantiation.

$$(39) \quad \left[ \begin{array}{l} \text{q-params} : \left[ \begin{array}{l} \text{restr} = \text{person} : \text{Ppty} \\ \text{witness} : \exists(\text{restr}) \end{array} \right] \\ P : \text{Ppty} \\ \text{cont} = \left[ \begin{array}{l} \text{scope} = P : \text{Ppty} \\ c1 = \text{witness} : \exists(\text{restr}, \text{scope}) \end{array} \right] : \text{Rtype} \end{array} \right]$$

We assume a constructional specification for a sluice as in (40), deriving from Ginzburg (2012). A sluice denotes a question (i.e., a function from records into propositions) whose domain is the type denoted by the *wh*-phrase and whose range is that given by MaxQUD’s proposition where the *wh*-phrase’s variable is substituted for that associated with the antecedent:

$$(40) \quad \text{sluice-int-cl.cont} = (\text{whP.rest})\text{MaxQUD.prop}[\text{antecedent.x} \mapsto \text{whP.x}]$$

The sluice is triggered by utterance prediction that LatestMove is *A asserts that Someone P’ed*. This gives rise to QUD update, via Assertion QUD-incrementation with (41a) as maximal element of QUD and the antecedent for a sluice, as in (41b), which is predicted to mean (41c) immediately after it is uttered:

- (41) a.  $\exists x, P[\text{Person}(x) \wedge P(x)]$   
 b. A: Someone ... B: Who?  
 c. ‘Who is that person (that has some as yet uninstantiated property)?’

## 6. Conclusions and further Work

In this paper we provide data related to the potential for clarification, repair, and sluicing in mid-utterance. This data shows that the “competence grammar” must be formulated in a way that enables incremental (minimally word by word and even mid-word) semantic composition to be effected. In particular, this data constitutes an argument for incremental access to the contextual repository QUD. This approach has parallels to Dynamic Syntax (Kempson et al., 2001), and particularly recent dialogue-friendly versions (Purver et al., 2011; Kempson et al., 2016), where the central idea is online, incremental construction of meaning representations. However, the incremental account presented here not only allows the representation of utterances, but the internal state of a dialogue agent, including background beliefs and the events in the situated context, to be updated online for entire interactions. In a more detailed presentation we will present a small grammar/context fragment. In future work we hope to investigate experimentally the processing of data of the kind presented here.

# Control, logophorocity, and harmonic modality in Gengbe desire reports<sup>1</sup>

Thomas GRANO — *Indiana University*

Samson LOTVEN — *Indiana University*

**Abstract.** With a special focus on jussive clauses, we present and account for a puzzling interaction between mood choice, embedding verb choice, and antecedent choice for logophoric subjects in attitude reports in Gengbe (a Niger-Congo language closely related to Ewe, spoken in southern Togo and Benin). The account draws on the property theory of control (Chierchia, 1984; Dowty, 1985), the property theory of imperatives (Portner, 2004), and the view that logophors abstract to yield derived properties (Pearson, 2015). Insofar as Gengbe jussive clauses are similar in distribution and function to Romance subjunctive clauses, a primary theoretical contribution of the paper is in showing that Portner's property analysis of imperatives can be fruitfully extended to subjunctive clauses, thereby achieving a theoretical unification of sentence mood and verbal mood. We also sketch a variant of the account couched in Kratzer's (2013) decomposition approach to embedding, whereby jussive clauses in Gengbe desire reports instantiate harmonic modality.

**Keywords:** attitude reports, control, jussives, logophors, modality, mood

## 1. Introduction

The grammatical category MOOD is typically taken to subsume at least two subtypes. Following Portner's (2009) terminology, SENTENCE MOOD has to do with clause type oppositions like those illustrated in (1), and VERBAL MOOD prototypically has to do with selected verbal forms such as the well studied Romance indicative/subjunctive opposition illustrated with the Spanish data in (2).

- |     |                                                      |               |
|-----|------------------------------------------------------|---------------|
| (1) | SENTENCE MOOD                                        |               |
|     | a. John left.                                        | DECLARATIVE   |
|     | b. Did John leave?                                   | INTERROGATIVE |
|     | c. Leave!                                            | IMPERATIVE    |
| (2) | VERBAL MOOD                                          |               |
|     | a. Juan cree que Pedro <b>es</b> feliz.              | INDICATIVE    |
|     | 'Juan believes that Pedro is.IND happy.'             |               |
|     | b. Juan quiere que Pedro <b>sea</b> feliz.           | SUBJUNCTIVE   |
|     | <i>Lit.</i> : 'Juan wants that Pedro be.SBJV happy.' |               |

The context for this paper is set by the theory of sentence mood advanced by Portner (2004) and further elaborated by Portner (2007); Zanuttini et al. (2012). Following the widely influential tradition of Stalnaker (1978), Portner takes the position that declarative clauses denote propo-

---

<sup>1</sup>We would like to thank our linguistic consultant Gabriel Mawusi for his tireless efforts in producing and commenting on the Gengbe sentences reported here and Samuel Obeng for supporting this research. We would also like to thank audiences at Indiana University as well as at *SuB* 21 for their helpful feedback on the content of the paper.

sitions and that making an assertion amounts to adding a proposition to the Common Ground, which can be modeled as a set of propositions. In a similar vein, Portner follows Hamblin (1973); Karttunen (1977) in analyzing interrogative clauses as denoting sets of propositions, and follows Ginzburg (1995); Roberts (1996) in modeling question speech acts as adding a set of propositions to the Question Set, which can be modeled as a set of sets of propositions. Finally, Portner's main contribution is in building on a proposal due to Hausser (1980) and analyzing imperative clauses as denoting properties of individuals. For Portner, directive force involves adding a property to the addressee's To-Do List, which is a set of properties that the participants in the conversation mutually assume that the addressee will try to make true of herself.

In this context, the narrow goal of this paper is to argue that JUSSIVE clauses in Gengbe<sup>2</sup> are also fruitfully analyzed as denoting properties of individuals, as evidenced primarily by how they interact with antecedent choice for logophoric pronouns in embedded contexts. We define jussive clauses in Gengbe as clauses that contain the preverbal marker *ně*, a marker which we correspondingly call the jussive marker and gloss as JUSS.<sup>3</sup> Some representative examples illustrating the distribution and interpretation of jussive clauses in Gengbe are given in the bracketed constituents in (3)–(6).

- (3) [Kòfí **ně** qù nú].  
Kofi JUSS eat thing  
'Kofi should eat.' / 'I want Kofi to eat.'
- (4) Kòfí dóòúsě̀̀ Àkú [bé **ně** qù nú].  
Kofi encourage Aku COMP JUSS eat thing  
'Kofi encouraged Aku to eat.'
- (5) Ámá **dží** [bé Àkú **ně** qù nú].  
Ama want COMP Aku JUSS eat thing  
'Ama wants Aku to eat.'
- (6) Ámá **káqóédží** [bé Àkú **ně** qù nú].  
Ama believe COMP Aku JUSS eat thing  
'Ama believes that Aku should eat.'

Assuming for the sake of argument that we are right in analyzing jussive clauses as property-denoting, what is the theoretical significance of this conclusion? If jussive clauses distributed and functioned just like imperative clauses, then our conclusion would simply count as further supporting evidence for Portner's theory of clause types, but not a novel theoretical proposal.

<sup>2</sup>Gengbe (also known as *Gen* or *Mina*) is a Niger-Congo language closely related to Ewe and spoken in southern Togo and Benin. According to Ethnologue, it has 278,900 speakers worldwide. All of the data reported here were collected at Indiana University by the authors in consultation with Gabriel Mawusi, a middle-aged male native Gengbe speaker from Batonou, Togo.

<sup>3</sup>A full list of the abbreviations we use in glosses is as follows: ACC = accusative, COMP = complementizer, EXH = exhortative, INDIC = indicative, JUSS = jussive, IMP = imperative, LOG = logophor, PL = plural, POT = potential, PRM = promissive, SBJV = subjunctive, 1/3SG = 1st/3rd-person singular

But in fact, jussive clauses do not function like imperative clauses: of the examples in (3)–(6), the only one we are aware of that could be translated using an imperative clause is (4), and even this is possible only in languages like Korean that allow embedded imperatives (see e.g. Zanuttini et al. 2012). Instead, jussive clauses behave more like Romance subjunctive clauses, useable to express optative-like meaning in unembedded contexts (3), and found in complements to directive (4) and desiderative (5) predicates. The only non-subjunctive-like behavior is witnessed in (6), where the jussive marker is embedded under ‘believe’ and expresses a deontic semantics; in Romance, by contrast, mood choice under ‘believe’ is subject to inter- and intra-linguistic variation, but the subjunctive in this environment in those cases where it is possible is not associated with a deontic semantics. (See e.g. Giorgi and Pianesi 1997 for a survey of mood choice in Romance.)

Given that the distribution and interpretation of Gengbe jussive clauses is not absolutely identical to the distribution and interpretation of Romance subjunctive clauses, we do not mean to suggest that they should have identical analyses. But we do take our property analysis of Gengbe jussive clauses to be highly suggestive of the more general utility of taking Portner’s type-theoretic approach to sentence mood and extending it to verbal mood as well, thereby contributing to a theoretical unification of the two major mood subtypes. Making this case constitutes a broader theoretical aim of this paper, and in the course of carrying out this broader aim, we will suggest below that Romance subjunctive clauses are also fruitfully analyzed as property-denoting.

The organization of the rest of this paper is as follows. In section 2, we lay out our core data and puzzles. In section 3, we show that the data can be accounted for via three key proposals: (1) logophors are obligatorily bound by an attitude predicate (following Pearson 2015), (2) jussive clauses denote properties, and (3) Gengbe ‘want’ selects for a property whereas Gengbe ‘believe’ is flexible in being able to select for either a property or a proposition. In section 4, we unpack these proposals, grounding them in ideas found in previous literature and advancing independent Gengbe-internal and cross-linguistic support for them. In section 5 we compare two analytical strategies for implementing the property analysis of jussive clauses, one whereby the jussive marker is an individual abstractor *à la* Zanuttini et al. (2012) and one whereby the jussive marker is an individual-relative priority modal that harmonizes with the embedding predicate in embedded contexts *à la* Kratzer (2013). Finally, section 6 concludes.

## 2. Core data and puzzles

The first observation we make is that Gengbe has a logophoric pronoun *jè* which at first glance seems to behave like an ordinary logophor in the sense of Clements (1975): it must be embedded under a speech or attitude predicate, and it is obligatorily co-referential with the subject of that predicate. In (7), multiple embedding gives rise to the expected ambiguity whereby *jè* can be co-referential either with *Ámǎ* (the subject of the immediately higher clause) or with *Kòfí* (the matrix subject).

- (7) **Kòfí<sub>1</sub> bé Ámá<sub>2</sub> káqóédzǐ** [bé **jè<sub>1/2/\*3</sub>** dù nú].  
 Kofi say Ama believe COMP LOG eat thing  
 ‘Kofi said Ama believes that he/she (= Kofi/Ama) ate.’

With this in mind, the core puzzle we want to solve is the observation that when *jè* is embedded under *dzǐ* ‘want’, the availability of different antecedents interacts with mood choice. As seen in (8), when *dzǐ* embeds the mood marker *lá* (which we analyze as a potential marker, following Essegbey’s 2008 treatment of Ewe *a*), the logophor obligatorily co-refers with the subject of the immediately higher clause (the hallmark of obligatory control in the sense of Landau 2000), but as seen in (9), when *dzǐ* embeds the jussive marker *ně*, the logophor is obviative with respect to the subject of the immediately higher clause and instead obligatorily co-refers with the subject of a higher embedding clause.<sup>4</sup>

- (8) (Àkú<sub>1</sub> bé Kòfí<sub>2</sub> bé) **Ámá<sub>3</sub> dzǐ** [bé **jè<sub>(\*1/\*2)/3/\*4</sub>** **lá** dù nú].  
 Aku say Kofi say Ama want COMP LOG POT eat thing  
 ‘(Aku said that Kofi said that) Ama wants to eat.’ (control)
- (9) (Àkú<sub>1</sub> bé) **Kòfí<sub>2</sub> bé Ámá<sub>3</sub> dzǐ** [bé **jè<sub>(1/2/\*3/\*4)</sub>** **ně** dù nú].  
 Aku say Kofi say Ama want COMP LOG JUSS eat thing  
 ‘(Aku said that) Kofi said that Ama wants him (= (Aku/Kofi) to eat.’ (obviation)

The pattern in (8)–(9) is not unique to *dzǐ* ‘want’ but is found also with other attitude predicates expressing desiderative, intentional or promissive meaning such as *wòsúsú* ‘intend’, *dzèàgbàgbá* ‘try’, *lè* ‘agree’, and *ffèdzògbè* ‘pledge’.

While we take the mood–coreference interaction in (8)–(9) to be the core explanandum of this paper, there are two subsidiary puzzles that we take to be important clues in understanding (8)–(9), and we want to make sure that our analysis accounts for these subsidiary puzzles as well. The first subsidiary puzzle has to do with what happens when the complement to *dzǐ* ‘want’ has a non-logophoric, full-NP subject. In this situation, what we see is that the mood marker *lá* is simply unacceptable (10) and *ně* has to be used instead (11).

- (10) \***Kòfí bé Ámá dzǐ** [bé **Àkú lá** dù nú].  
 Kofi say Ama want COMP Aku POT eat thing  
 Intended: ‘Kofi said Ama wants Aku to eat.’

<sup>4</sup>Further strengthening the analytical connection to control and obviation phenomena, it bears noting that logophoric *objects* behave differently, admitting free choice of antecedent in the context of jussive marking (and potential marking would be ungrammatical here because of the full-NP subject; cf. (10)):

- (i) **Kòfí bé Ámá dzǐ** [bé Àkú<sub>3</sub> **ně** kpó **jè<sub>1/2/\*3</sub>**].  
 Kofi say Ama want COMP Ama JUSS see LOG  
 ‘Kofi said Ama wants Aku to see him/her (= Kofi/Ama).’

This subject/object asymmetry is likely connected to the fact that control is a subject-oriented phenomenon: generally only subject positions can be controlled. Unfortunately, though, this subject/object asymmetry is not something that we will be able to account for in this paper.

- (11) Kòfí bé Ámá **dʒí** [bé Àkú **ně** qù nú].  
 Kofi say Ama want COMP Aku JUSS eat thing  
 ‘Kofi said Ama wants Aku to eat.’

The second subsidiary puzzle has to do with what happens when *dʒí* ‘want’ is replaced with *káqóédʒí* ‘believe’. As we already saw in (7) above, *káqóédʒí* ‘believe’ can combine with complements that are not overtly marked for mood. But overt mood marking is also possible. Considering first full-NP subjects in the complement clause, we see that both *lá* and *ně* are acceptable and give rise to a difference in meaning suggested by the supplied free translations: *lá* gives rise to a future-oriented meaning (12) whereas *ně* gives rise to a deontic meaning (13).

- (12) Kòfí bé Ámá **káqóédʒí** [bé Àkú **lá** qù nú].  
 Kofi say Ama believe COMP Aku POT eat thing  
 ‘Kofi said Ama believes that Aku will eat.’
- (13) Kòfí bé Ámá **káqóédʒí** [bé Àkú **ně** qù nú].  
 Kofi say Ama believe COMP Aku JUSS eat thing  
 ‘Kofi said Ama believes that Aku should eat.’

Finally, when the full-NPs in (12)–(13) are replaced by the logophor, yet another interesting pattern emerges: when the mood marker *lá* is used, the logophor can take either of the higher subjects as its antecedent, just as in (7) where there is no overt mood marking. This is illustrated in (14). But when the mood marker *ně* is used, we see the return of the *dʒí* ‘want’-like behavior witnessed in (9) above: only the more distant subject is available as an antecedent. This is illustrated in (15).

- (14) Kòfí<sub>1</sub> bé Ámá<sub>2</sub> **káqóédʒí** [bé jè<sub>1/2</sub> **lá** qù nú].  
 Kofi say Ama believe COMP LOG POT eat thing  
 ‘Kofi said Ama believes that he/she (= Kofi/Ama) will eat.’
- (15) Kòfí<sub>1</sub> bé Ámá<sub>2</sub> **káqóédʒí** [bé jè<sub>1/\*2</sub> **ně** qù nú].  
 Kofi say Ama believe COMP LOG JUSS eat thing  
 ‘Kofi said Ama believes that he (= Kofi) should eat.’

The behavior seen in (12)–(15) is not unique to *káqóédʒí* ‘believe’; it is also borne out for other predicates including *já* ‘know’, *gblɔ̃* ‘say’, and *kúùdrɛ̃* ‘dream’.

### 3. The proposed solution in three stipulations

The goal of this section is to show that all of the puzzles associated with the data from the previous section can be accounted for with just three rather mundane stipulations. (We call them stipulations for now so as to focus on how they account for the data rather than on how they might be independently justified; the task of independently justifying the stipulations is taken up in section 4.) We will first describe the three stipulations, and then show how they make sense of the data.

The perspective from which we approach the puzzles begins with the recognition that these puzzles reduce to three kinds of asymmetries: logophoric subjects pattern unlike full-NP subjects, the jussive marker patterns unlike the potential marker, and ‘want’ patterns unlike ‘believe’. One way or another, then, the grammar of Gengbe will need to draw a distinction in each of these three areas. Each of the three stipulations we advance targets one of these asymmetries, putting the bulk of the explanatory burden on the semantic type system. Portner (2004) establishes the utility of exploiting the type system in understanding mood contrasts, which we take to provide a kind of *a priori* justification for going down this path.

The first stipulation identifies a contrast between logophors and ordinary full-NPs or pronouns: namely, what is special about a logophor is that it has to be bound by an attitude predicate (following Pearson 2015, who builds on Heim 2002; von Stechow 2002, 2003). So, if a structure contains a logophoric pronoun, that pronoun can be bound by an attitude predicate in the immediately higher clause, as in (16a), or by an attitude predicate in some higher clause, as in (16b), but if it is not bound by any attitude predicate at all, as in (16c), then the structure is ungrammatical.

- (16) **Stipulation #1:** A logophor has to be bound by an attitude predicate:
- a. Kofi say [ Ama **believe** [  $\lambda x$ . [ **LOG<sub>x</sub>** eat ] ] ] OK
  - b. Kofi **say** [  $\lambda x$ . [ Ama believe [ **LOG<sub>x</sub>** eat ] ] ] OK
  - c. Kofi say [ Ama believe [ **LOG<sub>x</sub>** eat ] ] ungrammatical

The second stipulation identifies a contrast between jussive and potential marking: in particular, the Gengbe jussive marker *nɛ́* contributes an individual argument whereas the potential marker *lá* does not. Assuming for concreteness that a Gengbe clause with no mood marking has a type  $\langle st \rangle$  denotation, this means that a jussive-marked clause will be type  $\langle e, st \rangle$ , as in (17a). By contrast, the potential marker has no interesting type-theoretic effect, as in (17b).

- (17) **Stipulation #2:** *nɛ́* ‘JUSS’ contributes an individual argument but *lá* ‘POT’ does not:
- a.  $[Kofi\ eat]_{\langle st \rangle} \rightarrow [\lambda x . Kofi\ JUSS\ eat]_{\langle e, st \rangle}$
  - b.  $[Kofi\ eat]_{\langle st \rangle} \rightarrow [Kofi\ POT\ eat]_{\langle st \rangle}$

Finally, the third stipulation identifies a contrast between *dʒí* ‘want’ and *káqóédʒí* ‘believe’: *dʒí* ‘want’ is type-theoretically rigid in only being able to combine with a property-denoting complement, whereas *káqóédʒí* ‘believe’ is type-theoretically flexible in being able to combine either with a property-denoting complement or a proposition-denoting complement. This is schematized in (18).

- (18) **Stipulation #3:** *dʒí* ‘want’ can only combine with a property whereas *káqóédʒí* ‘believe’ can combine with either a proposition or a property:
- a.  $\llbracket dʒí \rrbracket = \lambda P_{\langle e, st \rangle} \lambda x \lambda w . \forall w' \in \text{BEST}_{\text{desire}}(\text{DOX}(x, w)) : P(x)(w')$   $\langle \langle e, st \rangle, \langle e, st \rangle \rangle$
  - b.  $\llbracket káqóédʒí \rrbracket = \lambda p_{\langle st \rangle} \lambda x \lambda w . \forall w' \in \text{DOX}(x, w) : p(w')$   $\langle st, \langle e, st \rangle \rangle$
  - b'.  $\llbracket káqóédʒí' \rrbracket = \lambda P_{\langle e, st \rangle} \lambda x \lambda w . \llbracket káqóédʒí \rrbracket (P(x))(x)(w)$   $\langle \langle e, st \rangle, \langle e, st \rangle \rangle$   
 $= \lambda P_{\langle e, st \rangle} \lambda x \lambda w . \forall w' \in \text{DOX}(x, w) : P(x)(w')$

The fine-grained semantics of desire predicates will not be relevant for anything that follows but we assume for concreteness as in (18a) that ‘want’ involves a bouletic ( $BEST_{desire}$ -based) ordering source over the attitude holder’s doxastic alternatives, essentially following von Fintel (1999) (though cf. also Heim 1992; Giannakidou 1999 and many others for variations on this theme). Von Fintel’s semantics for ‘want’ is modified here so that the first argument of ‘want’ is a property whose unsaturated individual argument gets identified with the attitude holder (see Chierchia 1984, 1990; Dowty 1985, and more recently Stephenson 2010; Pearson 2016 for more sophisticated variants of this basic idea). As for ‘believe’, we adopt for concreteness the standard Hintikka view that it effects universal quantification over the attitude holder’s doxastic alternatives; crucially for us, it comes in both a  $\langle st, \langle e, st \rangle \rangle$  variant, as in (18b), as well as a  $\langle \langle e, st \rangle, \langle e, st \rangle \rangle$  variant, as in (18b’), the latter of which can be derived from the former as a type shift. Just like we did for ‘want’ in (18a), the type-shifted variant of ‘believe’ in (18b’) is set up in such a way that the unsaturated position associated with the property argument gets identified with the attitude holder.

With these three stipulations in place, all of the puzzling asymmetries laid out in the previous section immediately follow. Consider first what we called the core puzzle, i.e., the interaction seen in desire reports between mood marker choice and antecedent choice for logophors, repeated schematically in (19)–(20).

(19) Kofi<sub>1</sub> say [Ama<sub>2</sub> want [LOG<sub>\*1/2</sub> POT eat] ]                      want+LOG+POT → CTRL

(20) Kofi<sub>1</sub> say [Ama<sub>2</sub> want [LOG<sub>1/\*2</sub> JUSS eat] ]                      want+LOG+JUSS → OBV.

The unavailability of a long-distance antecedent construal for the logophor in (19) follows from the fact that only the local antecedent construal results in ‘want’ combining with a type  $\langle e, st \rangle$  complement, which is the only kind of complement it accepts. As schematized in (21), local binding of the logophor by ‘want’ renders the relevant complement a type  $\langle e, st \rangle$  expression (21a), whereas long-distance binding of the logophor by ‘say’ preserves the type  $\langle st \rangle$  status of the complement to ‘want’ and therefore results in type-mismatch-induced uninterpretability (21b).

(21) want+LOG+POT induces control:  
 a. Kofi say Ama [want $\langle \langle e, st \rangle, \langle e, st \rangle \rangle$  [ $\lambda x$ . LOG<sub>*x*</sub> POT eat] $\langle e, st \rangle$  ]                      ← OK  
 b. Kofi say [ $\lambda x$ . Ama want $\langle \langle e, st \rangle, \langle e, st \rangle \rangle$  [LOG<sub>*x*</sub> POT eat] $\langle st \rangle$  ]                      ← \*

In (20), by contrast, when a jussive-marked clause is used, the opposite holds. Local binding of the logophor by ‘want’ conspires with individual-argument-introducing JUSS to yield a type  $\langle e, \langle e, st \rangle \rangle$  complement for ‘want’, and this yields a type mismatch. But long-distance binding of the logophor by ‘say’ ensures that the complement to ‘want’ is type  $\langle e, st \rangle$  (achieved via the JUSS-induced individual argument added onto an underlyingly type  $\langle st \rangle$  clause), so the structure is interpretable. (We assume here and in what follows that ‘say’ is like ‘believe’ in being able to accept both  $\langle st \rangle$  and  $\langle e, st \rangle$  complements.)

(22) want+LOG+JUSS induces obviation:

- a. Kofi say Ama [want<sub><<e,st>, <e,st>></sub> [ $\lambda x \lambda y$ . LOG<sub>x</sub> JUSS eat]<sub><e, <e,st>></sub>]  $\leftarrow$  \*  
 b. Kofi say [ $\lambda x$ . Ama want<sub><<e,st>, <e,st>></sub> [ $\lambda y$ . LOG<sub>x</sub> JUSS eat]<sub><e,st></sub>]  $\leftarrow$  OK

The two subsidiary puzzles also fall into place. The first of the two subsidiary puzzles was that when ‘want’ embeds a full-NP subject, the embedded clause cannot be potential-marked and instead must be jussive-marked, as repeated schematically in (23)–(24).

(23) \*Kofi say [Ama want [Aku POT eat] ] want+full-NP+POT  $\rightarrow$  \*

(24) Kofi say [Ama want [Aku JUSS eat] ] want+full-NP+JUSS  $\rightarrow$  OK

The facts in (23)–(24) now similarly follow from type-theoretic principles, as schematized in (25). With no logophoric binding at stake, the potential marker results in a type  $\langle st \rangle$  denotation, which ‘want’ cannot handle, whereas the jussive marker yields a type  $\langle e, st \rangle$  complement, appropriate for ‘want’.

- (25) a. Kofi say [Ama want<sub><<e,st>, <e,st>></sub> [Aku POT eat]<sub><st></sub>]  $\leftarrow$  \*  
 b. Kofi say [Ama want<sub><<e,st>, <e,st>></sub> [ $\lambda x$ . Aku JUSS eat]<sub><e,st></sub>]  $\leftarrow$  OK

Finally, the second of the two subsidiary puzzles was the observation that when ‘want’ is replaced by ‘believe’, all of the restrictions go away, except that a logophor in a jussive-marked clause still resists local binding just like it does for ‘want’. This is repeated schematically in (26)–(29).

(26) Kofi say [Ama believe [Aku POT eat] ] believe+full-NP+POT  $\rightarrow$  OK

(27) Kofi say [Ama believe [Aku JUSS eat] ] believe+full-NP+JUSS  $\rightarrow$  OK

(28) Kofi<sub>1</sub> say [Ama<sub>2</sub> believe [LOG<sub>1/2</sub> POT eat] ] believe+LOG+POT  $\rightarrow$  AMBIG.

(29) Kofi<sub>1</sub> say [Ama<sub>2</sub> believe [LOG<sub>1/\*2</sub> JUSS eat] ] believe+LOG+JUSS  $\rightarrow$  OBV.

Turning first to (26)–(27), type-theoretic flexibility for ‘believe’ ensures that both kinds of mood markers will be acceptable when no logophors are present. As schematized in (30), potential-marking yields a type  $\langle st \rangle$  complement and jussive-marking yields a type  $\langle e, st \rangle$  complement.

(30) Type flexibility for ‘believe’ renders believe+full-NP+POT / believe+full-NP+JUSS both OK:

- a. Kofi say [Ama believe<sub><<st>, <e,st>></sub> [Aku POT eat]<sub><st></sub>]  $\leftarrow$  OK  
 b. Kofi say [Ama believe<sub><<e,st>, <e,st>></sub> [ $\lambda x$ . Aku JUSS eat]<sub><e,st></sub>]  $\leftarrow$  OK

Turning next to (28), here again type-theoretic flexibility for ‘believe’ ensures the availability of both binding options: as schematized in (31), long-distance binding yields a type  $\langle st \rangle$  complement and local binding yields a type  $\langle e, st \rangle$  complement.

- (31) Type flexibility also enables both binding options for believe+LOG+POT:
- a. Kofi say [ $\lambda x$ . Ama believe $\langle\langle st \rangle, \langle e, st \rangle\rangle$  [LOG<sub>x</sub> POT eat] $\langle st \rangle$  ] ← OK
  - b. Kofi say [Ama believe $\langle\langle e, st \rangle, \langle e, st \rangle\rangle$  [ $\lambda x$ . LOG<sub>x</sub> POT eat] $\langle e, st \rangle$  ] ← OK

Finally, we turn to (29): why does a jussive-marked clause force long-distance binding of the logophor? The answer is that local binding conspires with jussive marking to yield a type  $\langle e, \langle e, st \rangle \rangle$  complement, which ‘believe’ (just like ‘want’) cannot tolerate. This is schematized in (32).

- (32) But even with type flexibility, believe+LOG+JUSS induces obviation:
- a. Kofi say [Ama believe $\langle\langle st \rangle, \langle e, st \rangle\rangle / \langle\langle e, st \rangle, \langle e, st \rangle\rangle$  [ $\lambda x \lambda y$ . LOG<sub>x</sub> JUSS eat] $\langle e, \langle e, st \rangle \rangle$  ] ← \*
  - b. Kofi say [ $\lambda x$ . Ama believe $\langle\langle e, st \rangle, \langle e, st \rangle\rangle$  [ $\lambda y$ . LOG<sub>x</sub> JUSS eat] $\langle e, st \rangle$  ] ← OK

In short, we have now seen that all of the data in section 2 follow from the three stipulations in (16)–(18) about the expressions involved in the relevant structures. The task now before us is to independently justify these stipulations.

#### 4. Revisiting the three stipulations

##### 4.1. A logophor has to be bound by an attitude predicate

The first of our three stipulations, namely that a logophor has to be bound by an attitude, is not new to us and so we will not dwell on it extensively here. Pearson (2015) defends this view, attributing it to earlier work by Heim (2002); von Stechow (2002, 2003). It is a rather straightforward way of deriving the generalization that logophors can appear only in attitudinal contexts. Insofar as these authors were concerned with facts quite different from those at issue here, we take their work as providing independent justification for this proposal.

We are not committed to any particular way of encoding this proposal into the grammar, but for concreteness, we can adopt Pearson’s (2015) approach, following Heim (2002); von Stechow (2002, 2003), in hypothesizing that logophors enter the derivation with an uninterpretable feature [log]. This feature must be checked via binding by an operator that also bears the [log] feature. Attitude predicates bear the [log] feature, and an attitude predicate can pass this feature to an individual abstractor in the left periphery of its CP complement. Returning to our three crucial cases in (33), (33a–b) are both grammatical because the [log] feature on the logophor is checked by its binder, whereas (33c) crashes because the [log] feature on the logophor is not checked.

- (33)
- a. Kofi say [ Ama **believe**<sub>[log]</sub> [  $\lambda x$ <sub>[log]</sub> · [ LOG<sub>x</sub><sub>[log]</sub> eat ] ] ] OK
  - b. Kofi **say**<sub>[log]</sub> [  $\lambda x$ <sub>[log]</sub> · [ Ama believe [ LOG<sub>x</sub><sub>[log]</sub> eat ] ] ] OK
  - c. Kofi say [ Ama believe [ LOG<sub>x</sub><sub>[log]</sub> eat ] ] ungrammatical

#### 4.2. *Né* ‘JUSS’ contributes an individual argument whereas *lá* ‘POT’ does not

We turn our attention now to the proposal that the jussive marker *né* contributes an individual argument whereas the potential marker *lá* ‘POT’ does not. The first thing to note is that in unembedded contexts, *lá* is typically used to express future possibility (34) (cf. Essegbey 2008), whereas *né*, as already seen in the introduction, is used to indicate a speaker-oriented desire or priority (35).

- (34) Kòfí **lá** qù nú.  
Kofi POT eat thing  
‘Kofi will/might eat.’

- (35) Kòfí **né** qù nú.  
Kofi JUSS eat thing  
‘Kofi should eat.’ / ‘I want Kofi to eat.’

We also note that Ameka (2008), investigating the cognate Ewe jussive particle *né*, provides some examples suggesting that this marker sometimes has an optative flavor, and we have confirmed that the same is true for Gengbe, as in (36).

- (36) gbògbò vó-wó **né** dògó.  
spirit bad-PL JUSS exit  
‘Let evil spirits come out.’ (Gengbe version of Ameka’s 2008:152 Ewe example)

We take this priority-oriented, optative-like status to be highly suggestive that *né* is in the same family of morphemes identified by Zanuttini et al. (2012) as jussives, which for them include imperatives (37), promissives (38), exhortatives (39), and (possibly) optatives (40) — though their focus is on the former three and they do not commit to a particular analysis of optatives. The data in (37)–(40) are all taken from their paper.

- (37) Cemsim-ul sa-**la**.  
lunch-ACC buy-IMP  
‘Buy lunch!’ (Korean imperative, Zanuttini et al. 2012:1234)

- (38) Cemsim-ul sa-**ma**.  
lunch-ACC buy-PRM  
‘I will buy lunch.’ (Korean promissive, Zanuttini et al. 2012:1234)

- (39) Cemsim-ul sa-**ca**  
lunch-ACC buy-EXH  
‘Let’s buy lunch.’ (Korean exhortative, Zanuttini et al. 2012:1234)

- (40) k<sup>h</sup>a:y  
eat-IMP.3SG  
‘Let him eat.’ (Bhojpuri optative, Zanuttini et al. 2012:1252)

Zanuttini et al. (2012) propose that jussives are individual abstractors that, when standing in a sufficiently local syntactic configuration with the subject, bind that subject and impose a person restriction on it, as schematized in (41). What distinguishes different kinds of jussives is the value of the person restriction: second-person for imperatives, first-person (exclusive) for promissives, and first-person (inclusive) for exhortatives. The person value also determines whose To-Do List the property gets added to when the utterance is successful in its illocutionary aim: the addressee's for imperatives, the speaker's for promissives, and both the speaker's and the addressee's for exhortatives.

- (41) For any phrase XP,  

$$[\text{JUSS}[\text{person: } \nu]_k \text{ XP}]^{g,c} = [\lambda x : x = [[\text{person: } \nu]_k]^{g,c} . [\text{XP}]^{g[k \rightarrow x],c}]$$
(Zanuttini et al. 2012:1265)

In a footnote (p. 1252, note 30), Zanuttini et al. mention a suggestion by Patrick Grosz for fitting optatives into this setup, namely by ‘relaxing the restriction that it should be possible for the addressee to bring about the situation described’, so that the property associated with the optative is added to the addressee's To-Do List and ‘the addressee is committed to the judgment that a world in which [the content associated with the optative holds] is preferable to one in which [it] doesn't, even though we know that the addressee cannot bring the world to this preferable state’. While conceivable, this suggestion seems to us to fit awkwardly with the fact that on this view, imperatives, promissives and exhortatives all receive an analysis whereby the person restriction they impose matches the participant associated with the targeted To-Do List, whereas optatives target the addressee's To-Do List despite generally being compatible with subjects of any person value.

In light of this, what we would like to suggest as an alternative is that optatives induce individual abstraction without any person restriction. The status of the utterance as a property has the discourse-theoretic effect of endowing it with a ‘world-to-word’ direction of fit (in the sense of Searle 1969), but the lack of person restriction has the consequence that it is not directed at any particular individual's To-Do List. This has the pragmatic effect of expressing a wish without imposing on anyone an obligation for its fulfillment. Applied to the Gengbe jussive marker  $n\acute{e}$ , this analysis amounts to (42).<sup>5</sup> (Cf. Sæbø 2009 for a strikingly similar approach to English *have*, though we will resist the urge to speculate here on whether an analytical connection between jussives/optatives and *have* is a good thing or not.)

- (42)  $[[n\acute{e}]] = \lambda p \lambda x . p$

In short, (42) helps make sense of otherwise puzzling asymmetries in how logophors behave in Gengbe attitude reports, and the suggestion made here now is that (42) is independently motivated by the broader distribution and function of the jussive marker in Gengbe paired with Zanuttini et al.'s (2012) property-theoretic approach to jussives. Despite these virtues, one might be reluctant to assign such a near-vacuous denotation to the jussive marker. In section 5

<sup>5</sup>Actually, it is an oversimplification to say that  $n\acute{e}$  comes with no person restriction: it disallows first-person subjects, both in matrix and in embedded contexts. The significance of this fact is unfortunately something that will have to be left for future research.

below, we entertain the alternative view that the jussive marker, in addition to contributing an individual argument, also has a modal semantics. First, though, we need to unpack our third proposal concerning the type-theoretic status of ‘want’ and ‘believe’.

4.3. *Dʒí* ‘want’ can only combine with a property whereas *káqóédʒí* ‘believe’ can combine with either a proposition or a property

The third and final proposal that we need to substantiate is the idea that *dʒí* ‘want’ can only combine with a property whereas *káqóédʒí* ‘believe’ is type-theoretically flexible in being able to combine either with a proposition or with a property. This proposal goes against the recent grain in the formal semantics literature of treating *all* clauses in a type-theoretically uniform way, whether that be as propositions (as explored by Stephenson 2010) or as properties (as explored by Pearson 2013), regardless of whether the clause is embedded or not, controlled or not, or interpreted *de se* or not. But it is not a new idea either: Dowty (1985) proposes that non-control complements are proposition-denoting whereas control complements are property-denoting, which, as Dowty discusses, has as a consequence that some embedding verbs (those that disallow control) are type  $\langle st, \dots \rangle$ , others (those that only accept control complements) are type  $\langle \langle e, st \rangle, \dots \rangle$ , and still others (those that admit both control and non-control complements) are  $\langle st, \dots \rangle / \langle \langle e, st \rangle, \dots \rangle$ -flexible.

Here we would like to entertain a variant of Dowty’s (1985) proposal whereby what determines whether the complement is proposition- or property-denoting is not whether it is controlled but rather what kind of mood marking it has. By way of independent motivation, consider the observation that English *want* admits nonfinite complements but not finite complements (43) whereas *believe* is flexible in admitting both kinds of complements (44).

- (43) a. John **wants** [Bill **to be** happy].  
b. \*John **wants** [that Bill **is** happy].

- (44) a. John **believes** [Bill **to be** happy].  
b. John **believes** [that Bill **is** happy].

This situation bears a striking resemblance to that of Romance: ‘want’ is rigid in only accepting subjunctive complements to the exclusion of indicative complements, as seen in the Spanish and Italian examples in (45) and (46), respectively, whereas ‘believe’ gives rise to variability: it ordinarily takes an indicative complement in Spanish (47) and an subjunctive complement in Italian (48).

- (45) Juan **quiere** [que Pedro {**sea**/\***es**} feliz].  
‘Juan wants that Pedro be.SBJV/INDIC happy.’ Spanish
- (46) Gianni **vuole** [che Pietro {**sia**/\***è**} felice].  
‘Gianni wants that Pietro be.SBJV/INDIC happy.’ Italian

- (47) Juan **cree** [que Pedro **es** feliz].  
 ‘Juan believes that Pedro is.INDIC happy.’ Spanish
- (48) Gianni **crede** [che Pietro **sia** felice].  
 ‘Gianni believes that Pietro be.SBJV happy.’ Italian

We can encode these subcategorization facts via a cross-linguistic extension of the same type-theoretic machinery that supports our analysis of the Gengbe facts. In particular, suppose that cross-linguistically, ‘want’ rigidly selects for a property (49) whereas ‘believe’ flexibly selects for either a proposition or a property (50).

- (49)  $\llbracket \text{want} \rrbracket = \lambda P_{\langle e, st \rangle} \lambda x \lambda w. \forall w' \in \text{BEST}_{\text{desire}}(\text{DOX}(x, w)): P(x)(w')$   $\langle \langle e, st \rangle, \langle e, st \rangle \rangle$
- (50) a.  $\llbracket \text{believe} \rrbracket = \lambda p_{\langle st \rangle} \lambda x \lambda w. \forall w' \in \text{DOX}(x, w): p(w')$   $\langle st, \langle e, st \rangle \rangle$   
 b.  $\llbracket \text{believe}' \rrbracket = \lambda P_{\langle e, st \rangle} \lambda x \lambda w. \forall w' \in \text{DOX}(x, w): P(x)(w')$   $\langle \langle e, st \rangle, \langle e, st \rangle \rangle$

Then the subcategorization facts follow, as long as Romance subjunctive clauses and English nonfinite clauses (regardless of whether they are controlled or not) are property-denoting just like Gengbe jussive-marked clauses (51), whereas finite indicative clauses are proposition-denoting (52).

- (51) Infinitives/subjunctive clauses  
 a.  $\llbracket \text{PRO to be happy} \rrbracket = [\lambda x \lambda w. x \text{ is happy in } w]$   $\langle e, st \rangle$   
 b.  $\llbracket \text{Bill to be happy} \rrbracket = [\lambda x \lambda w. \text{Bill is happy in } w]$   $\langle e, st \rangle$   
 c.  $\llbracket \text{Pedro sea feliz} \rrbracket = [\lambda x \lambda w. \text{Pedro is happy in } w]$   $\langle e, st \rangle$
- (52) Finite indicative clauses  
 a.  $\llbracket \text{Bill is happy} \rrbracket = [\lambda w. \text{Bill is happy in } w]$   $\langle st \rangle$   
 b.  $\llbracket \text{Pedro es feliz} \rrbracket = [\lambda w. \text{Pedro is happy in } w]$   $\langle st \rangle$

To be sure, there is a rich set of empirical facts and a rich literature surrounding the question of what grammatical factors conspire to determine what kind of finiteness or mood marking a clause will have in a given environment. (See e.g. Portner and Rubinstein 2013 for a recent assessment.) Our type-theoretic proposal is intended not as a *replacement* for existing proposals about what semantic properties characterize indicative- vs. subjunctive-selecting verbs but rather as an *implementation* of any such proposal. It does not say anything interesting about *why* verbs have the type signature they do and hence ultimately needs to be embedded into a theory that does.

## 5. Harmonic modality?

It is crucial to our account of the data that the jussive marker  $n\acute{e}$  contributes an individual argument, and in section 4.2 above, we proposed that this is *all* the jussive marker does. But our analysis is also consistent with the view that  $n\acute{e}$  does more than just this. And given that this marker occurs in contexts associated with a priority semantics, we would like to entertain the

possibility that  $n\acute{e}$  is a priority modal in the sense of Portner (2007, 2009). The individual argument it contributes could then be understood naturally as an argument that helps determine the set of worlds that the modal quantifies over, as in (53) (the basic shape of (53), discounting the individual argument, is inspired by the approach to modals found in Kratzer 2013). According to (53),  $n\acute{e}$  combines with a situation description  $p$  and returns a relation between individuals and situations. This relation is true of an individual  $x$  and a situation  $s$  iff all those worlds compatible with  $x$ 's priorities in  $s$  are worlds that contain a situation verified by  $p$ . (Actually, this is a simplification: technically, we need a circumstantial modal base and a priority-oriented ordering source: see Portner 2009:135. We suppress this detail here for ease of presentation.)

$$(53) \quad \llbracket n\acute{e} \rrbracket = \lambda p_{\langle st \rangle} \lambda x \lambda s. \forall w' \in \text{PRIORITY}(x, s): \exists s' [s' \leq w' \wedge p(s')] \\ \text{where } \text{PRIORITY}(x, s) = \{w' \mid w' \text{ is compatible with } x\text{'s priorities in } s\}$$

This approach then has consequences for the compositional semantics of desire reports like (54).

$$(54) \quad \text{Ámá } d\acute{z}\acute{í} \text{ [bé } \text{ Àkú } n\acute{é} \text{ qù nú].} \\ \text{Ama want COMP Aku JUSS eat thing} \\ \text{'Ama wants Aku to eat.'}$$

With modal meaning built into the jussive marker, we need to correspondingly shift the modality out of the desire predicate. In particular, we can adopt the semantics for  $d\acute{z}\acute{í}$  'want' in (55), thereby arriving at a meaning like (56) for the desire report in (54).

$$(55) \quad \llbracket d\acute{z}\acute{í} \rrbracket = \lambda P_{\langle e, st \rangle} \lambda x \lambda s. \text{want}(s) \wedge \text{EXPERIENCER}(s) = x \wedge P(x)(s)$$

$$(56) \quad \llbracket \text{Ama want COMP Aku JUSS eat thing} \rrbracket = \\ \exists s [\text{want}(s) \wedge \text{EXPERIENCER}(s) = \text{Ama} \wedge \forall w' \in \text{PRIORITY}(\text{Ama}, s): \exists s' [s' \leq w' \wedge \text{Aku} \\ \text{eats in } s']] \\ \text{'There is a situation } s, s \text{ is a wanting whose experiencer is Ama, and all those worlds} \\ \text{compatible with Ama's priorities in } s \text{ are worlds in which there is a situation in which} \\ \text{Aku eats.'}$$

This approach reflects a Kratzer 2013-style decompositional 'neo-Davidsonian' approach to clausal embedding (cf. also Moulton 2009; Bogal-Allbritten 2016; Grano 2016).<sup>6</sup> On this analysis,  $d\acute{z}\acute{í} \dots n\acute{é}$  ('want ... JUSS') instantiates the same kind of harmonic modality that Kratzer (2013) points to in motivating her approach to clausal embedding, such as the examples in (57)–(58).

$$(57) \quad \text{It seems to us entirely } \textbf{desirable} \text{ that there } \textbf{ought to} \text{ be a constitutional amendment.} \\ \text{(Kratzer 2013:slide 17)}$$

<sup>6</sup>One notable way in which we depart from these previous approaches, though, is that the previous approaches treat the attitude predicate as composing with its clausal complement via Predicate Modification (or Restrict), whereas we treat it as composing with its complement via Functional Application. This is needed on our account in order for the attitude predicate to be able to regulate the type of its complement ('want' needing a property but 'believe' being compatible with either a property or a proposition).

- (58) The urgency of the situation **requires** that the dig **must** continue regardless of the weather and comfort. (Kratzer 2013:slide 18)

In examples like (57)–(58), the bolded modals in the embedded clause seem to be redundant with the bolded embedding predicates. On Kratzer’s decompositional approach to embedding, this redundancy is readily made sense of, because the modality is located solely on the modals and the embedding predicates merely serve to help fix the modal base(/ordering source) by supplying a situation variable.

A potential source of cross-linguistic support for the harmonic modality approach to (54) comes from the Yiddish and Yiddish English *want...should* locution, exemplified in (59)–(60).

- (59) Ikh **vil** er **zol** geyn.  
 1SG want 3SG should go  
 ‘I want him to go.’ (Yiddish, Sadock 2012)

- (60) You **want I should** help you?  
 (see discussion at <http://language.log.ldc.upenn.edu/n11/?p=11847>)

Here we see a striking parallel between Yiddish/Yiddish English and Gengbe in the sense that in both languages, ‘want’ routinely embeds a marker that, in matrix contexts, can be used to express priority semantics. If Yiddish (and Yiddish English) ‘should’ and Gengbe *ně* are to have the same analysis, this means either that ‘should’ does not have a modal semantics but is rather merely an individual abstractor, or that Gengbe *ně* does have a modal semantics, along the lines suggested here.

To recap, there are two ways of cashing out the proposal that *ně* has the type-theoretic consequence of introducing an individual argument. On this first approach we entertained, it is a pure individual abstractor with no other content. On the second approach we entertained, it is a priority modal that introduces an individual argument which in turn helps determine the worlds that the modal quantifies over. Notably, the individual argument plays very different roles depending on which approach is taken: on the first approach, it corresponds to the hypothetical individual on whose To-Do List the relevant property is placed and who consequently bears an obligation to make the property true of herself. On the second approach, by contrast, it corresponds to the individual whose desires or goals make the content associated with the property a priority.

It will be beyond the scope of this paper to adjudicate between these two approaches, but a couple of issues at stake can be mentioned. One potential advantage of the modal approach is that it more readily makes sense of the fact that *ně* can be embedded into a belief report in such a way that it has a transparent priority-oriented semantics, as in (61). On the individual abstractor approach, it is unclear why the mere status of the embedded clause as a property would give it a priority flavor. (It also bears noting that in examples like this, the modal approach commits us to positing an appropriate modal in the left-periphery of the embedded clause, just as Kratzer 2013 does for belief reports that do not contain an overt modal.)

- (61) Ámá kááqóédzǐ [bé Àkú nǎ qù nú].  
 Ama believe COMP Aku JUSS eat thing  
 ‘Ama believes that Aku should eat.’

The two approaches also have different consequences for the illocutionary force of examples like (62). On the individual abstractor approach, (62) has a special illocutionary force in virtue of being property-denoting and the priority flavor is a consequence of this. But on the modal approach, (62) is just an assertion (proposition-denoting, the individual argument of the modal being, by hypothesis, speaker-bound in matrix contexts) and its priority flavor is a consequence of its modality. More research will be needed to determine what kind of illocutionary force (62) in fact has.

- (62) Kòfí nǎ qù nú.  
 Kofi JUSS eat thing  
 ‘Kofi should eat.’ / ‘I want Kofi to eat.’

## 6. Conclusions

The central narrow conclusion of this paper is that a property analysis of Gengbe jussive clauses helps make sense of an otherwise puzzling interaction between embedding verb choice, mood choice, and antecedent choice for logophors. Of broader significance is the prospect of extending this property analysis to subjunctive and infinitival clauses on a cross-linguistic scale, thereby enabling a theoretical unification across superficially disparate but underlyingly related mood categories. In this connection, an important question that still needs to be addressed is: if we are correct in extending the property analysis of jussive clauses to subjunctive clauses and infinitives cross-linguistically, why do the specific puzzles we see in Gengbe not show up in more familiarly studied languages? We think that it is because Gengbe has two properties that are not typical among better studied languages. First, it has logophoric pronouns, which are crucial to the central puzzle. Second it has ‘full’ (in the sense of being ‘finite’ or ‘non-truncated’) clauses as complements to verbs like ‘want’; if this were not the case, we might not expect to see overt logophors or overt mood markers in these complements and hence the puzzles would not arise. So the suggestion is that it is only when these two properties co-occur in a language that they conspire with the possibly universal type-theoretic principles entertained in this paper to give rise to the set of puzzling facts that we saw in section 2.

There is one final theoretical point to be made: we think that it is also in light of the two aforementioned properties of Gengbe that we see in Gengbe the recruitment of logophoricity to achieve syntactic control. In (63), repeated from (8) above, the subject of the bracketed clause is obligatorily identified with an argument of the immediately higher clause, which is precisely the hallmark of obligatory control in the sense of Landau (2000).

- (63) (Àkú<sub>1</sub> bé Kòfí<sub>2</sub> bé) Ámá<sub>3</sub> dzǐ [bé jè<sub>(\*1/\*2)/3/\*4</sub> lá qù nú].  
 Aku say Kofi say Ama want COMP LOG POT eat thing  
 ‘(Aku said that Kofi said that) Ama wants to eat.’

This is significant for two reasons. First, it possibly constitutes evidence against Landau’s

(2015:38) claim, following Culy (1994), that logophors never occur in obligatory control complements. If ‘obligatory control complement’ is to be defined in a non-circular way, it seems to us difficult to escape the conclusion that (63) instantiates a logophor in an obligatory control complement. Second, speaking more broadly, our analysis of (63) is consonant with the recent trend in control theory of not viewing controlled subjects as instantiations of a dedicated inaudible pronoun PRO but instead as a species of expression that enjoys wider grammatical currency such as minimal pronouns (Kratzer, 2009; Landau, 2015) or DP copies left behind by movement (Hornstein, 1999). Both the minimal pronoun approach and the movement approach give rise to the expectation that controlled subjects should be phonologically overt under some conditions (as overt pronouns or as pronounced copies, respectively). And also on both approaches, control is not a theoretically primitive notion but is rather an emergent consequence of the lexical items in the sentence and how they interact with each other, which is precisely how our theory treats Gengbe sentences like (63).

# Operating over (internal) ‘covert-based’ alternatives with scalar focus-sensitive particles: Evidence from Modern Hebrew<sup>1</sup>

Yael GREENBERG — *Bar Ilan University*

**Abstract.** This paper examines a range of readings found with the Hebrew focus sensitive particle *bixlal* and its accented version *BIXLAL* observed in Migron 2003, and in a series of works by Greenberg and Khrizman. Following ideas in these works the paper argues that *bixlal* is a member of the typology of *even*-like operators in Hebrew, along the unmarked particle *afilu*, and that the range of readings found with *BIXLAL* results from the fact that the same *even*-like operation is done over ‘covert-based’, and in particular degree-based and domain-based, alternatives. This parameter of variation is shown to be relevant for other scalar particles, both *even*-like and *only*-like, cross linguistically. The paper is finished by briefly examining another non-standard type of alternatives operated over by some scalar particles, namely speech act alternatives. The general conclusion is that ‘type of alternatives’ is a relevant parameter for scalar focus particles in natural language.

**Keywords:** *even*, *only*, scales, alternatives, focus, degrees, domains, gradable adjectives, multidimensional adjectives, NPIs, speech acts, typologies.

## 1. Introduction: Classical parameters of variations in typologies of *even*-like particles and the new parameter examined in this paper

The lexical entry of *even* is usually taken to be some version or other of (1) (cf. Horn 1969, Karttunen and Peters 1979, Rooth 1985, 1992, Herburger 2000, Guerzoni 2003, Chierchia 2013, etc.). In prose, (1) says that *even* (C)(p)(w) presupposes that *p* is stronger on a contextually given scale (e.g. it is less likely / more noteworthy) than all its distinct focus alternatives in C, and asserts that *p* is true:

- (1)  $\|even\|_{g,c} = \lambda C. \lambda p. \lambda w: \forall q \in C \ q \neq p \rightarrow p >_C q. p(w) = 1$   
Where  $C \subseteq \|p\|^F \wedge \|p\|^O \in C \wedge \exists q \ q \neq p \wedge q \in C$

This entry has been very prominent in the literature on scalarity and polarity sensitivity, but it also raised discussions and debates. A significant contribution to these debates comes from typological research of languages where more than one *even*-like operator exists. Such research identified a number of parameters along which *even*-like operators may vary, concerning, e.g. the high vs. low position of prejacent in the scale in the scalar presupposition and the logical properties of the licensing environment for the *even*-like particle, the scopal properties of the particle, the nature of the scale, the presence of an existential presupposition in addition to the scalar one, etc. (See, e.g. Rullmann 1997, Giannakidou 2007, Gast and van der Auwera 2011, Crnič 2011 for reviews and suggestions).

---

<sup>1</sup> For helpful comments thanks to Elitzur Bar-Asher-Siegal, Gennaro Chierchia, Luka Crnič, Micky Daniels, Edit Doron, Danny Fox, Nirit Kadmon, Lena Miashkur, Dina Orenstein, Moria Ronen, Susan Rothstein, Galit Sassoon, Aldo Sevi, Malte Zimmermann, and especially Keren Khizman. This research was supported by ISF grant 1655/16.

The main goal of the present paper is to argue for the existence of yet another relevant parameter of variation, not discussed so far in the literature on overt *even*-like typologies, namely the ability / inability of the particle to operate over what we will call ‘covert-based’ alternatives. The main empirical support for the linguistic relevance of this parameter is a range of differences between two members of the *even*-like typology in Hebrew: the default *even*-like particle, *afilu*, and the particle *bixlal*. We will concentrate on a number of readings found with the accented version of *bixlal*, *BIXLAL*, observed in Migron 2003, Greenberg and Khrizman 2012a,b, Greenberg 2014, 2016b, which can be paraphrased as *very*, *in general*, *at all*, etc. Inspired by ideas in these works we claim that these readings can be derived by assuming that *BIXLAL* still denotes the same *even*-like operation as *bixlal*, but that instead of operating over standard focus alternatives, it operates over ‘covert-based’, and more specifically, over domain-based and degree-based alternatives to its prejacent.<sup>2</sup> This kind of operation will be shown to be relevant also for some *only*-like particles. More generally, then, the (in)ability to operate over ‘covert-based’ alternatives seems to be a relevant parameter of variation for scalar focus particles cross linguistically.

The paper is structured as follows: Section 2 presents the basic data to be accounted for, namely the membership of *bixlal* in the typology of *even*-like particles in Hebrew (along with the unmarked form, *afilu*), and the challenge posed by the special readings of *BIXLAL*. Section 3 proposes that these special readings should be derived by assuming that *BIXLAL* is an *even*-like operator over degree-based and domain-based alternatives, and illustrates the advantages of this proposal in sentences with one-dimensional and multidimensional adjectives. Section 4 briefly considers, and rejects, an alternative, intensifier-based analysis of *BIXLAL*. Section 5 takes a wider perspective and looks at other overt and covert *even*-like as well as *only*-like operators over degree and / or domain-based alternatives. In section 6 we briefly examine the existence of apparently non-scalar readings of *bixlal*, which we propose to analyze as *even*-like operations over speech acts alternatives. Section 7 concludes and summarizes more generally potential specifications of the ‘type of alternatives’ parameter for some scalar focus particles.

## 2. The data

### 2.1. *Bixlal* is a member of the family of *even*-like particles in Hebrew

The standard, default *even*-like particle in Hebrew is *afilu*. We propose, however, that like many other languages (see e.g. Giannakidou 2007, Crnič 2011, Gast and van der Auwera 2011), Hebrew has more than one member in this typology. In particular, following Greenberg 2014, Greenberg and Orenstein 2016, we propose that besides *afilu* Hebrew has at least three more members in this family, namely the high register particle *af*, the ‘NPI’ *ve-lu* (similar to the English *so much as*), and the particle *bixlal*, which will be the main focus of this paper.

The claim that *bixlal* is an *even*-like operator is not trivial, though, as it is never mentioned in dictionaries or traditional Hebrew grammars as a translation of *even*, along *afilu*. The reason seems to be that the most prominent uses of this particle are found in its accented version, *BIXLAL*, which, as discussed below, is not translated as *even* but as *very*, *in general*, *at all*,

<sup>2</sup> In Greenberg 2014 such alternatives are called ‘internal’, rather than ‘covert-based’.

etc.<sup>3</sup> Nonetheless, as originally observed in Migron 2003, *bixlal* CAN be translated as *even*, and substituted by *afilu*. An example is (2):

- (2) Context: Discussing Danny’s and Yosi’s great success in the competition:  
 Dani zaxa be-medalyat kesef, ve-yosi **afilu** / **bixlal** zaxa be-[zahav]<sub>F</sub> / # [bronza]<sub>F</sub>  
 Danny won in-medal silver and-Yosi afilu / bixlal won in-gold bronze  
 “Danny won a silver medal, and Yosi even won [gold]<sub>F</sub> / # [bronze]<sub>F</sub>”

In such sentences *bixlal* behaves like *afilu* and *even* in indicating that *p* is stronger than its alternative (*Yosi won gold* ><sub>c</sub> *Yosi won silver*). Moreover, like *even* and *afilu*, *bixlal* is infelicitous when *p* is weaker than its alternative (*Yosi won bronze* <<sub>c</sub> *Yosi won silver*).

Another property that *bixlal* shares with *afilu* is its scopal behavior with respect to surface negation: unlike English *even*, and just like Hebrew *afilu*, *bixlal* can scope either above a negated predicate, or below such a predicate, but not between negation and the predicate:<sup>4</sup>

- (3) A: dani lo rakad ba-mesiba. ve-ma im yosi?  
 Danny not danced in-the-party and-what with Yosi  
 “Danny didn’t dance in the party. And what about Yosi?”  
 B: a. hu **afilu/bixlal** lo shar b. hu lo shar **afilu/bixlal** c. hu lo #**afilu/#bixlal** shar  
 he afilu/bixlal not sang he not sang afilu/bixlal he not afilu/bixlal sang  
 “He even didn’t sing” “He didn’t sing even” “He didn’t even sing” (intended)

Finally, there are cases where the only way to translate English *even* to Hebrew is by using *bixlal* (not *afilu*). Such cases are found when the particle associates with whole questions, as in Iatridou and Tetevosov’s (2016) examples of ‘our *even*’ in (4) and (5):

- (4) A: Let’s meet at Oleana’s for dinner. B: What do they even serve / serve even?  
 (5) A: Did Olivia get the Fields Medal? B: Is Olivia even a mathematician?

Iatridou and Tetevosov propose that in such cases *even* does not associate with any focused constituent inside the prejacent (e.g. with the accented *mathematician* in (5)). Rather, it associates with the entire question, and indicates that the prejacent question (e.g. *What do they serve in the restaurant?* / *Is she a mathematician*) is the least likely to be ignorant about, or to be asked. Moreover, they propose that in languages like Russian and German the choice between ‘garden variety *even*’ and ‘our *even*’ over questions is lexically encoded, so that some *even*-like particles (Russian *daže* and German *sogar*) can only function as ‘garden variety’ *even*, whereas others (*voobščē* and *überhaupt*, respectively) operate over questions.<sup>5</sup>

Now crucially, in Hebrew only *bixlal*, not *afilu* can be used as ‘our *even*’ over questions:

<sup>3</sup> In addition, *bixlal* has another, apparently non-scalar reading, translated as *actually* by Migron 2003. We briefly discuss this reading in section 6 below.

<sup>4</sup> For space reasons, we do not attempt to explain this pattern here.

<sup>5</sup> Iatridou and Tetevosov’s (2016) analysis of *überhaupt* as an *even*-based operator thus differs from e.g. Anderssen’s (2006) analysis of this particle as a general domain widener and Rohas-Esponda’s (2014) analysis as marking a move to a higher QUD. We adopt their analysis for *bixlal* as well. See also section 6 for a brief discussion of *voobščē* and *überhaupt*.

- (6) A: Let's meet at Oleana's for dinner  
 B: ma hem **bixlal** / #**afilu** magishim?  
 what they bixlal / afilu serve  
 "What do they even serve?"

- (7) A: "Did Olivia get the Fields Medal?  
 B: Olivia **bixlal** / #**afilu** matematikait?  
 Olivia bixlal / afilu mathematician  
 "Is Olivia even a mathematician?"

Given this data, then, *afilu* is similar to German *sogar* and Russian *daže*, in being able to function only as 'garden variety' *even*. In contrast, *bixlal* seems more flexible, as it can denote both an *even*-like operation over whole questions, like German *überhaupt* and Russian *voobščē*, as well as function as 'garden variety' *even* (as in (2)).

The conclusion at this stage, then, is that *bixlal* is indeed a member of the Hebrew *even*-like family, alongside the default particle, *afilu*, and it shares with *afilu* and *even* the same lexical entry, namely (1) above.

## 2.2. The challenge: a variety of readings with *BIXLAL*

A challenge to the *even*-like analysis of *bixlal* is the fact that when it is accented (as *BIXLAL*) it induces a variety of readings which make it different from both *even* and *afilu*. As originally observed by Migron 2003, the most prominent of these readings is found when *BIXLAL* combines with negated predicates, and is paraphrased as *at all*, as in (8). Migron emphasizes, however, that *BIXLAL* is different from English *at all* in that it is not an NPI, since it can appear in matrix sentences or in Upward Entailing contexts, as in (9), where it is paraphrased as *in general*. Greenberg and Khrizman 2012a,b observe that in such contexts *BIXLAL* can be also be paraphrased as *very* (10), or *completely* (11):

- (8) A: dani lo gavoha. ve-yosi? B: hu **BIXLAL** lo gavoha/ hu lo gavoha **BIXLAL**  
 Danny not tall and-Yosi he BIXLAL not tall / he not tall BIXLAL  
 "Danny is not tall. And Yosi?" "He is not tall at all"
- (9) A: dani xaxam be-xeshbon. ve-yosi? B: hu **BIXLAL** xaxam.  
 Danny smart at-math and-Yosi he BIXLAL smart  
 "Danny is smart at math. And Yosi?" "He is very smart / smart in general"
- (10) A: dani gavoha. ve-yosi? B: hu **BIXLAL** gavoha.  
 Danny tall and-Yosi he BIXLAL tall  
 "Danny is tall And Yosi?" "He is very tall"
- (11) A: le-dani ein shum maxala. ve-yosi? B: hu **BIXLAL** bari.  
 to-Danny there is no disease and-Yosi he BIXLAL healthy  
 "Danny has no disease. And Yosi?" "He is completely healthy"

How should such readings be analyzed? It is possible, of course, to suggest that *BIXLAL* is many-way ambiguous, and that its semantics when accented is completely distinct from the *even*-like semantics we suggested that its unaccented version has. In the next section, however, we take another route. Based on preliminary suggestions in Migron 2003, Greenberg and Khrizman 2012a,b and Greenberg 2014, 2016b, we propose a more unified analysis of *bixlal* and *BIXLAL* where it denotes the same *even*-like operator in all its uses just like *even* and *afilu*, but varies in the type of alternatives it can operate over.

### 3. The proposal: An *even*-like operator over degree-based and domain-based alternatives

#### 3.1. The core proposal

We suggest that *even*, *afilu* and *bixlal* / *BIXLAL* all have the semantics in (1) above, presupposing that their prejacent, *p*, is stronger on the relevant scale than all its contextually supplied focus alternatives, *q*, in *C*, and asserting that *p* is true. However, whereas given the data above, *even* and *afilu* can only operate over standard, ‘Roothian’ focus alternatives, *BIXLAL* can operate over ‘covert-based’, and in particular degree- and domain-based alternatives when it is accented.<sup>6</sup>

Operating over ‘Roothian’ alternatives is done in the standard manner: the alternatives to *p* are identical to it, besides an overt, focused element (which is usually accented), which is substituted by another overt element of the same semantic type. For example, in (2) above, where *p* is *Yosi won [gold]<sub>F</sub>*, the alternatives are derived by substituting the overt focused element ‘gold’ with other overt elements of the same semantic type, yielding e.g. *Yosi won silver*, *Yosi won bronze*, etc.

In contrast, ‘covert-based’ alternatives are derived by letting the operator associate with a covert element in *p*. In such cases the alternatives to *p* differ from it by the identity of this covert element, while crucially, all overt material in *p* stays fixed in *q*. This leads to a situation where the alternatives to *p* differ from it only in their interpretation, though on the surface, i.e. in terms of their overt material, they seem identical to it.

#### 3.2. Illustrations with one-dimensional adjectives

To illustrate the proposal, consider first the way *BIXLAL* is interpreted in (10), with the one-dimensional adjective *tall*. We suggest that in this case both the prejacent of *BIXLAL*, *p* and the contextually salient alternative, *q*, are of the form: *Yosi is POS tall*, which, following, e.g. Kennedy and McNally 2005 has the interpretation in (12), saying that the degree to which Yosi is tall is at least as high as the standard of tallness:

<sup>6</sup> An obvious question is why the operation over covert-based alternatives is found only with the accented version of the particle, *BIXLAL*. Based on ideas in Egg and Zimmermann 2011, and in Greenberg and Khrizman 2012a,b, Greenberg 2014, Greenberg 2016b suggests an information-structure based explanation for this pattern. But describing this explanation is beyond the scope of this paper.

$$(12) \quad p = \exists d [d \geq \mathbf{stand}_{tall} \wedge \mathbf{tall}(\mathbf{Yosi}, d)]$$

$$q = \exists d [d \geq \mathbf{stand}_{tall} \wedge \mathbf{tall}(\mathbf{Yosi}, d)]$$

This, of course, raises an immediate question: If  $p$  and  $q$  are identical, how can the scalar presupposition ( $p >_c q$ ) of the *even*-like operator *BIXLAL* be met? The answer, we suggest, is that the covert **stand** variables in  $p$  and  $q$  are assigned two different values.<sup>7</sup> In  $q$  we get **stand**<sub>default</sub> – constructed based on the value to the standard variable in the preceding sentence *Danny is POS tall*. In contrast, in  $p$  we assign **stand** a higher value, **stand**<sub>high</sub>, such that **stand**<sub>high</sub> > **stand**<sub>default</sub>. This allows  $p$  to end up being stronger than  $q$ , as required in the scalar presupposition, and as seen in (13). The effect is intuitively paraphrased in (14):

$$(13) \quad \exists d [d \geq \mathbf{stand}_{high, tall} \wedge \mathbf{tall}(\mathbf{Yosi}, d)] >_c \exists d [d \geq \mathbf{stand}_{default, tall} \wedge \mathbf{tall}(\mathbf{Yosi}, d)]$$

(14) A: Danny is tall relative to the contextually default standard, **stand**<sub>default</sub>, and what about Yosi?

B: He is even tall relative to the higher standard, **stand**<sub>high</sub>,

(10), as well as its intuitive paraphrase in (14) lead to the inferences that Yosi is very tall, and that he is taller than Danny. To derive these inferences we suggest that, since in the salient sentence (*Danny is POS tall*) the relevant standard being used is the lower one, **stand**<sub>default</sub>, and since, a higher standard, **stand**<sub>high</sub> is made salient in the prejacent of *even*, the proposition  $\exists d [d \geq \mathbf{stand}_{default, tall} \wedge \mathbf{tall}(\mathbf{Danny}, d)]$  raises the scalar implicature that the stronger alternative,  $\exists d [d \geq \mathbf{stand}_{high, tall} \wedge \mathbf{tall}(\mathbf{Danny}, d)]$ , is false. We end up then, with the understanding that Danny is tall relative to the default standard, but not relative to a higher standard. Hence, Yosi, who is taken to be tall relative to the higher standard (due to the scalar presupposition of *BIXLAL*), is understood to be taller than Danny, as well as ‘very tall’.

Turning now to the *at all* reading of *BIXLAL* in (8), found with a negated predicate, in this case we take both  $p$  and  $q$  to be of the form in (15), asserting that it is not the case that the degree to which Yosi is tall is at least as high as the standard of tallness. Then, to satisfy the scalar presupposition of *BIXLAL* ( $p >_c q$ ), we assign the standard variable in  $p$  a LOWER value, **stand**<sub>low</sub>, than the salient standard in  $q$ , **stand**<sub>default</sub>. We thus end up with the presupposition in (16), and with the intuitive paraphrase of (8) in (17):

$$(15) \quad p = \neg \exists d [d \geq \mathbf{stand}_{tall} \wedge \mathbf{tall}(\mathbf{Yosi}, d)]$$

$$q = \neg \exists d [d \geq \mathbf{stand}_{tall} \wedge \mathbf{tall}(\mathbf{Yosi}, d)]$$

$$(16) \quad \neg \exists d [d \geq \mathbf{stand}_{low, tall} \wedge \mathbf{tall}(\mathbf{Yosi}, d)] >_c \neg \exists d [d \geq \mathbf{stand}_{default, tall} \wedge \mathbf{tall}(\mathbf{Yosi}, d)]$$

(17) Danny does not reach the contextually salient standard of tallness, **stand**<sub>default</sub>, Yosi does not even reach a lower standard, **stand**<sub>low</sub>, i.e. he is not tall at all.

<sup>7</sup> See Greenberg (to appear) for a more detailed analysis, where *BIXLAL* associates with the covert comparison class argument of *POS*.

### 3.3. Illustrations with multidimensional adjectives

We would now like to derive the readings found when *BIXLAL* appears in sentences with multidimensional adjectives, e.g. with *smart* and *healthy*, as in (9) and (11) above.

To do that we start by following Sassoon 2013, 2016 in assuming that multidimensional adjectives (*healthy*, *ill*, *smart*, etc.) involve cardinality measurement of ‘respects’ or ‘dimensions’ (e.g. *healthy* / *ill* w.r.t. *blood pressure* / *sugar level*, *John is smart* w.r.t. *math* / *humanities*, etc.). Each of the dimensions is itself a gradable property, introducing its own scale and standard degree, similarly to the standard degree used for one-dimensional adjectives like *tall*. We will henceforth call this standard degree *stand<sub>d</sub>*, to distinguish it from another standard operative with multidimensional adjectives, namely *stand<sub>n</sub>*. This latter standard is taken by Sassoon to be the standard number of dimensions required to be satisfied with each multidimensional adjective. This standard number, *stand<sub>n</sub>*, is sometimes lexically determined: for example, Sassoon argues that by default, to be healthy is to reach the standard degree of health in ALL relevant dimensions, e.g. blood pressure and sugar level and heart condition etc. In contrast, to be ill is to reach the standard degree of illness in at least SOME dimension. *Healthy* and *ill*, then, can be classified as ‘universal’ and ‘existential’ multidimensional adjectives, respectively. In other cases, the standard number of dimensions is contextually determined. For example, to be smart is to be smart relative to a contextually determined number of dimensions (e.g. math, history, linguistics, etc.).

Given these ideas, then, we can assume that in the ‘positive form’ of a sentence like *Yosi is A* (where A is a multidimensional adjective) there is a covert *POS*, as in (18), and that such a sentence is interpreted as in (19):

(18) *Yosi is POS A* (where A is a multidimensional adjective)

(19)  $\exists n [n \geq \textit{stand}_{n,A} \wedge |\lambda G. G \in \text{Dim}_A \wedge G \in \mathbf{D} \wedge \exists d [d \geq \textit{stand}_{d,G} \wedge G(\textit{Yosi}, d)]| \geq n]$

In words, such a sentence is true iff there is a number, *n*, of gradable dimensions G which are relevant dimensions of A (i.e. members of the domain *D*) for which Bill’s degree exceeds the standard degree, namely *stand<sub>d</sub>*. And this number *n* exceeds the standard number of dimensions, namely *stand<sub>n</sub>*, in the domain of relevant dimensions for A.

The important point for us now is that (19) has three contextual covert variables, namely the underlined *stand<sub>d</sub>*, *stand<sub>n</sub>* and *D*. Since we take *BIXLAL* to be an *even*-like operator over covert-based alternatives, we predict that when it is present each of these three covert variables can be in principle exploited to create such ‘covert-based’ alternatives.

The prediction is indeed borne out. To illustrate that consider first (9) above. Here we can exploit the variability of either *stand<sub>d</sub>* or *stand<sub>n</sub>*. This gives us (at least) three possibilities. First, the alternatives can vary w.r.t. the value of *stand<sub>d</sub>*, assigning a higher value to this variable in *p* than in *q*. The resulting interpretation is that Danny is smart-w.r.t.-math relative to the contextually salient standard, and Yosi is even smart-w.r.t.-math relative to a higher standard. Hence Yosi is considered very smart (w.r.t.-math), e.g. his grades at math are higher. This reading can be intuitively paraphrased as in (20):

- (20) A: Danny is smart (at math). He always gets an A in the math exams.  
 B: And Yosi is even VERY smart (at math). He always gets an A+ in these exams.

The alternatives can also vary w.r.t. the value of *stand<sub>n</sub>* – assigning a higher value to this variable in *p* than in *q*. This can be achieved in two ways, and lead to two readings: first, Yosi can end up being smart with respect to an additional dimension (besides math), so the resulting interpretation is that Danny is smart-w.r.t.-one-dimension (i.e. smart-w.r.t.-math) and Yosi is even smart with respect to two dimensions, e.g. with respect to both math and history. Alternatively, Yosi can end up being smart w.r.t. all (relevant) dimensions, leading to the interpretation that Danny is smart-w.r.t.-one-dimension (i.e. smart-w.r.t.-math) and Yosi is even smart with respect to ALL (relevant) dimensions (math, history, art, linguistics, ...). This option is what leads to the ‘in general’ use of *BIXLAL*. The two options can be now more intuitively paraphrased as in B’s two answers in (21):

- (21) (Context: Students in this college study math, biology, physics, history, philosophy and linguistics)  
 A: Danny is smart. He has great grades at math.  
 B1: And Yosi is even VERY smart. He is also great in history.  
 B2: And Yosi is even VERY smart. He is great in all fields, i.e. smart in general.

The third variable that can be exploited to yield covert-based alternatives with *BIXLAL* is the domain restriction variable, *D*. Consider for example (11) above, with the ‘universal’ multi-dimensional adjective *healthy*, in the following context: we are organizing a challenging trip, and in order to join this trip, all candidates should be healthy, i.e. should have normal values along important medical parameters, namely blood pressure, sugar level and heart functioning. In this case we take *p*, the prejacent of *BIXLAL* (*Yosi is POS healthy*), to be stronger than its apparently identical alternative *q* (which is again *Yosi is POS healthy*), similarly to what we did with the other cases in (8)-(11). Here, though, we cannot take *p* to be stronger than *q* due to a higher value assigned to *stand<sub>d</sub>*, since there is no specific dimension of health where Yosi’s degree is claimed to be higher. Nor do we assign *stand<sub>n</sub>* a higher value, since the value for this standard in A’s utterance is already maximal, due to the default specification of this standard with adjectives like *healthy*: i.e. Danny is already considered healthy with respect to all relevant dimensions (blood pressure, sugar level and heart functioning). Instead, to make *p* stronger than *q* in this case we can assign the domain variable, *D*, two distinct values: *D<sub>default</sub>* in *q*, *D<sub>wide</sub>* in *p*, where *D<sub>default</sub>*  $\subset$  *D<sub>wide</sub>*. Given this suggestion, then, the intuitive paraphrase of (11) is as in (22):

- (22) Danny is healthy with respect to all dimensions of health relevant for the trip, i.e. all dimensions in *D<sub>default</sub>*, and Yosi is even healthy w.r.t. additional, less relevant dimensions, i.e. all dimensions in the wider domain, *D<sub>wide</sub>*.

To support this proposal, we can remind ourselves what is independently known about domain widening in other constructions. Following e.g. Kadmon and Landman 1993 ideas on *any* (as in *I don’t have any potatoes*), we take domain **restriction** to be used in order to exclude ‘irrelevant’ entities (e.g. small or rotten potatoes). Domain **widening** thus typically indicates that such entities can be now considered relevant. This seems to be exactly what happens in (11) as well. This sentence can be very naturally be continued with “He doesn’t even

have a mild cold”. In contrast, continuing (11) with “He doesn’t even have cancer” will sound very odd, as predicted.

We can now also predict that with ‘existential’ multidimensional adjectives (like *ill*), *BIXLAL* will not yield domain widening. This is because such an operation will not make *p* stronger than its alternative (cf. e.g. discussions of Kadmon and Landman 1993, Krifka 1995, Chierchia 2013 on *any*). Indeed, unlike (11) with *healthy*, (23) with *ill* can be naturally continued with “He even has cancer”, but continuing it with “he even has a mild cold” sounds very odd:

- (23) A: dani xole, ve-yosi? B: hu **BIXLAL** xole.  
 Danny ill and-Yosi? he BIXLAL ill  
 “Danny is ill. And Yosi?” “He is very ill”

Notice also that *BIXLAL* can induce domain widening in the Hebrew correlate of the Kadmon and Landman’s 1993 example in (24) with a negated predicate, yielding again an *at all* reading. In this case, too, we suggest that *BIXLAL* denotes an *even*-like operation over the covert domain variable, ending up with the intuitive paraphrase in (25):

- (24) ein li tapuxey adama BIXLAL  
 not-have to-me potatoes BIXLAL  
 “I don’t have potatoes at all”

- (25) I don’t have potatoes in  $D_{\text{default}}$ , and I don’t even have less relevant potatoes in  $D_{\text{wide}}$ .

To summarize so far, we argued that *BIXLAL* is an *even*-like operator, similar to English *even*, and Hebrew *afilu*, and that the range of readings found with it can be derived by assuming that it operates over a special kind of alternatives, namely ‘degree-based’ and ‘domain-based’ alternatives. What all these cases have in common is an abstract / structural property: the ability to apply the *even*-like operation over ‘covert-based alternatives’ (cf. Erlewine 2014 on association with covert variables). Thus, wherever its prejacent contains a covert contextual variable, *BIXLAL* can exploit it by assigning this variable a distinct value which will make *p* stronger than *q*, as required by the scalar presupposition.

#### 4. Rejecting an intensifier-based analysis of *BIXLAL*

Since many of the readings found with *BIXLAL* seem to lead to some sort of intensification, one might wonder whether, instead of claiming that this particle is a special *even*-like operator over special, covert-based alternatives, we can come out with a simpler analysis, namely that *BIXLAL* is a flexible intensifier. There are two reasons, however, why such an analysis cannot work, both have to do with properties that *BIXLAL* shares with *even* / *afilu* which set it apart from intensifiers. These are the scopal interaction of *BIXLAL* with negation and its sensitivity to standards of comparison.

Above we have already noted that the unaccented particle *bixlal* behaves like *afilu* with respect to surface negation. In particular, we saw in example (3) above, that both particles can precede surface negation, and can appear after the neg+predicate combination, but cannot ap-

pear between negation and the main predicate. As can be seen now in (26), *BIXLAL* behaves in exactly the same way. In contrast, the scopal behavior of Hebrew intensifiers with respect to surface negation is much more flexible. This can be seen, for example, in the behavior of *me’od* (‘very’) in (27):<sup>8</sup>

- (26) A: dani lo gavoha, ve-yosi?  
 Danny not tall and-Yosi  
 “Danny is not tall. And what about Yosi?”  
 B: a. hu BIXLAL lo gavoha b. hu lo gavoha BIXLAL c. #hu lo BIXLAL gavoha  
 he BIXLAL not tall he not tall BIXLAL he not BIXLAL tall  
 “He is not tall at all”
- (27) A: dani lo gavoha, ve-yosi?  
 Danny not tall and-Yosi  
 “Danny is not tall. And what about Yosi?”  
 B: a. hu ME’OD lo gavoha b. hu lo gavoha ME’OD c. hu lo ME’OD gavoha  
 he very not tall he not tall very he not very tall  
 “He is very not tall” “He is not very tall” “He is not very tall”

In addition, *BIXLAL* shares with *afilu*, as well as with English *even*, another interesting property which sets it apart from intensifiers. In (10) above, for example, (‘*Danny is tall, and Yosi is BIXLAL* (“very”) *tall*’), the presence of *BIXLAL* in B’s utterance immediately leads to the inference that Danny, mentioned in A’s utterance is tall as well. Crucially, this inference is present not only when Danny’s tallness is explicitly asserted, as in (10), but also in (28), which immediately entails that being 1.75m tall is considered tall. This is indicated by the infelicity of the continuation “He is not that tall” in A’s utterance. Indeed, when *BIXLAL* is absent this inference completely disappears, and the first sentence can be naturally continued with “He is not that tall”:

- (28) A: dani hu 1.75 (#hu lo gavoha), ve-yosi? B: hu BIXLAL gavoha  
 Danny is 1.75 he not tall and-Yosi he BIXLAL tall  
 “Danny is 1.75m tall (he is not tall), and Yosi?” “He is even VERY tall”

This makes *BIXLAL* different from intensifiers like English *very* and Hebrew *me’od*. For example, the mere presence of *me’od* (‘very’) or *mamash* (‘really’) in (29) does not lead to any inference that being 1.75m tall is considered ‘tall’, and A’s utterance is perfectly compatible with the continuation “He is not tall”:

- (29) A: dani hu 1.75. hu lo gavoha, ve-yosi? B: hu MEOD/MAMASH gavoha  
 Danny is 1.75 he not tall and-Yosi he very /really tall  
 “Danny is 1.75m tall (He is not tall), and Yosi?” “He is VERY / REALLY tall”

Crucially, the unique inference found with *BIXLAL* in (28) makes it similar to English *even*, as observed in Greenberg 2015, 2018. Consider (30) and (31):

<sup>8</sup> The behavior of the intensifier *me’od* (‘very’) in this respect seems typical of Hebrew intensifiers in general, and found also with *mamash* (‘really’) or *le-gamrey* (‘completely’) (although the latter is limited to modify Up-per closed adjectives, cf. Kennedy and McNally 2005).

- (30) A: Danny is 1.75m tall.  
 B1: and Yosi is taller.  
 B2: and Yosi is even taller.

- (31) A: Danny is 1.75m. tall  
 B1: and Yosi is 1.78m.  
 B2: and Yosi is even 1.78m.

It is well known that comparatives based on relative adjectives, as in B1’s answer in (30), do not entail the positive form of the adjectives they are based on, for neither the source nor the target of the comparison (e.g. Kennedy and McNally 2005). Indeed, *Yosi is taller than Danny* does not entail or even imply that Yosi or Danny is tall, and can be naturally continued with ... *but both are short*. The interesting thing happens in B2’s answer, with *even*: here, Greenberg 2015, 2018 observes, the presence of *even* leads exactly to these entailments. Indeed, continuing *Yosi is even taller* with ... *but both are short* leads to infelicity.<sup>9</sup> As can be seen in (31) this effect is not limited to comparatives. Here too the presence of *even* in B’s utterance entails that being 1.75m as well as being 1.78m are considered tall. Hebrew *afilu* yields exactly the same effects as *even* in such cases.

Based on such data, Greenberg 2015, 2018 proposes that for *even* *p* to be felicitous, both *p* and its alternatives *q* must intuitively ‘lead to’ a degree of a scale associated with a gradable property *G*, which is at least as high as the standard for this gradable property. This observation is not accounted for by the traditional semantics for *even*, according to which *p* should be only required to be stronger (less likely / more noteworthy) than *q*. Combining this observation with several other pieces of data which pose challenges for the popular ‘comparative likelihood’ view of *even* (see, e.g., Greenberg 2016a, 2018 for discussion), Greenberg offers a revised, ‘gradability-based’ semantics for *even*, which is sensitive to standards of comparison along a contextually supplied scale. Reviewing this proposal in detail is beyond the scope of this paper. The important point at this stage is that in terms of sensitivity to standards, *BIXLAL* seems to behave exactly like *even* and *afilu*, and unlike intensifiers. This, together with its behavior with surface negation, further supports the analysis of *BIXLAL* as an *even*-like particle, as suggested above.

## 5. Some cross-linguistic / cross-constructional support for the linguistic reality of the operation over ‘covert-based’ alternatives

We proposed that *BIXLAL* is not an intensifier, but an *even*-like operator, which unlike English *even* and Hebrew *afilu* operates over ‘covert-based’, namely degree-based and domain-based alternatives. More generally, we take the data in sections 3 and 4 to indicate that the ability / inability to operate over such ‘covert-based’ alternatives is a relevant parameter for *even*-like operators in Hebrew. But is Hebrew the only language where operation over such ‘covert-based’ alternatives is possible? Clearly our proposal would be more convincing if we find more manifestations of this parameter. Luckily, the answer seems to be positive.

<sup>9</sup> Umbach 2009 notes a similar effect with German *noch*. We believe, however, that the mechanism involved is different.

One type of candidate is the covert *even* operator argued to be involved in the semantics of some NPIs, as in Krifka 1995 and Chierchia 2013. For example, Chierchia 2013 takes minimizers like *give a damn* to involve the covert *even*-like operator *E*. *Give a damn*, according to Chierchia’s proposal, expresses the property of caring to the most minimal degree, namely  $\lambda x \exists s \text{ care}(x, s, d_{\min})$ , and it obligatorily triggers degree-based alternatives of the form  $\lambda x \exists s \text{ care}(x, s, d')$ , where  $d' > d_{\min}$ . Similar considerations apply to expressions with *at all*,<sup>10</sup> which also triggers degree-based alternatives. These obligatorily triggered alternatives must be operated upon (‘exhaustified’), and Chierchia argues that what operates over them is the covert *even*-like operator *E*, which requires its associate to be stronger (e.g. less likely) than all alternatives. Chierchia shows how such an operation is only licensed in Downward Entailing contexts, hence the NPI-hood of *give a damn* and *at all*.<sup>11</sup>

In addition to this covert *even*-like operator over covert degree-based alternatives with *at all*, Chierchia proposes that some NPIs, e.g. *any*, involve a covert operator over domain-based alternatives as well, namely the *only*-like operator *O* (or *exh*). For example, a sentence like *I don’t have any potatoes* has a similar assertion to that of *I don’t have potatoes*, namely  $\neg \exists x \text{ Potato}(x) \wedge D(x) \wedge \text{Have}(I, x)$ , but it obligatorily triggers subdomain alternatives of the form  $\neg \exists x \text{ Potato}(x) \wedge D'(x) \wedge \text{Have}(I, x)$ , where  $D' \subset D$ . These alternatives then must be exhaustified by the covert *only*-like operator *O*, which rejects all stronger alternatives. This is only licensed in Downward Entailing contexts, hence the NPI-hood of *any*. We can see, then, that in Chierchia’s 2013 theory the covert *only*-like and *even*-like operators are allowed to operate over covert domain-based and degree-based alternatives, namely the type of alternatives Hebrew *BIXLAL* operates over, given the analysis developed above.

In addition to these covert operators we can also find potential candidates for being overt operators over such covert-based alternatives. One such particle is the Hindi *bhii*. Lahiri 1998 argues that when *bhii* combines with the numeral *ek* (‘one’) it yields numeral-based alternatives (e.g. *one, two, three*), whereas when it combines with the indefinite *koi* it seems to associate with the ‘contextually weakest predicate’. Chierchia 2013 reinterprets this observation and proposes that in this case *bhii* expresses an *even*-like operation over domain-alternatives, similarly to what we proposed above for *BIXLAL*.

The Russian *voobščē* is another potential candidate for being an overt *even*-like operator over covert-based alternatives. Above we already saw Iatridou and Tetevosov’s 2016 claim that *voobščē* expresses an *even*-like operation over questions. But Iatridou and Tetevosov 2016 mention in a footnote that it can yield an *at all* reading with negated predicates, as in (32). Moreover, *voobščē* seems to also yield a *very / -er than* reading in UE contexts (cf. Miashkur 2017a,b), as in (33):

<sup>10</sup> According to Chierchia 2013, though, *at all* involves ‘scale reversal’ as well.

<sup>11</sup> Our analysis of *BIXLAL* above thus makes two contributions to this analysis of *at all*: on the one hand, it supports the general line of an *even*-based analysis of *at all*: in particular, since *BIXLAL*, which is independently analyzed above as an *even*-like operator, is the only way to express *at all* in Hebrew, we have overt evidence that the semantics of *at all* indeed involves an *even*-like semantics. On the other hand, our analysis of *BIXLAL* seems to show that there are maybe two strategies for deriving *at all* readings cross linguistically: in contrast to Chierchia’s 2013 analysis of English *at all*, Hebrew *BIXLAL* as *at all* is NOT taken as the alternative-triggering expression which then necessitates a covert *even*-like operator to operate over these alternatives. Instead, the Hebrew *at all*, i.e. *BIXLAL*, is the (overt) *even*-like operator itself.

- (32) Lev **voobščē** ne čital “Devida Kopperfil’da”  
 Lev voobščē NEG read.PST David Copperfield  
 “Lev did not read ‘David Copperfield’ at all” (Iatridou and Tetevosov 2016)
- (33) A: Džon 1.85m. A Bill? / Čto nasčet Billa?  
 John 1.85m but Bill / what on account of Bill  
 “John is 1.85m. And what about Bill?”  
 B: On **voobščē** vysokij.  
 he voobščē tall  
 “He is even very tall / taller”

These readings are not available with the standard *even*-like operator in Russian *daže*, and they can be analyzed in a similar fashion to the operation over degree-based alternatives with *BIXLAL* proposed above. Notice also that German *überhaupt*, which was analyzed as ‘our *even*’ over questions in Iatridou and Tetevosov 2016, has been reported to yield *at all* and *in general* readings too (cf. Anderssen 2006, Rojas Esponda 2014). Given our analysis of *BIXLAL* above we propose to analyze these uses of *überhaupt* too as involving an *even*-like operation over covert-based alternatives.<sup>12</sup>

Finally, there seem to also be attested overt *only*-like operators over ‘covert-based’ alternatives, for example, the Hebrew exclusive particles *be-sax ha-kol* and *STAM*, discussed in Orenstein and Greenberg 2014, Orenstein 2016, and Greenberg and Orenstein 2016. We will concentrate here on *be-sax ha-kol*, which can express both a regular exclusive reading, similar to the default *only*-like operator, *rak*, as well as an ‘approximative’ reading, similar to that found with *more or less*. Compare, for example, *rak* and *be-sax ha-kol* in (34a,b):

- (34) Context: John and Mary booked a room in a hotel and asked that the room will be clean, large, with view to the sea. After John checks the room he tells his wife:
- a. ha-xeder **rak** naki  
 the-room rak clean  
 “The room is only clean”
- b. ha-xeder **be-sax ha-kol** naki  
 the-room be-sax ha-kol clean  
 “The room is only / more or less clean”

In (34a), with *rak* we get a regular scalar reading of exclusives, rejecting standard, ‘Roothian’ focus alternatives which are stronger than the prejacent, similarly to what we get with English *only* or *just* (cf. Coppock and Beaver 2014). This yields the intuitive paraphrase in (35a). In contrast, with *be-sax ha-kol* we can also get a new ‘approximative’ reading, intuitively paraphrased in (35b). Orenstein and Greenberg 2012, 2014, Orenstein 2016, Greenberg and Orenstein 2016 argue that under this approximative reading *be-sax ha-kol* is still an exclusive operator, but that what is rejected is a degree-based alternative. In particular, the proposal is that both the prejacent of *be-sax ha-kol*, *p*, and the alternative *q* are of the same form: *The room is POS clean*, namely,  $\exists d[d \geq \text{stand}(\text{clean}, C) \wedge \text{clean}(\text{the room}, d)]$ , but the standard variable in

<sup>12</sup> Notice, though, that the range of interpretations *überhaupt* induces is more limited than with both *bixlal* and *voobščē*. A full analysis of these particles is beyond the scope of this paper (but see Miashkur 2017a,b for a fuller picture of *voobščē* vs. *daze*).

$p$  is assigned a lower value than the default value in  $q$ , which is the maximal degree of cleanliness. The resulting interpretation is that the room is not clean relative to the maximal standard, but clean relative to a lower standard, similarly to *more or less clean*.

- (35) a. The room is only clean and not more than that: not clean and large, not clean with view to the sea, etc.  
 b. The room is only more or less clean, and not more than that: it is not maximally clean.

The operation over ‘covert-based’ alternatives, then, can be added to the list of parameters along which *only*-like particles vary (cf. Tomaszewicz 2012, Coppock and Beaver 2014, Orenstein and Greenberg 2014, Orenstein 2016, Greenberg and Orenstein 2016). More generally, the analysis of Hebrew *BIXLAL* as an *even*-like operator over covert-based alternatives, can be positioned in a wider cross linguistic and cross constructional context. The emerging picture is that the (in)ability of scalar operators to operate over ‘covert-based’ alternatives should be taken as a relevant parameter of variation in this wider typology.

## 6. A direction for further research: Scalar operators over a range of speech acts alternatives

A challenge to our *even*-like analysis of *bixlal* and *BIXLAL* is the existence of some uses of *bixlal*, originally pointed out by Migron 2003, which on the surface do not seem scalar at all. Consider, for example, (36):

- (36) A: Rina carfatiya?  
       Rina French  
       “Is Rina French?”  
 B: lo. Hi bixlal britit  
       no she bixlal British  
       “No way. She is actually British.” (cf. Migron 2003)

In (36) *bixlal* is not translated as *even*. Moreover, the prajacent of *bixlal*, *She is British*, does not stand in any scalar relation to the salient alternative, *She is French*. In particular, (36) does not seem to indicate that being British is ‘stronger’, e.g. less likely or more noteworthy, than being French. Indeed, Migron takes this use of *bixlal* to be translated as *actually*, and to merely indicate the shift from one alternative to the other in an unordered set of alternatives.

Given this data one can take *bixlal* to be simply ambiguous between a scalar and a non-scalar reading (cf. also Kadmon and Sevi 2014 for a suggestion). But perhaps we can still analyze this use of *bixlal* under the *even*-like semantics proposed above. The crucial observation we would like to make in this connection, following Greenberg and Khrizman 2012b, Greenberg 2014, 2016b, Greenberg and Orenstein 2016, is that the presence of *bixlal* in (36) indicates a correction speech act, which crucially involves strong / significance denial. Intuitively, in (36) we take the proposition that Rina is British to correct and as part of this correction to strongly deny the proposition that Rina is French. This effect makes this ‘corrective’ use of *bixlal* different from that of *actually* (which indeed seems to merely indicate a shift of one proposition in the discourse to an alternative one).

As a support of this observation, notice that if the denial is explicitly marked as being minor, the use of *bixlal* is infelicitous. For example, in (37) *bixlal* is only felicitous if the speaker takes having turquoise eyes as being significantly different from having blue eyes:

- (37) A: le-dani yesh einaym kxulot  
           to-dani there-is eye blue  
           “Danny has blue eyes”  
       B: #lo be-diyuk / mamaS lo. yesh lo bixlal eiynam be-ceva TURKIZ  
           not precisely really not there-is to-him bixlal eyes in-color turquoise  
           #Not precisely / Absolutely not. He actually has TURQUOISE eyes”

As a preliminary proposal, then, we suggest that *bixlal* in (36) and (37) is another manifestation of discursive-*even*, similar to ‘our *even*’, *voobšče*, *überhaupt*, and *bixlal* over questions, discussed in Iatridou and Tetevosov 2016 and in section 2 above. The difference is that instead of operating over questions alternatives, in the cases discussed here we get an *even*-like operation over denials, indicating that the denial is ‘stronger’ on the relevant scale than alternative denials. Thus, (36)-(397) can be paraphrased as (38)-(39), respectively:

(38) Not only is Mary not French, she is even British!

(39) Not only does John not have blue eyes, he even has turquoise eyes!

Interestingly, we find parallel behavior of Russian *voobšče*, expressing an *even*-like operation over denials as well, as in (40) (K. Khizman, and O. Miashkoor p.c.):

- (40) A: ty kak istinnyj gruzin dolzhen ocenit' eto vino  
           you as real Georgian must appreciate this wine  
           “Being a genuine Georgian, you should be able to appreciate this wine”  
       B: ty chto??? kakoj ja gruzin... ya voobšče tatarin  
           you what what I Georgian I voobšče a Tatar  
           “What’s wrong with you? I am not Georgian, I am a Tatar.”

Moreover, in addition to these *even*-like operators over speech acts, it seems that there are also *only*-like particles which can operate over speech act alternatives. First, similarly to ‘our *even*’ the exclusive *only* seems to be able to operate over questions, as in (41), where it indicates that the question “When will he arrive?” is the only (relevant) thing the speaker is ignorant about. In addition, Greenberg and Orenstein 2016 point out that exclusives like *only* / *just* seem to be able to operate over denial speech acts, as in (42), indicating that the only thing to deny in the statement that Mary is a great teacher is that she speaks very quietly. In both cases the exclusive gives a similar effect to the adversative particle *but*. Finally, Wiagand 2016 discusses an ‘unexplanatory’ use of *just*, as in (43), indicating that the speaker does not know the reason or cause for the fact that the lamp broke (beyond a minimal reason or cause), and analyzes it as operating over speech act alternatives as well:

(41) When John is here we will go to the movies. Only when will he exactly arrive?

(42) Mary is a great teacher. She just speaks so quietly.

(43) I was sitting here and the lamp just broke (Wiagand 2016)

An important task, then, is to find ways to capture the data concerning both the *only*-like and the *even*-like operations over the full range of speech acts alternatives in a precise and systematic way. For space reasons we leave this task for further research (cf. Iatridou and Tenevsov 2016, Wiagand 2016 and Daniels 2018 for suggestions).

## 7. Summary

The starting point of this paper was a range of readings found with the Hebrew particle *bixlal* and its accented version *BIXLAL*, originally observed and discussed in Migron 2003 and in a number of works by Greenberg and Khrizman. Inspired by the intuitions in these works, we argued that (a) the unaccented *bixlal* is a member of the typology of *even*-like operators in Hebrew, along the unmarked particle *afilu*, and that (b) the range of readings found with *BIXLAL* results from the same *even*-like operation done over ‘covert-based’, namely degree-based and domain-based alternatives. We supported this analysis of *bixlal* and *BIXLAL*, and rejected an intensifier-based analysis, by pointing out the similar scopal behavior of these particles to *afilu* relative to surface negation, and the unique sensitivity of *BIXLAL* to standards of comparison, independently observed also for English *even* (Greenberg 2015, 2018). The behavior of *bixlal* and *BIXLAL* was then located in a wider set of observed facts concerning other overt and covert *even*-like and *only*-like particles which can be taken to operate over covert-based alternatives. We also discussed another non-standard type of alternatives operated over by some scalar particles, namely speech act alternatives.<sup>13</sup>

The emerging picture, then, points to the existence of a general parameter of variation for scalar, *even*-like and *only*-like particles, namely the type of alternatives that the particle can operate over (cf. Orenstein 2016, Greenberg and Orenstein 2016). A description of the different specifications of this parameter, and the manifestation of some of the scalar particles discussed above along these specifications, are schematically given in the following table:

| The ‘Type of alternatives’ parameter for scalar ( <i>even</i> -like and <i>only</i> -like) operators <sup>14</sup> |                                                   |                                                               |
|--------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|---------------------------------------------------------------|
|                                                                                                                    | <i>Even</i> -like particles                       | <i>Only</i> -like particles                                   |
| Can operate over standard ‘Roothian’ focus alternatives:                                                           | <i>even, afilu, bixlal, sogar, daze, covert E</i> | <i>only, just, merely, rak, be-sax ha-kol, covert O (exh)</i> |
| Can operate over ‘covert-based’ (e.g. degree-based and domain-based) alternatives:                                 | <i>bhii, BIXLAL, voobšče, überhaupt, covert E</i> | <i>be-sax ha-kol, STAM, covert O (exh)</i>                    |
| Can operate over ‘Speech act’ alternatives (e.g. questions, denials, explanations)                                 | <i>even, überhaupt, bixlal, voobšče</i>           | <i>just, only, rak</i>                                        |

<sup>13</sup> Cf. Wiagand 2016, who takes the operation over speech act alternatives to be a special case of operation over ‘covert-based’ alternatives (which, following the terminology of Greenberg 2014, she calls ‘internal’ alternatives).

<sup>14</sup> Cf. Liu 2016, who considers a ‘type of alternatives’ parameter as well, for Chinese *even*-like and *only*-like particles. Liu’s parameter, however, seems to me more similar to the ‘type of scale’ parameter, discussed in Coppock and Beaver 2014, Orenstein and Greenberg, 2014, Orenstein 2016, Greenberg and Orenstein 2016.

We hope that future research will contribute to the understanding of this picture, by examining the variation of additional scalar particles along this ‘type of alternative’, parameter both within and across languages, by refining the theoretical tools used to capture this parameter, and by examining the interaction of this parameter with other more well studied parameters along which *even*-like and *only*-like operators can vary.

# Two strategies of reopening QUDs — evidence from German *auch* & *noch*<sup>1</sup>

Mira GRUBIC — University of Potsdam

**Abstract.** This paper argues for a domain restriction account for *wh*-words in questions using *resource situations*, in parallel with the domain restriction of quantifiers proposed in Kratzer (2011). It is argued that under a situation semantic account assuming resource situations, the different behaviour of additive particles can be explained: Under a *question under discussion* account, additive particles like *too* and *also* are used when a (possibly covert) question is ‘reopened’ in order to add a further true answer (Beaver and Clark 2008, i.a.). This paper suggests that there are two ways in which a question can be re-addressed: it can either be reopened with (i) a different resource situation or (ii) with a different topic situation. This can explain the different behaviour of the additive particles *auch* and *noch* in German.

**Keywords:** situation semantics, questions, additive particles

## 1. Introduction

The domain of *wh*-elements is contextually restricted, just like the domain of quantifiers: While in (2), there may have been many people at the party, but nobody relevant to the speaker/hearer, the question in (1) also only asks for party-goers relevant to the person posing the question.

- (1) Who came to the party?                      (2) Nobody came to the party.

Kratzer (2011) presents a situation-semantic account of quantifier restriction according to which a subsituation of the topic situation (= the situation that the utterance is about) is responsible for the restriction. This paper proposes that the same is the case for *wh*-questions like (1): the restriction of alternatives inherent in these questions is argued to come about via resource situations. The situation semantic background for this paper will be provided in section 2.

It is also argued that under a QUD account of additive particles, the behaviour of the German particles *auch* (= “also, too”) and *noch* (= “still”, “in addition”) provides evidence for such a treatment of *wh*-questions: First, *noch* is most felicitous with an overt topic situation shifter (e.g. *dann* ‘then’) in declarative utterances. Second, *noch* is the preferred additive particle in questions, whereas *auch* seems to indicate that the speaker knows the answer to the question (Umbach, 2012). Third, in contrast to *auch*, which requires the focus of the host sentence to be distinct from that of the antecedent, *noch* imposes no such distinctness requirement. It is argued here that these differences can be accounted for under an analysis that assumes that both *auch* and *noch* indicate that a previous question is reopened, but whereas *auch* indicates reopening of the question with respect to a new resource situation, *noch* indicates reopening of the question with respect to a new topic situation. The background assumptions concerning additive particles, the German data, the analysis and a comparison with earlier analyses are presented in section 3.

---

<sup>1</sup>I would like to thank the audiences at Sinn und Bedeutung and at the ESSLLI 2016 workshop “Formal, Probabilistic and Typological Approaches to Discourse Particles and Modal Adverbs” (where I presented a partly overlapping talk on the typology of additive particles) for their feedback.

## 2. Situations

### 2.1. The topic situation

In a situation semantic account, propositions are functions from situations (i.e. parts of worlds) to truth values. This means that the truth of a declarative utterance is evaluated with respect to the situation that it is about, its *topic situation* (Kratzer, 2011). Kratzer illustrates this using the example in (3) (from Barwise and Etchemendy, 1987: 122): Here, ‘*Claire has the three of clubs*’ is intuitively false, even though it is true in the evaluation world that Claire has the three of clubs. This intuition can be captured by assuming that this sentence is evaluated with respect to a subsituation of the evaluation world, a subsituation which is part of Game 1.

- (3) (Emily is playing a card game (Game 1), and somewhere else, Claire is playing cards (Game 2). Both have the three of clubs.)  
Someone, watching game 1, mistakes Emily for Claire & says:  
# Claire has the three of clubs.

The topic time (Klein, 1994), the interval about which the utterance makes a claim, temporally delimits the topic situation (Kratzer, 2011: §3). Temporal or locative adverbials provide further information about the topic situation (Klein, 2008: 289).

According to Kratzer (2011), the topic situation of a sentence can be derived from its *question under discussion* (QUD) (Roberts, 1998, 2012). In a QUD account, every declarative utterance is assumed to be an answer to an (often implicit) assumed hearer-question, the current question under discussion. In the absence of an explicit QUD, the focus/background division of the utterance indicates which implicit QUD the speaker attributes to the addressee at this moment in discourse. For example, an utterance with so-called *broad* focus, in which the whole sentence is in focus, is assumed to answer a very general question, e.g. *What happened?* (4),<sup>2</sup> while an utterance with narrow focus, in which a subconstituent of the sentence is in focus, is assumed to answer a question which asks for the constituent in focus, e.g. (5). The topic situation of the answer is the same as that of its question, e.g. (a subsituation of) a specific party in (4) or (5).

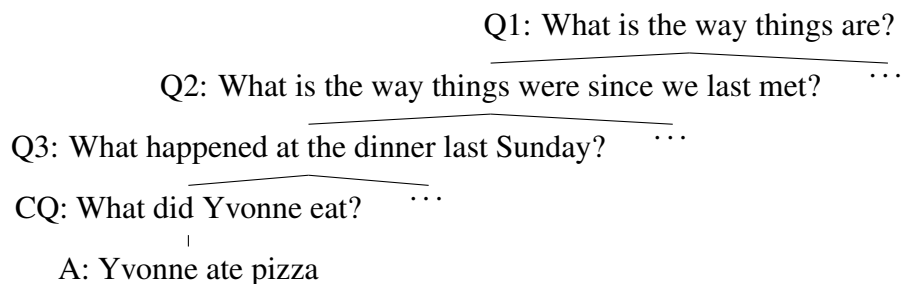

- |                                             |                                          |
|---------------------------------------------|------------------------------------------|
| (4) (What happened?)<br>Amy and Ben danced. | (5) (Who danced?)<br>AMY AND BEN danced. |
|---------------------------------------------|------------------------------------------|

The idea of implicit QUDs is used to model the idea each declarative utterance is believed, by the speaker, to address the currently most relevant lack of information that the hearer has.

The QUD account also accounts for discourse coherence, by proposing a hierarchy of questions (Roberts, 2012). Here, the notational convention used in Büring (2003) to display this hierarchy as a *discourse tree* is adopted, e.g. (6). The dominating nodes are superquestions, the daughter nodes subquestions, and sister nodes are in temporal order, such that questions further to the right are asked later. The current question under discussion is lowest in the tree.

<sup>2</sup>In the examples, SMALL CAPS are used to indicate stress (where relevant), **bold font** and *italics* are used for highlighting the important parts of the example. # is used for infelicity, ?? and ? for marginal felicity.

(6)

The topmost question “*What is the way things are*” is about the actual world  $w_0$ , to completely answer it would mean to know everything about our actual world, i.e. to be able to identify which world in context set is the actual world (Roberts, 2012: 5). Since this is impossible to answer in one sentence (if at all), this question is recursively split up into subquestions. Any superquestion entails its subquestions in the sense of Groenendijk and Stokhof (1984: 16): every complete answer to the superquestion also answers the subquestions (Roberts, 2012: 7). For example, a full answer to Q3 in (6), listing all that happened at the dinner, would also answer the current question *What did Yvonne eat?*. According to Schwarz (2009: 166), there is also a relation between the topic situations of the questions in the QUD hierarchy: each subquestion is about part of the situation asked about in its superquestion. For example, the situation of Yvonne eating something asked about in the current question is a subsituation of the dinner-last-Saturday-situation asked about in its superquestion Q3.

Following Schwarz (2009: 93–94), the topic situation is represented as a free situation pronoun (7), which is an argument to a topic operator (8). Applying this topic operator to a proposition and a topic situation yields the set of all counterparts (‘ $\approx$ ’ is the counterpart relation) of the topic situation in which the proposition is true, see (9) for an example. Thereby, counterparts of the topic situation are situations in other worlds which in all relevant respects are exactly like the topic situation.

(7)

(8)  $[[\text{topic}]] = \lambda p. \lambda s'. \lambda s. s \approx s' \ \& \ p(s)$ (9)  $[[s_2 \text{ topic Yvonne ate pizza}]]^g$   
 $= \lambda s. s \approx g(2) \ \& \ \text{Yvonne ate pizza in } s$ 

Since the topic situation pronoun is free, it receives a value from the context, namely the situation that its immediate QUD is about. This situation is salient since the QUD is salient.

## 2.2. The resource situation

As discussed in Kratzer (2011), there is evidence that for quantifier restriction, another situation is needed, the *resource situation*. For example, as shown in (10) (from Soames, 1986: 357), there are cases of restriction to a subset of the individuals present in the topic situation. The topic situation here contains the test persons in a sleep lab, as well as the research assistants. The quantifier *everyone*, however, is implicitly restricted to the test persons. This is seen as

evidence that the restriction of quantifiers is not provided by the topic situation, but, in this case, by a subsituation of the topic situation.

- (10) **Everyone** is asleep and being monitored by a research assistant. (Soames 1986)

Similarly, examples involving so-called incomplete definite descriptions such as (11) (from McCawley, 1979: 378) can be used to argue for the necessity of resource situations. Definite descriptions like *the dog* require the referent to be the unique salient dog. In the topic situation of (11), however, there are two dogs. The felicity of such examples can be explained under the assumption that the referent is presupposed to be the unique salient individual of this kind in the resource situation (Schwarz, 2009), which in this case might involve members of the household.

- (11) (Context: the family dog got into a fight)  
I'll have to see to it that **the dog** doesn't get near that dog again.

One main proposal of this paper is that *wh*-phrases are also restricted via resource situations. The individuals that can potentially replace the *wh*-phrase in the answer are said to be restricted, too. For example, in (12), in the same sleep lab situation, the possible answers can plausibly be argued to be restricted to those that involve test persons.

- (12) Who is asleep and being monitored by a research assistant?

Additionally, in a question-answer sequence like (13), where the *wh*-phrase is replaced by a quantifier in the answer, the resource situation of the *wh*-element and the quantifier are arguably the same, again involving only the test persons.

- (13) Q: Who is asleep and being monitored by a research assistant?  
A: Everyone!

A question, in the QUD approach, denotes the set of its possible answers (14) (following Hamblin 1973). For example, the denotation of the question in (14) is a set of possible answers in which the *wh*-element is replaced by a relevant individual.<sup>3</sup> Thereby, the *wh*-phrase denotes a set of individuals. In (14), *who* the set of human individuals in the resource situation. The resource situation is represented as a situation pronoun, which is the first argument of *who*, cf. (15b), where the value for the free situation pronoun is provided by the assignment function *g*.

- (14) [[who was asleep]]  
= {Amy was asleep, Ben was asleep, Cem was asleep, Dana was asleep ...}

- (15) a. [[who]] =  $\lambda s. \lambda x. x$  is a human in *s*  
b. [[who *s*<sub>1</sub>]]<sup>g</sup> =  $\lambda x. x$  is a human in *g*(1)

The *wh*-phrase is combined with the predicate via pointwise functional application (e.g. Rooth

<sup>3</sup>It is debated whether plural individuals are possible alternatives for singular individuals, cf. Beaver and Clark (2008) for discussion.

1992, 1996). This is a process of combining two sets, by which every member of the first set is combined with every member of the second set by standard functional application. Thus (14) is derived as shown in (16), or more generally in (17).

- (16) {Amy is asleep in  $g(2)$ , Ben is asleep in  $g(2)$ , Cem ...}

- (17)  $[[\text{who } s_1 \text{ was asleep in } s_2]]$   
 $= [[\text{was asleep in } s_2]] ([[\text{who } s_1]])$   
 $= \{ \lambda s. s \approx g(2) \ \& \ x \text{ was asleep in } s \mid x \text{ is a human in } g(1) \}$

To sum up, statements are made about a topic situation, and evaluated for truth or falsity with respect to this topic situation. The topic situation can be identified with the help of overt cues, e.g. tense, temporal or locative adverbials, but usually it is identified because it is inherited from the sentence's QUD, the (usually implicit) hearer-question that the sentence answers. Evidence from the restriction of quantifiers and definite determiners shows that in addition, a resource situation must be assumed. The following section will present evidence from the German additive particles *auch* and *noch* that both topic and resource situations play a role for additive particles.

### 3. Additive particles

Additive particles like English *also/too* do not contribute to the truth-conditional meaning of the sentence, they merely introduce a presupposition. They are focus-sensitive: the presupposition changes when the placement of the focus changes.

- (18) John also introduced BILL to Sue.  
 PRESUPP: John introduced somebody else to Sue.

- (19) John also introduced Bill to SUE.  
 PRESUPP: John introduced Bill to somebody else.

The presupposition of additive particles is different from those of many other presupposition triggers (e.g. *stop*) in that it needs to be salient, i.e. on the minds of the speaker and the addressee, rather than merely mutually known. For example, the utterance in (20), *Mary stopped smoking*, is possible without the information that Mary used to smoke being recently mentioned or otherwise salient. For the additive particle in (21), *Bill smokes, too*, to be felicitous, the information that somebody else smokes (e.g. *Mary smokes*) must be recently mentioned, or in the immediate non-linguistic context (e.g. the addressee might be smoking at the time of utterance). If it is merely mutually known that somebody else smokes, but not salient at this time in discourse, this is not enough to license the use of *too*. For this reason, the additive presupposition has been classified as anaphoric (Kripke 2009; Beaver and Zeevat 2007; Tonhauser et al. 2013, i.a.)

- (20) Mary stopped smoking.  
 PRESUPP: Mary used to smoke  
 (doesn't have to be salient)
- (21) Bill smokes, too.  
 PRESUPP: Somebody (e.g. Mary) smokes  
 (has to be salient!)

There are several different ways to model the anaphoricity of additive particles (e.g. Heim 1992; Geurts and van der Sandt 2004, cf. Ruys 2015 for a discussion). The approach adopted here is a QUD account of additive particles. Under this account, additive particles are anaphoric because they indicate that the current QUD is already partially answered in the recent context (Beaver and Clark, 2008; Jasinskaja and Zeevat, 2009). For example, in the case of (21), the relevant part of the QUD hierarchy would look like (22): the same question has been asked and answered before, and is reopened, thereby indicating that the previous answer (*Mary smokes*) was a partial answer, and providing a further partial answer (*Bill smokes*).

- (22)
- 
- ```

  graph TD
    A[...] --- B[Who smokes?]
    A --- C[Who smokes?]
    B --- D[MARY smokes]
    C --- E[BILL smokes, too]
  
```

The complete answer (Mary and Bill smoke) must be stronger than either of the partial answers alone. For this reason, examples like (23), where one of the answers entails the other, are infelicitous (Kripke, 2009; Beaver and Clark, 2008).

- (23) #Bill smokes, and Bill and Mary smoke, too.

This section introduced the general QUD account adopted in this paper. The following sections discuss the additive particles *auch* and *noch* in German. It will be argued that while both indicate that a QUD is reopened, *auch* indicates reopening with respect to the same topic situation (but a different resource situation), whereas *noch* indicates reopening with respect to a different topic situation.

### 3.1. German additive particles

In German, *auch* (=‘also’, ‘too’) is the standard additive particle. Unstressed *auch* associates with focus (cf. e.g. Jacobs, 1983; König, 1991; Krifka, 1998: i.a.). Like other German focus-sensitive particles, *auch* prefers to be as close to the focus as possible (see Buring and Hartmann 2001’s Closeness Principle), as shown in (24)–(25).

- (32) Otto hat **auch/noch** einen SCHNAPS getrunken.  
 Otto has PRT a Schnaps drunk.  
 “Otto also drank a SCHNAPS.”  
 (PRESUPP: Otto drank something else (e.g. a beer))

It however differs from better-studied additive particles like *also/too* (E.)/*auch* (G.) in interesting ways. The following section will describe some of these differences. The main claim will be that both additive particles indicate that a QUD is reopened. *Noch* indicates that it is reopened with respect to a new topic situation, whereas *auch* indicates that new alternatives are taken into consideration, i.e. that the resource situation is changed.

### 3.2. Differences between ‘auch’ and ‘noch’

This section describes three important differences between *auch* and the additive use of *noch*: First, that *noch* is most felicitous with overt topic situation shifters, second, that it is the ‘neutral’ additive particle in questions, whereas *auch* leads to ‘showmaster questions’ and third, that it allows for the reopened QUD to be answered in the same way.

**Overt topic situation shifters** In contrast to *auch*, additive *noch* is not entirely felicitous in standard additive contexts, where the antecedent (e.g. *Otto had a beer*) is immediately followed by a parallel utterance ‘*He also had a schnaps*’, cf. (33).

- (33) Otto had a beer.  
 Er hat **auch/??noch** einen SCHNAPS getrunken  
 he has PRT a schnaps drunk  
 (intended:) “He also had a schnaps.”

Instead, *noch* is most felicitous if there is an overt indication of a shift in topic situation (e.g. with *dann* (‘then’), *ansonsten/sonst* (‘otherwise’)), see (34).

- (34) Otto had a beer.  
*Dann* hat er **noch** einen SCHNAPS getrunken.  
 then has he PRT a schnaps drunk  
 “And he also drank a schnaps.”

This is also discussed in Umbach (2012: 1851), who proposes that in such sentences, “*dann* indicates that the two answer events combined by *dann* do not overlap”, and provides example (35) as evidence. Here, according to Umbach, the thunderstorm (without rain) and the rain count as two separate, non-overlapping, events.

- (35) There was a thunderstorm  
*Dann* hat es **noch** GEREGET.  
 then has it PRT rained  
 “It rained in addition.”

The reverse, i.e. that *auch* is most felicitous if there is no shift in topic situation, can be observed in cases of accommodation. For example, in (36)–(37), there is an overt indication of a new topic situation (*the next year*) in the host sentence of the additive particle, making it an utterance about a different topic situation than the overtly presented antecedent. In the case of *noch* in (36), this is not problematic: *noch* links these two utterances without any need for accommodation.

- (36) In 2014, Max visited his parents for Christmas.  
*Das Jahr danach* hat er **noch** die Eltern seiner FREUNDIN besucht  
 the year after has he PRT the parents of.his girlfriend visited  
 “In addition, the next year, he visited the parents of his girlfriend.”  
 → He visited his parents in 2014 & his girlfriend’s parents in 2015

In the case of *auch* in (37), however, the prominent reading is that Max visited his and his girlfriend’s parents the next year, i.e. an antecedent about the same topic situation (*the next year*) is accommodated.<sup>4</sup>

- (37) In 2014, Max visited his parents for Christmas.  
*Das Jahr danach* hat er **auch** die Eltern seiner FREUNDIN besucht.  
 the year after has he PRT the parents of.his girlfriend visited  
 “The next year, he visited the parents of his girlfriend too.”  
 → He visited his parents in 2014 & **his and his girlfriend’s parents in 2015**

Example (38) is a similar example: this is a variation of Umbach’s example (35), replacing *noch* by *auch*. Again, as in (37), the new topic situation — introduced by *dann* — is understood to involve a thunderstorm in addition to rain.

- (38) There was a thunderstorm  
*Dann* hat es **auch** GEREGET.  
 then has it PRT rained  
 “Then it rained, too.”

**Questions** In questions, *noch* is most felicitous, whereas *auch* indicates that the questioner knows that a further answer is true, i.e. the *auch*-question is a kind of ‘showmaster question’, according to Umbach (2012). For example, Umbach notes that in a context like (39), only Lisa’s aunt, who knows everything that happened at the zoo, can ask the *auch*-question in (39a). Lisa’s mother, who didn’t accompany them to the zoo and doesn’t know what happened there, can only ask the *noch*-question in (39b). The *auch* question is thus asked by a person who already has a particular answer in mind, hence Umbach’s term ‘showmaster question’.

- (39) (Little Lisa tells her mother what happened when she visited the zoo with Auntie.)  
 A: Und was ist im Zoo AUCH passiert?  
 and what is in.the zoo PRT happened  
 “What happened at the zoo, too?”

<sup>4</sup>This difference between *noch* and *auch* is very subtle, and is currently being experimentally tested.

M: Und was ist im Zoo NOCH passiert?  
 and what is in.the zoo PRT happened  
 “What else happened at the zoo?”

This is accounted for by the current approach as follows: in the showmaster question in (40a), Lisa’s aunt reopens the same QUD with respect to a different resource situation, i.e. she indicates that in her first answer, Lisa has not taken all relevant alternatives into account. Reopening the QUD with respect to the same topic situation but a different resource situation, as in the case of *auch*, indicates that relevant alternatives were forgotten or ignored, whereas reopening the QUD with respect to a new topic situation, as in the case of *noch*, merely slightly shifts the topic of conversation, and is thus the ‘neutral’ variant in overt questions.

**Stressed ‘noch’** When a QUD is reopened using *noch*, the same answer is available again. According to Umbach (2012), *noch* in (40) associates with a deaccented focused constituent, namely ‘Schnaps’.

(40) Otto had a schnaps. And you won’t believe it:  
 Er hat NOCH einen Schnaps getrunken.  
 he has PRT a schnaps drunk  
 “He had another schnaps.” / “# He had a schnaps, too”

Example (41), in contrast, is odd, independent of the accenting pattern.

(41) Otto had a schnaps. And you won’t believe it:  
 #Er hat *auch* einen Schnaps getrunken.  
 he has PRT a schnaps drunk  
 “# He had a schnaps, too”

This can be explained by the fact that, since the QUD (*What did Otto drink?*) is reopened with respect to a new topic situation in (40), the same answer (*Otto drank a schnaps*) will still be informative. In (41), in contrast, the QUD is reopened with respect to the same topic situation, thus only a different answer (e.g. *Otto drank a beer*) would be felicitous.<sup>5</sup>

To sum up, *auch* and *noch* differ first with respect to their occurrence with overt topic situation shifters, which is most felicitous with *noch*. Second, in questions, *noch* is the standard additive particle, while *auch* seems to indicate that the speaker knows the answer to the question. This was attributed to the resource situation-shifting nature of *auch*. Third, a *noch*-answer can be the same as its antecedent answer, while an *auch*-answer has to differ. This is due to the topic shift inherent with *noch*: it allows for the same alternatives to become available again.

<sup>5</sup>There seems to be a connection between stressed *noch* and additive or incremental *more* (Greenberg, 2010, 2012), which Greenberg analyses as indicating further development of a previous eventuality.

(i) Otto had one more schnaps.

This is an interesting account, which would also complement nicely an account of *noch* along the lines of Ippolito (2007), but since the *noch* and *more* data differ in some respects, a discussion of this is left for future work.

### 3.3. Analysis of ‘auch’ and ‘noch’

Unstressed *auch* indicates that there is a previous answer to the same QUD, but with a more restricted set of alternatives. The current QUD extends this set to include previously neglected relevant alternatives. For example, the answerer in (42) might have thought of the alternatives {a schnaps, a glass of wine, a glass of cider} in the first answer, but forgotten the beer. By uttering an *auch*-sentence, she thus repairs this by considering a new domain of alternatives which now includes the beer. The question is thus reopened with respect to a new resource situation, as represented in the discourse tree in (42).

(42)

This is essentially the analysis given in Umbach (2012: 1860–1861) for unstressed *auch*, who proposes the term *extension question* for questions with shifted resource situations, cf. Umbach’s definitions in (43)–(44).

(43) unstressed *auch* in answers addresses an extension question;  
unstressed *auch* in questions indicates that the question is an extension question.

(44) A question  $Q = \langle B, D \rangle$  is an extension question with respect to a preceding question  $Q' = \langle B', D' \rangle$  iff (i)  $B = B'$ , (ii)  $D \cap D' = \emptyset$ , (iii)  $D \cup D'$  is a superordinate domain.

In contrast, *noch* indicates that there is a previous answer to a parallel QUD about a different topic situation in the discourse context, cf. (45).

(45)

This requirement that the preceding QUD be about a different topic situation can be represented as in (46)–(47). Thereby, *noch* does not indicate anything about the domain of alternatives, i.e. it does not require the domain to be different or the same in the two questions.

(46) *noch* in answers addresses a shifted question ;  
*noch* in questions indicates that the question is shifted.

(47) A question  $Q = \langle B, D \rangle$  about  $S$  is a shifted question with respect to a preceding question  $Q' = \langle B', D' \rangle$  about  $S'$  iff (i)  $B = B'$ , (ii)  $S \neq S'$

## 3.3.1. Combining ‘auch’ and ‘noch’

Since it is possible to combine *auch* and *noch*, the account for *auch* does not require the topic situation to remain the same, and the account for *noch* does not require the resource situation to remain the same. The prediction thus is that both situations would be different from those of the antecedent, cf. (48), leading to a few predictions, briefly discussed below.

(48)

**Prediction I:** *auch noch* should allow for a topic situation shift (without accommodation) (49), like *noch*.

- (49) In 2014, Max visited his parents for Christmas.  
*Das Jahr danach* hat er **auch noch** die Eltern seiner FREUNDIN besucht.  
 the year after has he PRT PRT the parents of.his girlfriend visited  
 “The next year, in addition, he visited the parents of his girlfriend.”  
 → He visited his parents in 2014 & his girlfriend’s parents in 2015

**Prediction II:** *auch noch* should indicate a shift of resource situation, and thus lead to show-master questions (like *auch*), which seems to be the case: the question in (50) is much more natural when it is posed by the aunt than when it is posed by the mother.

- (50) (Little Lisa tells her mother what happened when she visited the zoo with Auntie.)  
 Auntie: Und was ist im Zoo auch noch passiert?  
 and what is in.the zoo PRT PRT happened  
 “What else happened at the zoo, too?”

**Prediction III:** *auch noch* should indicate a shift of resource situation, and thus disallow giving the same answer again (like *auch*). This is in fact the case: (51) is infelicitous, unless *auch* is understood to associate with the full VP in its scope, leading to the presupposition that he did something else apart from drinking another schnaps. This is the reading obtained when *noch* is accented, and there is a slight pause between *auch* and *noch*.

- (51) Otto had a schnaps. And you won’t believe it:  
 #Er hat **auch noch** einen Schnaps getrunken.  
 he has PRT PRT a schnaps drunk  
 (intended:) “He had another schnaps.”

### 3.3.2. Comparison with other approaches

**Dimroth 2002** The proposal presented here for *noch* is reminiscent of a proposal in Dimroth (2002) for stressed NOCH as in (52). Dimroth proposes that stressed NOCH associates with the topic time, just like stressed AUCH associates with a (contrastive) topic.

- (52) Otto had a schnaps. And you won't believe it:  
Er hat NOCH einen Schnaps getrunken.  
he has PRT a schnaps drunk  
‘He had another schnaps.’

A problem with this, which has already been voiced in Nederstigt (2006), is that if *noch* could associate with something topical and thus out-of-focus, it should be able to stand alone, as stressed AUCH can, cf. (53).

- (53) At 10p.m., Otto had a schnaps. And at 11 p.m.?  
AUCH./#NOCH.

The other accounts known to me (e.g. Nederstigt, 2006; Eckardt, 2007; Umbach, 2012) all assume that *noch*/NOCH associates with focus in all examples.

**Eckardt 2007:** Eckardt (2007) proposes that (unstressed) *noch* can be used to reopen a QUD if the previous answers are positive. According to her, the QUD is reopened as a sub-QUD, involving a subset of its super-QUD's domain, i.e. the discourse tree would look as in (54). *Noch* can also be used in such a reopened QUD, if it is overt.

- (54) Who (of A,B and C) can swim?  
Ali can swim    Who (of B and C) can swim?  
                               |  
                             Ben can swim

This is used to explain the observation that *noch* is often used for the last element in a list of positive answers, cf. (A) in (55).

- (55) Q: Who (of A, B and C) can swim?  
A: ALI kann schwimmen, und BEN kann **noch** schwimmen, aber CEM *kann nicht schwimmen*.  
“ALI can swim, and BEN can swim, but CEM can’t swim”

This account would predict that the answer in (56) is bad, a prediction that I don't share.<sup>6</sup>

<sup>6</sup>Note however that judgments on these particles are notoriously difficult.

- (56) Q: Who (of A, B and C) can swim?  
 A: (#) ALI kann schwimmen, BEN *kann nicht schwimmen*, aber CEM kann **noch** schwimmen.  
 “ALI can swim, BEN can’t swim, but CEM can swim”

Umbach (2012), in her discussion of this account, notes that it is problematic because it cannot account for all of the differences between *noch* and *auch*. For example in *noch*-questions, the domain of alternatives is clearly extended.

**Umbach 2012** According to Umbach’s own proposal, *noch* and unstressed *auch* both reopen a QUD with an extended domain (57).

- (57)
- 
- ```

graph TD
    Root[ ] --- Q1[Who (of {A,B}) can swim?]
    Root --- Q2[Who (of {C,D}) can swim?]
    Q1 --- A1[Ali can swim]
    Q2 --- A2[Cem can swim]
  
```

The main difference between the two is that the alternatives in the case of *noch* are in a temporal order, an order of (expected) time of mentioning. This temporal order allows to distinguish string-identical alternatives (*schnaps*<sub>1</sub>, *schnaps*<sub>2</sub>) in the case of stressed NOCH, which can not be distinguished in the case of *auch*.

For stressed AUCH, Umbach (2012) proposes that it reopens a QUD with a subset of the original domain, as Eckard had proposed for *noch*, cf. (58).

- (58)
- 
- ```

graph TD
    Root[ ] --- Q1[Who (of {A,B,C}) can swim?]
    Root --- Q2[Who (of {B,C}) can swim?]
    Q1 --- A1[Ali can swim]
    Q2 --- A2[Ben can swim]
  
```

She analyses *auch* in *wh*-questions as an instance of stressed AUCH, with the *wh*-element as a topic. This accounts for ‘showmaster questions’:

- (59) Wer kann AUCH schwimmen? “Who can swim, too?”

The current account rejects the idea that the exact same QUD (about the same topic situation) can be reopened with respect to a subset of the same domain (as proposed by Eckardt for *noch* and Umbach for AUCH). Implicit QUDs essentially reflect **speaker assumptions** about the alternatives relevant for the hearer. Thus to remind the speaker that she forgot a relevant alternative means to extend the domain of alternatives.

In addition, an ordering of alternatives by order of mentioning is not adopted in the current account, since additive particles, being anaphoric, always involve another answer being mentioned earlier than the current one. It is therefore hard to imagine a context in which *auch* would be

licensed but *noch* wouldn't under this account. A final difference between the current account and Umbach's is that the *wh*-element in AUCH-questions is not assumed to be a topic.

#### 4. Summary and outlook

The behaviour of the German additive particles *auch* and *noch* provides evidence for resource situations in *wh*-questions: *auch* indicates that a QUD about the same topic situation is reopened, with a different resource situation, i.e. considering further alternatives, whereas *noch* indicates reopening of a question, but about a different topic situation.

There are several questions remaining for future discussion. First, many examples involving *noch* are very subtle. It is thus of vital importance to test the phenomena discussed in these papers with a large group of native speakers. This will be done in future work. Second, it is not entirely clear how the account for additive *noch* discussed in this paper relates to the other uses of *noch* as *still*, e.g. the temporal use in (60), the related locative use in (61), the marginality use in (62), and the comparative use in (63), i.a. (e.g. König, 1977; Löbner, 1989; Krifka, 2000; Umbach, 2009).

- (60) TEMPORAL/ASPECTUAL  
 Es regnet noch.  
 It rains still  
 "It is still raining."  
 PRESUPPOSITION: It was raining earlier  
 CONVERSATIONAL IMPLICATURE: It will stop raining soon
- (61) LOCATIVE/MARGINALITY  
 Osnabrück liegt noch in Niedersachsen.  
 Osnabrück lies still in Niedersachsen  
 "Osnabrück is still in Lower Saxony."
- (62) MARGINALITY  
 Paul ist noch gemässigt. (Peter ist schon radikal)  
 Paul is still moderate Peter is already radical  
 "Paul is still moderate. (Peter is already radical)"
- (63) COMPARATIVE  
 Berta ist noch größer als Adam.  
 Berta is still taller than Adam  
 "Berta is even taller than Adam."

While the topic situation in (60) (e.g. "now") is certainly different from that of the earlier event, the current analysis neither captures the presupposition that the two events are of the same kind ("rain") nor the implicature that later, there will be no event of this kind. The analysis presented here can thus not easily be applied to cases like (60) and other, e.g. non-temporal, *noch* examples.

In contrast, it is a great advantage of the accounts of Eckardt (2007) and Umbach (2012) that they do intuitively relate to previous accounts of the temporal reading in (60). For example, Eckardt's proposal that *noch* adds a positive answer to a QUD after a preceding stretch of discourse containing positive answers to this QUD is related to Löbner (1989)'s analysis of temporal *noch*, which assumes that (60) adds a current period of rain, after a presupposed preceding period of rain. Umbach, in contrast, relates her proposal to Krifka (2000)'s account, in which *noch* imposes an order on focus alternatives (e.g. *it is raining, it isn't raining* in (60)) on a temporal scale, such that the alternative *it is raining* precedes the alternative *it isn't raining*. Umbach assumes that the different alternatives, i.e. the current utterance and its antecedent, are also ordered on a temporal scale, but not concerning the event time of the mentioned events but concerning the time of mention in discourse: the *noch*-sentence presupposes an ordering such that there is an alternative that is lower on the scale, i.e. was mentioned earlier.

Therefore, an important aspect of future work on this particle will be to find a unified account for the additive use described here and temporal and other uses of *noch*.

# Internal and external readings of *same*: Evidence for a uniform account<sup>1</sup>

Daniel HARDT — *Copenhagen Business School*

**Abstract.** *Same* is an anaphoric element that performs a comparison, which can either be external or internal to a sentence. Hardt and Mikkelsen (2015) show that *same*, unlike other anaphoric expressions, imposes a parallelism constraint, and they present three types of examples showing that *same* is infelicitous in the absence of parallelism. Hardt and Mikkelsen propose an account that applies uniformly to internal and external readings; however, the evidence they present largely targets external readings – they don't offer empirical evidence that clearly supports the uniform approach. Furthermore, Barker (2007) argues that internal readings must be treated differently than external readings. In this paper, I show that the parallelism effects observed by Hardt and Mikkelsen in fact apply to internal readings as well. This provides support for a uniform treatment of internal and external readings of *same*. It also suggests that discourse relations, which typically apply to separate overt predications, also apply to the implicit predications that arise in distributional structures.

**Keywords:** *same*, anaphora, parallelism

## 1. Introduction

*Same* performs a comparison, which can either be external, as in (1), or internal, as in (2).

- (1) John read *War and Peace*. Tom read the same book.
- (2) Every boy read the same book.

In (1), the definite *the same book* must be identified with the antecedent NP, *War and Peace*. It would appear to impose a semantic identity condition on an antecedent expression in surrounding discourse. In this way *same* is like pronouns, definites, and ellipsis, all of which require identity with an antecedent. In (2), the internal reading is licensed, or controlled, by a quantified NP, *every boy*. Since Carlson (1987), it has been recognized that the controller need not be a NP, but can be a variety of syntactic categories. Barker (2007) captures this diversity of controllers with an account that only applies to internal readings. Hardt and Mikkelsen (2015), on the other hand, argue for treating internal and external readings in a uniform way, and they argue furthermore that *same* gives rise to a discourse parallelism requirement. They give three types of observations in support of this theory. But all three of these observations concern external readings, and not internal readings. Thus they don't provide concrete empirical support for their proposal that internal and external readings receive the same treatment.

In this paper, I present new arguments in favor of a uniform account of external and internal readings of *same*: I show that all three of Hardt and Mikkelsen's observations, distinct antecedent, parallel antecedent, and negated antecedent, apply to internal readings as well as external readings.

---

<sup>1</sup>Thanks to Line Mikkelsen for useful input.

## 2. Background

### 2.1. Internal readings

As pointed out by Carlson (1987), *same* can give rise to internal readings. He points out that this requires a distributive element, a quantifier or coordination. We term this element the controller (shown in **bold**). So in (3), the controller is the QP *Every boy*, while in (4) it is the conjoined NP *John and Sam*. As (5) and (6) illustrate, the controller need not be a nominal category – here we observe a conjoined V and a conjoined PP.

- (3) **Every boy** read the same book.
- (4) **John and Sam** read the same book.
- (5) Sam **praised and criticized** the same book.
- (6) Sam assigned the same book **in March and in April**

As Carlson puts it, in the internal reading, the sentence “provides its own context” for the interpretation of *same*. Any conjoined constituent can function as controller, it would appear, as long as it is interpreted distributively. Heim (1985) also acknowledges the diversity of potential controllers. This is dealt with explicitly by Barker (2007)[p. 25], who introduces a structural postulate which makes it possible to  $\lambda$  abstract over any distinguished element. In what follows, I will simply assume that a controller can be any syntactic object that can participate in coordination.

### 2.2. External readings

While internal readings “provide their own context”, one can observe analogous readings for *same* where surrounding discourse provides the context, as in (7), which is directly analogous to (4) above.

- (7) **John** read *War and Peace*. **Sam** read the same book.

We can think of *John* and *Sam* as controllers in (7). Note that, just like internal readings, external readings exhibit a diversity of controllers – verbs in (8) and prepositional phrases in (9).

- (8) John **praised** *War and Peace*. Then he **criticized** the same book.
- (9) John assigned *War and Peace* **in March**. He assigned the same book **in April**.

Much previous literature (Brasoveanu (2011); Heim (1985)) emphasizes the evident analogy between internal and external readings. But Barker (2007) argues that his proposed account

should only apply to internal readings, and while Hardt and Mikkelsen (2015) follow most previous literature in seeking a uniform account, their empirical arguments, based on parallelism, don't seem to naturally apply to internal readings. Thus, the question of a uniform treatment of internal and external readings is left rather open. In what follows, I will show that Hardt and Mikkelsen's parallelism arguments can also be made with respect to internal readings. The key to doing this is to look at examples where the controllers are verbal rather than nominal categories.

### 3. Hardt and Mikkelsen's proposal

Hardt and Mikkelsen take as their starting point a double indexing approach for *same*, as proposed by Brasoveanu (2011). This is a natural reflection of the fact that *same* compares two expressions: a local containing expression and its antecedent.

#### 3.1. Brasoveanu's account

I illustrate the account of Brasoveanu (2011) with respect to (10).

(10) Every<sup>u<sub>0</sub></sup> boy read the<sup>u<sub>1</sub></sup> same<sup>u<sub>1</sub></sup> book.

Intuitively, the interpretation is this:

(11) for every pair of boys  $b_1$  and  $b_2$  and pair of books  $k_1$  and  $k_2$  such that  $b_1$  read  $k_1$  and  $b_2$  read  $k_2$ ,  $k_1 = k_2$

To capture this, Brasoveanu defines a distribution operator that distributes over pairs of individuals, and then gives *same* and *different* the ability to access such pairs. Brasoveanu gives the following meaning for *same*:

(12)  $\text{same}_{u_n}^m \rightsquigarrow \lambda P_{et} . \lambda v_e . P(v); *(\underline{P(u_{n+m})}; [\text{identical}\{u_{n+m}, u_n\}])$

On Brasoveanu's account *same* compares a containing NP with an antecedent NP. The challenge for internal readings is that there is no explicit antecedent for *same*. To address this, Brasoveanu posits a distribution operator which allows comparison of individuals within the domain of quantification.

To understand how this works, consider the drs for (10):

(13)  $\text{max}^{u_0}([\text{atoms-only}\{u_0\}, \text{boy}\{u_0\}]);$   
 $\text{dist}_{u_0}([u_1 | \text{atoms-only}\{u_1\}], \text{singleton}\{u_1\}, \text{book}\{u_1\};$   
 $*(\underline{(\text{book}(u_{1+2}))}; [\text{identical}\{u_{1+2}, u_1\}]; [\text{read}\{u_0, u_1\}])$

The contribution of *every boy* is the maximal set of boys, while the *dist* operator tests each element of that set to see that it satisfies the nuclear scope. In doing this *dist* in fact examines

all pairs of elements, call them  $boy_1$  and  $boy_2$ , and checks each element to see that it satisfies the nuclear scope, which itself involves an update, namely a book associated with each boy – these boy-book pairs are termed *stacks*. In this example each stack has length 2; in general they can be of any length. Thus *dist* checks every pair of stacks,  $s_1$  and  $s_2$ , to ensure that both  $s_1$  and  $s_2$  satisfy the nuclear scope. These expressions make use of the stack-concatenation operator,  $*$ , which examines its two input stacks, and concatenates them. The concatenated stack can then be used to compare two analogous individuals, using the offset, which is the length of the input stacks.

$$\begin{array}{|c|c|} \hline u_0 & u_1 \\ \hline boy1 & book1 \\ \hline \end{array} * \begin{array}{|c|c|} \hline u_0 & u_1 \\ \hline boy2 & book2 \\ \hline \end{array} = \begin{array}{|c|c|c|c|} \hline u_0 & u_1 & u_2 & u_3 \\ \hline boy1 & book1 & boy2 & book2 \\ \hline \end{array}$$

The resulting stack makes available two discourse referents,  $u_1$  and  $u_3$ ; in the drs above, the **identical** condition is placed on these two discourse references, as desired. The distribution operator ensures that all possible pairs of stacks will be compared, which in this case means that all pairs of boys read the identical book.

Hardt and Mikkelsen take issue with Brasoveanu, in that they claim that *same* is different, in that it indexes eventualities, unlike *different* and other anaphoric expressions.

### 3.2. Parallelism

The main claim of Hardt and Mikkelsen (2015) is that *same* requires parallelism. More specifically, the clause containing *same* and the antecedent clause must be related by Parallel, as defined here, following Kehler (2002):

- (14) Parallel: Infer  $P(a_1, a_2, \dots)$  from the assertion of  $S1$  and  $P(b_1, b_2, \dots)$  from the assertion of  $S2$ , for a (non-trivial) common  $P$  and similar  $a_i$  and  $b_i$ .

Parallel requires a common relation  $P$  that subsumes the relation of both  $S1$  and  $S2$ , as well as similar parallel elements. To satisfy Parallel, two eventualities must contain similar predicates applied to similar arguments. Two predicates count as similar if they both entail a non-trivial common relation. The arguments are similar to the extent that similar predicates apply to them. An intuitive way of computing this can be found in accounts such as Asher (1993) and Prüst et al. (1994), where parallelism is thought of as a kind of most specific unifier, which captures the semantic commonality between the two eventualities.

### 3.3. Semantic representation

Hardt and Mikkelsen (2015) follow Brasoveanu in giving a uniform treatment of *same* in this way, whether it appears with internal or external readings. However, recall that Hardt and Mikkelsen define *same* somewhat differently, so that, on their account, a Parallel condition is placed on the containing and antecedent eventualities.

The meaning for *same* for Hardt and Mikkelsen builds on that given in Brasoveanu (2011), with two key modifications: first, *same* compares eventualities rather than individuals. Second, the comparison is the discourse condition Parallel, rather than a simple identity.

This is the meaning for *same* proposed by Hardt and Mikkelsen (2015):

$$\text{same}_{e_n}^m \rightsquigarrow \lambda P_{et}. \lambda v_e. P(v); *[\text{parallel}\{e_{n+m}, e_n\}]$$

The subscript  $e_n$  indexes *same* to the containing eventuality, and the antecedent eventuality is determined by adding the offset  $m$  to  $n$ . The discourse condition Parallel is applied to these two eventualities.

We return now to (10), which receives the following representation:

$$(15) \quad [\text{Every}^{u_0} \text{ boy read the}^{u_1} \text{ same}_{e_2}^3 \text{ book.}]^{e_2}$$

With this indexing, the subscript for *same*,  $e_2$ , indexes the containing S, rather than the containing NP as in Brasoveanu's system. Other than that, the analysis proceeds in exactly the same way; the superscript on *same* is the offset, which is the size of the stack. Then, by using the *stack concatenation* operator  $*$  below, the drs allows *same* to impose Parallel on two instantiations of the eventuality,  $[\text{read}\{u_0, u_1\}]$ .

$$(16) \quad \begin{aligned} &\mathbf{max}^{u_0}([\mathbf{atoms-only}\{u_0\}, \text{boy}\{u_0\}]); \\ &\mathbf{dist}_{u_0}([u_1, e_2 | \mathbf{atoms-only}\{u_1\}], \mathbf{singleton}\{u_1\}, \text{book}\{u_1\}), e_2 : \text{read}\{u_0, u_1\}; \\ &*\mathbf{parallel}\{e_{2+3}, e_2\} \end{aligned}$$

$$\begin{array}{c} \begin{array}{ccc|ccc} u_0 & u_1 & e_2 & & & \\ \hline \text{boy1} & \text{book1} & \text{read}(\text{boy1}, \text{book1}) & & & \end{array} & * & \begin{array}{ccc|ccc} u_0 & u_1 & e_2 & & & \\ \hline \text{boy2} & \text{book2} & \text{read}(\text{boy2}, \text{book2}) & & & \end{array} \\ \\ = & \begin{array}{ccc|ccc|ccc} u_0 & u_1 & e_2 & u_3 & u_4 & e_5 & & & \\ \hline \text{boy1} & \text{book1} & \text{read}(\text{boy1}, \text{book1}) & \text{boy2} & \text{book2} & \text{read}(\text{boy2}, \text{book2}) & & & \end{array} \end{array}$$

Hardt and Mikkelsen's meaning for *same* can be applied for internal readings just as it is applied for external readings. However, the imposition of Parallel for internal readings would appear to be vacuous – as Hardt and Mikkelsen, say, for internal readings “it is somewhat difficult to discern the interpretive effect of *same*” (p 25). And indeed it is unusual to impose a discourse condition on the implicit predications that arise from distributive structure in this way. However, as we will see, there are in fact clear effects of parallelism on these internal readings.

#### 4. Hardt and Mikkelsen's observations – external readings

Hardt and Mikkelsen (2015) present a series of contrasts that distinguish *same* from *different*, as well as other anaphoric forms. In each case *same* is ruled out where *different* and other

anaphoric forms are allowed.

### Distinct antecedent

The following example is originally due to Hardt et al. (2012), who observe that it is most naturally read as describing a single fish-catching event, and on that reading, *same* is infelicitous, while other forms are acceptable.

- (17) a. John caught a big fish, and  
b. he caught it/\*the same fish without any fishing equipment.

Hardt et al. (2012) observe that *same* requires that the antecedent and containing clause must be distinct events. Hardt and Mikkelsen (2015) argue that this is a consequence of their parallelism constraint: Parallel is not satisfied because the containing clause, (17b), has a manner modifier, *without any fishing equipment*, which lacks a corresponding parallel element in the antecedent clause, (17a). Moreover, no such parallel element can be inferred, without losing the single-event reading.

- (18) [John<sup>u<sub>1</sub></sup> caught a<sup>u<sub>2</sub></sup> big fish]<sup>e<sub>3</sub></sup>,  
a. and [he<sub>u<sub>1</sub></sub> caught it<sub>u<sub>2</sub></sub> without any fishing equipment]<sup>e<sub>4</sub></sup>.  
b. \*and [he<sub>u<sub>1</sub></sub> caught the<sup>u<sub>4</sub></sup> same<sub>e<sub>5</sub></sub><sup>-1</sup> fish without any fishing equipment]<sup>e<sub>5</sub></sup>.

The following is the drs for the antecedent clause in (18):

- (19) [u<sub>1</sub>, u<sub>2</sub>, e<sub>3</sub> | u<sub>1</sub> = John, fish(u<sub>2</sub>), big(u<sub>2</sub>), e<sub>3</sub> : caught {u<sub>1</sub>, u<sub>2</sub>}]

The following is the drs for the continuation in (18a), which is acceptable:

- (20) [e<sub>5</sub> | e<sub>5</sub> : caught {u<sub>1</sub>, u<sub>2</sub>, without-equipment}]

(21) gives the drs for the infelicitous continuation with *same*:

- (21) [u<sub>4</sub>, e<sub>5</sub> | fish(u<sub>4</sub>), u<sub>4</sub> = u<sub>2</sub>, e<sub>5</sub> : caught {u<sub>1</sub>, u<sub>4</sub>, without-equipment}];  
\*[parallel {e<sub>5</sub>, e<sub>4</sub>}]

Here we can see that Parallel fails. We can see that e<sub>5</sub> is caught(u<sub>1</sub>, u<sub>4</sub>, without-equipment), and e<sub>4</sub> is caught(u<sub>1</sub>, u<sub>4</sub>). Thus Parallel fails because there are not similar parallel elements.

### Negated antecedent

- (22) John didn't read *War and Peace*.  
a. He read a different book.  
b. \*Susan read the same book.  
c. Susan read it.

According to Hardt and Mikkelsen (2015), a negated antecedent is ruled out for *same*, because the antecedent eventuality must be accessible, as defined in DRT (Kamp and Reyle (1993)). They argue that this shows that the effect is a consequence of the fact that *same* imposes the Parallel condition on the containing and the antecedent eventuality; if the antecedent eventuality is not accessible, the drs would be ill-formed.

Hardt and Mikkelsen provide the following indexing for (22):

- (23) [not [John<sup>u<sub>1</sub></sup> read *War and Peace*<sup>u<sub>2</sub></sup>]<sup>e<sub>3</sub></sup>].  
 a. [He<sub>u<sub>1</sub></sub> read a<sup>u<sub>4</sub></sup> different<sub>u<sub>4</sub></sub><sup>-2</sup> book]<sup>e<sub>5</sub></sup>.  
 b. \*[Susan<sup>u<sub>4</sub></sup> read the<sup>u<sub>5</sub></sup> same<sub>e<sub>6</sub></sub><sup>-3</sup> book]<sup>e<sub>6</sub></sup>.  
 c. [Susan<sup>u<sub>4</sub></sup> read it<sub>u<sub>2</sub></sub>]<sup>e<sub>5</sub></sup>.

The following is the drs for the antecedent clause, (23).

- (24) [u<sub>1</sub>, u<sub>2</sub> | u<sub>1</sub> = John, u<sub>2</sub> = war-and-peace, not[e<sub>3</sub> | e<sub>3</sub> : read{u<sub>1</sub>, u<sub>2</sub>}]]

The drefs u<sub>1</sub> and u<sub>2</sub> are introduced at the top level drs, because they represent names. However, the eventuality dref e<sub>3</sub> is introduced in the drs that is embedded under **not**. Because of this, e<sub>3</sub> is not accessible to subsequent discourse. (25) shows the drs for the continuation in (23a).

- (25) [u<sub>4</sub>, e<sub>5</sub> | book{u<sub>4</sub>}, e<sub>5</sub> : read{u<sub>1</sub>, u<sub>4</sub>}] ; \*(book(u<sub>4-2</sub>); [disjoint{u<sub>4</sub>, u<sub>2</sub>}])

Here, *different* simply compares the drefs u<sub>4</sub> and u<sub>2</sub>. There is no accessibility problem, since u<sub>2</sub> is introduced by the name *War and Peace* and is therefore accessible at the top level drs.

The drs for (23b) is as follows:

- (26) [u<sub>4</sub>, u<sub>5</sub>, e<sub>6</sub> | u<sub>4</sub> = Susan, book{u<sub>5</sub>}, u<sub>5</sub> = u<sub>2</sub>, e<sub>6</sub> : read{u<sub>4</sub>, u<sub>5</sub>}] ;  
 \*[parallel{e<sub>6</sub>, e<sub>3</sub>}]

The problem here is that *same* must compare two eventualities, e<sub>6</sub> and e<sub>3</sub>, but since e<sub>3</sub> is embedded under negation, it is not accessible. Finally, the drs for the continuation with a pronoun in (23c) is as follows:

- (27) [u<sub>4</sub>, e<sub>5</sub> | u<sub>4</sub> = Susan, e<sub>5</sub> : read{u<sub>4</sub>, u<sub>2</sub>}]

It is clear that this is acceptable: the pronoun is simply co-indexed with the accessible antecedent, u<sub>2</sub>.

Notice that on Brasoveanu's analysis, *same* would not be ruled out, since, like *different*, it merely requires an accessible NP antecedent, in this case *War and Peace*. Of course, it might appear that *War and Peace* is also inaccessible, since it is embedded within the negation. However, it is standard in DRT to treat proper names differently; they are normally accessible at the top level drs. See Kamp and Reyle (1993) for details.

## Parallel antecedent

- (28) John praised *War and Peace*.  
 a. And Bill read it/\*the same book.  
 b. But Bill criticized the same book.

According to Hardt and Mikkelsen (2015) *same* is ruled out in (28a), because Parallel is not satisfied by the antecedent clause *John praised War and Peace*, because it is not possible to infer a common non-trivial P that subsumes *read* and *praised*. Compare (28a) to the felicitous (28b): here Parallel is satisfied because one can infer from the verbs *criticize* and *praise* a common non-trivial P, namely *evaluate*, with similar parallel elements  $\langle \text{John}, \text{Bill} \rangle$  and  $\langle \text{War and Peace}, \text{the book} \rangle$ .

This is illustrated here for one version of (28):

- (29) [John<sup>u<sub>1</sub></sup> praised *War and Peace*<sup>u<sub>2</sub></sup>]<sup>e<sub>3</sub></sup>.  
 a. \* And [Bill<sup>u<sub>4</sub></sup> read the<sup>u<sub>5</sub></sup> same<sup>-3</sup><sub>e<sub>6</sub></sub> book]<sup>e<sub>6</sub></sup>  
 b. But [Bill<sup>u<sub>4</sub></sup> criticized the<sup>u<sub>5</sub></sup> same<sup>-3</sup><sub>e<sub>6</sub></sub> book]<sup>e<sub>6</sub></sup>

Here we translate (29a) into the following drs's:

$$[u_1, u_2, e_3 | u_1 = \text{John}, u_2 = \text{war-and-peace}, e_3 : \text{praise}\{u_1, u_2\}]$$

$$[u_4, u_5, e_6 | u_4 = \text{Bill}, \text{book}\{u_5\}, u_5 = u_2, \\ e_6 : \text{read}\{u_4, u_5\}]; *[\text{parallel}\{e_6, e_3\}]$$

Observe that Parallel is imposed on eventualities  $e_6$  (read(Bill, War and Peace)) and  $e_3$  (praise(John, War and Peace)). As discussed above, Parallel fails here because the predicates *praise* and *read* do not entail a non-trivial common property.

## 5. New observations – internal readings

In this section, we show that all the observations offered by Hardt and Mikkelsen (2015) with respect to external readings in fact apply in a similar way to internal readings.

### Distinct antecedent

The following example is due to Barker (2007):

- (30) a. David hit and killed Goliath.  
 b. David hit and killed the same man.

As Barker observes, with Goliath, there is an ambiguity – there could be two events, a hitting event and a killing event, or there could be one event in which the hitting of Goliath was the killing of Goliath. With *same*, this ambiguity goes away – the hitting and killing must be

distinct events. This is in fact observed by Hardt and Mikkelsen (2015), who point out that their Parallel constraint requires that the two events it relates are distinct. This is in fact completely analogous to the distinct antecedent claim given above with respect to external readings.

Following Hardt and Mikkelsen, we assume that (30a) receives the following drs representation:

$$(31) \quad [v_0, v_1, v_2 | v_0 = \mathbf{hit}, v_1 = \mathbf{killed}, v_2 = v_0 \cup v_1];$$

$$\mathbf{dist}_{v_2}([u_3, u_4, e_5 | \mathbf{john}\{u_3\}, \mathbf{man}\{u_4\}, e_5 : v_2\{u_3, u_4\};$$

$$*[\mathbf{parallel}\{e_{5+4}, e_5\}])$$

$$= \begin{array}{|c|c|c|c|} \hline v_2 & u_3 & u_4 & e_5 \\ \hline \text{hit} & \text{john} & \text{man1} & \text{hit}(\text{john}, \text{man1}) \\ \hline \end{array} * \begin{array}{|c|c|c|c|} \hline v_2 & u_3 & u_4 & e_5 \\ \hline \text{killed} & \text{john} & \text{man2} & \text{killed}(\text{john}, \text{man2}) \\ \hline \end{array}$$

$$= \begin{array}{|c|c|c|c|c|c|c|c|} \hline v_2 & u_3 & u_4 & e_5 & v_6 & u_7 & u_8 & e_9 \\ \hline \text{hit} & \text{john} & \text{man1} & \text{hit}(\text{john}, \text{man1}) & \text{killed} & \text{john} & \text{man2} & \text{killed}(\text{john}, \text{man2}) \\ \hline \end{array}$$

The condition **parallel** is applied to the two eventualities,  $e_5$  and  $e_9$ . As discussed above, Hardt and Mikkelsen argue that the Parallel condition quite generally includes a requirement that the two eventualities are distinct. Since it is *same* that introduces the parallelism requirement, this explains the fact that (30a) allows the same-event reading, while (30b) does not.

### Negated antecedent

Above we saw that Hardt and Mikkelsen (2015) claimed that negated antecedents for *same* were ruled out because of the parallelism constraint. In particular, since *same* required parallelism between the containing and antecedent clauses, a negated antecedent clause rendered it inaccessible, resulting in an ill-formed drs.

In (32) we show an analogous effect with an internal reading, where there is a negated antecedent, and we see that *same* is ruled out, although an ordinary definite description (without *same*) is acceptable.

$$(32) \quad \text{John } \mathbf{didn't read}, \mathbf{but did skim} \text{ the book} / * \text{the same book}.$$

As observed by Carlson (1987), a controller can be a coordinated element that is interpreted distributively. Here, we have two coordinated verbal elements. Crucially, the coordination includes a negative polarity in the first conjunct and positive polarity in the second.

$[v_0, v_1, v_2 | v_0 = \text{did\_not\_read}, v_1 = \text{did\_skim}, v_2 = v_0 \cup v_1];$   
 $\text{dist}_{v_2}([u_3, u_4, e_5 | \text{john}\{u_3\}, \text{book}\{u_4\}, e_5 : v_2\{u_3, u_4\}; *[\text{parallel}\{e_{5+4}, e_5\}])$

$v_2$	$u_3$	$u_4$	$e_5$	*			
did_not_read	john	book1	not(read(john, book1))				
$v_2$	$u_3$	$u_4$	$e_5$				
skimmed	john	book2	skimmed(john, book2)				
=							
$v_2$	$u_3$	$u_4$	$e_5$	$v_6$	$u_7$	$u_8$	$e_9$
did_not_read	j	b1	not(read(j, b1))	skimmed	j	b2	skimmed(j, b2)

Here, we see that Parallel is applied to events  $e_5$  and  $e_9$  – it fails, because  $e_5$  is negated.

### Parallel antecedent

It was observed by Hardt and Mikkelsen (2015) that Parallel gives rise to a preference for predicates that are semantically related. For example, *praise* and *criticize* both entail a common property, *evaluate*. On the other hand, *investigate* and *reject* are not related in a parallel way; rather, *reject* in this case is a consequence of *investigate*. Here we see this effect with internal readings.

- (33) a. John investigated and rejected the theory  
 b. \* John investigated and rejected the same theory.

- (34) John praised and criticized the same theory.

Below we show how this contrast is captured. We begin with the representation of the acceptable (34):

$[v_0, v_1, v_2 | v_0 = \text{praised}, v_1 = \text{criticized}, v_2 = v_0 \cup v_1];$   
 $\text{dist}_{v_2}([u_3, u_4, e_5 | \text{john}\{u_3\}, \text{theory}\{u_4\}, e_5 : v_2\{u_3, u_4\}; *[\text{parallel}\{e_{5+4}, e_5\}])$

$v_2$	$u_3$	$u_4$	$e_5$	*			
praised	john	theory1	praised(john, theory1)				
$v_2$	$u_3$	$u_4$	$e_5$				
criticized	john	theory2	criticized(john, theory2)				
=							
$v_2$	$u_3$	$u_4$	$e_5$	$v_6$	$u_7$	$u_8$	$e_9$
praise	j	t1	praise(j, t1)	criticized	j	t2	criticized(j, t2)

We observe that Parallel is imposed on eventualities  $e_5$  (praise(john, theory1)) and  $e_9$  (criticized(john, theory2)). Because of the semantic relationship between *praise* and *criticize*, Parallel is satisfied.

We turn now to the unacceptable (33b):

$[v_0, v_1, v_2 | v_0 = \text{investigated}, v_1 = \text{rejected}, v_2 = v_0 \cup v_1];$   
 $\text{dist}_{v_2}([u_3, u_4, e_5 | \text{john}\{u_3\}, \text{theory}\{u_4\}, e_5 : v_2\{u_3, u_4\}; *[\text{parallel}\{e_{5+4}, e_5\}])$

$v_2$	$u_3$	$u_4$	$e_5$	
investigated	john	theory1	investigated(john, theory1)	*
$v_2$	$u_3$	$u_4$	$e_5$	
rejected	john	theory2	rejected(john, theory2)	

=

$v_2$	$u_3$	$u_4$	$e_5$	$v_6$	$u_7$	$u_8$	$e_9$
investigated	j	t1	investigated(j, t1)	rejected	j	t2	rejected(j, t2)

Here, Parallel is imposed on eventualities  $e_5$  (investigated(john, theory1)) and  $e_9$  (rejected(john, theory2)). The predicates *investigate* and *reject* don't have a non-trivial entailed property, and thus Parallel is not satisfied.

## 6. Conclusions

Hardt and Mikkelsen (2015) show that *same* differs from other, related expressions, in that it gives rise to a parallelism requirement that must hold between the containing clause and an antecedent clause. They show this by presenting three types of parallelism effects: distinct antecedent, negated antecedent, and parallel antecedent. These effects were all shown to hold for external readings – cases where the antecedent clause and the containing clause appear in separate, overt predications. Although Hardt and Mikkelsen's account is formulated to apply in the same way for internal readings, they do not show that parallelism has clear effects in the case of internal readings.

In this paper, I have shown that all these parallelism effects, distinct antecedent, negated antecedent, and parallel antecedent, apply to internal readings just as they do for external readings. This is perhaps surprising – discourse constraints such as parallelism typically are applied to separate overt predications, rather than the implicitly distinct predications that arise in distributional structures.

I think these parallelism effects have not previously been observed for internal readings, because the typical internal readings have involved quantificational NP controllers, such as (2).

In such cases, it is difficult to see how to construct examples that potentially violate parallelism. In this paper we have seen that they are readily constructed in examples involving controllers that are coordinated verbal categories. These examples can give rise to implicit predications that are not necessarily parallel, since the coordinated elements can differ in polarity, event structure or the semantic content of the predication, all of which are crucial in satisfying parallelism.

While it is well-established that anaphoric elements are sensitive to parallelism, the observations in this paper, like those of Hardt and Mikkelsen (2015), do not merely show that parallelism is relevant to the interpretation of *same*. Rather, the claim is that *same* is unacceptable in the absence of parallelism, and this is captured quite directly, by making the parallelism constraint part of the lexical meaning of *same*. The observations in this paper provide additional support for this view.

# Presupposition projection from disjunction in online processing<sup>1</sup>

Aron HIRSCH — *Massachusetts Institute of Technology*

Jérémy ZEHR — *University of Pennsylvania*

Florian SCHWARZ — *University of Pennsylvania*

**Abstract.** Stalnaker (1973, 1974) suggested that presuppositions are evaluated dynamically in a way that crucially takes into account the ‘left-to-right’ unfolding of linguistic expressions. Recently, even more explicit considerations of the timing of online processing have been invoked to account for patterns of presupposition projection (e.g. Schlenker, 2008, 2009; Chemla and Schlenker, 2012; Hirsch and Hackl, 2014). However, relatively little is known about the actual time course of presupposition interpretation, in particular in environments that involve projection. In this paper, we take disjunction as our testing ground, and use visual world eye tracking data to shed light on the unfolding of presupposition projection in real time. Our key generalization is that presuppositions are evaluated immediately when the interpreter encounters the trigger in the left-to-right parse, bearing out a key assumption in the relevant theoretical literature, namely that presupposition projection can be related to incremental processing.

**Keywords:** presupposition, presupposition projection, disjunction, eye-tracking, visual world paradigm, experimental pragmatics

## 1. Introduction

A central issue in presupposition theory is the problem of *presupposition projection*: how are the presuppositions of a complex sentence determined from those of its atomic parts? As shown in (1), presuppositions interact with certain embedding expressions differently from entailments:

- (1) a. The bathroom is in a funny place.
- b. The bathroom is not in a funny place.

The entailed contribution of the predicate *is in a funny place* is affirmed in (1a), but denied in (1b). Yet, the inference that there is a bathroom, introduced by the definite description *the bathroom* is conveyed by both sentences: the existence presupposition of the definite description projects from the scope of negation in (1b).

In this paper, we study the interaction between presupposition projection and *online processing*, focusing on *co-ordinate constructions*, which exhibit a complex pattern of projection effects. In the general case, presuppositions project from both the first and second co-ordinate: both of the sentence variants in (2) presuppose that there is a bathroom.

---

<sup>1</sup>We thank the audiences at SuB 21 (Edinburgh), the Schwarz Lab meeting at UPenn, and the Experimental Syntax and Semantics Lab meeting at MIT for useful comments and discussion. We also thank Kendra Carson and Claire Huang for their assistance in preparing auditory stimuli and collecting data, and Dorothy Ahn for the visual stimuli. This project has been supported by NSF-grant BCS-1349009 to Florian Schwarz.

- (2) a. The rooms have odd shapes, and the bathroom is in a funny place.
- b. The bathroom is in a funny place, and the rooms have odd shapes.

However, it has long been observed that presupposition projection from conjunction can depend on the linear order of the conjuncts, in particular in cases where the conjunct not containing the presupposition trigger entails the presupposition:

- (3) a. There is a bathroom, and the bathroom is in a funny place.
- b. #The bathroom is in a funny place, and there is a bathroom.

The effect of the first conjunct entailing the presupposition of the second conjunct in (3a) is that the sentence as a whole has no presupposition at all. In contrast, the reverse conjunct order in (3b) seems to be infelicitous. Intuitively, this is due to a clash between the requirement introduced by the presupposition in the first conjunct that it be taken for granted that there is a bathroom, and the presentation of that very notion as new information in the second, i.e., the redundancy of the second conjunct seems to induce infelicity here.

The simple example above suggests that linear order interacts with presupposition projection. Most early accounts of projection effectively stipulated this type of effect as a lexical property of sentential connectives (Karttunen, 1973; Heim, 1983). Recent approaches, though, have sought a more explanatory perspective by linking projection to online processing: asymmetric projection in conjunction emerges from the left-to-right nature of processing (Schlenker, 2009: cf. Schlenker 2008; Fox 2008; Chemla and Schlenker 2012; Hirsch and Hackl 2014). While this move towards greater explanatory adequacy is conceptually appealing, these approaches crucially rely on assumptions about online processing that have not been empirically tested, in particular with regards to how projection is evaluated in real time.

Our goal is to directly test one key assumption in this regard, namely (4), which we take to be an implicit or explicit feature of all accounts linking projection behavior to online processing:

(4) **Rapid Incremental Presupposition Evaluation ('RIPE')**

The interpreter decides whether or not a presupposition projects immediately when they encounter the trigger in the left-to-right parse.

Although (4) seems intuitive given general evidence for rapid incremental interpretation, it is not obviously borne out in all cases. An apparent corollary of (4) would seem to be that only material which *precedes* a given presupposition trigger should be able to influence whether or not the presupposition projects. However, there are cases where material *following* the trigger is relevant. Consider the contrast in (5), involving disjunction. (5b) is a well-known example due to Barbara Partee (Partee, 2005), and (5a) is a minimal variant thereof.

- (5) a. Either the bathroom is in a funny place, or Mary is lost.
- b. Either the bathroom is in a funny place, or there is no bathroom.

In both cases, the presupposition trigger (*the bathroom*) is in the first disjunct, while the second disjunct is varied, with an impact on projection: in (5a), the presupposition projects, but it does not in (5b), i.e. only (5a) gives rise to an inference that there is a bathroom. Indeed, the point of (5b) is to communicate agnosticism about whether there is a bathroom.

The pattern in (5) looks inconsistent with RIPE: if projection is evaluated in online processing as soon as the trigger is encountered, then downstream material should not play a role. Given this apparent evidence *against* RIPE, we take disjunction as our empirical object of study. To foreshadow, we argue that, despite initial appearances, disjunction is in fact compatible with RIPE, following Hirsch and Hackl (2014). Our main contribution here is to provide novel empirical evidence from visual world eye-tracking that directly supports RIPE in disjunction.

## 2. RIPE: motivation and puzzles

We begin by illustrating how asymmetric projection in conjunction can be derived from effects of real time processing (§2.1-2.3). The account we sketch follows Schlenker (2009) — and relies on RIPE. This motivates our choice to pursue RIPE. In the last part of the section, we make explicit the puzzle for RIPE posed by disjunction (§2.4-2.5).

### 2.1. Background: asymmetric projection in dynamic semantics

Stalnaker (1973) developed a seminal analysis of presupposition, by which presuppositions impose requirements on the discourse context. The context is modeled as the set of possible worlds in which all propositions mutually agreed upon by the conversational participants are true (the ‘context set’,  $c$ ). A presupposition constrains  $c$  such that if a sentence  $S$  globally presupposes a proposition  $p$ , then  $S$  can only be felicitously uttered in contexts where  $p$  is true at every world in  $c$ .  $c$  is assumed to evolve as the discourse unfolds, and the felicity requirement applies to the context set that takes all previous parts of the discourse into account.

Heim (1983) extended Stalnaker’s approach to a more general model of context update where the context relative to which a presupposition is evaluated is not necessarily  $c$  itself. To illustrate, consider conjunction. Heim models the denotation of lexical items not in terms of truth-conditions, but rather in terms of the impact they have on the context set (their ‘context change potential’). Conjunction is defined to sequentially update  $c$  with the propositions expressed by the two conjuncts (‘+’ corresponds to intersection applied to the sets of possible worlds that  $c$ ,  $\phi_1$ , and  $\phi_2$  stand for):

- (6) a. ‘ $S_1$  and  $S_2$ ’ uttered in context  $c$
- b.  $(c + \phi_1) + \phi_2$

The key consequence of this sequential update is that  $S_1$  and  $S_2$  are interpreted relative to different contexts:  $S_1$  is directly evaluated relative to  $c$ , while  $S_2$  is interpreted relative to a context  $c'$  resulting from updating  $c$  with the proposition expressed by  $S_1$  ( $c' = c + \phi_1$ ). In turn,

presuppositions triggered in the two conjuncts are evaluated differently: a presupposition of  $S_1$  must be true at all worlds in  $c$ , while a presupposition of  $S_2$  must be true at all worlds in  $c'$ .

Heim's system is well suited to capture asymmetric projection in conjunction. Concretely, recall (7), where the presupposition trigger *the bathroom* occurs in the first conjunct:

- (7) #The bathroom is in a funny place, and there is a bathroom.

The presupposition is evaluated relative to  $c$  and imposes the requirement that the make-up of  $c$  conform to (8). By constraining the initial context, the presupposition is felt to project.<sup>2</sup>

- (8)  $c \subseteq \{w : \text{there is a bathroom in } w\}$

The situation is different when the order of the conjuncts is permuted in (9). In this case, the presupposition is evaluated relative to the context  $c'$  output by updating  $c$  with the first conjunct (*There is a bathroom*), as in (10a). The presupposition of *the bathroom* then places the constraint on  $c'$  in (10b).

- (9) There is a bathroom, and the bathroom is in a funny place.

- (10) a.  $c' = c \cap \{w : \text{there is a bathroom in } w\}$   
 b.  $c' \subseteq \{w : \text{there is a bathroom in } w\}$

Because  $c'$  only contains those worlds in  $c$  at which there is a bathroom, the condition in (10b) is necessarily met, independent of the original make-up of  $c$ . Thus, the presupposition does not place any constraint on the initial context and is not felt to project.

## 2.2. From lexical stipulation to online processing

While Heim's approach offers an elegant analysis for the projection properties of conjunction (and other connectives), it does not achieve full explanatory adequacy. Heim relies on a specific lexical entry for conjunction, which is not formally motivated on independent grounds. In particular, nothing in the framework rules out an alternative entry for conjunction where the conjuncts update the initial context in the reverse order (Rooth p.c. to Heim, Soames 1989, Heim 1990):

- (11) a. ' $S_1$  and  $S_2$ ' uttered in context  $c$   
 b.  $(c + \phi_2) + \phi_1$  cf. (6b)

<sup>2</sup>Note that not only is the presupposition felt to project in (7), but the conjunction as a whole is also felt to be degraded. This is easily explained by the fact that the second conjunct winds up as contextually trivial, as it does not add anything new to  $c$ . Stalnaker (1973) already argued this to be a violation of a constraint against redundancy.

With this entry,  $S_2$  is interpreted relative to  $c$ , and  $S_1$  is interpreted relative to  $c + \phi_2$ . Thus, presuppositions would always project from the *second* conjunct, but variably from the *first* conjunct, depending on the content of the second.

It does not seem to be a lexical idiosyncrasy that update proceeds as in (6), and not as in (11). In (6), update proceeds left-to-right, as  $c$  is updated with the first conjunct and then the second. In (11), update proceeds right-to-left. The correlation between update order and the left-to-right linear order of the conjuncts can be explained in a principled way if update is directly linked to online processing. This is the direction pursued in recent work, and we outline one illustrative approach here: Schlenker's (2009) theory of local contexts.

Departing from Heim, Schlenker returns to a classical semantic framework, where sentence meanings are modeled as truth-conditions. When interpreting a sentence  $S$  in a context  $c$ , the interpreter must determine whether the proposition  $S$  expresses ( $\phi_S$ ) is true or false at each world in  $c$ . Worlds at which  $\phi_S$  is true should be kept in  $c$  and worlds at which  $\phi_S$  is false should be eliminated. Schlenker proposes that, when the interpreter parses a sub-constituent  $E$  of  $S$ , they simplify their task as much as possible by disregarding those worlds in  $c$  at which they can be sure that the interpretation of  $E$  does not affect the overall truth-value of  $S$ . The set of worlds under consideration when  $E$  is processed is the *local context* for  $E$ . Local contexts are computed online, so only information preceding  $E$  can be taken into account when determining its local context.

Let us consider how Schlenker's approach applies to conjunction. Two stages of the left-to-right parse for a schematic conjunction are flagged in (12):

(12) [0]  $S_1$  and [1]  $S_2$

At stage [0], the interpreter starts by considering all worlds in  $c$ , and  $c$  itself is thus the local context for  $S_1$ . After parsing  $S_1$ , the interpreter can identify worlds in  $c$  at which  $\phi_1$  is true and false. Because  $\phi_1 \wedge \phi_2$  is necessarily false if  $\phi_1$  is false,  $\phi_2$  only affects the truth-value for the conjunction at worlds where  $\phi_1$  is true; at those worlds, the conjunction is true if  $\phi_2$  is true and false otherwise. Accordingly, when they parse  $S_2$ , the interpreter only considers worlds at which  $\phi_1$  is true: the local context for  $S_2$  is  $c + \phi_1$ . With the local contexts for  $S_1$  and  $S_2$  being  $c$  and  $c + \phi_1$ , the dynamics of context update closely mirror Heim's entry in (6).

Since context update is integrated with online processing, the only way for presupposition projection behavior to be linked to context update is for it too to be integrated with online processing – and, in this way, we arrive at the need for RIPE (which is implicit in Schlenker's discussion). For concreteness, consider the parse of (7) above with the stages shown in (13):

(13) [0] The bathroom [1] is in a funny place and [2] there is a bathroom.

At stage [0], parsing of the first disjunct begins and the local context is  $c$ . With RIPE, the presupposition is evaluated immediately on encounter of *the bathroom* at stage [1]. At this

point, the local context remains  $c$ , so the presupposition is evaluated relative to  $c$  and projects.<sup>3</sup>

Permuting the conjunct order results in the presupposition being evaluated in a different local context, exactly as in Heim's system:

- (14) [0] There is a bathroom and [1] the bathroom [2] is in a funny place.

At stage [1], the local context for the second conjunct,  $c'$ , is determined by updating  $c$  with the proposition that there is a bathroom. Then, at stage [2], the presupposition of *the bathroom* is evaluated relative to  $c'$ . Just as for Heim, the presupposition is guaranteed to be satisfied in  $c'$  regardless of the make-up of  $c$ , so fails to project.

In sum, by integrating context update and presupposition evaluation with online processing, Schlenker achieves the same predictions as Heim did, but without lexical stipulation. RIPE plays a key role in the account, as it ensures that a presupposition is evaluated relative to the local context for the conjunct in which that presupposition is triggered.

### 2.3. Previous evidence for RIPE

Given conceptual rationale for RIPE, we ask: what empirical evidence can be used to directly test RIPE? While psycholinguistic work on the online processing of presupposition is still in a nascent state, early results seem to accord with RIPE.

Several self-paced reading studies have shown fairly immediate effects of contextual manipulations bearing on the status of presuppositions, with increased reading times when the context was inconsistent with the presupposition (Schwarz, 2007; Tiemann et al., 2011). This is in line with presuppositions being evaluated right away when the trigger (and other material in the sentence required to flesh out the content of the presupposition) is encountered. Schwarz and Tiemann (2016) further corroborate this with temporally more fine-grained reading time measures from eye-tracking during reading, and Schwarz (2014, 2015); Romoli et al. (2015) provide parallel evidence from visual world eye tracking.

There is, however, a limitation to the previous results: the bulk of evidence for RIPE comes from studies looking at presupposition triggers in simple, unembedded contexts, so no issues of projection arise.<sup>4</sup> This is potentially problematic insofar as the predictions of RIPE could be descriptively adequate for unembedded occurrences of presupposition triggers, but not extend to embedded contexts where projection is an issue. By studying co-ordination, our experiments

<sup>3</sup>As we discussed earlier (cf. (3b)), the presupposition marks its content as information taken for granted in the global context, and continuing the sentence by asserting it results in redundancy. (Note that the presupposition equally affects the local context for the second conjunct, since it is a subset of the global context.)

<sup>4</sup>The key exception to this is Schwarz and Tiemann (2016), who look at the presupposition of *again* under negation and in conditionals, with results that they argue show that evaluating projection presuppositions relative to the global context takes longer than in the case of unembedded ones; we return to the relation between our results and theirs in the general discussion.

directly assess whether RIPE makes adequate predictions when projection is involved. We focus on disjunction which seems to pose a particular challenge for RIPE.

## 2.4. The disjunction puzzle

Schlenker's incremental system makes a key prediction for disjunction: when a presupposition trigger occurs in the first disjunct, the presupposition should project, just as presuppositions project from a first conjunct. Consider the disjunction data seen earlier:

- (5) a. [0] Either the bathroom [1] is in a funny place, or [2] Mary is lost.
- b. [0] Either the bathroom [1] is in a funny place, or [2] there is no bathroom.

Regardless of the connective, the local context at the outset of the parse is *c*. Given RIPE, the presupposition is evaluated at stage [1], relative to *c*. Thus, the presupposition should constrain *c* and be felt to project.

The prediction is borne out in (5a) – but fails in (5b). Whether or not the presupposition projects, then, depends on the second disjunct. When the second disjunct is independent of the presupposition, it projects, as in (5a). But, at least when the second disjunct expresses the negation of the presupposition, it does not project, as in (5b). This effect of the second disjunct looks at odds with RIPE, since the second disjunct is not encountered until stage [2], after the presupposition is evaluated at stage [1]. Given RIPE, it looks as though the second disjunct comes too late to influence projection.

One reaction to this puzzle may be to abandon RIPE so that the interpreter delays all projection decisions until the end of the sentence. In that case, we would expect that projection could be affected both by information that precedes and follows the presupposition trigger. In fact, this option is explicitly considered by Schlenker, who suggests that the asymmetries that can ultimately be attributed to RIPE merely have the status of a processing preference, and can in principle be overridden by a symmetric evaluation of presuppositions. In doing so, however, we lose a straightforward account of asymmetric projection in conjunction<sup>5</sup> and must regress to lexical stipulation to account for the contrast in (a)symmetry between the two types of co-ordination.<sup>6</sup> Here, we pursue the possibility that the disjunction data can be reconciled with RIPE.

## 2.5. Reconciling Disjunction with RIPE

Hirsch and Hackl (2014) suggest a way to reconcile the disjunction pattern with RIPE. In their

<sup>5</sup>But note that the empirical picture for conjunction is less clear than it may seem at first. For an attempt at settling this experimentally, see Mandelkern et al. (2017), who do not find any evidence for symmetric projection in conjunction.

<sup>6</sup>In principle, one could also consider a processor that waits to assess projection until the end of the sentence but then bases its computations on linear order, but this would effectively bring us back to stipulating an effect of order, rather than deriving it independently, so we will leave this possibility aside in what follows.

view, the interpreter always makes a decision about whether or not to project a presupposition immediately on encounter of the trigger, but that decision can be revised later in the parse. RIPE is correct, but commitments made at intermediate stages of parsing can be altered.

We start with the first part of the disjunction which is shared by (5a-b), and focus on two stages of the incremental parse, as annotated below.

(5a-b) [0] Either the bathroom [1] is in a funny place, ...

Parsing of the first disjunct begins at stage [0], at which point the local context is the initial context set. At stage [1], *the bathroom* is encountered and, by RIPE, the interpreter evaluates the presupposition. The presupposition places the constraint on  $c$  in (8), so projects globally.

$$(8) \quad c \subseteq \{w : \text{there is a bathroom in } w\}$$

This result accords with intuitions for (5a), but not (5b). Hirsch and Hackl's account for (5b) relies on a later stage of parsing, subsequent to stage [1]. Consider the full parse, including the second disjunct:

(5b) [0] Either the bathroom [1] is in a funny place, or there is no bathroom [2].

The core idea is that (5b) involves a pragmatic garden path, where the interpreter commits to projection immediately on encounter of the trigger at stage [1] – as expected based on RIPE – and then revises that commitment later at stage [2], after the second disjunct is encountered. The downstream revision is motivated by independent principles of discourse interpretation. In particular, Hirsch and Hackl note that a disjunction  $p$  or  $q$  is subject to the felicity constraint in (15), motivated by general Gricean principles (see also Schlenker 2008):

(15) **Non-opinionatedness (NO)**

To felicitously use a disjunction  $p$  or  $q$ , the speaker must not believe  $p$ ,  $\neg p$ ,  $q$ , or  $\neg q$ .

If the condition in (8) holds, then the notion that the building in fact has a bathroom has to become part of the common ground prior to evaluation of the disjunction in (5b). This means that the speaker must believe (or is at least acting as if they believed) that the building has a bathroom, which in turn commits the speaker to believing that the second disjunct in (5b) is false. In other words, because the second disjunct is equivalent to the negation of the presupposition, projecting the presupposition leads to a violation of Non-Opinionatedness. Having committed to projection at stage [1], the interpreter inevitably runs into an NO violation when they parse the second disjunct at stage [2]. This, Hirsch and Hackl propose, leads to the interpreter back-tracking on their earlier commitment so as to respect NO. This can be done by appealing to some version of a local accommodation operator (Heim, 1983), which effectively results in presupposed content being treated on par with regular entailed content (also see the A-operator of Beaver and Krahmer, 2001).

Note that NO is a principle that applies specifically to disjunctions. As a result, the situation in conjunctions is not parallel, and it does not come as a surprise under this view that one does not seem to observe the same right-to-left filtering in the case of conjunctions (also see footnote 5). This proposal therefore offers an explanatory account of the contrast in incrementality between conjunctions and disjunctions, and thus escapes the stipulative aspect of an alternative approach *à la* Heim where the two connectors are lexically defined to meet the projection observations.

## 2.6. Section summary

We have seen that RIPE is a central assumption of an account linking asymmetric projection in conjunction to online processing – an account achieving significant explanatory depth. Though disjunction seems to provide counter-evidence, Hirsch and Hackl suggest that disjunction could be compatible with RIPE after all. The goal now is to directly test whether RIPE holds in disjunction. We use visual world eye-tracking experiments to assess the time course of presupposition projection, and in particular to test whether commitments to projected presuppositions are reflected in eye movements prior to the second disjunct having fully unfolded.

## 3. Experiment 1: trigger in first disjunct

Exp. 1 investigated disjunctions with a presupposition trigger in the first disjunct. Consistent with RIPE, our results support Hirsch and Hackl's idea that the interpreter rapidly assumes that the presupposition projects upon encountering the trigger, before the second disjunct unfolds.

### 3.1. Design & Methods

The experimental stimuli included disjunctions like (16), with the presupposition trigger *stop* in the first disjunct. In (16), *stop* triggers the presupposition that Henry went to the aquarium prior to Wednesday (in shorthand: *Aquarium* < *Wd*). The assertion in the first disjunct is that Henry did not go to the aquarium from Wednesday on ( $\neg$ *Aquarium* > *Wd*).

- (16) Either Henry stopped going to the aquarium on Wednesday,  
or he waited until Saturday to go to the movies.

Participants heard recordings of sentences like (16) while their gaze was tracked relative to a visual display. The visual display consisted of three pictures, each containing a character and a calendar strip with iconically represented activities (Schwarz, 2014), as in Figure 1. Participants' task was to choose the character they took the sentence to be about.

The crucial picture is the target picture, which came in three variants, corresponding to three experimental conditions, illustrated in Fig. 1A-C. In addition, there was a distractor picture and a 'covered box' (adapted from Huang et al., 2013), where crucial information on what happened on relevant days in the calendar strip is blacked out.

Figure 1: Illustration of Target variants and Covered Box for Exp. 1

The logic of the design was to manipulate whether or not the presupposition of *stop* was met in the target picture, and assess whether the presupposition being met increased the likelihood of participants fixating on the target as the sentence unfolded. In Condition A, the presupposition is met: for the sample item above, Henry went to the aquarium before Wednesday in A. In Conditions B-C, the presupposition fails, since other activities took place prior to Wednesday (Condition B), or no activities did (Condition C). In the item above, the character went to the library prior to Wednesday in Condition B. We refer to B as the DiffActivity (PsFalse) condition and C as the SameActivity (PsFalse) condition. While B constitutes a minimal control condition for A in that they share the same day structure, C was included to control for any independent effect of the presence of slots featuring the mentioned stopped activity.

While the target varies in whether or not the presupposition is satisfied, the distractor picture (not shown) is incompatible with the presupposition in all cases. In the covered box, activities prior to Wednesday are obscured, so the presupposition *could* be satisfied, but is not necessarily so: in the sample item, the character may or may not have gone to the aquarium on Monday and Tuesday. In this way, the covered box is always *compatible* with the presupposition.

Factoring in the assertion now, neither target variant ultimately verifies both the presupposition and the assertion. In Condition A, where the presupposition is verified, the assertion fails, since the character continued to go to aquarium after Wednesday, and went to the beach, not the movies, on Saturday. In Conditions B and C, the presupposition fails, as discussed, and the assertion fails as well. The covered box is ultimately, then, the only picture participants can select: in the covered box, the character does go to the movies on Saturday, verifying the non-presupposing disjunct.

Since we are interested in the online looking pattern, however, more important for our purposes is the status of the assertion *prior to the end of the sentence*. We focus on the critical region underlined in (16). Prior to encounter of *movies* at the end of the sentence, all pictures are still potentially compatible with the assertion, since all have an activity on Saturday. In this way, we can isolate effects of presupposition at this point.

**Predictions** The critical measure is the relative proportion of fixations on the target relative to the covered box in the online data. If participants rapidly compute the presupposition of *stop* and assume projection, per RIPE, an effect of condition should emerge in the critical region: participants should be more likely to fixate on the target image in Condition A (PsTrue) than in either Conditions B or C (PsFalse). In those conditions, their gaze should be drawn to the covered box comparatively more strongly, since the covered box is the only potential presupposition match. On the other hand, if presuppositions are not rapidly evaluated on account of the trigger, but rather are deferred until the full disjunction is fully processed, no effect of condition is predicted. For the behavioral measure, participants are expected to select the covered box as the best overall picture match in all cases, as discussed.

While RIPE predicts an effect of condition during the critical region, an alternative lexicalist approach which stipulates that disjunctions project a conditional presupposition *symmetrically* for triggers in either disjunct does not. If the semantics of disjunctions is such that the second disjunct can affect whether or not a presupposition introduced in the first disjunct has to be met globally (cf. (11b)), then the evaluation of this presupposition most plausibly would be deferred until the second disjunct is processed. In that case, no effect of condition should emerge in the critical region.

**Participants and Procedure** 24 items were created with the properties described above, with 4 versions each (a fourth control condition, not discussed here for reasons of space, had a target where both the presupposition and the entailed content of the first disjunct were true). In addition, there were 30 fillers, all of which involved disjunctions, with varying properties (such as truth of 1st vs. 2nd disjunct, presence of presupposition trigger, etc.) to counterbalance a number of different factors across the experiment. 35 students at the University of Pennsylvania participated for course credit. The experiment was implemented in the Experiment Builder software by SR Research, and data was collected on an EyeLink 1000 eye tracker.

### 3.2. Results

**Data Analysis** Eye movement data were analyzed beginning at the onset of the disjunction marker *or*, in order to measure proportions of looks to the target after the first disjunct had been fully heard but before the second disjunct had been completed. Since the key alternative candidate for matching the disjunction was the covered box (which was compatible with a global interpretation of the presupposition), we computed a target advantage score where looks to the covered box were subtracted from looks to the target. For purposes of analysis, proportions were transformed to Elogits, and the analysis for individual time-windows used mixed effect models with subjects and items as random effects, as well as a slope for condition to the extent

Figure 2: Looks to Target-Looks to Covered Box by Condition relative to onset of ‘or’

that these models converged. Significance of individual effects was assessed through model comparisons with minimally varied models where the condition-factor had been removed.

The graph in Fig. 2 illustrates Target Advantage scores over time for the second disjunct (the black line indicates the mean disambiguation point, corresponding to the onset of *movies* in (16)). There is a clear effect of presupposition: during the second disjunct, participants are significantly more likely to fixate on the target in Condition A (PsTrue) than in Conditions B-C. The contrast with condition B (DiffActivity) is present early on (0-500ms;  $\beta = 2.14$ ,  $SE = 0.61$ ,  $t = 3.52$ ,  $\chi^2 = 10.06$ ,  $p < 0.01$ ), but does not last throughout. The contrast with condition C (SameActivity) emerges first in the 500-1000ms time window ( $\beta = 1.48$ ,  $SE = 0.60$ ,  $t = 2.47$ ,  $\chi^2 = 6.08$ ,  $p < 0.5$ ), and lasts through the remainder of the ambiguous period.

**Discussion** The contrast in the proportion of looks in the second disjunct indicates that the manipulation of whether or not the presupposition is met in the target picture has an effect. This is consistent with the idea that the interpreter assumes projection online, i.e. when the trigger is in the first disjunct, they immediately compute the presupposition and assume projection. This is in line with the prediction of RIPE, but not with an alternative possibility where the potential relevance of the second disjunct for projection is taken into consideration before any consideration of the presupposition is undertaken.

#### 4. Experiment 2: trigger in second disjunct

In Experiment 2, we extend the data set by testing whether RIPE is supported when the presupposition is triggered in the *second* disjunct, rather than the *first*. Again, our results support the idea that the presupposition is rapidly computed and assumed to project online.

##### 4.1. Extending to trigger-second order

As a first step, let us consider what the incremental system we sketched based on Schlenker (2009) predicts for a disjunction with a presupposition trigger in the second disjunct. The disjunction in (17) offers an illustration:

- (17) Either [0] Mary's lost, or [1] the bathroom [2] is in a funny place.

As with any parse, the local context at stage [0] is simply the entire context set,  $c$ . At stage [1], the local context for the second disjunct,  $c'$ , is determined. A disjunction  $S_1$  or  $S_2$  is true at any world where one or both of  $\phi_{S_1}$  and  $\phi_{S_2}$  is true. The content of  $S_2$ , therefore, affects the truth-value of  $\phi_{S_1} \vee \phi_{S_2}$  only at worlds which  $\phi_{S_1}$  is false. As such,  $c'$  in (17) is that subset of  $c$  containing only worlds at which Mary is not lost:

- (18)  $c' = c \cap \{w : \text{Mary is not lost at } w\}$

At stage [2], *the bathroom* is encountered and the presupposition is evaluated relative to  $c'$ . For it to be satisfied, the building must have a bathroom at every world in  $c'$ , as in (19a). The predicted overall presupposition, then, can be paraphrased as the conditional in (19b).

- (19) a.  $c' \subseteq \{w : \text{the building has a bathroom at } w\}$   
 b. If Mary isn't lost, the building has a bathroom.

In predicting a conditional presupposition, Schlenker's approach converges with proposals in dynamic semantics which stipulate an entry for *or* by which a presupposition triggered in the second disjunct projects as conditional (Beaver, 2001: contra Geurts 1999). Yet, this prediction is problematic. Intuitively, (17) does not presuppose (19b), but rather something stronger: the presupposition is simply that the building has a bathroom, independent of whether or not Mary is lost. Observing a non-conditional presupposition where a conditional is predicted is known as *the proviso problem*. Though the proviso problem may seem to argue against an account like Schlenker's altogether, the situation is more complex, as there are examples where a conditional presupposition is observed. A well-known case is (20) (adapted from Geurts, 1996: p. 271), where the intuited presupposition is that if John is a diver, he has a wetsuit.

- (20) Either John isn't a diver, or he brought his wetsuit on the trip.

To explain the non-conditional presupposition of (17), many authors accept the prediction of a conditional presupposition, but augment the account with a pragmatic mechanism which strengthens the conditional to a non-conditional. In (17), (19b) is strengthened to (21):

- (19b) If Mary isn't lost, the building has a bathroom.  
 (21) The building has a bathroom.

Different accounts of strengthening have been advanced (van der Sandt, 1992; Geurts, 1999; Beaver, 2001; Singh, 2007; Schlenker, 2011; Lassiter, 2012). While we cannot go into great detail for reasons of space, the last two in particular lend themselves to an integration with the present discussion. Briefly, they assume that conditional presuppositions get strengthened if the material featuring in the antecedent is taken to be irrelevant for whether or not the presupposition holds. For Schlenker (2011), in particular, this is introduced as a process that makes reference to left-to-right order in processing, parallel to the motivation for RIPE above: preceding material can be considered for presupposition evaluation, but also can be deemed irrelevant

in this regard if it contextually fails to bear on whether or not the presupposition holds. For our purposes, this suggests that resolving the proviso problem is a process that takes place equally rapidly as presupposition projection in general, so that strengthened presuppositions should be detectable in online processing measures. Experiment 2, then, directly extends the approach from Experiment 1 by looking at the effect of presupposition triggers in the second disjunct.

#### 4.2. The paradigm

The test sentences in Experiment 2 consisted of disjunctions such as (22), where the aspectual verb *continue* occurs in the second disjunct and triggers the presupposition that Henry went to the movies prior to Wednesday (movies < Wd).

(22) On Wednesday, Henry either went to the aquarium, or he continued going to the movies.

As in Experiment 1, each test sentence was paired with a visual display made up of three pictures: a target, a distractor, and a covered box. The target picture was varied between two experimental conditions, as in Fig. 3.<sup>7</sup> In both, the first disjunct (that Henry went to the aquarium) is true. In Condition A, the presupposition of *continue* is met as well, as Henry went to the movies on Sunday, Monday, and Tuesday. In Condition B, Henry did not go to the movies before Wednesday (but only after Wednesday), so the presupposition is false. Thus, the target image in both conditions is compatible with the asserted content of the disjunction as a whole (given that it matches the first disjunct), but differs minimally between conditions in whether the presupposition is verified (version A; hence, PsTrue) or not (version B; PsFalse). In the covered box, Henry's activities on Monday, Tuesday, and Wednesday were obscured, as in (3), leaving it open whether or not the presupposition (or the disjunction as a whole) is matched in this picture. The distractor (not shown here) was neither compatible with the presupposition nor the assertion, as it had a different activity prior to Wednesday.

**Predictions** The crucial data are again provided by the online eye-tracking measure. In this case, we define the critical region as extending from the onset of *continue* to the onset of the last word of the sentence, as in (22). Note that, unlike in Experiment 1, the presupposition trigger itself is part of this critical region. While the full second disjunct is needed to flesh out the content of the presupposition (that Henry went to *movies* before Wednesday), the encounter of *continue* alone already suffices to draw the inference that the character in question had *some* sequence of activities preceding Wednesday. As a result, already at the beginning of the critical region, we may see an effect of condition. A greater proportion of looks to the target is expected in Condition A (some activity on Monday-Wednesday) than in Condition B (no activity on these days). As the noun *movies* is encountered, this asymmetry should remain since the target in A satisfies the full presupposition (that Henry went to the *movies* prior to Wednesday). But, crucially, an effect prior to *movies* can give clear evidence that the presupposition is considered rapidly, prior to the end of the clause (even before the full content of the presupposition has been provided).

<sup>7</sup>In addition, there were two further conditions where the first disjunct was false in the target picture for counterbalancing purposes; we do not discuss these here in detail for reasons of space.

Figure 3: Illustration of Target variants and Covered Box for Exp. 2

To re-iterate, any effect of condition in Experiment 2 would implicate *two* rapid online processes relating to presupposition interpretation. First, the presupposition of *continue* has to be considered rapidly for any effect to arise. Secondly, the relationship of this presupposition to the preceding linguistic context has to be determined immediately as well, to determine that having gone to the aquarium on Wednesday (the content of the first disjunct) is not likely to bear on the question of going to the movies prior to Wednesday, leading to strengthening of the presupposition to a non-conditional one (assuming, as before, a conditional presupposition, in line with a RIPE-based account of projection, to begin with).

The secondary measure of picture selection is also informative in Experiment 2, as it allows us to assess whether participants adopt a strengthened non-conditional presupposition in the final interpretation. In Condition A, the target matches the strengthened presupposition and assertion, so is the expected response regardless. In Condition B, however, the strengthened presupposition is not met, so participants must select the covered box if they adopt that interpretation. Otherwise, if they compute a conditional presupposition or locally accommodate a strengthened presupposition, they can select the overt picture. In addition to the selection itself, we collected reaction time data from the offset of the sentence to the time of picture selection.

**Participants & Procedure** The experimental stimuli consisted of 24 items structured as in the sample item above. In addition, there were 30 filler items, again varying crucial properties, such as presence of a trigger and truth or falsity of the disjunction as a whole, for purposes of counterbalancing to avoid potential experiment-level strategic effect and to mask the experimental manipulations. 48 undergraduate students at the University of Pennsylvania participated in the experiment for course credit. As in Exp. 1, the experiment was implemented in Experiment Builder, and data was collected on an EyeLink1000 eye tracker.

Figure 4: Proportion of looks to Target by condition in Exp. 2, relative to the onset of *continue*. Black line marks mean disambiguation point (corresponding to *movies* in (22))

### 4.3. Results

**Eye movement data** The graph in Fig. 4 shows the proportion of looks to the target by condition relative to the onset of the presupposition trigger *continue*, with the black line again indicating the mean onset of the disambiguating word (*movies* in illustrations above).

A difference between the conditions with A (PsTrue) and B (PsFalse) versions of the Target emerges already before 1000ms after the onset of *continue*. This is reflected in a significant effect during the time-window starting with the onset of *continue* and ending with the onset of the disambiguating noun (the correlate of *movies*) as confirmed by mixed-effect model analyses on Elogit-transformed proportions of looks to target and subsequent model comparison ( $\beta = 0.77$ ,  $SE = 0.35$ ,  $t = 2.18$ ,  $\chi^2 = 4.61$ ,  $p < 0.5$ ), suggesting that the presupposition of *continue*, that some activity must have been going on prior to Wednesday, is already having an effect on the interpretation prior to the full second disjunct unfolding. This is consistent with the prediction of RIPE. Right after participants encountered *continue*, they are more likely to fixate on the target if the presupposition is verified than if the presupposition fails.

**Behavioral data** Beginning with response pattern by condition, participants were more likely to select the target picture in Condition A (96%), where the presupposition was met, than in Condition B (75%), where it was not, but where the covered box offered a viable alternative choice where the presupposition could be met. A logistic mixed-effect model analysis revealed this difference to be statistically significant ( $\beta = 3.45$ ,  $SE = 0.52$ ,  $z = 6.59$ ,  $p < 0.001$ ).

While Condition A and Condition B differ, it is notable that participants still do select the target with high frequency in Condition B (75%). This suggests that participants often do *not* have a strengthened presupposition projected in the final interpretation. This looks initially at odds with the online data which provide evidence for an effect of presupposition in the critical region. We suggest that those target choices obtained after participants strengthened the conditional presupposition, but then revised this strengthening.

This explanation is further consistent with the reaction time data.

Reaction times by condition and response choice also reveal a telling pattern. Fairly unsurprisingly, covered box choices when the presupposition was not met in the target picture (Condition B) were slower than target choices (8061 vs. 6874 ms respectively). However, target choices were furthermore significantly faster when the presupposition was met (6297ms, version A), as confirmed by mixed effect model analyses and model comparison ( $\beta = -653$ ,  $SE = 281$ ,  $t = -2.33$ ,  $\chi^2 = 4.97$ ,  $p < 0.5$ ). This suggests that even though the target picture was the majority choice overall in the B version, this choice was not as straightforward as in the A version, presumably due to the difference in the presupposition being met. Importantly, such a delay would not be expected if target choices in Condition A and B equally obtained with a satisfied conditional presupposition.

## 5. Discussion

Our starting point in this paper was the observation of an asymmetry in presupposition projection in conjunctions. We argued that recent explanatory accounts for this asymmetry based on left-to-right processing share an implicit assumption, which we made explicit in the form of RIPE. We then reviewed cases that are not as clearly asymmetric, in particular disjunction. Facing this contrast between conjunctions and disjunctions, we were left with two alternatives: either give up the general asymmetric model based on RIPE and stipulate an asymmetric lexical entry for conjunctions and a symmetric entry for disjunctions, or maintain RIPE and explain apparent symmetry in disjunctions as resulting from a more complex process involving an initial commitment to projection, which is then rescinded in cases where this conflicts with independent pragmatic principles, in particular NO.

The goal of our experiments was to show that empirical evidence on processing is indeed consistent with RIPE, in that it reflects early commitments to projected presuppositions. We focused on disjunctions, where RIPE makes a crucial prediction: while RIPE predicts early commitment to presupposition projection, approaches that posit a symmetric entry for disjunctions would naturally account for speakers not committing to projection before encountering the entire second disjunct. We saw that the results are consistent with RIPE, in that our eye-tracking data from Experiment 1 suggest early commitment to presupposition projection, contrary to what is expected according to lexicalist approaches. We furthermore saw that a strengthening mechanism endorsed by most recent authors takes place rapidly when the presupposition trigger appears in the second member of a disjunction, which is again in line with a rapid processing and integration of presuppositions.

Taking the results at face value, especially those from Experiment 2, one might consider a third possibility, namely that presuppositions are initially taken to project unconditionally from the first and second disjuncts as well. That is, one might interpret the results of the second experiment not as showing that there is rapid strengthening of an underlying conditional presupposition (as we concluded), but rather as showing that processing presuppositions does not take preceding information into consideration at first. Such an interpretation would be reminiscent of some early accounts of presupposition projection, endorsing what is known as the cumulative hypothesis (Langendoen and Savin, 1971). The presupposition-suspension mechanism (e.g. local accommodation) involved in Hirsch and Hackl's back-tracking mechanism,

which is used to account for the optionality of projection from the first member of a disjunction, could then be held responsible for the optionality of projection from the second member despite the posited initial commitment in projection. While this view would be compatible with our results taken in isolation, we argue that it is not tenable in the more general landscape of presupposition projection. First, as illustrated with the sentence in (20), presuppositions sometimes project *conditionally* out of disjunctions. This observation is at odds with a parser that would *unconditionally* project presuppositions as soon as it encounters a trigger. Moreover, while a process such as local accommodation possibly taking place both in the first and second member of a disjunction is well in line with the apparent symmetry of disjunctions, it is hard to see how the mere availability of local accommodation could account for the asymmetry of conjunctions. By contrast, note that RIPE does not suffer the same criticism, since resorting to local accommodation in disjunctions is motivated by an independent pragmatic principle, Non-Opinionatedness, which does not apply to conjunctions: the lack of presupposition projection in conjunctions where a trigger appears in the second conjunct results from the conditional nature of the presupposition induced by incremental-processing, and not from local accommodation.

More generally, our results provide new insights into the online processing of presuppositions and therefore further constrain theories of presupposition projection. Insofar as decisions about presupposition projection are made right away, the range of options for lexically encoded projection properties, should there be the need for any, is substantially reduced. An important task to carry out in more detail in future work is to relate the present results to previous findings, such as those by Schwarz and Tiemann (2016), who conclude based on evidence from eye-tracking during reading that projection takes time. While that conclusion may at first sight seem at odds with the interpretation of our data offered here – that projection decisions are made rapidly –, this need not be the case, as the steps the processor engages in to determine whether a presupposition project could well start out right away when the trigger is encountered, and yet take time to complete. Furthermore, it is worth noting that the time-windows of our effects are only immediate in the broader sense that they show up prior to relevant further information having been introduced, which is again perfectly consistent with the notion that the overall process of presupposition projection does take a certain amount of time to complete. Finally, yet another important direction for future work is to extend the present methodology to other connectives, and in particular to settle the question of whether or not conjunctions display any genuinely symmetric projection effects.

# On the role of classifiers in licensing Mandarin existential wh-phrases<sup>1</sup>

Hsin-Lun HUANG — *University of Massachusetts Amherst*

**Abstract.** As in many languages in the world, wh-phrases in Mandarin can be interpreted as more than interrogative, depending on where they appear. This paper focuses on one of the non-interrogative readings of Mandarin wh-phrases, the existential reading, and presents an account of the licensing conditions for this particular reading by examining its distribution. Moreover, this paper aims to tackle the issue concerning the required co-occurrence of existential wh-phrases and classifiers in certain environments, a puzzle that has received much notice (Li, 1992; Lin, 1998; Liao, 2011) but is not yet resolved. This paper argues that Mandarin wh-phrases require two ingredients to be existential, non-veridicality (Xie, 2007; Lin et al., 2014) and existential closure ( $\exists$ ) (Kratzer and Shimoyama, 2002). And classifiers play the role of providing existential force to the wh-phrase when  $\exists$  is unavailable. The (un-)availability of  $\exists$  is conditioned by the application site of  $\exists$  and the syntactic heights of non-veridical operators, whose scope constitutes the licensing domain for the wh-phrase:  $\exists$  is unavailable when it falls outside the scope of the non-veridical operators, given a licensing condition proposed in this paper that limits the application of  $\exists$  to wh-phrases to being within a non-veridical domain. In that case, a classifier is required for the existential interpretation of the wh-phrase.

**Keywords:** Mandarin, classifiers, wh-phrases, non-veridicality, existential closure

## 1. Introduction

The interpretation of Mandarin wh-phrases can vary, depending on the environments they appear in. Besides the interrogative reading, (1a),<sup>2</sup> Mandarin wh-phrases can have other non-interrogative readings, one of them being **existential**, (1b) (Huang, 1982; Cheng, 1991, 1994, 1995; Li, 1992; Lin, 1996, 1998, 2004, 2014; a.o.):

- |     |    |                                 |    |   |
|-----|----|---------------------------------|----|---|
| (1) | a. | Zhangsan xihuan <b>shenme</b> ? | b. | Zhangsan <b>bu</b> xihuan <b>shenme</b> |
|     |    | Zhangsan like    what           |    | Zhangsan not like    what               |
|     |    | ‘What does Zhangsan like?’      |    | ‘What doesn’t Zhangsan like?’           |
|     |    |                                 |    | ‘Zhangsan doesn’t like anything.’       |

However, the existential reading is not readily available in all situations: A wh-indefinite is not grammatical in most positive episodic sentences (Li, 1992; Lin, 1998). The following sentence can only obtain an interrogative interpretation:

---

<sup>1</sup>I would like to thank my two main advisors of this project, Seth Cable and Vincent Homer, for enlightening me and leading me along the way. I would also like to thank Kyle Johnson, Rajesh Bhatt, and the audience at the UMass Semantics Workshop fall 2015 for their valuable comments and suggestions. Yangsook Park and Jon Ander Mendia have my biggest gratitude for helping me with some of the semantic issues in the project. Finally, I would like to thank Rong Yin for many of the judgements on the scope readings of the wh-phrases. Of course, any errors that remain would be my own.

<sup>2</sup>Unlike English, Mandarin is a wh-in-situ language. In other words, there is no overt movement of the wh-phrase to Spec.CP to take scope, as in the case of English. To obtain the reading where the wh-phrase takes scope over the matrix clause, it is generally assumed that wh-phrases are inherently quantificational and undergo LF movement to take scope. Please see Huang (1982) for a more detailed account of Mandarin wh-interrogatives.

- (2) Zhangsan kandao-le **shenme**  
 Zhangsan see-ASP<sup>3</sup> what  
 ‘What did Zhangsan see?’/\*‘Zhangsan saw something.’

Various licensing conditions have been proposed for Mandarin existential wh-phrases. Yet one fact that has been noted in the literature but not accounted for is the required co-occurrence of these wh-phrases and classifiers in certain environments (Li, 1992; Lin, 1998; Liao, 2011):

- (3) a. Zhangsan haoxiang mai-le-(ge) **shenme**  
 Zhangsan seem buy-ASP-CL what  
 ‘It seems that Zhangsan bought something.’  
 b. Zhangsan bixu mai-\*(ge) **shenme**  
 Zhangsan must buy-CL what  
 ‘Zhangsan must buy something.’

Being in the scope of epistemic and deontic modals (i.e. *haoxiang* (‘seem’) in (3a) and *bixu* (‘must’) in (3b)) is reported to be one of the licensing conditions for existential wh-phrases. But clearly, the obligatory presence of the classifier in the deontically modalized environment suggests that we need to take into account the role classifiers play in licensing existential wh-phrases that distinguishes between the licensing environments as those in (3).

In fact, the deontic environment is not the only environment that requires a classifier for existential wh-phrases. In the remainder of this paper, we will scrutinize the distributions of existential wh-phrases and classifiers. The goal is to develop an analysis that implements classifiers into the licensing conditions for the wh-phrases, capturing their distribution correlation.

### 1.1. Distribution of existential wh-phrases

The following are the reported environments where existential wh-phrases are licensed:

- Under negation, in polar questions, and in conditionals:  
 (Huang, 1982; Cheng, 1994; Li, 1992; Lin, 1996, 1998, 2004, 2014)

- (4) Zhangsan **mei** chi **shenme** (5) Zhangsan chi-le **shenme** **ma**?  
 Zhangsan not eat what Zhangsan eat-ASP what Q  
 ‘Zhangsan didn’t eat anything.’ ‘Did Zhangsan eat anything?’
- (6) **Yaoshi** Zhangsan chi-le **shenme**, qing gaosu wo  
 if Zhangsan eat-ASP what please tell me  
 ‘If Zhangsan eats anything, please tell me.’

<sup>3</sup>ASP stands for *aspect*. *Le*, in this case, is a perfective aspect in Mandarin. For following glosses, CL = *classifier*; Q = *question particle*; DE = *modification marker*; PAR = *particle*.

— Under epistemic modality:

(e.g. epistemic adverbs (7), non-factive epistemic verbs (8), and the inference *le* (9))<sup>4</sup>

- (7) **Keneng/xiangbi shei** you qifu ta le  
possibly/probably who again bully him ASP  
'Possibly/most probably, somebody bullied him again.' (Lin, 1998)

- (8) Zhangsan **yiwei/renwei** wo mai-le **shenme**, keshi wo genben mei mai renhe dongxi  
Zhangsan think/think I buy-ASP what but I at-all not buy any thing  
'Zhangsan thinks that I bought something, but I didn't buy anything at all.' (Li, 1992)

- (9) Ta kandao-(le) **shenme le**  
he see-ASP<sub>perfective</sub> what ASP<sub>inchoative</sub>  
'(It seems that) he saw something.' (Li, 1992)

— In BEFORE-clauses:

- (10) **Zai** dui yuangong zuo **shenme zhiqian**, duo kaolu kaolu  
at to employee do what before more think think  
'You (should) think twice before doing something to the employees.' (Xie, 2007)

— Under imperfective/progressive aspect:

- (11) Wo jinqu de shihou, ta **zhengzai** he **shenme**  
I enter DE time he ASP<sub>progressive</sub> drink what  
'When I went in, he was drinking something.' (Xie, 2007)

— In disjunction:

- (12) **Yaome shei** lai-guo, **yaome** wo wangji guan chuangu le  
either who come-ASP either I forget close window ASP  
'Either somebody came (broke in), or I forgot to close the window.' (Xie, 2007)

— Under deontic modality:

- (13) Zhangsan **bixu** mai-\*(ge) **shenme**  
Zhangsan must buy-CL what  
'Zhangsan must buy something.'

<sup>4</sup>According to Li (1992), a way of indicating circumstantial inferences in Mandarin is through the sentence-final *le*, which is different from the perfective aspect *le* that attaches to verbs. The sentence-final *le* is often seen as an inchoative *le* that signals a change of state has occurred (Li and Thompson, 1981), and this property correlates with the fact that the inchoative *le* is often used in people's inferential statements.

- In “future” environments: (Lin, 1998)  
(e.g. modal verbs (14), imperatives (15), and verb complements (16))

- (14) Wo mingtian **hui** qu mai-\*(**ge**) **shenme** dongxi song ta  
I tomorrow will go buy-CL what thing give him  
‘I will go to buy something for him tomorrow.’
- (15) Guo-lai chi-\*(**dian**) **shenme** ba!  
come eat-CL what PAR  
‘Come over to eat something.’
- (16) Wo xiawu **dasuan**<sup>5</sup>qu mai-\*(**ben**) **shenme** shu lai kan  
I this-afternoon plan go buy-CL what book come read  
‘I plan to buy some book to read this afternoon.’

For convenience, the following table summarizes the overall licensing environments for existential wh-phrases shown above, and a divide is made between the environments based on the obligatory presence of classifiers:

- (17) Distributions of existential wh-phrases and classifiers:

**No classifiers required:**

- Negation
- Polar questions
- Conditionals
- Epistemic modality:
  - ◇ Epistemic adverbs
  - ◇ Non-factive epistemic verbs
  - ◇ Inference *le*
- BEFORE-clauses
- Imperfective/Progressive
- Disjunction

**classifiers required:**

- Future environment:
  - ◇ Deontic modality
  - ◇ Imperatives
  - ◇ Verbs with future-event-denoting complements

## 2. The classifier puzzles

Given the distribution of classifiers in the licensing environments of existential wh-phrases, we can roughly frame our first classifier puzzle as follows:

- (18) Classifier puzzle #1:  
Why does an existential wh-phrase require a classifier only in certain environments?

<sup>5</sup>The complement of verbs like *dasuan* (‘plan’) typically refer to actions in the future (Lin, 1998).

Another classifier puzzle concerns an observation made by Liao (2011), where the requirement of classifiers in the deontic environment can be lifted when the environment is embedded under an epistemic one:

- (19) Zhangsan **haoxiang bixu** mai-(ge) **shenme**  
 Zhangsan seem must buy-CL what  
 ‘It seems that Zhangsan must buy something.’ (Liao, 2011)

Thus, we may ask:

- (20) Classifier puzzle #2:  
 Why is the classifier no longer needed in the above situation?

The next section is dedicated to developing an analysis that aims to tackle these puzzles by implementing classifiers into the licensing mechanism for Mandarin existential wh-phrases.

### 3. Analysis

Contra Huang (1982), this paper adopts the point of view that wh-phrases are inherently non-quantificational and acquire their quantificational force externally (Cheng, 1991; Tsai, 1999, 2003, 2010). They are analyzed as denoting sets of alternatives under Hamblin (1973) style semantics, following Kratzer and Shimoyama’s (2002) treatment of Japanese indeterminate pronouns, as well as Li and Law’s (2014) treatment of Mandarin wh-phrases:<sup>6</sup>

- (21) a.  $\llbracket \text{shenme (‘what’)} \rrbracket^{w, g} = \{x_e : \text{thing}_w(x)\} \in D_{\langle e \rangle/t}^7$   
 b.  $\llbracket \text{shei (‘who’)} \rrbracket^{w, g} = \{y_e : \text{person}_w(y)\} \in D_{\langle e \rangle/t}$

If the denotations of wh-phrases percolate up to the CP level via Pointwise Function Application (Yatsushiro, 2009), we will get the denotations of wh-questions, where each wh-question denotes a set of propositions. In order for a wh-phrase to be interpreted as existential, the set of propositions has to be captured by a sentential  $\exists$ , existentially closing the set (Kratzer and Shimoyama, 2002; pg. 7):

- (22) For  $\llbracket \alpha \rrbracket^{w, g} \subseteq D_{\langle st \rangle} : \llbracket \exists \alpha \rrbracket^{w, g} = \{\lambda w' . \exists p [p \in \llbracket \alpha \rrbracket^{w, g} \& p(w') = 1]\}$

Classifiers are hypothesized to be serving the role of  $\exists$  within the domain of  $vP$ . Reasons for this hypothesis will be made clear later, but it is important to note that the existential closure of wh-phrases (either by the covert  $\exists$  or by a classifier) is not without conditions. We simply cannot close the sets denoted by wh-phrases anywhere, given the following sentence:

<sup>6</sup>The motivation for Li and Law’s (2014) treatment of Mandarin wh-phrases as sets of alternatives comes from the intervention effects when a focus operator like *zhiyou* (‘only’) enters certain hierarchical configurations with the wh-phrase.

<sup>7</sup>The type  $\langle e \rangle/t$  is the type of sets of alternatives defined in Yatsushiro (2009). The semantic composition of wh-phrases in this paper follows Yatsushiro’s (2009) system, where wh-phrases compose via Pointwise Function Application and end up generating sets of propositions, i.e. the denotation of wh-questions.

- (23) Zhangsan zuotian chi-le-(ge) shenme  
 Zhangsan yesterday eat-ASP-CL what  
 ‘What did Zhangsan eat yesterday?’ / \*‘Zhangsan ate something yesterday.’

Even in the presence of a classifier, the wh-phrases in (23) can only be interpreted as an interrogative rather than an existential. Therefore, we also need to factor in all and only the environments where the existential reading is found. Given the nature of the licensing environments in the introduction, Xie (2007) and Lin et al. (2014) propose *non-veridicality* in the sense of Zwarts (1995) as the licensing condition for Mandarin existential wh-phrases:

- (24) (Non-)veridicality for propositional operators:  
 A propositional operator  $F$  is veridical iff  $Fp$  entails  $p$ :  $Fp \models p$ ; otherwise,  $F$  is non-veridical.  
 (Lin, Weerman, and Zeijlstra, 2014)

All of the boldfaced items (other than the wh-phrases) in (4) to (16) can be viewed as a non-veridical operator under the definition above,<sup>8</sup> leaving aside the case of imperatives, which has no overt operators though non-veridical in nature.

Taking the environmental factor into account, I propose the following licensing conditions for Mandarin existential wh-phrases that connect  $\exists$  and non-veridicality:

- (25) General licensing conditions for existential wh-phrases:
- a. Non-veridicality:  
 A wh-phrase can only be grammatical under an existential reading when closed by  $\exists$  in a non-veridical environment (i.e. in the scope of a non-veridical operator).
  - b. Existential closure:
    - (i)  $\exists$  applies higher than  $vP$  with the following semantics:  

$$\llbracket \exists \rrbracket^{w, g} = \lambda \alpha_{\langle st \rangle / t} \lambda w' . \exists p [p \in \alpha \wedge p(w') = 1]$$

( $\langle st \rangle / t$  being the type of sets of propositions)
    - (ii) A classifier can close the set denoted by its argument wh-phrase:<sup>9</sup>  

$$\llbracket CL \exists \rrbracket^{w, g} = \lambda \alpha_{\langle e \rangle / t} \lambda P_{\langle e, est \rangle / t} \lambda y \lambda w' . \exists z [z \in \alpha \wedge P_{w'}(z)(y) = 1]$$

<sup>8</sup>One might wonder why the *imperfective/progressive* aspect is viewed as non-veridical. According to Xie (2007), who follows Giannakidou (2002) in defining non-veridicality over temporal relations denoted by aspectual operators, an aspectual operator is veridical iff the topic time strictly follows the time of the resultant state of an eventuality the aspectual operator is predicated of. Otherwise, the aspectual operator is non-veridical. Since under the *imperfective/progressive* aspect the topic time is included in the event time of an eventuality (of which the time of resultant state is a part), the *imperfective/progressive* aspect is therefore non-veridical.

<sup>9</sup>This application assumes the structure proposed in Cheng and Sybesma (1999, 2005) for Mandarin nominals, where the classifier is a functional head  $CL(ASSIFIER)$  that forms a constituent with the wh-phrase following it:

- (i)
- 
- ```

      graph TD
      CLP --- CL
      CLP --- NP
      NP --- whphrase[wh-phrase]
  
```

Although rather stipulative, we need the condition of non-veridicality in (25a) to rule out sentences like (23), where the wh-phrase could potentially be existentially closed by  $\exists$  or a classifier. Moreover, once we factor in the positions of the non-veridical operators, the condition in (25a) and the hypothesis that  $\exists$  applies higher than  $\nu$ P (25b) can help us account for the environment-dependent co-occurrence of the wh-phrase and classifiers, which will be the focus of the next section.

This analysis also makes predictions about the scope of the wh-phrase, depending on where it is existentially closed. It will be shown that the predictions are borne out after establishing the syntactic positions of the non-veridical operators and their interactions with  $\exists$ .

### 3.1. Application of $\exists$

The account for the classifier requirement in existential wh-phrase licensing will resort to the interaction between the non-veridical operators and the application site of  $\exists$ . The licensing reasoning goes as follows: (i) A wh-phrase has to be existentially closed within a non-veridical domain, (25a). (ii)  $\exists$  applies higher than  $\nu$ P, (25b), contrary to the common assumption that it applies low at VP (Diesing, 1990, 1992). (iii) If the non-veridical operator is no higher than  $\nu$ P, existentially closing the wh-phrase would be ungrammatical, i.e. a violation of (25a). (iv) In that case, a classifier comes in as a replacement for  $\exists$  (hence the hypothesis that classifiers serve as  $\exists$  within the domain of  $\nu$ P).

Given this reasoning, we are in other words saying that the environments where classifiers are required are environments where the non-veridical operators scope lower than  $\exists$ . This statement can be corroborated by the clausal structure in Tsai (2010), where different types of modals assume different syntactic heights:<sup>10</sup>

---

<sup>10</sup>Tsai (2010) reaches this structure after investigating the syntactic and scope interactions between the different types of modals (i.e. epistemic, deontic, and dynamic modals). His argument is not presented here due to reasons of space. For a detailed argument for this structure, I refer the readers to Tsai (2010).

(26)

Given the positional difference between the epistemic and deontic modals, whose scopes constitute the licensing domains for existential wh-phrases, we can now explain the contrast between the epistemic and deontic environments in terms of the classifier requirement:

- (27) **Haoxiang shei qifu-le Zhangsan**  
 seem who bully-ASP Zhangsan  
 ‘It seems that somebody bullied Zhangsan.’  
 $[TP_3 \text{ haoxiang } [TP_2 \exists [TP_1 \text{ shei}_i [vP \text{ t}_i [VP \text{ qifu-le Zhangsan } ]]]]]$

$\llbracket (27) \rrbracket^{w, g} = \exists w'' \in \mathcal{M}_{(w, \text{epistemic})} \cdot \exists p [p \in \{\lambda w' \cdot \text{bully}_{w'}(y, \text{ZS}) \mid \text{person}_w(y)\} \wedge p(w'') = 1]$ <sup>12</sup>

- (28) **Zhangsan haoxiang chi-le shenme**  
 Zhangsan seem eat-ASP what  
 ‘It seems that Zhangsan ate something.’  
 $[TP_3 \text{ haoxiang } [TP_2 \exists [TP_1 \text{ Zhangsan}_i [vP \text{ t}_i [VP \text{ chi-le shenme } ]]]]]$

$\llbracket (28) \rrbracket^{w, g} = \exists w'' \in \mathcal{M}_{(w, \text{epistemic})} \cdot \exists p [p \in \{\lambda w' \cdot \text{eat}_{w'}(\text{ZS}, x) \mid \text{thing}_w(x)\} \wedge p(w'') = 1]$

<sup>11</sup>The covert existential closure  $\exists$  is put in Spec.TP in the structure of (27). This is a position where it can compose with the TP of type  $\langle st \rangle/t$  given its semantics. However, it is not limited to being in this position. It can be in any position where its argument's type allows it to compose, as long as that position is higher than  $vP$ .

<sup>12</sup>For a thorough derivation of the semantics of the current and following examples, please see the appendix.

The epistemic modal is a sentential operator whose non-veridical licensing domain for the wh-phrase encompasses the application site of  $\exists$ . Therefore, the wh-phrase can be closed by  $\exists$  and interpreted as an existential, following the condition in (25a). On the other hand, the deontic modal scopes low (at  $vP$ ) and  $\exists$  falls outside of its non-veridical domain. As a result, the wh-phrase, be it a subject or an object, cannot be closed by  $\exists$  and obtain the existential reading:

- (29) **Shei yinggai xi matong**  
 who should wash toilet  
 \*‘Somebody should wash the toilet.’ / ‘Who should wash the toilet?’  
 \* $[\text{TP}_2 \exists [\text{TP}_1 \text{shei}_i [\text{vP}_2 \text{yinggai} [\text{vP}_1 t_i [\text{VP xi matong} ]]]]]$

- (30) **Zhangsan yinggai chi shenme**  
 Zhangsan should eat what  
 \*‘Zhangsan should eat something.’ / ‘What should Zhangsan eat?’  
 \* $[\text{TP}_2 \exists [\text{TP}_1 \text{Zhangsan}_i [\text{vP}_2 \text{yinggai} [\text{vP}_1 t_i [\text{VP chi shenme} ]]]]]$

Due to the unavailability of  $\exists$ , the set of alternatives denoted by the wh-phrase cannot be existentially closed but has to percolate up, leading to the obligatory interrogative reading, i.e. the reading of a wh-question.

### 3.2. Classifiers as $\exists$

The only way for the wh-phrase to be existential in this case of low-scoping non-veridical operators is for the classifier to take over the job of  $\exists$  and close the set denoted by the wh-phrase with the semantics proposed in (25bii), repeated here as (31a):

- (31) a.  $\llbracket \text{CL}_{\exists} \rrbracket^{w, g} = \lambda \alpha_{\langle e \rangle / t} \lambda P_{\langle e, \text{est} \rangle} \lambda y \lambda w'. \exists z [z \in \alpha \wedge P_{w'}(z)(y) = 1]$ <sup>13</sup>  
 b. Zhangsan **yinggai/bixu** mai-dian shenme  
 Zhangsan should/must buy-CL what  
 ‘Zhangsan should/must buy something.’  
 $[\text{TP Zhangsan}_i [\text{vP}_2 \text{yinggai/bixu} [\text{vP}_1 t_i [\text{VP mai-dian}_{\exists} \text{shenme} ]]]]$

$$\llbracket \text{shenme} \rrbracket^{w, g} = \{x_e : \text{thing}_w(x)\}$$

$$\llbracket \text{DP}_1 \rrbracket^{w, g} = \lambda P_{\langle e, \text{est} \rangle} \lambda y \lambda w'. \exists z [z \in \{x_e : \text{thing}_w(x)\} \wedge P_{w'}(z)(y) = 1]$$

$$\llbracket (31b) \rrbracket^{w, g} = \forall w'' \in \mathcal{M}_{(w, \text{deontic})} . \exists z [z \in \{x_e : \text{thing}_w(x)\} \wedge \text{buy}_{w''}(ZS, z) = 1]$$

<sup>13</sup>The denotation proposed for classifiers as  $\exists$  may seem too restrictive since its second argument position assumes a predicate of type  $\langle e, \text{est} \rangle$ , i.e. the type of transitive verbs. However, we can allow for slight variation of the denotation between those in (ii), assuming the verbal structure proposed by Huang, Li, and Li (2009) in (i):

(i)

However, if what we have in the case of low-scoping deontic modals is a wh-subject as in (29), inserting a classifier before the wh-subject would not help for two reasons: (i) the wh-subject falls outside of the non-veridical licensing domain (i.e. outside of the scope of the deontic modals), and (ii) Mandarin classifiers are clitic-like items that usually need to attach to numerals, demonstratives, or verbs, and cannot stand alone sentence-initially:

- (32) \***Ge ren** xihuan Zhangsan  
 CL person like Zhangsan  
 ‘Somebody likes Zhangsan.’

The clitic need of classifiers thus makes sentences with a [CL + Wh] subject ungrammatical, even under an interrogative reading:

- (33) \***Ge shei** yinggai xi matong  
 CL who should wash toilet  
 \*‘Somebody should wash the toilet.’ / \*‘Who should wash the toilet?’  
 \*[TP [DP **ge/ge**<sub>∃</sub> **shei**]<sub>i</sub> [<sub>vP</sub><sub>2</sub> **yinggai** [<sub>vP</sub><sub>1</sub> *t<sub>i</sub>* [<sub>VP</sub> xi matong ]]]]

If we try to generalize the contrast between the epistemic and deontic modals under discussion to other licensing environments, we can see that generally speaking, the requirement of classi-

- (ii) For [CL + Wh] direct objects (DOs),  

$$\llbracket \text{CL}_{\exists} \rrbracket^{w, g} = \lambda \alpha_{\langle e \rangle / t} \lambda P_{\langle e, \langle e, \text{est} \rangle \rangle} \lambda x \lambda y \lambda w'. \exists z [z \in \alpha \wedge P_{w'}(z)(x)(y) = 1]$$
  
 For [CL + Wh] indirect objects (IOs),  

$$\llbracket \text{CL}_{\exists} \rrbracket^{w, g} = \lambda \alpha_{\langle e \rangle / t} \lambda P_{\langle e, \text{est} \rangle} \lambda y \lambda w'. \exists z [z \in \alpha \wedge P_{w'}(z)(y) = 1] = (31a)$$

Please note that when  $\text{CL}_{\exists}$  shows up with a wh-phrase as the indirect object, the denotation for  $\text{CL}_{\exists}$  remains the same as in the case of transitive verbs, because the first argument position in the denotation of the di-transitive verb will have been saturated by the direct object before the verb composes with the  $[\text{CL}_{\exists} + \text{Wh}]$  IO.

<sup>14</sup>As will be clear in later sections, Mandarin classifiers assume two types of functions, that of regular classifiers (i.e. those that go with regular NPs) and that of  $\exists$  (as in the case of existential wh-phrases). The two types are differentiated by the  $\exists$  subscript on the classifier:  $\text{CL}_{\exists}$  closes the set of alternatives denoted by the wh-phrase and renders it existential while CL is transparent to the set denotations of wh-phrases and the DP [CL + Wh] remains a wh-interrogative.

fiers can be seen as a reflection of high vs. low non-veridical operators. All of the non-veridical operators that do not require a classifier in their scope to license an existential wh-phrase are sentential (or not sentential but higher than  $\nu P$  as in the case of the imperfective/progressive aspect), or can embed structures bigger than a  $\nu P$  (e.g. non-factive epistemic verbs). Classifiers are needed elsewhere; that is, under the operators that are not higher than a  $\nu P$  (e.g. deontic modals) or cannot embed structures larger than a  $\nu P$  (e.g. the *future* verbs, which cannot embed a full finite TP). Our first puzzle concerning the environment-dependent requirement of classifiers is thus solved.

#### 4. Classifier distribution

Having established the licensing mechanism for Mandarin existential wh-phrases, we can now also explain our second classifier puzzle, where the classifier that was once required under a deontic modal is no longer needed when the deontic modal is further embedded under an epistemic modal:

- (34) Zhangsan **haoxiang bixu** mai-(ge) **shenme**  
 Zhangsan seem must buy-CL what  
 ‘It seems that Zhangsan must buy something.’  
 $[TP_3 \text{ haoxiang } [TP_2 \exists [TP_1 \text{ Zhangsan}_i [\nu P_2 \text{ bixu } [\nu P_1 t_i [\nu P \text{ mai-(ge)} \exists] \text{ shenme } ]]]]]]$

As shown by the LF above, the epistemic modal expands the licensing domain of the wh-phrase from the  $\nu P$  to the sentential level to include the high  $\exists$ , providing another option of existential closure for the wh-phrase. As a result, the classifier is no longer necessary for the existential reading. The second classifier puzzle is also solved.

Given the way the current account is set up, it makes a prediction that if we expand the licensing domain of the wh-phrase by embedding a classifier-requiring environment under a non-classifier-requiring one, we can remove the need of a classifier for licensing the wh-phrase. The following examples show that this prediction is indeed borne out:<sup>15</sup>

- (35) Zhangsan **hui** qu mai-(xie) **shenme** dongxi song ta **ma**?  
 Zhangsan will go buy-CL what thing give him Q  
 ‘Will Zhangsan go to buy something for him?’  
 $[CP [TP_2 \exists [TP_1 \text{ Zhangsan hui qu mai-(xie)} \exists] \text{ shenme dongxi song ta } ]] \text{ ma}]?$

<sup>15</sup>The existential interpretation of the wh-subject in the case of low non-veridical operators (e.g. deontic modals) that was non-rescuable by the insertion of a classifier can now be rescued under embedding, as predicted, given the availability of  $\exists$  made by domain expansion. Example (29) embedded under the polar question particle *ma* is shown here for illustration:

- (i) **Shei yinggai** xi matong **ma**?  
 who should wash toilet Q  
 ‘Should somebody wash the toilet?’  
 $[CP [TP_2 \exists [TP_1 \text{ Shei}_i [\nu P_2 \text{ yinggai } [\nu P_1 t_i [\nu P \text{ xi matong } ]]]]] \text{ ma } ]?$

- (36) **Yaoshi** Zhangsan **bixu** chi-(**dian**) **shenme**, qing gaosu wo  
 if Zhangsan must eat-CL what please tell me  
 ‘If Zhangsan must eat something, please tell me.’  
 [TP<sub>2</sub> **yaoshi**  $\exists$  [TP<sub>1</sub> Zhangsan **bixu** chi-(**dian** <sub>$\exists$</sub> ) **shenme**, ...]]
- (37) Wo **yiwei** Zhangsan **dasuan** zhao-(**ge**) **shei** lai bangang  
 I think Zhangsan plan find-CL who come help  
 ‘I thought Zhangsan planned to find somebody to help.’  
 [TP<sub>3</sub> Wo **yiwei** [CP [TP<sub>2</sub>  $\exists$  [TP<sub>1</sub> Zhangsan **dasuan** zhao-(**ge** <sub>$\exists$</sub> ) **shei** ... ]]]]

Above are three instances of non-veridical operators that require a classifier in their scope (a modal verb **hui** (‘will’) in (35), a deontic modal **bixu** (‘must’) in (36), and a *future* verb **dasuan** (‘plan’) in (37)) being embedded under operators that do not (the polar question particle **ma** in (35), a conditional morpheme **yaoshi** (‘if’) in (36), and a non-factive epistemic verb **yiwei** (‘think’) in (37)). And the classifiers are now optional in all of the instances.

## 5. Scope of wh-phrases

The issue about what options of existential closure are available to the wh-phrase makes another prediction about the scope interpretation of the wh-phrase. In the examples shown above, we should have scope ambiguity of the wh-phrase, depending on what it is closed by in its licensing domain. And we do indeed find scope ambiguity in cases like those:

- (38) Zhangsan **haoxiang** **bixu** chi-dian **shenme**  
 Zhangsan seem must eat-CL what  
 ‘It seems that Zhangsan must eat something.’ (seem > must > CL <sub>$\exists$</sub> )  
 ‘It seems that there is something such that Zhangsan must eat it.’ (seem >  $\exists$  > must)

The scope ambiguity exists under the assumption that classifiers only serve as  $\exists$  in the case of existential wh-phrase licensing when needed. In other words, they do not necessarily close the set denoted by the wh-phrase if the higher covert  $\exists$  is also available. Consequently, the wh-phrase has two options of existential closure given the domain expansion by the epistemic modal, leading to the scenario where the two options of existential closure fall on either side of the low non-veridical operator (i.e. the deontic modal). Hence, the wide and narrow scope reading of the wh-phrase with respect to the low non-veridical operator are both accessible.

Given the presence of the classifier in (38) and the possibility of obtaining a wide scope reading of the wh-phrase, we are in a way saying that classifiers are ambiguous between  $\exists$  and regular classifiers so that the set denotation of the wh-phrase can percolate up the structure and be closed by the higher  $\exists$  in the latter case.<sup>16</sup> This is a necessary hypothesis to make, given how the licensing mechanism is constructed: Existentially closing the wh-phrase in environments other than non-veridical would result in ungrammaticality. However, the following sentence is grammatical, but only with an interrogative reading of the wh-phrase:

- (39) Zhangsan tingdao-le-**xie shenme**  
 Zhangsan hear-ASP-CL what  
 \*‘Zhangsan heard something.’ / ‘What did Zhangsan hear?’

Furthermore, in the absence of a classifier in environments like (38), the wh-phrase is predicted to be non-ambiguous and have only wide scope with respect to the low non-veridical operator, which is attested by the following example:

- (40) Zhangsan **haoxiang bixu** chi **shenme**  
 Zhangsan seem must eat what  
 \*‘It seems that Zhangsan must eat something.’ (\**seem* > *must* >  $CL_{\exists}$ )  
 ‘It seems that there is something such that Zhangsan must eat it.’ (*seem* >  $\exists$  > *must*)

It is the higher covert  $\exists$  that is existentially closing the wh-phrase in this case under the licensing domain of the high non-veridical operator. Given the application site of  $\exists$ , i.e. higher than  $\nu P$ , the wh-phrase necessarily has wide scope with respect to the low non-veridical operator.

<sup>16</sup>According to Cheng and Sybesma (1999, 2005), from whom I adopt the structure of Mandarin nominals, the function of the CL head is the  $\iota$  operator that renders the definite reading of the NP it composes with. Apparently, our analysis of wh-phrases as denoting sets of alternatives would not be able to compose with a regular classifier if we follow Cheng and Sybesma’s analysis. Therefore, we need to propose another denotation for the classifier so that it can compose with a wh-phrase and pass up the wh-phrase’s set denotation:

(i)  $\llbracket CL_{wh} \rrbracket^{w, g} = \lambda f_{(e)/t} . f$

The classifier in this case is treated as denoting an identity function whose first argument is a set of alternatives. This denotation guarantees the exclusive relationship between this type of regular classifiers and wh-phrases (as opposed to the  $\iota$ -classifier with regular NPs), as well as the derivation of the interrogative reading of a wh-question as in (39).

## 6. Conclusion

To conclude, the analysis of licensing Mandarin existential wh-phrases presented in this paper builds on two major factors that make necessary conditions for the existential interpretation of wh-phrases: Non-veridicality and existential closure ( $\exists$ ). By attributing the role classifiers play in the licensing mechanism to fulfilling the function of  $\exists$  when  $\exists$  is unavailable, we are able to account for the distribution of classifiers that is environment-dependent. The (un-) availability of  $\exists$  is conditioned by two other factors: The application site of  $\exists$ , i.e. above vP, and the syntactic heights of non-veridical operators that license the wh-phrase. Given our hypothesis that a wh-phrase can only be grammatically closed by  $\exists$  in a non-veridical domain, classifiers are required to take over the job of  $\exists$  when the licensor of the wh-phrase is a low non-veridical operator, outside of whose scope  $\exists$  falls. Thus, the distribution of classifiers in the case of existential wh-phrases is licensor-related, i.e. their environment-dependent nature, and their obligatory presence can be made optional under the expansion of the non-veridical licensing domain by embedding a low licensor below a high licensor to include the covert  $\exists$  that was once out of reach. And the availability of both means of existential closure in this case renders the wh-phrase scope ambiguous, which is also proven true in this paper.

## Appendix. Semantic derivations of existential wh-phrases

The proposed denotations for Mandarin wh-phrases:

- (i)  $\llbracket \text{shenme ('what')} \rrbracket^{w, g} = \{x_e : \text{thing}_w(x)\} \in D_{\langle e \rangle/t}$   
 (ii)  $\llbracket \text{shei ('who')} \rrbracket^{w, g} = \{y_e : \text{person}_w(y)\} \in D_{\langle e \rangle/t}$

Yatsushiro's (2009) definition of Pointwise Functional Application:

- (iii) Semantic types of alternative sets (Yatsushiro, 2009; pg. 152)  
 For any type  $\alpha$ ;  $\alpha/t$  is the type of sets of entities of type  $\alpha$ ,  $D_{\alpha/t} = \text{POW}(D_\alpha)$   
 (iv) Pointwise Functional Application (Yatsushiro, 2009; pg. 153):  
 If  $X$  is a phrase with two immediate subconstituents  $Y$  and  $Z$ , then  $\llbracket X \rrbracket^g$  is defined as follows:
- .....  
 if  $\llbracket Y \rrbracket^g$  is of type  $\alpha$ ;  $\llbracket Z \rrbracket^g$  is of type  $\langle \alpha, \beta \rangle$ , then  $\llbracket X \rrbracket^g = \llbracket Z \rrbracket^g(\llbracket Y \rrbracket^g) \in D_\beta$ ;  
 .....  
 if  $\llbracket Y \rrbracket^g$  is of type  $\alpha/t$ ;  $\llbracket Z \rrbracket^g$  is of type  $\langle \alpha, \beta \rangle$ , then  $\llbracket X \rrbracket^g = \{\llbracket Z \rrbracket^g(y) \mid y \in \llbracket Y \rrbracket^g\} \in D_{\beta/t}$ ;  
 .....  
 if  $\llbracket Y \rrbracket^g$  is of type  $\alpha$ ;  $\llbracket Z \rrbracket^g$  is of type  $\langle \alpha, \beta \rangle/t$ , then  $\llbracket X \rrbracket^g = \{z(\llbracket Y \rrbracket^g) \mid z \in \llbracket Z \rrbracket^g\} \in D_{\beta/t}$ ;  
 .....  
 if  $\llbracket Y \rrbracket^g$  is of type  $\alpha/t$ ;  $\llbracket Z \rrbracket^g$  is of type  $\langle \alpha, \beta \rangle/t$ ,  
 then  $\llbracket X \rrbracket^g = \{z(y) \mid z \in \llbracket Z \rrbracket^g \text{ and } y \in \llbracket Y \rrbracket^g\} \in D_{\beta/t}$   
 .....

Semantic derivation of (27):

- (27) **Haoxiang shei** qifu-le Zhangsan  
 seem who bully-ASP Zhangsan  
 'It seems that somebody bullied Zhangsan.'  
 $[\text{TP}_3 \text{ haoxiang } [\text{TP}_2 \exists [\text{TP}_1 \text{ shei}_i [\text{VP } t_i [\text{VP } \text{qifu-le Zhangsan } ]]]]]$

$$\begin{aligned} \llbracket \text{Zhangsan} \rrbracket^{w, g} &= \text{Zhangsan} \in D_e \\ \llbracket \text{qifu} \rrbracket^{w, g} &= \lambda x \lambda y \lambda w' . \text{bully}_{w'}(y, x) \in D_{\langle e, \langle e, \text{st} \rangle \rangle} \\ \llbracket \text{VP} \rrbracket^{w, g} &= \lambda y \lambda w' . \text{bully}_{w'}(y, \text{ZS}) \in D_{\langle e, \text{st} \rangle} \\ \llbracket \text{TP}_1 \rrbracket^{w, g} &= \{\lambda w' . \text{bully}_{w'}(y, \text{ZS}) \mid \text{person}_w(y)\} \in D_{\langle s \rangle/t} \\ \llbracket \exists \rrbracket^{w, g} &= \lambda \alpha_{\langle \text{st} \rangle/t} \lambda w'' . \exists p [p \in \alpha \wedge p(w'') = 1] \\ \llbracket \text{TP}_2 \rrbracket^{w, g} &= \lambda w'' . \exists p [p \in \{\lambda w' . \text{bully}_{w'}(y, \text{ZS}) \mid \text{person}_w(y)\} \wedge p(w'') = 1] \in D_{\langle \text{st} \rangle} \\ \llbracket \text{haoxiang} \rrbracket^{w, g} &= \lambda P . \exists w''' \in \mathcal{M}_{(w, \text{epistemic})} . P(w''') = 1 \\ \llbracket \text{TP}_3 \rrbracket^{w, g} &= \exists w''' \in \mathcal{M}_{(w, \text{epistemic})} . \exists p [p \in \{\lambda w' . \text{bully}_{w'}(y, \text{ZS}) \mid \text{person}_w(y)\} \wedge p(w''') = 1] \end{aligned}$$

Semantic derivation of (28):

- (28) Zhangsan **haoxiang** chi-le **shenme**  
 Zhangsan seem eat-ASP what  
 ‘It seems that Zhangsan ate something.’  
 $[TP_3 \text{ haoxiang } [TP_2 \exists [TP_1 \text{ Zhangsan}_i [_{VP} t_i [_{VP} \text{ chi-le shenme } ]]]]]]$

$$\begin{aligned} \llbracket \text{chi} \rrbracket^{w,g} &= \lambda x \lambda y \lambda w' . \text{eat}_{w'}(y, x) \in D_{\langle e, \langle e, st \rangle \rangle} \\ \llbracket \text{VP} \rrbracket^{w,g} &= \{ \lambda y \lambda w' . \text{eat}_{w'}(y, x) \mid \text{thing}_w(x) \} \in D_{\langle e, st \rangle / t} \\ \llbracket TP_1 \rrbracket^{w,g} &= \{ \lambda w' . \text{eat}_{w'}(ZS, x) \mid \text{thing}_w(x) \} \in D_{\langle st \rangle / t} \\ \llbracket \exists \rrbracket^{w,g} &= \lambda \alpha_{\langle st \rangle / t} \lambda w'' . \exists p [p \in \alpha \wedge p(w'') = 1] \\ \llbracket TP_2 \rrbracket^{w,g} &= \lambda w'' . \exists p [p \in \{ \lambda w' . \text{eat}_{w'}(ZS, x) \mid \text{thing}_w(x) \} \wedge p(w'') = 1] \in D_{\langle st \rangle} \\ \llbracket \text{haoxiang} \rrbracket^{w,g} &= \lambda P . \exists w''' \in \mathcal{M}_{(w, \text{epistemic})} . P(w''') = 1 \\ \llbracket TP_3 \rrbracket^{w,g} &= \exists w''' \in \mathcal{M}_{(w, \text{epistemic})} . \exists p [p \in \{ \lambda w' . \text{eat}_{w'}(ZS, x) \mid \text{thing}_w(x) \} \wedge p(w''') = 1] \end{aligned}$$

Semantic derivation of (31b):

- (31b) Zhangsan **bixu** mai-**dian** **shenme**  
 Zhangsan must buy-CL what  
 ‘Zhangsan must buy something.’  
 $[TP \text{ Zhangsan}_1 1 [_{VP_2} \text{ bixu } [_{VP_1} t_1 [_{VP} \text{ mai } [_{DP} \text{ dian}_{\exists} \text{ shenme } ]]]]]]$

$$\begin{aligned} \llbracket \text{dian}_{\exists} \rrbracket^{w,g} &= \lambda \alpha_{\langle e \rangle / t} \lambda P_{\langle e, \langle e, st \rangle \rangle} \lambda y \lambda w' . \exists z [z \in \alpha \wedge P_{w'}(z)(y) = 1] \\ \llbracket DP \rrbracket^{w,g} &= \lambda P_{\langle e, \langle e, st \rangle \rangle} \lambda y \lambda w' . \exists z [z \in \{x : \text{thing}_w(x)\} \wedge P_{w'}(z)(y) = 1] \\ \llbracket \text{mai} \rrbracket^{w,g} &= \lambda x \lambda y \lambda w'' . \text{buy}_{w''}(y, x) \in D_{\langle e, \langle e, st \rangle \rangle} \\ \llbracket VP \rrbracket^{w,g} &= \lambda y \lambda w' . \exists z [z \in \{x_e : \text{thing}_w(x)\} \wedge \text{buy}_{w'}(y, z) = 1] \in D_{\langle e, st \rangle} \\ \llbracket \text{VP}_1 \rrbracket^{w,g} &= \lambda w' . \exists z [z \in \{x_e : \text{thing}_w(x)\} \wedge \text{buy}_{w'}(g(1), z) = 1] \in D_{\langle st \rangle} \\ \llbracket \text{bixu} \rrbracket^{w,g} &= \lambda P . \forall w''' \in \mathcal{M}_{(w, \text{deontic})} . ## Composing discourse parenthetical reports<sup>1</sup>

Julie HUNTER — *Universitat Pompeu Fabra, Barcelona and Université Paul Sabatier, Toulouse*  
Nicholas ASHER — *IRIT, CNRS, Toulouse*

**Abstract.** Hunter (2016) proposed that a speech report with a parenthetical interpretation but non-parenthetical syntax will contribute a modal discourse relation of the form  $\Diamond R$  to discourse logical form. This paper provides a compositional account of the mechanism by which these modal relations are triggered. It then extends Hunter's proposal to reports involving factive embedding verbs and provides an explanation of why explicit discourse connectives sometimes block parenthetical readings of reports in their scope.

**Keywords:** coercion, discourse connectives, discourse structure, factive verbs, parenthetical reports, speech reports

### 1. Introduction

As observed in Simons (2007) and Urmson (1952) *inter alia*, sometimes the main point of a speech or attitude report is conveyed by the embedded clause alone. Compare (1) and (2):

- (1) a. Liz is sad.  
b. A famous critic said that her new album isn't worth a dime.
- (2) a. John didn't come to my party.  
b. Jill said that **he was out of town**.

In both (1) and (2), (b) is naturally understood as offering an explanation of the content of (a); the intuitive explanantia are in bold. In (1), it is the fact that the critic said what she did that explains why Liz is upset; in other words, the entire report contributes to the explanation. On the most natural reading of (2), however, the embedded clause of (2b) alone contributes to the explanation; the fact that Jill said what she did plays a backgrounded, evidential role.

Urmson (1952) called uses of embedding verbs like that in (2) *parenthetical*. In these uses, embedding verbs play a secondary role, apparently serving to provide evidence for, or qualification of, the reported content. In this way, they resemble verbs of speech or attitude in the slifted clauses (Ross, 1973) of syntactically parenthetical reports such as (3).

- (3) He was out of town, Jill said.

Despite the similarity between (2b) and (3), we will assume that (2b) has a parenthetical reading (because *say* has a parenthetical reading) but non-parenthetical syntax. That is, following Simons (2007), we will assume that in (2b), the content expressed by the clause in bold falls in the scope of the embedding verb *say*, as the surface form of the report suggests.

---

<sup>1</sup>We gratefully acknowledge research support from ERC research grant 269427.

Hunter (2016) developed a discourse-based account of reports with parenthetical readings but non-parenthetical syntax. In particular, Hunter proposed that the discursive contribution of a parenthetical report is to introduce a modal rhetorical relation between the embedded content of the report and the discourse preceding the report. In this paper, we build on the account of coercion developed in Asher (2011) and Asher and Luo (2012) to provide a compositional analysis of Hunter's proposal. We then extend the resulting account to model two facts about parenthetical reports not covered in other models: the fact that factive verbs such as *found out* can also be used parenthetically, as observed in Simons (2007), and the fact that certain discourse connectives seem to block parenthetical readings of reports in their syntactic scope, as discussed in Hunter and Danlos (2014). (4b), for instance, only has a non-parenthetical reading.

- (4)    a.    John didn't come to my party  
        b.    because Jill said he was out of town.

We begin in Section 2 with a presentation of Hunter (2016)'s proposal. We then present the basics of Asher and Luo's account and our application of it in Section 3. Section 4 extends the resulting compositional account to parenthetical readings of factive verbs, and Section 5 examines the effects of explicit discourse connectives on the interpretation of reports.

## 2. The function of discourse parenthetical reports

Following Hunter (2016), we will call reports with a parenthetical interpretation but non-parenthetical syntax, such as (2b), *discourse parenthetical* to indicate that their parenthetical interpretation follows from discursive facts. There are no morphological features, like the evidential markers found in many languages, that force (2b) to receive an evidential reading. Nor should we assume that (2b) has an underlying parenthetical syntax that differs from its surface form. (See Simons, 2007: for arguments against a syntactic account.) There may be semantic differences between a parenthetical reading of a report and a non-parenthetical reading of the same report in the sense that the two interpretations might support different entailments. Normally, an instance of a speech or attitude report with a non-factive embedding verb such as *say* does not entail any level of commitment to the embedded clause, as illustrated by (1). In the absence of further context, however, the discourse in (2) arguably entails the possibility that John was out of town: if the speaker is not committed to this possibility, the relevance of (2b) to (2a) is unclear. Still, these entailments do not follow from (1b) and (2b) alone; they are *discourse-level* entailments that result from the interaction of a report and another discourse unit in the preceding discourse.

That the interpretation of a discourse parenthetical report results from the way a report is used in a discourse has been observed numerous times in the literature on parenthetical reports in English (Hooper, 1975; Simons, 2007; Urmson, 1952). Formal models of their discursive behavior are harder to come by. What does it mean to say that a parenthetical reading follows from the way that a report is used? How do we define the discourse function of a parenthetical report?

Simons (2007) sketched a diagnostic for parenthetical readings using question/answer pairs like (5).

- (5) a. Why wasn't John at the party?  
b. Jill said that he was out of town.

In (5), only the embedded clause of (5b) is 'at-issue', in Simons' sense, because only the embedded clause provides an answer to the question posed in (5a). According to Simons' proposed diagnostic, a parenthetical report is one in which only the embedded clause is at-issue. Thus this diagnostic predicts, seemingly correctly in this case, that (5b) is parenthetical.

This suggestion is not yet an account, however, because it does not provide a general model of discourse function that could be applied in the absence of explicit question/answer pairs. In the case of (2), we can imagine that (2b) answers a question like *Why not?*, but short of a predictive account of how one can identify implicit questions, Simons' question/answer-based diagnostic cannot be used for arbitrary discourses. Moreover, the diagnostic does not yield an analysis of cases in which a speaker explicitly denies the embedded content of a seemingly parenthetical report. Suppose, for example, that the speaker in (2) followed (2b) with (6):

- (6) But that's a total lie because I saw him out walking his dog early the next morning.

Given (6), we cannot say that the embedded content of (2b) answers the question *Why not?* or *Why didn't John come to your party?*—the speaker explicitly commits herself to the negation of that content.

A final concern is how to model reports for which both the embedded clause and the report as a whole are relevant to the discourse but in different ways. To put this in terms of Simons' diagnostic, how do we handle cases in which both the embedded clause and the report as a whole answer questions that have been posed in the discourse, as in (7)?

- (7) a. Why didn't John come to your party? Did anyone tell you?  
b. Jill said he was out of town.

In such examples, it's hard to say that one part of the report is at-issue while the other isn't; it's rather that the embedded clause and the report as a whole are *at-issue relative to different discourse units*. Of course, in (7), the second question is obviously very relevant to the first, but as emphasized in Hunter (2016), this is not always the case; the two parts of a report can be relevant to separate discourse units whose relevance to one another is much less clear.

Hunter (2016) argues that rhetorical theories (Asher, 1993; Asher and Lascarides, 2003; Hobbs, 1985; Mann and Thompson, 1988) can provide a model for the discourse function of parenthetical reports that generalizes Simons' suggestion and is more suitable for arbitrary discourses.<sup>2</sup>

<sup>2</sup>This suggestion has been made before. See Danlos and Rambow (2011); Dinesh et al. (2005); Hardt (2013); Hunter et al. (2006). Hunter (2016) examines past efforts to model parenthetical reports in rhetorical accounts and details many of the problems faced by these earlier proposals.

In a theory of rhetorical structure, what it means to have a certain discourse role or function is to enter into a particular rhetorical relation (or set of relations). The heart of Hunter (2016)'s proposal is that a report  $p$  is parenthetical just in case the embedded clause of  $p$  enters into a rhetorical relation  $R$  with a discourse unit that is discourse prior to  $p$ —that is, prior to the entire main clause of  $p$ —and the attributive predicate does not contribute to this relation. In (2), for example, (2a) is discourse prior to (2b), but the attributive predicate of (2b) does not contribute to the explanatory relation that is proposed to hold between the content in its scope and (2a):

(8) Explanation(*John didn't come to my party, he was out of town*)

This approach bypasses the need for implicit questions<sup>3</sup>, allows that both the embedded clause and the report as a whole can play independent rhetorical roles, and generalizes Simons' diagnostic for parenthetical reports on the assumption that answering a question yields a rhetorical relation between a question and its answer.

An important aspect of Hunter's proposal is that the rhetorical relation that relates the embedded clause of a parenthetical report to the preceding discourse will fall in the scope of a possibility operator. (8) poses a problem as it stands because Explanation is a *veridical* relation (Asher and Lascarides, 2003). This means that an instance of (8) cannot be true in a context unless both of its arguments are true in the same context. This is intuitively correct for (2): for John's being out of town to explain his absence at the party, he must have actually been out of town. The logical form in (8) is therefore too strong; as stressed by Simons (2007), reports are often used in situations like (2) precisely to hedge one's commitment to the embedded content. In some contexts it might be possible to infer full speaker commitment to this content, but a parenthetical use of a report does not in and of itself require such a strong commitment.

To weaken the entailments of a parenthetical report, the first step is to exploit the syntactic and semantic features of the report and assume that the attributive predicate takes not only syntactic scope over the embedded clause, but discourse scope over it as well. That is, the embedded clause is related to the attributive predicate via a rhetorical relation of Attribution, and the embedded clause is subordinate to the attribution predicate in the discourse representation. (9) gives the contribution of the Attribution relation to the logical form of the discourse.

(9) Attribution(*Jill said that, he was out of town*)

Semantically, this means that the embedded content of a report will not be entailed, at least not in virtue of figuring in an Attribution relation. (10) describes the entailments of the two arguments of an Attribution relation.

- (10) a. *Jill said that*:  $\models \exists p.\text{said}(\text{Jill}, p)$   
 b. *he was out of town*: specifies the content of  $p$ , but  $\not\models p$

<sup>3</sup>We leave open here the possibility that discourse relations might be modelled in a question-based model, though see Hunter and Abrusán (2016) for a discussion.

Of course, the Attribution relation is a general one that will apply to non-parenthetical reports as well. As such, Attribution will not support the stronger entailments that we see with parenthetical reports. Thus we arrive at the following impasse: if in building the representation for a parenthetical report, we ignore the discursive contribution of the Attribution relation, we will predict overly strong entailments. If we add Attribution to correct this, we end up with overly weak entailments.

To get around this problem, Hunter (2016) proposed a general rule that any time a discourse unit  $\beta$  figuring in an Attribution relation of the form  $\text{Attribution}(\alpha, \beta)$  is rhetorically related to a unit  $\gamma$  that is textually prior to  $\alpha$ , and thus outside of the scope of the Attribution, a relation  $R$  that can be inferred to hold between  $\gamma$  and  $\beta$  based on the contents of  $\gamma$  and  $\beta$  alone is weakened to  $\Diamond R$ . This rule is formalized in PA below, where  $e$  and  $e'$  are edges in a discourse graph that connect nodes representing discourse units;  $\alpha, \beta$  and  $\gamma$  are labels for discourse units; and  $l$  is a labelling function that maps each edge to a label for a discourse relation (e.g., Attribution).

$$\text{PA: } (\exists e. e(\alpha, \beta) \wedge l(e) = \text{Attribution}) \rightarrow (\exists \gamma \exists e' (\gamma <_t \alpha \wedge e'(\gamma, \beta)) \rightarrow \exists R (l(e') = R) \rightarrow \Diamond R)$$

The effects of PA are illustrated in Figure 1.

Figure 1: Relations to units inside Attributions

PA is designed to capture the idea that when a speaker uses a report parenthetically, she uses the attributive predicate as a kind of buffer so that the embedded content can be relevant, but she does not have to fully commit to its content. From the perspective of discourse structure, PA reflects the fact that even if an attribution predicate does not seem relevant or ‘at-issue’ with regard to the preceding discourse, it nevertheless plays a crucial function in the overall discourse by affecting the relation inferred between its embedded clause and the preceding discourse.

Some consequences of adopting PA are, first, that it respects the constraint of veridicality imposed by many discourse relations, including Explanation, because a modal discourse relation only entails the possibility that its arguments are true:

$$(11) \quad \Diamond R(\alpha, \beta) \models \Diamond(\alpha \wedge \beta)$$

A full commitment to the content of  $\beta$  will be consistent with a formula of the form  $\Diamond R(\alpha, \beta)$ , but it will not be necessary. At the same time, commitment to  $\neg\beta$  will be inconsistent with a formula of the form  $\Diamond R(\alpha, \beta)$ , as desired.

A further desirable consequence is that both  $\alpha$  and  $\beta$  can be discourse relevant. Nothing in this proposal hinges on a binary distinction between at-issue and not-at-issue content, which, as argued in Hunter (2016), is untenable when we look at the way reports are actually used in longer stretches of discourse.

Hunter's account, however, leaves some important questions about the nature of PA unanswered. First, what triggers PA and can we derive it compositionally? Also, does  $\Diamond R(\alpha, \beta)$  yield the right entailments for  $\alpha$ ? Are there any examples in which a parenthetical report weakens a speaker's commitment to the argument  $\alpha$ ? In the next section, we argue that the transformation described by PA is a type of coercion, as understood in the frameworks of Asher (2011) and Asher and Luo (2012), and explain the entailments of a formula of the form  $\Diamond R(\alpha, \beta)$  in more detail.

### 3. Coercion

*Coercion* is an observed process whereby the meaning of a predicate  $P$  combines with the meaning of an expression  $e$  in its scope to produce a meaning shift. To illustrate, the predicate *is a very fancy and tasty Bordeaux* in (12) combines with the noun phrase *this bottle*, yet the final interpretation does not involve a predication of the bottle, but of the *contents* of the bottle.

(12) This bottle is a very fancy and tasty Bordeaux.

The combination of *is a very fancy and tasty Bordeaux* with *the bottle* coerces a shift in meaning. Coercion, many have argued, is the result of an adjustment to either the meaning of the predicate, the meaning of the argument, or to the composition that fits their meanings together, so that the argument of the predicate satisfies the predicate's selectional restrictions, which in "ordinary circumstances" the argument does not. In (12) the predicate has to hold of wine or at least something that is edible or potable, and a mechanism of coercion like that proposed in Asher (2011) reinterprets the predication so that the predicted meaning is something like *the content of this bottle is a very fancy and tasty Bordeaux*.

Our claim is that a relation of the form  $\Diamond R$  that relates the embedded content of a parenthetical report to the preceding discourse is the product of coercion, triggered by a conflict between the demands of the Attribution relation and the demands of  $R$ . To unpack this claim, we begin with a brief overview of some relevant aspects of *Segmented Discourse Representation Theory* (SDRT; Asher and Lascarides, 2003), the formal framework that we will use to develop our coercion account.

The language of SDRT contains a countable set of discourse unit labels  $DU = \{\pi, \pi_1, \pi_2, \dots\}$ , and a finite set of discourse relation symbols  $\mathbb{R} = \{R, R_1, \dots, R_n\}$ , and formulas  $\phi, \phi_1, \dots$  from some fixed language  $L$  for describing elementary discourse move contents, where  $L$  is a language like that of higher order logic used in, for instance, Montague Grammar. SDRT formulas are of the form  $\langle \pi : \phi \rangle$ , where  $\phi$  is either: (i) a formula of  $L$ ; (ii) a relational formula of the form  $R(\pi_1, \pi_2)$ , which says that  $\pi_1$  stands in relation  $R$ , e.g., Explanation or Attribution, to  $\pi_2$ ;

(iii) a formula of the form  $\Diamond\psi$  where  $\psi$  is an SDRT formula; or (iv) a conjunction of SDRT formulas. To provide an illustration, (2) yields three discourse units,  $\pi_1, \pi_2$ , and  $\pi_3$ :

$\pi_1$  : John didn't come to my party.

$\pi_2$  : Jill said that

$\pi_3$  : he was out of town.

Each of these units is then associated with a formula of  $L$ — $\phi_1$ ,  $\phi_2$  and  $\phi_3$ , respectively—that specifies its content. For  $\phi_2$ , for example, the formula is  $\exists p.\text{said}(\text{Jill}, p)$ ; for  $\phi_3$ , the formula is,  $\text{Out-of-town}(\text{Sel}(\text{John}, \text{Jill}, \text{party}))$ , where  $\text{Sel}$ , a part of the vocabulary of  $L$ , is a function picking out an appropriate individual type variable or discourse referent from the logical forms for the discourse so far (the formulas for  $\pi_1$  and  $\pi_2$ ). The combination of  $\pi_1 - \pi_3$  in (2) will also yield two further formulas,  $\text{Attribution}(\pi_2, \pi_3)$  and  $\Diamond \text{Explanation}(\pi_1, \pi_3)$ .

How do we derive these formulas? While the Attribution relation between  $\pi_2$  and  $\pi_3$  is syntactically determined and triggered by the embedding verb *say*, the derivation of  $\Diamond \text{Explanation}(\pi_1, \pi_3)$  involves a more complicated process. SDRT requires that any discourse unit  $\pi'$  must, if it is not discourse initial, be rhetorically connected to some other unit  $\pi$ , if it is to make a coherent contribution to the discourse in which it figures; every coherent discourse can be represented as a directed, acyclic and weakly connected graph. This means that at least one part of the report in (2b) must be related to the preceding discourse. In this case, the preceding discourse consists of a single unit, so the task is simplified: either  $\pi_2$  or  $\pi_3$  must be related to  $\pi_1$ .<sup>4</sup>

Often, the relation to the preceding discourse is not specified via a syntactic connection or an explicit discourse connective such as *because*. Where the selection of a relation or a discourse constituent is left unspecified, SDRT exploits the  $\text{Sel}$  function;  $\text{sel}_{\mathbb{R}}(\text{sel}_{\Pi}\{\pi_m, \dots\}, \text{sel}_{\Pi}\{\pi_n, \dots\})$ , for instance, says that some relation from the set  $\mathbb{R}$  of relations must be selected to apply to a selection of constituents from  $\{\pi_m, \dots\}$  and from  $\{\pi_n, \dots\}$ . In (2), the connection between (2b) and (2a) is not explicitly marked, so the axioms of SDRT only yield a very underspecified contribution:

$$(13) \quad \text{sel}_{\mathbb{R}}(\pi_1, \text{sel}_{\Pi}\{\pi_2, \pi_3\}).$$

In words this means that some discourse relation selected from the set  $\mathbb{R}$  of discourse relations must hold between the constituent  $\pi_1$  and one of the constituents introduced in (2b). Which discourse relation and which constituent are ultimately chosen to flesh out an underspecified formula depends on semantic and syntactic constraints and the surrounding discourse context. Combining the discourse units  $\pi_1 - \pi_3$  from (2), their associated contents, (13), and  $\text{Attribution}(\pi_2, \pi_3)$ , we arrive at the logical form in (14). (14) is given in the SDRT language using a richly typed, dynamic, compositional framework (Asher and Pogodalla, 2011).

$$(14) \quad \exists \pi_1, \pi_2, \pi_3 (\pi_1 : \neg \text{come}(\text{john}, \text{my-party}) \wedge \pi_2 : \text{say}(\text{jill}, \pi_3) \wedge \pi_3 : \text{out-of-town}(\text{john}) \\ \wedge \lambda x \lambda y \text{sel}_{\mathbb{R}}(y, x)(\pi_1)(\text{sel}_{\Pi}\{\pi_2, \pi_3\}) \wedge \text{Attribution}(\pi_2, \pi_3))$$

<sup>4</sup>Were (2) embedded in a larger discourse, both  $\pi_2$  and  $\pi_3$  might be related to the preceding discourse. In fact, adding discourse connections can increase the unity and coherence of a discourse. This is captured in the principle Maximise Discourse Coherence from Asher and Lascarides (2003).

Let's now look at how we would resolve the underspecification in (14) in the context of a coercion story. The contents of  $\pi_1$  and  $\pi_3$  support  $\text{Explanation}(\pi_1, \pi_3)$ , and in fact, this is the most probable connection to  $\pi_1$  in this case. Normally we would infer this relation to resolve the choice of rhetorical relation in (13), but because of the Attribution relation between  $\pi_2$  and  $\pi_3$ , we run into a conflict.

To make this conflict precise, we begin by assigning types to the variables  $\pi_1, \pi_2, \dots$  that represent discourse units in SDRT. There are two types for discourse representation variables, UP (U), for *uncommitted*, and DOWN (D), for *determinate*. The general idea is that the content associated with a variable of type D will be entailed by the discourse; for a variable of type U, neither its associated content nor the negation of this content will be entailed. Veridical relations, including Explanation, Elaboration, Narration, Contrast, and so on, are of type  $D \rightarrow D \rightarrow D$ . Non-veridical relations, including Conditional and Disjunction, have the type  $U \rightarrow U \rightarrow D$ . Attribution is a *right*-nonveridical relation, meaning that it is non-veridical in its right argument; that is, it has the type  $D \rightarrow U \rightarrow D$ .

The proposed typing for Attribution is designed to reflect the fact that the act of attributing content to an agent should not in itself require speaker commitment to the attributed content. As it stands, however, it does not capture the fact that the content inside of an Attribution's scope might itself contain relations that are veridical. For instance, consider:

(15) [Jill said that] $_{\pi_1}$  [John went running at 6] $_{\pi_2}$  [and he went to dinner with Julie at 7.] $_{\pi_3}$

where  $\pi_1, \pi_2$ , and  $\pi_3$  label the elementary discourse units.<sup>5</sup> The SDRS  $K$  for (15) contains a complex discourse unit,  $\pi_0$ , that itself contains a discourse relation. (16) gives its logical form.

(16)  $\exists \pi_0, \pi_1, \pi_2, \pi_3 (\text{Attribution}(\pi_1, \pi_0) \wedge \pi_0 : \text{Narration}(\pi_2, \pi_3))$

The formula  $\text{Attribution}(\pi_1, \pi_0)$  requires  $\pi_0$  to be of type U, but this conflicts with the type D assigned to the veridical relation  $\text{Narration}(\pi_2, \pi_3)$ . A similar problem arises with conditionals:

(17) [If John doesn't have to work this evening] $_{\pi_1}$  [then he will go running] $_{\pi_2}$  [or he'll go play squash.] $_{\pi_3}$

We get the following logical form:

(18)  $\exists \pi_0, \pi_1, \pi_2, \pi_3 (\text{Conditional}(\pi_1, \pi_0) \wedge \pi_0 : \text{Disjunction}(\pi_2, \pi_3))$

The relation Conditional requires  $\pi_0$  to be of type U; Disjunction requires it to be of type D.

In the case of both Conditional and Attribution, we need to capture the fact that veridical relations in their scope are only veridical *relative to a context* introduced by the antecedent of the conditional or the attribution predicate, respectively. To do this, we relativize types to con-

<sup>5</sup>We use square brackets to mark the boundaries of discourse units.

texts.<sup>6</sup> A context will be represented as a *segmented discourse representation structure* (SDRS) or formula under the scope of an operator; the outermost SDRS  $K_0$  is a context, as is any SDRS  $K_i$  that is a constituent of  $K_0$  and is within the scope of an operator. Note that a formula under the scope of a modal operator also serves as a typing context. If a discourse unit is typed  $D$  in a context  $K$ , which we will write as  $\pi^K : D$ , then its normal entailments are entailed in  $K$ ; more precisely, if  $\pi^K : D$ , the content associated with  $\pi$  must be satisfied at worlds or points of evaluation in which any relations in  $K$  involving  $\pi$  are satisfied. If a discourse unit  $\pi$  is such that  $\pi^K : U$ , then the content of  $\pi$  is not entailed in  $K$  even if it figures in a relation  $R$  that is entailed in  $K$ . By relativizing types to contexts, we capture the idea that while a speaker may not be committed to the content of a report, when she attributes content to another agent, she commits *to the other agent being committed* to the report's content. Note that in an SDRS, an instance of a discourse relation  $R$  occurs in one and only one context.

The relation between the entailments of a context  $K$  and the entailments of a context  $K'$  embedded in  $K$  obeys the following retyping rule: where  $K$  is a context,  $\pi^K : u$ , and where  $K'$  is a constituent of  $K$  under the scope of a modal operator or intensional relation, then  $\pi^{K'} : d$  is an allowable typing. We also allow type raising from  $D$  to  $U$  when we shift from a context  $K'$  to a context  $K$  in which  $K'$  is embedded: if  $\lambda \pi \psi$  requires a discourse unit of type  $U$  as argument in  $K$ , but is given an argument  $\pi_1$  of type  $D$  from  $K'$ , then a general coercion permits us to rewrite the type of  $\pi_1$  to  $U$ ; i.e.  $\pi_1^K : U$ . Finally, for any constituent  $\pi$  in  $K$  introduced by an indicative clause not in the scope of an intensional operator or intensional relation in  $K$ ,  $\pi^K : D$ .

We say that an SDRS  $K$  has a *consistent type assignment* just in case:  $K$  respects the retyping rule; the discourse relations in  $K$  have arguments of the type required by the semantics of the relations; and for every context  $K'$ , and for every discourse unit  $\pi$  in  $K'$ ,  $\pi$  has a unique type assignment relative to  $K'$ . The SDRS  $K$  for (16), for instance, has a consistent type assignment in which  $\pi_1 : D$  and, after type raising,  $\pi_0 : U$  in  $K$ . But  $\pi_0$  is an SDRS in the scope of an intensional relation; it therefore constitutes a typing context of its own and specifies its own assignments to discourse units figuring in discourse relations in  $\pi_0$ . In this context,  $\pi_0$  is of type  $D$ —i.e.,  $\pi_0^{\pi_0} : D$ ; and we also have  $\pi_1^{\pi_0} : D$  and  $\pi_2^{\pi_0} : D$ , which yields a consistent typing of  $K$ .

We note that examples like (19) do not require any kind of retyping or context shifting. While (19b) and the embedded clause of (19a) have the same propositional content, they contribute different discourse units and can therefore receive different type assignments.

- (19) a. Jill said John was out of town.  
b. And (indeed) he was out of town.

The types we have assigned to discourse units are distinct from the types assigned to contents, just as the contents associated with discourse units are distinct from the units themselves. The fact that (19b) serves as a correction or amplification of (19a) is because the same content is now linked to a label that commits the speaker to John's being out of town.

<sup>6</sup>For more on typing within contexts, see the notion of *coercive sub-typing*, e.g. Luo (1999).

The conflict that induces the coercion observed with the parenthetical report in (2b) is triggered by the fact that the Attribution relation and the Explanation relation in (2) share the same second argument, namely  $\pi_3$ , but Explanation types this argument as D, while Attribution types it as U. More generally, discourse parenthetical reports will always trigger this kind of conflict; as explained in Hunter (2016), we do not find the embedded clauses of discourse parenthetical reports in non-veridical relations such as Disjunction or Conditional. The only available reading of (20), for example, is one in which *Linda said* takes scope over the entire conditional.

(20) If John finishes his housework, then Linda said he'll come to the party.

In this case, the report is not parenthetical.

To resolve the conflicting type requirements imposed by a formula of the form Attribution( $\pi, \pi'$ ) on the one hand and a veridical relation that takes  $\pi'$  as an argument on the other, something has to give: either the type assignment for a constituent, the type of the predicates over the constituents (i.e. the discourse relations), or the way these predicates combine with their arguments has to change. Our retyping rule will not solve the conflict: suppose we replace  $\lambda x \lambda y \text{sel}_R(y, x)(\pi_1)(\text{sel}_{\Pi}\{\pi_2, \pi_3\})$  in (14) with Explanation( $\pi_1, \pi_3$ ), which requires  $\pi_3$  to have the type D. Raising  $\pi_3$  from D to U will leave Explanation with an argument of type U, which conflicts with its veridical semantics. The retyping rule would only work if the entire Explanation were under the scope of the Attribution.

Retyping  $\pi_3$  from U to D in Attribution( $\pi_2, \pi_3$ ) will not work either. An important principle of the account of coercion in Asher (2011) is that lexical items or grammatically determined types do not change their type due to coercion, and Asher (2011) adduces considerable evidence for this principle. We believe that this principle is also plausible at the discourse level. Given this assumption and the fact that the Attribution relation is grammatically determined, we cannot change the type requirements of Attribution. It follows that  $\pi_3$  will retain its typing of U in the context of the Attribution, and there is therefore no consistent type assignment for an SDRS that includes those two relations on  $\pi_3$ .

Shifting the type of  $\pi_1$  or  $\pi_2$  would also be ineffective, because doing so would only introduce a conflict between these discourse referents and the requirements of Explanation and Attribution, respectively. Shifting the inferred link between  $\pi_2$  and  $\pi_3$  is not allowed because the link is grammatically determined. The only possibility, then, is to shift the inferred link between  $\pi_3$  and  $\pi_1$ . To spell this out formally, we need two things. We need to specify how the predication within a given context changes using a functor that takes a relation  $R$  and its two arguments  $\alpha$  and  $\beta$  and returns a modified predication of  $R$  applied to  $\alpha$  and  $\beta$ ; this is easy to do with our types and the availability of a modal operator. The other task is to specify what predicate licenses the introduction of the functor.

We begin with the second task. In standard coercion cases, the licensing predicate is typically  $R$  itself. For discourse coercions, however, it is the discourse environment that typically licenses the coercion. In particular, it is the presence of the Attribution that licenses the coercion of the environment involving the Explanation relation. Given the contents of  $\pi_1, \pi_2$

and  $\pi_3$ , the discourse model selects the most plausible specification for  $\text{sel}_{\mathbb{R}}$  and  $\text{sel}_{\Pi}$  in (14):  $\text{Explanation}(\pi_1, \pi_3)$ . From the discourse model, we then rewrite the logical form in (14) as:

$$(21) \quad \exists \pi_1, \pi_2 (\pi_1 : \neg \text{come}(\text{john}, \text{my-party}) \wedge \pi_2 : \exists \pi_3 \text{say}(\text{jill}, \pi_3) \wedge \pi_3 : \text{out-of-town}(\text{john}) \\ \wedge \lambda x \lambda y \text{Explanation}(y, x)(\pi_1)(\pi_3) \wedge \text{Attribution}(\pi_2, \pi_3))$$

But now we have a type conflict on  $\pi_3$ , and  $\lambda$  reduction cannot proceed further: the type that  $\text{Explanation}$  requires of  $\pi_3$  (D) conflicts with the type assigned to it by  $\text{Attribution}$  (U) in  $K_{(21)}$ .

This type clash leads to the introduction of a coercion functor that can be specified as follows.

- Coercion to  $\Diamond R$ :  $f: \lambda \beta: U. \lambda \alpha: D. \lambda R: D \rightarrow D \rightarrow D. \Diamond R(\alpha, \beta)$ .

The presence of the  $\text{Attribution}$  entailing the typing  $\pi_3 : U$  together with the simple assertion of (2a) entailing  $\pi_1 : D$  and the discourse model's prediction of a veridical relation's holding of  $\pi_1$  and  $\pi_3$  license a rewriting of

$$(22) \quad \lambda x \lambda y \text{Explanation}(y, x)(\pi_1)(\pi_3)$$

as

$$(23) \quad f(\lambda x \lambda y \text{Explanation}(y, x))(\pi_1)(\pi_3)$$

$\lambda$ -reduction can proceed now that the types all match, yielding:

$$(24) \quad \Diamond \text{Explanation}(\pi_1, \pi_3)$$

So our final logical form for (2) looks like this:

$$(25) \quad \exists \pi_1, \pi_2 (\pi_1 : \neg \text{come}(\text{john}, \text{my-party}) \wedge \pi_2 : \exists \pi_3 \text{say}(\text{jill}, \pi_3) \wedge \pi_3 : \text{out-of-town}(\text{john}) \\ \wedge \Diamond \text{Explanation}(\pi_1, \pi_3) \wedge \text{Attribution}(\pi_2, \pi_3))$$

Note that  $f$  is a conservative functor that maintains consistency with the original requirement of a veridical relation  $R$  such that  $R \models \Diamond R$ . Note also, however, that  $\Diamond$  itself specifies a typing context, so that within the context of  $\Diamond$  it is consistent to have  $\pi_1 : D$  and  $\pi_3 : D$ , as would be needed if a veridical relation had fallen in the scope of *Jill said* in (2b) (cf. (15)).

The functor  $f$  does not change the type of either  $\alpha$  or  $\beta$ ; it rather shifts the relation inferred between them to a relation that is compatible with arguments of either type D or type U. Because the type of the arguments stays constant, the entailment in (11), repeated here as (26), does not reflect the actual entailments of an example like (2).

$$(26) \quad \Diamond R(\alpha, \beta) \models \Diamond(\alpha \wedge \beta)$$

In (2), the content of (2a) is asserted independently of the subsequent discourse, and is therefore

of type D; the functor simply renders the relation compatible with the typing of  $\pi_3$ , which is U. We can therefore make the stronger claim for an example like (2):

$$(27) \quad \Diamond R(\alpha, \beta) \models \alpha \wedge \Diamond \beta$$

This conforms to the intuition that (2a) is entailed in (2).

This entailment requires some unpacking. The formula (25) entails, as described in (27), that the content of  $\pi_1$  is satisfied at the actual world and the content of  $\pi_3$  is satisfied at a world consistent with the speaker's commitments. Yet to the extent that a causal relation might hold between the eventualities  $e_\alpha$  and  $e_\beta$  described by  $\alpha$  and  $\beta$ , respectively, the Explanation relation as well as  $e_\alpha$  and  $e_\beta$  must all hold in the same world. This is ensured by a fact about epistemic possibilities: given that  $\pi_1$  is asserted, the speaker is committed to it, and so the content of  $\pi_1$  holds at *all* worlds consistent with her commitments. What  $\Diamond \text{Explanation}(\pi_1, \pi_3)$  adds is the claim that in some of those commitment worlds,  $\pi_3$  is also verified, and furthermore, in at least some of those worlds,  $\pi_3$  describes an eventuality that caused that described by  $\pi_1$ . In other words, under the scope of  $\Diamond$ ,  $\pi_1$  and  $\pi_3$  are of both type D, so the constraints on Explanation are satisfied.

Interestingly, there is an asymmetry in coercion facts. While (2) seems to have a discourse parenthetical reading of the sort we have derived in (25), an example that inverts the form of (2) does not.

- (28)    a.    Jill said John is sick.  
           b.    He ate a bad clam.

The claim in (28b) is naturally interpreted either as extending the report context introduced by (28a)—thus committing Jill to the content of (28b)—or as providing an explanation not only of why John is sick but also, in effect, of why Jill said what she did.

As defined, the functor  $f$  only works if the *second* argument of the coerced relation is U. In (28) it is the first argument of the implicit causal relation that is typed U, so our functor  $f$  will not apply to this case. Our account thus predicts that we can never have an instance of a veridical relation whose left argument is the embedded clause of a report and whose right argument is outside of the scope of the report (i.e. we can never coerce the argument of an Attribution to D).

This is surprising and may even seem suspicious. Yet some data, including (28), suggest that we should not countenance a functor  $g$ :  $\lambda \beta: D. \lambda \alpha: U. \lambda R: D \rightarrow D \rightarrow D. \Diamond R(\alpha, \beta)$ . One reason for not stipulating the functor  $g$  is that alternative means of producing a modalized relation exist:

- (29)    a.    Jill said John is sick.  
           b.    Maybe it's because he ate a bad clam.

Simple assertions allow for modalisation in a way that reports do not. There is no way to lexically induce the possible explanation reading for (2)—a speaker must either choose a report construction, which carries the extra information of a source, or a simple modal. Combining the two leads to non-parenthetical readings of the reports. So the presence of such alternatives for the inverted ordering might explain the asymmetry between our intuitions about (2) and (28).

On the other hand, there are examples, like (30), in which something like coercion of the first argument seems to work.

(30) [The school said] $_{\pi}$  [Isabel is sick.] $_{\pi_1}$  Maybe [she caught Rose's flu.] $_{\pi_2}$

This example implies  $\Diamond\text{Explanation}(\pi_1, \pi_2)$ . However, note that (30) differs from (2) in that  $\pi_2$  falls within the scope of a modal. We think that (30) manifests a kind of modal subordination involving the intensional context provided by  $\text{Attribution}(\pi, \pi_1)$  and the modal operator contributed by *Maybe*. Modal subordination could allow for an attachment between the two discourse units of type U, yielding a formula of the form:

(31)  $\exists \pi, \pi_1, \pi_2 (\text{Attribution}(\pi, \pi_1) \wedge \pi : \text{school said} \wedge \pi_1 : \text{sick(isabel)} \wedge \Diamond(\text{Explanation}(\pi_1, \pi_2) \wedge \pi_2 : \text{caught(isabel, flu)}))$

Given that  $\Diamond$  is a normal modality, (31) implies  $\Diamond\text{Explanation}(\pi_1, \pi_2)$ .

(32) provides another case in which a  $\Diamond R$  is arguably inferred from a first argument of type U and a second argument of type D:

(32) [Where was John on Tuesday evening?] $_{\pi}$  [Jill said that] $_{\pi_1}$  [she and John went running at 6.] $_{\pi_2}$  [Then/After that, he and I had dinner at 7.] $_{\pi_3}$

(32) intuitively implies  $\Diamond\text{Narration}(\pi_2, \pi_3)$ . In this case, however, it is the surrounding discourse structure that indirectly sets up the coercion on Narration. The answer to the question in  $\pi$  includes  $\pi_2$  and  $\pi_3$ . But let's concentrate first just on relating  $\pi$ ,  $\pi_1$  and  $\pi_2$ . The connections between these units will parallel those between the units in (2), yielding  $\Diamond\text{QAP}(\pi, \pi_2)$ , where *QAP* stands for *Question-Answer-Pair*. Now  $\pi_3$  simply extends the answer that is being proposed by  $\pi_2$  to a more complicated answer: perhaps the proposed sequence of events answers the question posed in  $\pi$ . Semantically, this means that in some world  $w$  from the set of worlds compatible with the speaker's commitments,  $\pi_2$  and  $\pi_3$  hold in  $w$  and the eventuality described by  $\pi_3$  took place after the eventuality described by  $\pi_2$  in  $w$ . In other words, there is an attachment of  $\pi_3$  to  $\pi_2$  forming a Narration under the scope of the modal introduced by the QAP, in a manner similar to the logical form for (16). This gives the following, abbreviated logical form:

(33)  $\exists \pi, \pi_1, \pi_2, \pi_3, \pi_4. (\text{Attribution}(\pi, \pi_2) \wedge \Diamond\text{QAP}(\pi, \pi_4) \wedge \pi : \text{Where was John?} \wedge \pi_1 : \text{Jill said} \wedge \pi_2 : \text{running} \wedge \pi_3 : \text{dinner} \wedge \pi_4 : \text{Narration}(\pi_2, \pi_3))$ .

We note several consequences of (33). First, the Narration relation and its temporal consequences hold only between the events described in  $\pi_2$  and  $\pi_3$ , not the time of Jill's saying, as intuitions dictate. Second, because of (27),  $\Diamond\text{QAP}(\pi, \pi_4)$  entails  $\Diamond\text{Narration}(\pi_2, \pi_3)$ , as desired, even though this formula is not in the logical form. Third, this is the only possible SDRS given our constraints on consistent typing. We could not put  $\text{Narration}(\pi_2, \pi_3)$  outside the scope of the  $\Diamond\text{QAP}$  relation in (33), because  $\pi_2^{(33)} : U$  and this would conflict with typing demands of Narration as a veridical relation.

Example (32) does not provide a genuine motivation for adopting the functor  $g$  described above.  $\Diamond\text{Narration}$  is indeed entailed, but not because of a direct conflict between Narration and Attribution; it's epistemic status follows from the fact that  $\pi_3$  develops a context that is already modal. At the same time, given that the speaker asserts  $\pi_3$ , its contents will hold at all worlds consistent with her commitments, including the actual world whether or not it is also a  $\pi_2$  world. Thus we arrive at the following consistent top-level typing for (33):  $\pi^{(33)} : D$ ,  $\pi_1^{(33)} : D$ ,  $\pi_2^{(33)} : U$ , and  $\pi_3^{(33)} : D$ . Indeed, our typing rules mandate these. Our typing rules also permit  $\pi_2^{\pi_4} : D$ ,  $\pi_2^{\pi_4} : D$ , and  $\pi_4^{\pi_4} : D$  as part of a consistent typing.

Our account right now relies on the potentially controversial assumption that Attribution always types its second argument as  $U$ . We now turn to a discussion of this assumption in the context of factive embedding verbs.

#### 4. Factives

On our proposal, the type assigned to a rhetorical relation  $R$  is entailed by  $R$ 's semantics; it is a property of the relation itself. As a result, the type is unaffected by semantic differences between connectives that license  $R$ . This means that Attribution, for example, will have the type  $D \rightarrow U \rightarrow D$  even when triggered by a factive verb, as in (34).

- (34)    a.    John didn't come to my party.  
           b.    Jill found out that he's been working nights at the station.

This might at first seem counterintuitive. After all, a factive verb entails the truth of its complement, so shouldn't its complement have the type  $D$ ?

First of all, it is important to distinguish between the discourse contribution of a report and its interpretation. The discourse contribution determines what relation is added to the logical form for a discourse, but while these relations play a significant role in discourse interpretation, they do not tell the whole story. The content of discourse units certainly effects interpretation, and in the case of reports, world knowledge or opinions about the reliability of sources cited in reports (de Marneffe et al., 2012) can influence what information interpreters ultimately take away. There is therefore no problem with saying that discourse structure contributes certain entailments and that the content of discourse units, including the semantics of the various embedding verbs used in reports, can strengthen these entailments. A typing of  $U$  for a clause embedded under a factive verb is consistent with the demands of the verb, but the final discourse level entailments triggered by reports with factive verbs can ultimately be stronger. What we have

modeled is the general function of discourse parenthetical reports, and we take as basic that the attribution predicate of such a report acts as a buffer between the embedded content and the preceding discourse.

What's more, in many cases, the claim that discourse parenthetical reports involving factive embedding verbs trigger relations of the form  $\Diamond R$  is more than consistent with the demands of factive verbs—it is also borne out by the data. Even Attributions triggered by factive verbs allow a speaker to hedge her commitment to the discourse function of the embedded clause. If a speaker A asks, (a) “Why didn’t John come to the party?”, a speaker B can reply, (b) “Jill found out that he has taken on a night job” and thereby hedge her commitment to the Question/Answer relation suggested by the contents of (a) and (b), even while committing to the truth of the embedded clause in (b) in virtue of the factivity of *find out*. Factivity licenses an inference *from* the discourse logical form but does not contribute type information to its *construction*, and thus doesn’t affect the typing relevant to the interaction between attributions and the surrounding discourse context. This formalizes the observation in Simons (2007) that parentheticality and factivity are orthogonal notions.

Of course, intonation plays a role in the way that discourse parenthetical reports are ultimately interpreted. A more certain and declarative intonation for (b) above might encourage the interpretation of an Explanation rather than the weaker  $\Diamond$ Explanation relation. Intonation certainly plays an important, if poorly understood, role in discourse interpretation. Nevertheless, even a declarative intonation does not *force* the stronger interpretation. Speaker B could continue (b) with (c): “That might be why he didn’t come,” thereby making the  $\Diamond$ Explanation explicit. Our point is that the use of a factive verb in a discourse parenthetical report does not in and of itself require a non-modal relation; the systematic discourse contribution of *all* reports is the weaker  $\Diamond R$ . Strengthening of this relation at the level of discourse interpretation must be explained by independent factors.

## 5. Connectives

As we’ve seen, while the content of (2a) and the embedded content of (2b) together lead the discourse model to predict an Explanation relation, other information from (2) triggers a coercion. This coercion is blocked once we make the causal connection explicit as noted by Hunter and Danlos (2014). The report in (35b) can only receive a non-parenthetical reading.

- (35)    a.    John didn’t come to my party  
           b.    because Jill said he was out of town.

A consequence of our coercion story is that the typing demands of a connective with a grammatically determined scope must be satisfied. We predict this because the semantics of the connector *because* entails a non-modal commitment to Explanation over its complement clause, and our coercion account cannot change such grammatically given entailments.

The contrast between (36) and (37) also illustrates this point, though the data are more subtle.

- (36) a. Liz's album got a bad review.  
 b. John said she's really upset.
- (37) a. Liz's album got a bad review,  
 b. so John said she's really upset.

In (36b), John's saying what he did might be completely independent of the review mentioned in (36a); (36b) arguably has a parenthetical reading and licenses  $\Diamond$ Result. In (37b), to the extent that (37) is acceptable, we infer that John himself suspects that the review caused Liz's distress. The fact that John said what he did is thus a reaction to the review, so the matrix clause of (37b) describes a result of (37a). The matrix clause is of type D, so it satisfies the type demands of Result. At the same time, connecting (37b) to (37a) with Result is only really coherent if the embedded clause of (37b) is also related to (37a) with  $\Diamond$ Result. But our coercion story still applies to any connection between the embedded clause of the report with (37a). So in fact we predict a graph with both Result and  $\Diamond$ Result for (37).

Our prediction does not apply to all explicit connectives. Compare (38) with (35) or (39):

- (38) [A man died] $_{\pi_1}$  [after police say/said] $_{\pi_2}$  [he was hit by a fire truck.] $_{\pi_3}$
- (39) A man died because police said he was hit by a fire truck

While no inferred  $\Diamond$ Explanation to the embedded discourse unit is possible in (35) or (39), an inference to  $\Diamond$ Explanation is involved in the interpretation of (38) (Hunter and Danlos, 2014). This has to do with the semantics and discourse function of *after*, whose semantic scope is not determined by its syntactic position—in (38) the second argument of *after* is  $\pi_3$ . While it marks a temporal relation or possible temporal relation in this case, a causal relation between  $\pi_1$  and  $\pi_3$  is also inferred, and there our coercion account applies.

Finally, we note a possible difference between syntactically embedded markers like *because*, connectives like *after* and markers that are marked with a comma, such as *after that* and *afterwards* (cf. Danlos, 2013). Consider the following data from (Hunter & Danlos 2014):

- (40) John is very generous. For example, Jill said that he gave \$50 to a homeless man yesterday.
- (41) John didn't come to the party. Instead, Jill said that he went to dinner with his brother.

Parenthetical readings for (40) and (41) are possible with explicit connectives, but once we embed the connective inside the report, we lose the parenthetical reading of (41):

- (42) John didn't come to the party. Jill said instead that he went to dinner with his brother.

All of this suggests that while the typing demands imposed by discourse connectives must in

general be respected, further work is needed to understand differences between the various types of discourse connectives.

## 6. Conclusion

Our main goal in this paper has been to develop a compositional account of the discourse function of parenthetical reports. Hunter (2016) argued that the role of discourse parenthetical reports is to contribute a modal discourse relation to a discourse structure. The derivation of such relations was, however, left unexplained and the  $\Diamond$  relations that Hunter posited seemed more like primitive discourse relations. Such an approach does not take into account the fact that discourse parenthetical reports in fact arise from the interaction of an Attribution environment and the surrounding discourse context; the embedded content of a discourse parenthetical report and the discourse unit to which it attaches in the preceding discourse do not on their own support a relation of the form  $\Diamond R$ . In the account developed here,  $\Diamond R$  is derived from  $R$  via coercion and a context sensitive notion of typing (Asher and Luo, 2012). The Attribution relation plays a key role in this story by introducing a typing on its second argument that is incompatible with the requirements of the relation  $R$ .

We have also extended our basic account to discourse parenthetical readings of factive verbs. In our account, all reports with non-parenthetical syntax are modelled with the discourse relation Attribution, and Attribution always has the type  $D \rightarrow U \rightarrow D$ , regardless of the embedding verb involved. We argued not only that this is consistent with the demands of factives and a reasonable understanding of how discourse structure contributes to discourse interpretation, but also that discourse parenthetical readings of even factive verbs can entail merely modal relations. As pointed out in Simons (2007), factivity and parentheticality are orthogonal notions.

Finally, we have shown how our account predicts that the attribution clause of a report in the scope of an explicit discourse connective must be relevant to that connective. Pure discourse parenthetical readings in which the attribution predicate is not related to the preceding discourse, or at least not related to the unit to which the embedded clause is related, are predicted to be blocked by explicit connectives because our coercion operation cannot shift grammatically determined types. We did note, however, that some connectives seem to allow parenthetical readings. A detailed case study of different connectives is needed to complete our account, but we think this account is promising enough to warrant such a study in the future.

# Constraints on the embeddability of epistemic modals<sup>1</sup>

Michela IPPOLITO — *University of Toronto*

**Abstract.** In this paper I investigate occurrences of epistemic modals such as *must* and *might* embedded under three classes of attitude verbs: (i) doxastic and doxastic-like verbs like *believe*, (ii) desiderative verbs like *want*, and (iii) emotive doxastic and dubitative verbs like *fear*, *hope* and *doubt*. The first class allows both necessity and possibility epistemic modals; the second class allows neither necessity nor possibility epistemic modals; and finally, the third class allows possibility but not necessity epistemic modals. We begin our inquiry by reviewing Anand and Hacquard (2013)'s proposal. I present some challenges for the proposal and, in particular, for their proposal for class (iii). I show that the restrictions on embedded epistemic modals are similar to the restrictions on embedded V-to-C in German (Truckenbrodt (2006)) and argue that the two phenomena can be given similar explanations.

**Keywords:** epistemic modals, attitude verbs, embedded V-to-C.

## 1. Introduction

Epistemic modals can be sometimes embedded under propositional attitude verbs. This paper is a study of what constrains their distribution under attitude verbs, starting from the broad observation that there seem to exist three types of attitudes: those that license epistemic modals in their scope, those that do not allow epistemic modals in their scope, and those that allow possibility but disallow necessity modals. Building on Bolinger (1968)'s generalization, and building on a corpus study done by Hacquard and Wellwood (2012), Anand and Hacquard (2013) observe that epistemic modals are acceptable in the complement of doxastic verbs such as *think*, argumentative verbs such as *say*, and semi-factive verbs like *realize*.

- (1) a. John thinks that Mary must/might be innocent.
- b. John said that Mary must/might be innocent.
- c. John realized that Mary must/might be innocent.

The second type includes verbs that do not allow epistemic modals in their complement. These include desiderative verbs such as *want* and directives like *demand*.

- (2) a. #John wants Mary to have to be the murderer.
- b. #John demanded that Mary must/might have been the murderer.

The third kind includes emotive doxastic attitudes such as *fear* and dubitative verbs such as *doubt*: these verbs only allow possibility epistemic modals in their complement.

---

<sup>1</sup>I would like to thank the audiences at Sinn und Bedeutung 21, the Linguistics and Philosophy Workshop at the University of Chicago, the SemPrag reading group at the University of Toronto, as well as the linguists and philosophers at the University of Milano-Bicocca.

- (3) a. John fears that Mary may/might have known the killer.  
 b. #John fears that Mary must have known the killer.
- (4) a. John doubts that Mary may/might have known the killer.  
 b. #John doubts that Mary must have known the killer.

## 2. Anand and Hacquard (2013)

To account for the contrast between the attitude verbs that allow embedded epistemic modals and those that do not, Anand and Hacquard propose that (i) only “representational” attitudes can provide an information state and (ii) embedded epistemic modals quantify over an information state determined by the embedding attitude. Let’s begin with point (i). The non-representational nature of a desiderative verb like *want* derives – they claim – from the fact that *want*, unlike *believe*, has a comparative semantics. Following Stalnaker (1984), Asher (1987), Heim (1992), and more explicitly Villalta’s work on desiderative predicates (Villalta (2008)), they provide the semantics in (5).

- (5)  $[[\text{want}]]^{c,w,g} = \lambda p.\lambda x.\forall q \in g(C) \setminus p : p >_{DES_{x,w}} q$   
 where  $DES_{x,w}$  is defined as follows:  
 -for any  $w, w', w''$ :  $w' >_{DES_{x,w}} w''$  iff  $w'$  is more desirable to  $x$  in  $w$  than  $w''$ .  
 -for any  $p, q \subseteq W$ :  $p >_{DES_{x,w}} q$  iff  $\forall w'' \in q : [\exists w' \in p : [w' >_{DES_{x,w}} w'']]$  and  $\exists w' \in p : [\forall w'' \in q : [w'' \not>_{DES_{x,w}} w'']]$

Since *want* – they claim – is non-representational, it fails to provide an information state that will function as the “antecedent” for the embedded modal. As shown in (6), on the other hand, the attitude *believe* does provide an information state, i.e. the subject’s doxastically accessible worlds, which will then be the set of worlds quantified over by the embedded epistemic modal.

- (6)  $[[\text{believe}]]^w = \lambda p.\lambda x.\forall w' \in Acc_{dox}(w, x) : p(w') = 1$

Part (ii) of Anand and Hacquard’s story, i.e. that embedded epistemic modals quantify over an information state determined by the embedding attitude, builds on Yalcin (2010), whose goal was to account for the contrast between (7a) and (7b).

- (7) a. Imagine that [it’s raining but you don’t believe it is].  
 b. #Imagine that [it’s raining but it might not be].

Yalcin’s proposal is that the unacceptability of (7b) is due to the fact that the embedded epistemic modal “inherits” its modal base from the quantificational domain of the embedding attitude, generating a contradiction: (7b) asserts that all worlds compatible with the addressee’s imagination are worlds where it is raining and there is a world compatible with the addressee’s imagination where it is not raining. Extending this idea, Anand and Hacquard propose the general rule in (8).

- (8) For any attitude *att*,  
 $\llbracket \mathbf{att} \phi \rrbracket^{c,w,S,g} = \lambda x. \forall w' \in S' \llbracket \phi \rrbracket^{c,w',S',g} = 1$ , where  $S'$  is the quantificational domain provided by **att**.

In the majority of cases this creates structures with redundant meanings, equivalent to a modal sentence with the force of the embedded epistemic modal and the flavor of the embedding attitude.

- (9) a. John believes that Mary must be the killer  $\equiv$  for all worlds  $w$  compatible with John's doxastic state in the evaluation world, Mary is the killer in  $w$ .  
 b.  $\forall w \in DOX_J [\forall w'' \in DOX_J : \text{Mary is the killer in } w''] \equiv \forall w'' \in DOX_J : \text{Mary is the killer in } w''$
- (10) a. John believes that Mary might be the killer  $\equiv$  there is at least a world  $w$  compatible with John's doxastic state in the evaluation world such that Mary is the killer in  $w$ .  
 b.  $\forall w \in DOX_J [\exists w'' \in DOX_J : \text{Mary is the killer in } w''] \equiv \exists w'' \in DOX_J : \text{Mary is the killer in } w''$

The third type of attitude verbs we will discuss are emotive doxastic verbs like *fear* and *hope* and dubitative *doubt*. Let's begin with the former. Anand and Hacquard propose the semantics in (11): *a hopes that  $\phi$*  presupposes that *a*'s doxastic state is compatible with both  $\phi$  and  $\neg\phi$  and it asserts that  $\phi$  is compatible with *a*'s doxastic state and that  $\phi$  is preferable to  $\neg\phi$ .

- (11)  $\llbracket \mathbf{a} \text{ hope that } \phi \rrbracket^{c,w,S,g}$   
 a. defined iff  $\phi$ -verifiers in  $S' \neq \emptyset \wedge \phi$ -falsifiers in  $S' \neq \emptyset$ ;  
 (uncertainty condition)  
 if defined, =1 iff  
 b.  $\exists w' \in S' : \llbracket \phi \rrbracket^{c,w,S',g} = 1 \wedge$   
 (doxastic assertion)  
 c.  $\wedge \phi$ -verifiers  $>_{DES_{a,w}} \phi$ -falsifiers  
 (preference assertion)

When the complement is modalized, then we have (12).

- (12)  $\llbracket \mathbf{a} \text{ hope that } Modp \rrbracket^{c,w,S,g}$   
 a. defined iff  $Modp$ -verifiers in  $S' \neq \emptyset \wedge Modp$ -falsifiers in  $S' \neq \emptyset$ ;  
 (uncertainty condition)  
 if defined, =1 iff  
 b.  $\exists w' \in S' : \llbracket Modp \rrbracket^{c,w,S',g} = 1 \wedge$   
 (doxastic assertion)  
 c.  $\wedge Modp$ -verifiers  $>_{DES_{a,w}} Modp$ -falsifiers  
 (preference assertion)

Since *Modp* verifiers are the same as *p* verifiers (see Anand and Hacquard (2013) for a discussion of this point), a sentence such as *John hopes that it might be raining* carries an **uncertainty presupposition** (that there is a non-trivial subset of John's belief worlds where it is raining and a non-trivial subset where it is not raining); it makes a **doxastic assertion** (that there is at least some world compatible with John's beliefs where it is raining); and, finally, it also makes a **preference assertion** (that rain is more desirable to John than no rain). Crucially, the incompatibility between *hope* and *must* is explained away as a contradiction: *#John hopes that it must be raining* is ruled out as a contradiction between the doxastic assertion (that in all of John's doxastic worlds it is raining) and the uncertainty presupposition requiring John's doxastic state to be compatible with no rain.

Dubitative *doubt* receives a very similar semantics.

- (13)  $\llbracket \text{a doubts that } \phi \rrbracket^{c,w,S,g}$
- a. defined iff  $\phi$ -verifiers in  $S' \neq \emptyset \wedge \phi$ -falsifiers in  $S' \neq \emptyset$ ;  
(uncertainty condition)  
if defined, =1 iff
  - b.  $\exists w' \in S' : \llbracket \phi \rrbracket^{c,w,S',g} = 1 \wedge$   
(doxastic assertion)
  - c.  $\wedge \phi$ -falsifiers  $>_{PROB_{a,w}}$   $\phi$ -verifiers  
(preference assertion)

Just like in the case of *hope* and *fear*, embedding necessity modals under *doubt*, as in *#John doubts that it must be raining*, generates a contradiction between the uncertainty presupposition (requiring that John's doxastic state be compatible with rain and no rain) and the doxastic assertion (that John's doxastic state entails that it must be raining). In the next section, I will discuss some challenges for Anand & Hacquard's proposal.

### 3. Challenges

There are two challenges that one might raise to challenge the type of proposal defended by Anand and Hacquard. The first problem concerns the analysis of attitude verbs that show a mixed behavior with respect to the embeddability of epistemic modals, i.e. emotive doxastic and dubitative attitudes. In particular, this problem challenges the uncertainty presupposition that is essential in Anand and Hacquard's story to derive the unacceptability of embedded necessity modals. The second problem is a more general worry about Yalcin's "copying" analysis of the embedded epistemic modals when applied to the cases introduced above. Let us begin with the **uncertainty presupposition problem**.

#### 3.1. The uncertainty presupposition problem

There is an immediate prediction that the uncertainty presupposition story makes, i.e. that a negated sentence with *doubt* should also carry the uncertainty presupposition. However, this prediction is not fulfilled, as (14) clearly shows.

- (14) John doesn't doubt that Mary will win the race. He is certain that she will.

Similarly for *fear*: a negated sentence with this attitude should still carry the presupposition that the subject's doxastic state is compatible with both the prejacent and its negation. However, (15) shows that this is not the case.

- (15) The police no longer fear that John's death was a homicide; they are certain that it was an accident.

One could argue that with negation, the uncertainty presupposition is locally accommodated to avoid inconsistency, along the lines of (16).

- (16) NOT(John is uncertain about whether Mary will win the race) John doubts that Mary will win the race.

The problem with this story is that we think of local accommodation as a "rescuing" mechanism, a mechanism that is called upon to avoid a contradiction. What is troubling about the (alleged) uncertainty presupposition is that it is *always* incompatible with the meaning of negated *doubt*, regardless of any explicit sentence contradicting it. Compare (14) to (17).

- (17) John doesn't doubt that Mary will win the race.

What (17) shows is that, if there is a contradiction, it is not caused by the continuation in (14) but by the meaning of negated *doubt* itself. Anand and Hacquard's uncertainty presupposition is anomalous in that it is never consistent with a negative assertion, a logical environment that we standardly take to be transparent to presuppositions. Nor can such a presupposition be detected in the other two environments we typically resort to to identify presuppositions.

- (18) a. A: Does John doubt that Mary will win the race?  
B: Not at all, he's certain that she will.

- (19) a. John might know that it is raining outside. But if he (still) doubts that it is, then he will open the window.

The conclusion is that the crucial piece of Anand and Hacquard's account of the distribution of necessity epistemic modals embedded under emotive doxastics and doubitives is problematic and, as such, it undermines the whole proposal.

### 3.2. Epistemic flavor

Suppose Mary's colleagues have just returned from a walk outside and they tell her that there is a snowstorm outside. Since it's July, Mary doesn't believe them and insists that it can't be true. They tell her to go to the nearest window and look outside. Mary does and sees the snowstorm. Her colleagues can report Mary's belief with (20b) but not with (20a).

- (20) a. #Mary finally believes that there must be a snowstorm outside.  
 b. Mary finally believes that there is a snowstorm outside.

Anand and Hacquard's story assumes a standard semantics for the epistemic modal, where the modal is treated as a quantifier over possible worlds restricted by an epistemic accessibility function (called "conversational background" in Kratzer's system) as shown in (21).

$$(21) \quad \llbracket \text{must} \rrbracket^{w,f} = \lambda p_{\langle st \rangle} . \forall w' \in \cap f(w) : [p(w') = 1]$$

The modal base of the modal is  $\cap f(w)$ , where  $f$  is the epistemic accessibility function. Combining this semantics with Yalcin's proposal that, when embedded, the modal base of an epistemic modal is inherited from the modal base of the higher attitude, it follows that, when embedded under an attitude verb, an epistemic modal loses its modal base and, therefore, its epistemic flavor as well. However, the contrast between (20a) and (20b) shows that this is inaccurate: the epistemic flavor of the modal is retained. It looks like we have a choice to make: either we abandon Yalcin's idea (as applied to the problem we are concerned about in this paper) or we abandon the standard semantics for the modal. In what follows I am going to explore the latter option. The tentative conclusion will be that this is not an unproblematic solution after all.

An obvious alternative to the standard semantics for epistemic *must* is the proposal in von Fintel and Gillies (2010), according to which *must* has a strong semantics (quantifies over all worlds in which the speaker's direct evidence is true) but carries an "unsettledness" presupposition, according to which the speaker's direct evidence does not settle the truth of the prejacent.

- (22) Strong *must* + Evidentiality.  
 Fix a  $c$ -relevant kernel  $K$ :  
 a.  $\llbracket \text{must } \phi \rrbracket^{c,w}$  is defined only if  $K$  does not directly settle  $\llbracket \phi \rrbracket^c$   
 b.  $\llbracket \text{must } \phi \rrbracket^{c,w} = 1$  if  $B_K \subseteq \llbracket \phi \rrbracket^c$   
 where  $B_K = \cap K$  and  $K$  whatever direct information is available to the speaker.

However, we are faced again with the challenge of presuppositions disappearing all too easily, as shown in (23) and (24b).

- (23) A: Do the police believe that the murderer might be a woman?  
 B: #Hey, wait a minute! The police don't believe that their evidence doesn't settle whether the murderer is a woman.  
 B': No, they have ruled that out.
- (24) a. John doesn't believe that the keys might be in the car.  
 von Fintel & Gillies:  $>>$  John believes that  $K_J$  does not directly settle whether the keys are in the car.  
 b. John doesn't believe that the keys might be in the car since he saw them on the kitchen table just now.

One might hold that (24b), just like the cases we discussed above, is acceptable because the unsettledness presupposition is locally accommodated in the scope of negation. However, consider the question below.

- (25) A: Does the detective believe that the murderer might be a woman?  
 a. B: Not at all. He is certain that the murderer is a man.  
 b. B: Yes. In fact, he is certain that the murderer is a woman.

Both answers are fine. A defender of the unsettledness presupposition could explain the possibility of the negative answer in (25a) as the result of local accommodation. But explaining the positive answer in (25b) is harder. Locally accommodating the presupposition in the scope of the question operator would generate the question in (26).

- (26) Is it the case that (**the detective believes that his evidence does not directly settle whether the murderer is a woman** and it is consistent with his doxastic state that the murderer is woman)

However, positively answering (26) entails “endorsing” the presupposition and as such it should be in contradiction with the continuation in (25b).

The conclusion is that (i) if we adopt a Kratzerian semantics for epistemic modals combined with the Yalcin/Anand & Hacquard semantics in (8) we cannot explain the contrast in (20) and (ii) if we adopt the semantics in (8) combined with a presuppositional story like the one proposed by von Stechow & Gillies, we run into the projection problems just described. The source of these difficulties is, I claim, the semantics in (8).

#### 4. Constraints on embedded V-to-C movement in German

This section is about embedded V-to-C sentences in German, an apparently unrelated phenomenon that shows restrictions very similar to the restrictions on embedding epistemic modals. The V-to-C data discussed in this paper are from Truckenbrodt (2006). The V-to-C phenomenon has some of the properties of what Dayal and Grimshaw call “quasi-subordination” clauses which show properties of both main and subordinate clauses (Dayal and Grimshaw (2009)). V-to-C clauses have also been said to have assertive illocutionary force (e.g. Gärtner (2002)). In what follows, we will look at V-to-C sentences embedded under four kinds of attitudes and operators. Following the classification established in the V-to-C literature, these four groups are: (i) doxastic and speech act verbs, (ii) desiderative verbs, (iii) negation and inherently negative verbs such as *doubt*, and (iv) emotive doxastic verbs such as *hope*. By looking at these two phenomena in parallel, we will see that embedded German V-to-C clauses pattern like epistemic modals with respect to groups (i) and (ii) but show a split behavior with respect to groups (iii) and (iv): embedded V-to-C patterns like possibility epistemic modals with respect to emotive doxastics but like necessity epistemic modals with respect to negative or negated attitudes. The first observation is that V-to-C clauses in German can be embedded under doxastic verbs, speech act verbs, and so-called verbs of cognition.

- (27) a. Maria glaubt, Peter geht nach Hause.  
 Maria believes, Peter goes to house  
 Maria believes that Peter is going home.
- b. Maria behauptet, Peter geht nach Hause.  
 Maria claims, Peter goes to house  
 Maria claims that Peter is going home.
- c. Maria träumt, Peter geht nach Hause.  
 Maria dreams, Peter goes to house  
 Maria dreams that Peter is going home.

V-to-C sentences cannot be embedded under desiderative verbs.

- (28) \*Maria will, sie ist in diesem Fall in Berlin.  
 Maria wants, she is in this case in Berlin  
 Maria wants to be in Berlin in that case.

V-to-C can occur embedded under an emotive doxastic predicate like *hoffen*, “to hope”. However, V-to-C cannot occur embedded under an inherently negative verb like *zweifeln*, “to doubt”, or under a negated attitude verb as in (30b).

- (29) Maria hofft, sie ist in diesem Fall in Berlin.  
 Maria hopes, she is in that case in Berlin  
 Maria hopes that she is in Berlin in that case.
- (30) a. \*Hans bezweifelt, Peter geht nach Hause.  
 Hans doubts, Peter goes to house  
 Hans doubts that Peter is going home.
- b. \*Hans glaubt nicht, Peter geht nach Hause.  
 Hans believes not, Peter goes to house  
 Hans doesn’t believe that Peter is going home.

In the remaining part of this section, I will summarize Truckenbrodt (2006)’s proposal for embedded V-to-C in German. With the German facts and his apparatus in place, I will then return to the topic of embedded epistemic modals and lay down my proposal in the next section. Truckenbrodt proposes that embedding a V-to-C clause in German requires that the embedding predicate make salient a set of worlds  $B_w(x)$  that represents  $x$ ’s doxastic (or doxastic-like) state in  $w$ , where  $x$  is the subject of the attitude. It also requires that the proposition  $p$  expressed by the embedded CP be entailed by  $B_w(x)$ . Following Gärtner (2002), Truckenbrodt also proposes an “absorption” requirement.

- (31) Absorption:  
 The meaning of attitude + CP must entail  $B_w(x) \subseteq p$ .

To see how the proposal works, we will look at a case of grammatical embedding of a V-to-C sentence and a case of an ungrammatical embedding. The grammatical one is illustrated in (32).

- (32) Maria glaubt, Peter geht nach Hause.  
 Maria believes, Peter goes to house  
 Maria believes that Peter is going home.

The two requirements introduced above are satisfied: (i) the predicate makes salient a set of doxastic-like words, i.e.  $DOX_w(Maria)$  (see (33a)); (ii)  $DOX_w(Maria)$  entails the proposition expressed by the embedded clause, i.e. that Peter is going home as shown in (33b).

- (33) a.  $B_w(x) = DOX_w(Maria)$   
 b.  $DOX_w(Maria) \subseteq (\lambda w'. \text{Peter is going home in } w')$

Since (32) asserts that Maria's doxastic state entails that Peter is going home ( $DOX_w(Maria) \subseteq (\lambda w'. \text{Peter is going home in } w')$ ), the assertion entails (33b) and Absorption is satisfied. A violation of Absorption is the cause of the unacceptability of V-to-C under an inherently negative verb like *bezweifeln*, "to doubt". *To doubt* (and the same applies to *bezweifeln*) is a "weak" predicate: according to Truckenbrodt, saying that *a doubts p* only requires *a*'s doxastic state to be compatible with *p*, something that we can represent as:  $DOX_w(Hans) \cap (\lambda w'. \text{Peter is going home in } w') \neq \emptyset$ . Hence, the assertion is weaker than what V-to-C requires, i.e. that Hans's doxastic state entails that Peter is going home.

To sum up, embedded V-to-C requires that the proposition expressed by the complement clause be entailed by the doxastic state of the subject of the embedding attitude verb and this requirement cannot be weaker than what the whole sentence (matrix clause + embedded clause) asserts. In the next section we will go back to the restrictions on embedded epistemic modals and, building on the strong similarities with the restrictions on embedded V-to-C in German and on some of the insights of Truckenbrodt's proposal, we will defend a proposal that accounts for the constraints on embedded epistemic modals.

## 5. Back to embedded epistemic modals

I assume a standardly weak semantics for epistemic modals, along the lines of Kratzer (1981), Kratzer (1991), and following Stephenson (2007), I treat epistemic modals as being judge dependent, where the judge parameter is manipulated by an embedding attitude verb. Epistemic modals (both necessity and possibility modals) carry a doxastic presupposition requiring that the judge be in a certain (to be specified) doxastic relation to the modal statement. When embedded under an attitude verb, the latter will bind the judge parameter of the embedded epistemic modal. As a result, the doxastic presupposition will require that the subject of the attitude verb (now identified with the lower judge) be in a certain doxastic relation to the epistemic complement.<sup>2</sup> The meaning for both epistemic *must*  $\phi$  and *might*  $\phi$  are given in (34) and (35): the necessity modal presupposes that the subject believe the modal proposition, whereas the possibility modal presupposes that the subject's doxastic state is compatible with the modal statement. Similarly to the Kratzerian entries above, EPI is the epistemic conversational back-

<sup>2</sup>It is possible to maintain that even "unembedded" occurrences of an epistemic modal are actually embedded under a covert ASSERT operator, along the lines defended in Alonso-Ovalle and Menéndez-Benito (2010), among others. In this case, the embedded judge parameter would end up coinciding with the speaker.

ground and ST is the stereotypical ordering source ranking the accessible worlds according to how close they are to a set of stereotypes holding in the actual world.<sup>3</sup>

(34)  $\llbracket \text{must } \phi \rrbracket^{c,w,t,j}$  is defined just in case  $DOX_j(w) \subseteq (\lambda w'. \text{must}_j(w')(\phi))$ ; if defined,  $\llbracket \text{must } \phi \rrbracket^{c,w,t,j} = 1$  iff  $\forall w'' \in ST_w(EPI_j(w)) : p(w'') = 1$

(35)  $\llbracket \text{might } \phi \rrbracket^{c,w,t,j}$  is defined just in case  $DOX_j(w) \cap (\lambda w'. \text{might}_j(w')(\phi))$ ; if defined,  $\llbracket \text{might } \phi \rrbracket^{c,w,t,j} = 1$  iff  $\exists w'' \in ST_w(EPI_j(w)) : p(w'') = 1$

To illustrate this part of the proposal, take the case of the attitude verb *believe*, as in *John believes that it must be raining*. The structure shows that the judge parameter for the epistemic modal is abstracted over so that it can be manipulated by *believe*. As a result of this operation, the judge parameter of the modal is bound by the subject of the doxastic attitude.

Following Gärtner's and Truckenbrodt's proposal, I will adopt a variant of their Absorption principle. As shown in (37), this principle requires that the meaning of the attitude + CP be at least as strong as the doxastic presupposition of the epistemic modal. This principle rules out cases where the doxastic condition is stronger than (asymmetrically entails) the assertoric meaning of the complex sentence.<sup>4</sup>

(37) *Absorption Principle*

The doxastic presupposition must not be stronger than the meaning of attitude + CP.

When the meaning of attitude + CP and the doxastic presupposition are inconsistent, the sentence can be rescued if it is possible to locally accommodate the presupposition.

In what follows, we will go through the three types of embedding predicates we discussed above: doxastic-like predicates, desiderative predicates; emotive doxastic and dubitative verbs.

<sup>3</sup>The proposal sketched in this section of the paper shares some features with the proposal in Crnič (2014). The two proposals were developed independently.

<sup>4</sup>I assume that cases where the presupposition and the assertion are inconsistent are ruled out on independent grounds.

### 5.1. Embedding epistemic modals under different types of attitude verbs

The doxastic type is unproblematic: recall the observation that both necessity and possibility modals can be embedded under this kind of predicate. Here is an example discussed above.

- (38) John believes that the keys must be in the car.

The doxastic presupposition is that  $DOX_J(w) \subseteq (\lambda w'. \text{the keys must be in the car in } w')$  and, since the assertion is the same, Absorption is satisfied and the doxastic condition is “absorbed”. Note that in this proposal, (38) both presupposes and asserts that John believes that the keys must be in the car. This is not unprecedented, though: for example, consider the following sentences.

- (39) a. The king of France exists.  
b. God exists.

- (40) If John believes that the king of France exists, ...

In (39a), assuming a presuppositional analysis of the definite article, the presupposition of the definite description is that there exists a King of France, and the assertion is that he exists. Assuming the view according to which proper names presuppose the existence of their reference, (39b) presupposes that God exists and it asserts just that. (40) is a different case. Here, the presupposition triggered again by the definite article is that a King of France exists and, since it is embedded under the attitude *believe*, it is John’s doxastic state that is required to entail that there exists a King of France: someone uttering the conditional antecedent in (40) would seem to be presupposing exactly the content of the antecedent itself. Since whether John’s doxastic state entails that a King of France exists is precisely the content of the conditional supposition, the presupposition has been argued to be suspended or locally accommodated. We leave the exact nature of this process aside. What we are interested here is merely pointing out that the identity of presupposition and assertion is not unique to (38).

The emotive doxastic and dubitative predicates are more challenging: they allow possibility but not necessity modals. Let’s begin with the former type.

- (41) a. John fears that Mary may/might have known the killer.  
b. #John fears that Mary must have known the killer.

I assume here that *to fear* has a doxastic assertoric component according to which *a fears that p* asserts that  $p \cap DOX_\alpha(w) \neq \emptyset$ . *To fear* also has a (un)desirability component (that *p* is less desirable than  $\neg p$  to the attitude’s holder) but since this component is not doxastic, I am leaving the issue of its precise status aside in the present discussion.<sup>5</sup> Now, let’s begin with the unacceptability of embedded *must*. As we can see in (42), the assertion (in (42a)) is weaker than the doxastic presupposition (in (42b)). Therefore, Absorption fails.

<sup>5</sup>One possibility is that the (un)desirability component of *fear* is presupposed. A question like (i) is interpreted as a question about the possibility of a certain eventuality (as in (a)) and not as a question about its desirability (as in (b)):

- (42) a.  $DOX_J(w) \cap (\lambda w'. \text{must}_J(w')(\lambda w''. \text{the keys are in the car in } w'')) \neq \emptyset$   
 b.  $DOX_J(w) \subseteq (\lambda w'. \text{must}_J(w')(\lambda w''. \text{the keys are in the car in } w''))$

Not with *might*, however. The doxastic presupposition (in (43b)) requires that John's doxastic state be compatible with the embedded clause; hence, it is not stronger than the assertoric content of *fear* + CP. In other words, the doxastic presupposition only requires that there be some doxastic worlds where the relevant evidence/knowledge is true and the keys are in the car. Embedding *might* under *to fear* satisfies Absorption because the presupposition is identical to the assertion in (43a).

- (43) a.  $DOX_J(w) \cap (\lambda w'. \text{might}_J(w')(\lambda w''. \text{the keys are in the car in } w'')) \neq \emptyset$   
 b.  $DOX_J(w) \cap (\lambda w'. \text{might}_J(w')(\lambda w''. \text{the keys are in the car in } w'')) \neq \emptyset$

Dubitative verbs such as *to doubt* show the same restrictions as emotive doxastic attitude verbs, i.e. they are compatible with possibility but not necessity epistemic modals.<sup>6</sup> The relevant examples are repeated below.

- (44) a. John doubts that Mary may/might have known the killer.  
 b. #John doubts that Mary must have known the killer.

I will assume that the doxastic assertoric content in a sentence like *a doubts that p* is that *a*'s doxastic state does not entail *p*:  $\neg(DOX_\alpha(w) \subseteq \phi) (\equiv \neg\phi \cap DOX_\alpha(w) \neq \emptyset)$ .<sup>7</sup> Let's begin with embedded *must*: as we can see in (45), Absorption fails because the assertion in (45a) and the doxastic presupposition in (45b) are inconsistent.

- (45) a.  $DOX_J(w) \cap (\lambda w'. \neg \text{must}_J(w')(\lambda w''. \text{the keys are in the car in } w'')) \neq \emptyset$   
 (it's doxastically possible that it is not epistemically necessary that the keys are in the car; i.e. it's possible that it is consistent with J's knowledge that the keys are not in the car)  
 b.  $DOX_J(w) \subseteq (\lambda w'. \text{must}_J(w')(\lambda w''. \text{the keys are in the car in } w''))$   
 (it is doxastically possible that it is epistemically necessary that the keys are in the car)

- (i) Do you fear that the Raptors will lose?  
 a. Do you think it's possible that the Raptors will lose?  
 b. Do you find it undesirable that the Raptors will lose?

The semantics for *fear* might then look like this:

- (ii)  $\llbracket \alpha \text{ fears that } \phi \rrbracket$  is defined only if  $\phi <_{DES, \alpha} \neg\phi$ ; if defined, = 1 if  $\exists w' \in DOX_\alpha(w) : \phi(w') = 1$

This would also explain the judgment in (15).

<sup>6</sup>It might be that *fear* and *be afraid* have slightly different semantics, but for reasons of space I cannot explore this possibility here.

<sup>7</sup>This seems a fairly weak semantics for *doubt* since intuitively an utterance of *a doubts that p* conveys that *a* believes *p* to be somewhat unlikely. Whether this "unlikelyhood" meaning should be part of the assertoric content of the sentence, is not clear. The verb *to doubt* seems to have an evidential component, which might be responsible for this stronger interpretation. A more detailed investigation of the meaning of this predicate is needed.

When the embedded modal is a weak modal (*might* or *may*), Absorption succeeds because the weakness of the modal weakens the whole doxastic condition, as shown in (46b).

- (46) a.  $DOX_J(w) \cap (\lambda w'. \neg(\text{might}_J(w'))(\lambda w''. \text{the keys are in the car in } w'')) \neq \emptyset$   
 b.  $DOX_J(w) \cap (\lambda w'. (\text{might}_J(w'))(\lambda w''. \text{the keys are in the car in } w'')) \neq \emptyset$

The doxastic presupposition in (46b) requires that John's doxastic state be compatible with it being epistemically possible that the keys are in the car, while the assertion in (46a) is that it is doxastically possible that the evidence/knowledge is incompatible with the keys being in the car. Since these two components are consistent and the doxastic presupposition in (43b) is not stronger than the assertion, Absorption is satisfied.

This correctly predicts that when *to doubt* is negated, embedding *must* is possible: the assertion is that John believes that it is epistemically necessary that the keys are in the car, and this is exactly what the doxastic condition requires. A similar situation arises with embedded *might*.

## 5.2. Back to embedded V-to-C

Recall that embedded V-to-C patterns like embedded epistemic modals with respect to doxastic verbs and desiderative verbs but shows a split with respect to the other categories. This is summarized again in (47).

- (47) a. V-to-C patterns like possibility epistemic modals when embedded under emotive doxastic verbs.  
 b. V-to-C patterns like necessity epistemic modals when embedded under inherently negative or negated attitude verbs.

One might try to capture the difference between German embedded V-to-C and embedded epistemic modals by proposing that embedded V-to-C in German requires Absorption to be weaker than what we proposed for epistemic modals.

- (48) a. Strong Absorption (epistemic modals): the doxastic presupposition cannot be stronger than the assertion.  
 b. Weak Absorption (V-to-C): doxastic presupposition and assertion must be merely compatible.

I have repeated the relevant examples in (49a) and (49b). Recall that in German, a V-to-C clause can be embedded under *hoffen*, “to hope”, but not under *bezweifeln*, “to doubt”.

- (49) a. Maria hofft, sie ist in diesem Fall in Berlin.  
 Maria hopes, she is in that case in Berlin  
 Maria hopes that she is in Berlin in that case.  
 b. \*Hans bezweifelt, Peter geht nach Hause.  
 Hans doubts, Peter goes to house  
 Hans doubts that Peter is going home.

Let us begin with (49b). If you doubt that  $p$ , the assertion is that  $\neg p$  is (doxastically) possible, while the doxastic presupposition that comes with the V-to-C configuration is that the subject believes that  $p$ . Assertion and doxastic condition are incompatible and Weak Absorption is not satisfied. Things are different with *hoffen*, “to hope”: if you hope that  $p$ , the assertion is that  $p$  is (doxastically) possible. Since this is compatible with the V-to-C doxastic presupposition that the attitude’s subject believes that  $p$ , Weak Absorption is satisfied.

### 5.3. Negated attitude verbs

Our next task is to look into the (un)acceptability of V-to-C in negated sentences and relate this discussion to the behavior of epistemic modals embedded under negated attitude verbs. The following German sentence with negation is judged unacceptable in Truckenbrodt (2006).

- (50) \*Hans glaubt nicht, Peter geht nach Hause.  
       Hans believes not, Peter goes to house  
       Hans doesn’t believe that Peter is going home.

However, other sentences with negation are judged fine by the same author. In (51) we have a periphrastic negative form.<sup>8</sup>

- (51) Es ist nicht der Fall dass Hans glaubt Peter geht nach Hause.  
       it is not the case that Hans believes Peter is going home  
       It is not the case that Hans believes that Peter is going home.

As for English, epistemic modals embedded under negated *believe* seems acceptable in most contexts.<sup>9</sup>

- (52) After reviewing the evidence, the police no longer believe that it must/might be a homicide.

This is especially interesting when one compares the acceptability of (52) with the (relative) unacceptability of *doubt* + *must*. The puzzle is the following. We have argued that embedding a necessity epistemic modal under *doubt* violates (Strong) Absorption because the doxastic condition is inconsistent with the assertion. Therefore, embedding *must* under negated *believe*

<sup>8</sup>Judgments improve also if negation is in the quantifier *niemand* as in the following response to the question *Who believes that Peter is going home?*:

- (i) NIEMAND glaubt, Peter geht nach Hause.  
       nobody believes Peter is going home  
       NOBODY believes that Peter is going home

<sup>9</sup>There is variability in the judgments with negation. For example, some speakers accept (i) but find (ii) rather odd:

- (i) I believe that it must have been hard to write on epistemic modals.  
       (ii) I don’t believe that it must have been hard to write on epistemic modals.

Hopefully, the accommodation story that we will tell can help towards explaining this variability.

should also fail Absorption since the assertion (that the subject does not believe  $p$ ) is inconsistent with the doxastic condition (that the subject believes  $p$ ). One way to resolve this tension is to propose that, when Absorption is not met, the last resort is to locally accommodate the presupposition, *if possible*. In the cases we are considering here, what rescues embedding *must* under a negated *believe* is the possibility of locally accommodating the doxastic presupposition in the scope of negation. However, this possibility does not seem available to inherently negative verbs like *doubt*, as the following contrast shows:

- (53) a. Mary doesn't believe that John quit smoking because she knows that he is not a smoker.  
 b. ??Mary doubts that John quit smoking because she knows that he is not a smoker.

The last example suggests that, unlike negation, the inherent negative component of the verb *doubt* cannot be targeted for local accommodation. The contrast between (50) and (51) in German could be construed as also stemming from the possibility of locally accommodating the doxastic condition with the periphrastic form *es ist nicht der Fall dass* but not with postverbal *nicht*. However, more research on this is needed.

#### 5.4. Desiderative attitude verbs

As noted by many already, neither necessity nor possibility epistemic modals can be embedded under desiderative verbs like *want* and directive verbs like *demand*.

- (54) a. John wants the keys to have to be in the car. (\*epistemic)  
 b. #John demanded that Mary must have been the murderer.

As we saw above, this contrasts with emotive doxastic *to hope* which can embed possibility epistemic modal *might* (but not necessity *must*; cf. (3) and (4)).

Anand and Hacquard attribute the impossibility of embedding epistemic modals under *want* to the non-representational nature of this attitude verb, which they claim only has a desiderative (ranking) semantics, as shown in the entry below from Anand and Hacquard (2013).

$$(55) \quad \llbracket \mathbf{want} \rrbracket^{c,w,g} = \lambda p. \lambda x. \forall q \in g(C) \setminus p : p >_{des_{x,w}} q$$

This move is problematic, though, since we know that it is possible, and in fact even advisable, to provide a semantics for *want* which includes a doxastic component (Stalnaker (1984), Asher (1987), Heim (1992)). Below is a possible entry for *want*, modeled after Heim (1992). There is no reason to believe that the subject's doxastic state would not be made salient by (56).

$$(56) \quad \llbracket \mathbf{want} \rrbracket^{c,w,g} = \lambda p. \lambda x. (DOX_x(w) \cap p) <_{DES_{x,w}} (DOX_x(w) \cap \neg p)$$

There is, however, an interesting difference between *to hope* and *to want* which might be relevant in explaining their different behavior with respect to the embeddability of epistemic

modals. Consider the following examples.

- (57)
- a. John wants Mary to win the game.
  - b. John wants Mary to have won the game. (somewhat strange)
  - c. John hopes that Mary will win the game.
  - d. John hopes that Mary won the game.

*Want*, but not *hope*, is typically future-oriented (and more agentive), and if (57b) is acceptable at all, the verb *want* seems to be interpreted as synonymous to *hope* (with no agentivity and no futurity). Note that the majority of verbs that do not allow embedded epistemic modals have a future orientation: desiderative verbs (*want*, *wish*); directive verbs like commands (*command*, *order*), permissions (*allow*, *permit*), and prohibitions (*forbid*, *ban*); “future” verbs like *promise*. Note as well that if a “future” verb can take a non-future complement, then it does allow an epistemic modal (*expect*, *guess*).<sup>10</sup> Thus, what would explain the incompatibility of *want* and epistemic modals is not the lack of a representational component but its future orientation, which is somehow incompatible with epistemic modal verbs.<sup>11</sup>

## 6. Open questions and conclusion

One phenomenon that seems to share some features with embedded epistemic modals is *slifting* (Ross (1975), Grimshaw (2011), Reis (1996), Wagner (2004)) illustrated in the following example from Grimshaw (2011).

- (58) Mary, they say / I’m sure / it’s clear / the teacher explained to me, is a talented singer.

The phenomenon of slifting has been already connected to embedded V-to-C by Scheffler (2009): V2 embedding and slifting are possible with verbs of saying, belief, and verbs like *hope* and *fear*; neither one is possible with factive verbs, downward epistemic verbs, desiderative verbs like *want*, and negative verbs like *doubt*. One of the contributions of the present paper is to highlight that the constraints on embedded V-to-C (and slifting) show striking similarities to the constraints on the embeddability of epistemic modals. One open question is whether the proposal defended here can be extended to the slifting cases. A second issue that one might explore in the future is the issue of cross-linguistic differences. Anand and Hacquard’s paper offered some cross-linguistic experimental data but there is more variability than is conceded by the generalizations the authors take their data to support. The strongest variability I found is in the area of emotive doxastic and dubitative verbs. In addition to finding that a not marginal number of English speakers accept necessity epistemic modals under *hope*, *fear*, and *doubt*, I have encountered varieties of languages that accept necessity epistemic modals under *fear* and *doubt*. Below are some examples from Russian and Bengali. The acceptability contrast between (59a) and (59b) in Russian correlates with the different modal expression in the em-

<sup>10</sup>One might follow Abusch (2004) and her treatment of futurate predicates in assuming that the LF representation in (ia) for the complement of future oriented attitudes contains a future shifting operator as in (ib).

- (i)
- a. *want*:  $[_{CP} \lambda n [_{IP} n [_{FUT} [_{CP} \lambda n [_{IP} n VP]]]]]$
  - b.  $[[\mathbf{FUT}]] = \lambda P. \lambda t. P((t, \infty))$

<sup>11</sup>See Homer (2010) for more on the relation between epistemic modals and tense operators.

bedded clause: in (59b) an adverbial form is used. Note, also, that the modal expression used in Bengali is also adverbial.<sup>12,13</sup>

(59) Russian

- a. ??Ivan somnevaetsja chto Masha dolzhna byt' doma  
 Ivan doubts-refl that Masha must-F-sg to-be home  
 John doubts that Mary must be home
- b. Ivan somnevaetsja chto Masha dolzhno byt' doma  
 Ivan doubts-refl that Masha must-Adv(N-sg) to-be home  
 John doubts that Mary must be home.

(60) Bengali

- a. Johner bhoe Ø je niscoi norohotto hoeche  
 John-gen fear COP COMP certainly homicide happen-Pfv-3.pres  
 John is afraid that a homicide must have occurred.

To conclude, I have shown that the restrictions on which attitude verbs can embed epistemic modals bear a strong resemblance to the restrictions on embedded V-to-C movement in German, and that these two phenomena can be given similar explanations. I have proposed that epistemic modals presuppose that their judge (the owner of the epistemic state we quantify over) believes the modal claim. When embedded under attitude verbs, the judge parameter of the epistemic modal is bound by the attitude's subject and, as a result, it is the attitude's subject that is required to believe the embedded modal statement. I argued that the semantics proposed by Anand and Hacquard (2013) for emotive doxastic and dubitative verbs to explain the impossibility of embedding necessity epistemic modals is problematic. Instead, I have argued that Absorption can explain these restrictions once a minimal semantics for these attitude verbs is assumed. A weaker Absorption principle explains the restrictions on embedded V-to-C in German. Open questions remain, in particular about the incompatibility between future operators and epistemic modals (as discussed in the section on desiderative verbs), the relation between embedded epistemic modals/V-to-C and slifting, the behavior of factive predicates (which we haven't talked about in this paper), as well as the nature of Absorption itself.

# The temporal presuppositions of Somali definite determiners<sup>1</sup>

Rudmila-Rodica IVAN — *University of Massachusetts, Amherst*

Deniz ÖZYILDIZ — *University of Massachusetts, Amherst*

**Abstract.** Nominal temporal markers (NTMs) locate the time at which the property or relation denoted by a nominal holds of an entity (Enç, 1981). What distinguishes Somali from other languages with overt NTMs is that these markers are also definite determiners. We follow up on the observation that there is a contrast in the interpretation of definite determiners -KA and -KII, and propose that this contrast is a difference in the scalar implicatures triggered by each determiner. This difference is linked to an interaction between the temporal presuppositions of -KA and -KII and the lexical semantics of their NP complement. Our analysis captures the fact that these determiners do not obey common diagnostics of “nominal tense” (Tonhauser, 2007), while accounting for the data in Lecarme (1996) as well as the more recent proposal (Lecarme, 2008, 2012) that -KII and -KA track the (in)visibility of the entity denoted by the DP.

**Keywords:** Somali, determiners, definiteness, nominal TAM, presupposition

## 1. Introduction

The aim of this paper is to explain the contrast between what has been described in the literature as the “regular” definite determiner -KA (Green et al., 2015) and the “remote,” “tensed” or “evidential” definite determiner -KII (Lecarme, 1996, 2008, 2012) in Somali. A comparison between Somali -KII and Guaraní *-kue*, as discussed in Tonhauser (2007), illustrates that the current take on nominal temporal markers (NTMs) cannot fully account for the Somali data. We propose that a scalar implicature based account, in line with the work of Thomas (2014) for Mbyá Guaraní, and Altshuler and Schwarzschild (2013) on cessation implicatures in English, can capture the semantic contribution of Somali -KII. Our account relies on novel data involving contexts where this contrast obtains, and ones where it does not.

The choice between -KA or -KII for Somali nominals can give rise to temporal interpretations, as well as to (in)visibility readings, by which we mean that the denotation of the DP is judged to be visible or invisible to the discourse participants. We claim that these contrasts are due to a competition between -KA and -KII. Assuming that Somali NTMs behave like a regular tense system, similarly to Mbyá Guaraní (Thomas, 2014), we propose that -KA requires the NP predication to be true of an individual at topic time, while -KII requires it to be true at some salient time preceding topic time. Based on the *Open Interval Hypothesis* proposed by Altshuler and Schwarzschild (2013) (see also Cable 2017), whereby a present stative sentence asymmetrically entails its past tense variant, we assume that a sentence with a -KA marked nominal asymmetrically entails a sentence with its -KII marked counterpart. Thus, the use of -KII generates the implicature that the -KA alternative is false, resulting in the aforementioned

---

<sup>1</sup>We would like to thank our very patient informants, the audiences at the *UMass Funny Languages Afternoon* (02/19/2016), the *UMass Semantics Workshop* (03/08/2016), the *Definiteness Across Languages* workshop (Mexico City, June 24–26 2016), *Triple A 3* (Tübingen, July 4–6 2016) and *Sinn und Bedeutung 21* (Edinburgh, September 4–6 2016), and, naturally, Rajesh Bhatt, Seth Cable, Veneeta Dayal, Vincent Homer, Florian Schwarz, and Kristine Yu for their comments, helpful discussion and feedback, and for sparking our interest in this project.

interpretative contrasts. We speculate that contexts where the contrasts are not observed are ones where the relevant implicatures are not generated.

The paper is structured as follows. Section 2 provides background information regarding the elicitation, novel data confirming that both -KA and -KII pattern like definite determiners, and the core data regarding the relevant semantic contrasts between the two determiners. Section 3 focuses on nominal tense as discussed in the literature and on the key properties of nominal temporal markers identified by Tonhauser (2007) for Guaraní, namely precedence, change of state and existence. Section 4 discusses novel data which illustrate that two of three properties of Guaraní *-kue*, change of state and existence, do not hold of Somali -KII. In section 5, we present the core generalization and argue in favor of a competition based account for the two Somali definite determiners. Section 6 concludes.

## 2. Background Information

### 2.1. Elicitation

The data discussed in this paper was mainly collected from a primary consultant, who self reports as a native speaker of Standard Somali. The elicitations took place at the East African Cultural Center (EACC) in Springfield, Massachusetts, between September 2015 and May 2016. Four other occasional attendees of the EACC contributed on site, and a linguistically trained native speaker from Minnesota contributed by e-mail.

### 2.2. The definiteness of -KA and -KII

Somali has two noun classes, referred to in the literature as the masculine and the feminine (Saeed, 1993, 1999; Green et al., 2015). Masculine nouns are suffixed with morphemes whose initial segment is /k/ (phonologically realized as [k], [g] or [h] and noted K) as shown in (1a). As illustrated in (1b), for feminine nouns the initial segment of the suffix is /t/ (phonologically realized as [d], [dh], [sh] and noted T). All of the instances of the allomorphs in (1) are referred to as -KA and -KII throughout the paper.

- (1) a. *aqal-ka, aqal-kii, telefoon-ga, telefoon-gii*  
       house-KA house-KII telephone-KA telephone-KII  
       the house, the telephone (masculine)  
       b. *shimbir-ta, shimbir-tii, qorrax-da, qorrax-dii*  
       bird-KA bird-KII sun-KA sun-KII  
       the bird, the sun (feminine)

As previously mentioned, both -KA and -KII are claimed to be definite in the literature (Saeed, 1993; Lecarme, 1996; Green et al., 2015). Our data confirms that -KA and -KII marked nominals pattern like definites; consequently, for the purposes of this paper, they will be referred to as definite determiners. For a different take on definiteness in Somali and for arguments in favor

of the existence of a null definite determiner which is taken to be responsible for the definite interpretation of the nominals suffixed with -KA and -KII, see Özyıldız and Ivan (2017).

According to Heim (1983) and Matthewson (1998), definite noun phrases refer to familiar, previously introduced discourse referents. This holds true of both -KA and -KII marked NPs, as shown in example (2). Both definite determiners allow anaphoric reference to the boy introduced in the preceding piece of discourse.

(2) ANAPHORIC REFERENCE

Context: *A boy and a girl came. The boy laughed.*

- a. Wiil iyo gabadh baa yimid. Wiil-**kii** baa qoslay.  
boy and girl FOC came. boy-KII FOC laughed
- b. Wiil iyo gabadh baa yimid. Wiil-**ka** ayaa qoslay.  
boy and girl FOC came. boy-KA FOC laughed  
'A boy and a girl came. The boy laughed.'<sup>2</sup> [03/19/2016]

Furthermore, both -KA and -KII can refer to unique NPs in both immediate and larger situations. In (3), where the sun is a unique entity, the use of either determiner is grammatical.

(3) REFERENCE TO UNIQUE NPS

Context: *Axmed was working home all day. He decides to go out and sees the sun.*

- Marku baxay wux-uu arkay qorrax{-**ka/-kii**}.  
when went out FOC=3S saw sun-KA/-KII  
'When he went out, he saw the sun.' [03/07/2016]

According to Schwarz (2009, 2013), in languages with multiple definite determiners, these determiners can be either *weak* or *strong*.<sup>3</sup> Weak definite determiners cannot be used anaphorically, only being able to refer to NPs that are unique in the context, while strong definite determiners can also have anaphoric uses as in (2). The fact that both -KA and -KII are grammatical in example (2), which tests for anaphoricity, and (3), which tests for non-anaphoric reference, suggests that the strong/weak determiner distinction is not at play in regulating the distribution of Somali definite determiners. The difference between the two seems to lie elsewhere.

### 2.3. Core data

Work by Lecarme (1996, 2004, 2012) argues that -*kii* is a “tensed” determiner denoting the past tense (for arguments against this analysis, see Tonhauser (2006: pp. 325–333)). The temporal analysis of -KII is motivated by data like (4) (Lecarme, 1996: ex. (10), p. 161), where -KA is ungrammatical when referencing a past year. Lecarme argues that *sannad-kii* receives a temporal past interpretation, thus rendering it ungrammatical with future-oriented adverbials.

<sup>2</sup>It should be noted that different focus markers are used in the two subexamples. We speculate that this difference is due to the fact that the counterpart of (2a) with -KA, *wilka baa*, is morphologically ill-formed.

<sup>3</sup>This is not the weak/strong determiner distinction from Barwise and Cooper (1988).

- (4) a. sannad-**ka** *dambe*  
 year-KA next  
 ‘next year’
- b. sannad-**kii**/\*-**ka** *hore*  
 year-KII/\*-KA before  
 ‘last year’

Lecarme (1996, 2012) notes that -KII can also have temporal interpretations on nouns denoting a set of individuals, such as ‘student.’ We replicated this effect with the NP ‘president.’ In a context where Barack Obama is the current president, like in (5), the DP *madaxweynaha*, which bears -KA, may only refer to Obama, and not to Bush—who was the salient former president in the context. On the other hand, *madaxweynihii*, with -KII, may only refer to Bush, and not to Obama. Both sentences in (5) were judged true with this reference scheme. They were judged false when -KII was used in (5a) and -KA, in (5b).

(5) TEMPORAL CONTRAST between -KA and -KII

Context: *The year is 2016 and Barack Obama is the president of the United States.*

- a. Madaxweynaha wux-uu ku nool yahay guriga cad.  
 president-KA FOC=3S at lives house white  
 ‘The president lives in the White House.’ ≈ **Barack Obama**
- b. Madaxweynihii wux-uu ku nool yahay Texas.  
 president-KII FOC=3S at lives Texas  
 ‘The president lives in Texas’. ≈ **George Bush** [01/30/2016]

Lecarme (2012) also identifies a “modal” or “evidential” contrast between -KA and -KII, whereby visible entities are marked with the former and invisible entities with the latter. This effect was replicated in our elicitations. In the context of a solar eclipse, the use of -KA on the NP ‘sun’ implies that the sun is in plain sight, whereas the use of -KII implies that the sun is eclipsed.

(6) VISIBILITY CONTRAST between -KA and -KII

Context: *During a solar eclipse. Answer to “What are you doing?”*

Wax-aan fiirinayaa cadceed-**da**/-**dii**.

FOC=1S watching sun-KA/-KII

I’m watching the sun.

- a. Inference with -KA: The sun is visible.
- b. Inference with -KII: The sun is eclipsed.
- c. -KII is odd if the sun is visible; -KA is odd if the sun is eclipsed. [01/30/2016]

The use of -KII on an NP corresponding to a temporary state, like ‘rain,’ gives rise to the same effect. If the rain is ongoing and visible, then only -KA is felicitous.

(7) Context: *It’s raining and I’m outside.*

Roob{-**ka**/#-**kii**} baan eegayaa

rain-KA/-#KII FOC=1S watching

I’m watching the rain.

[05/11/2016]

We argue that a unified account can generate both the temporal and the invisibility readings presented in the examples above. Our proposal is laid out in Section 5. The next two sections give an overview of the properties of NTMs and argue that Tonhauser (2007)'s seminal account of Guaraní NTMs cannot be extended to Somali -KII.

### 3. Properties of nominal tense

The current section introduces the notion of NTMs and outlines the three properties identified by Tonhauser (2007) based on the future (-*rã*) and past (-*kue*) nominal markers of Guaraní. These three properties are *precedence*, *change of state* and *existence*.

#### 3.1. Nominal Tense

An important first observation is that both NPs and VPs can locate the time at which a property is true of an individual. For instance, in (8), the past tense 'watched *Harry Potter*' indicates that the activity is true of *x*, at some interval of time, *t*, which is a subpart of *yesterday*. On the other hand, 'linguistics grad student' is true of *x*, at some time, *t'*, which includes *yesterday*, the property of being a linguistics grad student generally spanning from 2 to 5 years.

(8) *Yesterday*, a linguistics grad student *watched* Harry Potter.

In (8) there is an overlap between the time interval at which *x* is a *linguistics grad student* and the time interval during which *x watches Harry Potter*. However, NPs and VPs within the same sentence need not hold true at the same time. Consider (9) where, in a context where all of the contextually relevant individuals stop being students, the property of being a 'student' was true of the individuals in every's restrictor before utterance time, and it is false at utterance time.

(9) Every student is now a UMass graduate.

The observation that verbal tense does not affect the temporal interpretation of noun phrases was first made by Enç (1981). She proposed that this can be captured by means of *nominal tense*. One morphological realization of nominal tense and aspect is represented by the morphemes in (10) which restrict the time interval at which the nominal they attach to is true.

(10) *ex-soldier, former friend, future president, wife-to-be*

Although subtly distinct from the phenomenon illustrated in (9), the affixes and adjectives in (10) point to the core intuition: the time at which the property (*soldier, friend, president, wife*) holds true of the individual is either before (*ex-, former*), or after (*future, -to-be*) topic time. According to Wilschko (2003), semantic nominal tense is universal; the crosslinguistic difference lies in whether nominal tense is syntactically marked. In fact, overt nominal TAM (tense and aspect morphology) is rare. Nordlinger and Sadler (2004) list twelve different languages which exhibit NTMs (Lake Miwok, Halkomelem, a.o.). Somali (Lecarme, 1996), Guaraní (Tonhauser, 2007) and Tsou (Chang, 2015) are ones that have been discussed more extensively.

### 3.2. Guaraní nominal TAM

Tonhauser's (2006; 2007) seminal account of nominal temporal markers in Guaraní discusses the morphemes *-kue* and *-rã*. Tonhauser argues that they are nominal *aspectual* markers and identifies three properties which NTMs might be expected to display cross-linguistically. The example below illustrates that Guaraní makes use both of a future nominal temporal marker, *-rã*, and of a past one, *-kue*. It should be noted that the example, glosses and translation below are taken from Tonhauser (2007), and that the two NTMs are not equivalent to the English adjectives *future* and *former*, the Guaraní nominal temporal markers having a wider use than their English counterparts.

- (11) Juan ha'e pa'i-**kue/-rã**.  
 Juan 3.PRON priest-KUE/-RA  
 'Juan is a former/future priest.' (Tonhauser (2007), ex. (8), page 836)

To capture the different properties of Guaraní NTMs, Tonhauser (2007) distinguishes between two main intervals: the NP time,  $t_{NP}$ , and the nominal time,  $t_{nom}$  (or possessive time,  $t_{poss}$ ). The NP time represents the evaluation time of the entire NP, the time at which the phrase is interpreted. This generally picks out topic time. The other relevant interval  $t_{nom}$  (or  $t_{poss}$ ) is the time at which the property (or relation) expressed by the noun phrase is true of the individual(s) in the relevant domain (or, in the case where the NP is relational, is true of the members of the relation). As previously mentioned, Tonhauser (2007) argues that nominal temporal (or aspectual) markers have three properties: *precedence*, *change of state* and *existence*, which are described in terms of the relations between  $t_{nom}$  and  $t_{NP}$ . These properties are outlined in the following subsections.

#### 3.2.1. The precedence meaning property

Perhaps the most salient meaning property of NTMs in general and of *-kue* and *-rã* is that they encode a precedence relation: respectively a past-time oriented relation and a future-time oriented one. In (12), the use of *-kue* conveys that the time at which the property of being a *priest* holds true of the individual precedes  $t_{NP}$ , while the use of *-rã* conveys that the predicate holds true of the individual after  $t_{NP}$ , and, consequently, after topic time.

- (12) PRECEDENCE RELATIONS
- |                                      |                    |           |
|--------------------------------------|--------------------|-----------|
| a. priest-KUE $\approx$ past priest  | $t_{nom} < t_{NP}$ | before TT |
| b. priest-Rã $\approx$ future priest | $t_{nom} > t_{NP}$ | after TT  |

In the case of possessives, the precedence relation can apply either to the possessive or to the nominal itself. In (13), for instance, which is adapted from Tonhauser (2007), both the Guaraní *che-róga-kue* and the English *my former house* are ambiguous between two possible readings. One interpretation is that the possessive time is located at  $t_{NP}$  (in this case, utterance time) and the nominal time,  $t_{nom}$ , precedes  $t_{NP}$ ; in this instance, the speaker is looking at the ruins of their house. The second reading is one where  $t_{nom}$  overlaps with  $t_{NP}$ , but  $t_{poss}$  is located prior to the noun phrase time; here, the speaker is looking at a building which was once their house.

(13) Ko'agã a-hecha che-róga-**kue**.

now SG-see SG-house-KUE

'I am seeing my former house.'

(Tonhauser, 2007: ex. (12), p. 838)

All of the occurrences of *-kue* discussed in this section are paralleled by similar examples with future-oriented NTM, *-rã*. However, we will henceforth only refer to examples with *-kue*, as Somali does not have a future oriented nominal temporal marker.

### 3.2.2. The change of state meaning property

Much like the English *former*, Guaraní *-kue* also encodes a change of state meaning, namely, the NP predication (or relation) ceases to hold true of an individual *x* before  $t_{NP}$  (or topic time).

- (14) a. \*Albus is a *former* teacher and he is *still* a teacher  
 b. Albus is a *former* teacher and now he's a teacher *again*

The examples in (14) (which can also be replicated for Guaraní *-kue*, see Tonhauser (2007: exx. (13/14), p. 838)) illustrate that the nominal predication, *teacher*, is true prior to  $t_{NP}$  and that it *ceases* to be true prior to  $t_{NP}$ . Furthermore, (14b) shows that neither the English *former* nor the Guaraní *-kue* encode that the property is *not* true at  $t_{NP}$ , but merely that it had stopped being true sometime before noun-phrase time. Albus can be a former teacher and a current teacher, the predication need not be false at  $t_{NP}$ .

Tonhauser (2007) points out that although both *-kue*, *former* and English past tense have the precedence meaning property, only the first two have the change of state property. The first utterance in (15) merely implicates that Hermione is no longer in the Hospital Wing at the time of utterance. The fact that *still* is felicitous in the second utterance illustrates that English past tense, unlike *former* or Guaraní *kue* does not semantically encode a change of state.

- (15) Hermione was in the Hospital Wing last week. She is *still* there today.

The observation that Guaraní *-kue* is *not* like English past tense in this instance serves as an argument for Tonhauser (2007) in favor of the view that *-kue* and *-rã* are *aspectual* nominal markers, and not tensed. We will return to this fact in section 4, where we compare Guaraní nominal TAM to Somali -KII.

### 3.2.3. The existence meaning property

The third property of NTMs identified by Tonhauser (2007) is that of existence, which assumes that both  $t_{nom}$  and  $t_{np}$  should fall within the time of existence of the individuals denoted by the noun phrase. This would account for the infelicity of *-kue* in the context below.

(16) Context:

*The town of San Isidro once had a priest called Jose. This man died as a priest.*

#pe pa'i-**kue** Jose

that priest-KUE Jose

'that ex-priest Jose'

(Tonhauser, 2007: ex. (21), p. 842)

It should be noted that English *former* is also not felicitous in (16). The intuition is that the property of being a *former* priest was never true of *Jose* while he was alive. The only context in which 'priest'-*kue* would be felicitous is one where *Jose* stopped being a priest while alive.<sup>4</sup>

3.2.4. Summary: -*kue* properties

To reiterate, Tonhauser (2007) proposes that there are three distinct properties which are true of Guaraní nominal temporal markers. These properties are summarized below.

(17) *NTM properties*

1. PRECEDENCE:  $t_{\text{nom}} / t_{\text{poss}}$  precedes  $t_{\text{NP}}$  (topic time)
2. CHANGE OF STATE: the property or relation ceased to be true before  $t_{\text{NP}}$
3. EXISTENCE: the time of the existence of  $x$  includes  $t_{\text{nom}}$  and  $t_{\text{NP}}$

According to Tonhauser (2007), these three properties are individually encoded in the lexical entry of -*kue*. The lexical entry for -*kue* as applied to property NPs is given below.<sup>5</sup> The formal semantic analysis below, applied to the denotation of predicates, establishes that for all properties  $P$  and entities  $x$ , the property  $\text{KUE}(P)$  is true of an individual,  $x$ , at the noun-phrase time,  $t_{\text{NP}}$ , in a world  $w$  if and only if there is a time  $t$  that precedes the noun phrase time and  $t$  is the situation time of  $P(x)$  in world  $w$  and the noun phrase time is included in the lifetime of  $x$ .

$$(18) \quad \forall P \forall x [ \text{KUE}(P)(x) = 1 \text{ at } t_{\text{NP}} \text{ in } w \text{ iff } \exists t_{\text{nom}} [ \\ t_{\text{nom}} < t_{\text{NP}} \ \& \ \tau(P(x)) = t_{\text{nom}} \text{ in } w \ \& \ t_{\text{NP}} \subseteq \tau(x) ] ]$$

Before moving on to the next section, it should be noted that both *existence* and *change of state* are hardwired into the lexical entry of -*kue*. For the intents and purposes of this paper, -*kue* behaves like English 'former,' but, as Tonhauser (2007) points out, this is a simplification.

4. Somali -KII vs. Guaraní -*kue*: -KII is not 'former'

This section tests whether the properties identified by Tonhauser (2007) for Guaraní -*kue* hold of Somali -KII. The data illustrate that although -KII has the precedence meaning property, it does not semantically encode the change of state or the existence properties. In this sense, -KII is different from -*kue* and English 'former.' Furthermore, we show that, unlike -*kue*, Somali -KII does behave like tense and it can give rise to temporal and invisibility implicatures.

<sup>4</sup>On the other hand, -*kue* would be felicitous in the context in (16) if it applied to a possessive relation: 'our priest'-*kue* would denote a possession relation which ceased to be true.

<sup>5</sup>The definition of -*kue* for possessive relations is similar.

#### 4.1. Lack of the *existence* property

The existence property refers to the fact that Guaraní *-kue* is not felicitous in contexts like the one in (16), where the property of being a priest held true of an individual right up to the moment of their death. We attempted to replicate this finding with our Somali consultants. The expectation was that if *-KII* had the existence property, a sentence like (19) would be infelicitous in the context given, with *-KII* on the subject NP.

(19) Context: *Uttered right after the current president's death...*

madaxweyni-**hii**/madaxweyna#-**ha** wuu dhintay  
 president-KII/president-KA FOC=3S.M died  
 'The president died.' [01/30/2016]

The example above illustrates that in a context where the individual picked out by the current 'president' dies *as* a president *-KII* is, in fact, felicitous. This is unexpected if *-KII* were to have the same meaning as Guaraní *-kue* and had the existence property. Furthermore, it seems that *-KA* is infelicitous in (19), presumably because there is no president in the context.<sup>6</sup> Nevertheless, the data shows that Somali *-KII*, unlike Guaraní, does not have the existence property.

#### 4.2. Lack of the *change of state* property

As shown in Section 3.2.2, the property of the NP that *-kue* attaches to ceased to be true of the individual picked out by the nominal prior to the noun phrase time. In contrast, the examples in this section suggest that *-kii* does not *obligatorily* trigger a change of state inference.<sup>7</sup> The context and item in (20) are replicated from Tonhauser (2007: ex. (44)).

(20) Context: *Yesterday I went to a bike shop and out of all of the bikes they had I chose one for my sister. I didn't have enough money yesterday. Tomorrow I'll go back to the shop and buy the bike I chose.*

Baskiil-**ka** / Baskiil-**kii** bari baan gadanaya  
 bike-KA / bike-KII tomorrow FOC.1S buy.FUT  
 'I will buy the bike tomorrow.' [11/04/2015]

According to Tonhauser (2007), in Guaraní the change of state interpretation in the context in (20) is necessary. For her consultants, 'bike' *-kue* may only refer to a broken bike (which renders the target sentence odd in the scenario above). In Somali, both *baskiil-ka* and *baskiil-kii* are perfectly felicitous and refer to a bike which had been previously introduced in the discourse. No change of state inference is drawn in this context. Further attempts to favor Guaraní-type change of state meanings on object denoting NPs were unsuccessful.

<sup>6</sup>Our primary informant comments: "If he died, you cannot say [*k*]a."

<sup>7</sup>There is a subtle difference between "change of state" (predication ceased to be true before but may be true again at topic time) and "cessation" (predication ceased to be true and is still not true at topic time) inferences (Altshuler and Schwarzschild 2012, Thomas 2014).

- (21) Context: *Shards of a broken jar are set on the table.*

Dhala-day-**dii** \*(jajabkee-**dii**) miiska ayuu saaran yahay

jar-POSS.1S-KII \*(shards-KII) table-KA FOC on is

‘The shards of my jar are on the table.’

Intended: ‘My (broken/former) jar is on the table.’

[01/30/2016]

The aim of the scenario above was to get our informants to express that an object was broken solely through the use of -KII. For the purposes of this elicitation task, a broken jar was brought into the elicitation session and set in plain view, on the table between the authors and the informant. It was found that the possessive construction *dhaladaydii*, ‘my jar-KII’ may only refer to an intact jar. As illustrated in (21), an overt genitive construction, ‘the shards of the jar,’<sup>8</sup> must be used in order to express the broken state of the object.

The change of state inference cannot be expressed by means of -KII alone. Somali seems to express the equivalent of the English ‘former NP’ by using the adjective *hore* in combination with a -KII marked NP.

- (22) Context: *We are talking about several students.*

*Maxamed is the one who dropped out of college / graduated.*

Maxamed waa arday-**dii** hore.

Maxamed DECL students-KII.PL ‘former’

‘Maxamed is one of the former students.’

[11/04/2015]

It is unlikely, however, that the combination of -KII and *hore* is equivalent to the semantics of ‘former NP,’ given that our informant accepts a continuation like in (23) to the sentence in (22).

- (23) *Out of the blue*

Maxamed waa arday-**dii** hore ee **wali** ardayga ah

Maxamed DECL students-KII.PL *hore* which **still** student-KA is

‘Maxamed is one of the previous<sup>9</sup> students who is still a student.’

[11/04/2015]

If anything in the semantics of -KII or of *hore* were uniformly equivalent to that of ‘former,’ the sentence should sound odd. This oddness is what we observe with Guaraní *kue* and English ‘former.’ We take this as evidence that Somali -KII does not obligatorily have the change of state property. In example (23), the behavior of Somali -KII parallels that of the English past tense in a stative sentence like (15), where a cessation inference (that Hermione is no longer in the Hospital Wing or that Maxamed is no longer a student) is triggered but is cancellable.

- (15) Hermione was in the Hospital Wing last week. She is *still* there today.

<sup>8</sup>Similar examples obtain for possession, where “my jar-*ki*” or “my phone-*ki*” alone cannot denote a jar/phone that *used to be* mine. Transfer of possession, in these cases, can be expressed with a relative clause. Our proposal predicts that change of state inferences should not obtain with permanent properties like ‘being a jar.’

<sup>9</sup>The word *hore* is translated in Qoorsheel (1978) as ‘ahead,’ ‘before,’ and ‘former,’ among other meanings.

The data explored in this section so far point to the fact that Somali -KII does not behave like English ‘former’ or like Guaraní *-kue*: -KII does not encode the properties of existence and change of state identified by Tonhauser (2007). While Somali -KII may be different from Guaraní NTMs, it does encode the precedence property. The following subsection further motivates the analysis of -KII as a nominal tense marker.

#### 4.3. The temporal contrast of Somali definite determiners

The previous subsection illustrated that -KII does not obligatorily generate a change of state inference. Nevertheless, this inference does arise in certain contexts. Example (5) is repeated below. Recall that in context, *president-KA* may only refer to the current president, Barack Obama, and the use of -KA in (5b) would lead to infelicity. Similarly, *president-KII* would not be felicitous in (5a), necessarily referring to George Bush, the salient past president, in (5b).

(5) Context: *The year is 2016 and Barack Obama is the president of the United States.*

- a. Madaxweynaha wux-uu ku nool yahay guriga cad.  
 president-**KA** FOC=3S at lives house white  
 ‘The president lives in the White House.’ ≈ **Barack Obama**
- b. Madaxweynihii wux-uu ku nool yahay Texas.  
 president-**KII** FOC=3S at lives Texas  
 ‘The president lives in Texas’. ≈ **George Bush** [01/30/2016]

Event nouns modified by -KII may also give rise to cessation implicatures. The example in (24) is replicated from Lecarme (2008: ex. (11), p. 204). The two sentences below were elicited during The Big E festival, an annual event in Springfield, MA, that takes place at the end of September. Crucially, (24a) can only be uttered if the exhibition is still running at Utterance Time, *exhibition-KII* being infelicitous in this scenario. The use of -KII is felicitous in (24b), where it is contextually given that the exhibition is closed at the time of speech; as in the case of (5), -KA is infelicitous if the speaker is aware that the festival ended.

(24) a. Context: *The Big E is ongoing at the time of speech.*

Bandhig-ga ma=ad daawatay?  
 exhibition-**KA** Q=2S see.2S.PAST  
 ‘Have you seen the exhibition?’

b. Context: *It is mid-October and The Big E recently ended.*

Bandhig-gii ma=ad daawatay?  
 exhibition-**KII** Q=2S see.2S.PAST  
 ‘Have you seen the exhibition?’ [09/27/2015]

In (23), in section 4.2, we observed that *student-KII* does not entail a change of state, but that it gives rise to a cancellable implicature that the individual denoted by the DP is not a student at UT. However, the ‘optionality’ of this inference is context-dependent: compare (22) with (25), where the change of state inference is obligatorily triggered.

- (25) Context: *Axmed graduated from school and got a job at a company.*

Arday-**gii**/#-**ga** wuxuu ka shaqayay hayad.  
 student-GII/-GA FOC=3S at working company  
 ‘The (former) student is working at a company.’

[05/11/2016]

The choice of -KII over -KA is context dependent and it is sensitive to a temporal contrast between the two, which may give rise to a *change of state* interpretation of the target sentence. The data indicates that this is a cancellable implicature reminiscent of the use of past tense in stative sentences (see (15)).

#### 4.4. The (in)visibility contrast of Somali definite determiners

Lecarme (2008, 2012), based on data like the one in (26), suggests that Somali definite determiners are sensitive to visibility from the perspective of the speaker: if the referent is absent from the immediate visual context, then -KII is used, whereas -KA would be inappropriate. Lecarme (2008) also notes that the contrast is not optional: the use of -KII is not felicitous if the referent is visible.

- (26) a. Context: *The speaker’s pen is in the drawer, invisible to the speaker.*

Qalin-kay-**gii**/\*-gu meeyey?  
 pen-M.POSS.1S-KII/\*-KA.TOP Q.is.M.S  
 ‘Where is my pen?’

- b. Context: *There are multiple pens on the desk.*

Qalin-kay-**gu** waa kee?  
 pen-M.POSS.1S-KA.TOP DECL Q.M  
 ‘Which one is my pen?’

(Lecarme, 2008: ex. (20), p.212)

This contrast was also replicated in our elicitations: *sun*-KII in (27b) may only refer to an ‘invisible,’ eclipsed sun, while *sun*-KA in (27a) necessarily refers to a visible sun.

- (27) a. Shalay waxa=an firinayay cadceed-**da**  
 yesterday FOC=1S look.PAST sun-KA

‘Yesterday I looked at the sun’ ≈ **visible**

- b. Shalay waxa=an firinayay cadceed-**dii**  
 yesterday FOC=1S look.PAST sun-KII

‘Yesterday I looked at the sun’ ≈ **eclipsed**

[01/30/2016]

However, the (in)visibility contrast is not always observed. In the scenario in (28), the sun is in plain sight, yet the use of -KII is licensed. This is unexpected under Lecarme’s (2008; 2012) account. Contrary with the generalization that -KII marked NPs are invisible entities, our data illustrates that invisibility does not always pattern with the remote definite determiner.

- (28) Context: *We are outside, taking a walk. The sun is shining.*

Cadce-**dii**/#-**da** cirkay joogta  
 sun-KII/#-KA sky be.at.PRES  
 ‘The sun is in the sky.’<sup>10</sup>

Another case where -KII refers to visible entities was that of (21), where the object in question, the jar, was in the immediate context of the informant (on the table, in front of the speaker). It seems that although invisibility readings *do* arise with -KII, they are not mandatory. Our account is sensitive to the ‘optionality’ of the invisibility and change of state readings.

## 5. Generalizations and proposal

### 5.1. Core generalizations

Somali encodes definiteness by means of (at least) two determiners: -KA and -KII. The choice of one over the other *may* give rise to change of state or invisibility readings. There are contexts in which these contrasts obtain (such as (5) for the temporal contrast and (6) for visibility) and contexts, like (3), where the implicatures are either cancelled or not generated. For convenience, the core data referenced throughout the paper is repeated below.

- (3) Context: *Axmed was working home all day. He decides to go out and sees the sun.*

Marku baxay wux-uu arkay qorrax{-**ka**/-**kii**}.  
 when went out FOC=3S saw sun-KA/-KII  
 ‘When he went out, he saw the sun.’ [03/07/2016]

- (5) Context: *The year is 2016 and Barack Obama is the president of the United States.*

- a. Madaxweynaha wux-uu ku nool yahay guriga cad.  
 president-KA FOC=3S at lives house white  
 ‘The president lives in the White House.’ ≈ **Barack Obama**
- b. Madaxweynihii wux-uu ku nool yahay Texas.  
 president-KII FOC=3S at lives Texas  
 ‘The president lives in Texas’. ≈ **George Bush** [01/30/2016]

- (6) VISIBILITY CONTRAST between -KA and -KII

Wax-aan firinayaa cadceed-**da**/-**dii**.  
 FOC=1S watching sun-KA/-KII  
 I’m watching the sun.  

- a. Inference with -KA: The sun is visible.
- b. Inference with -KII: The sun is eclipsed.
- c. -KII is odd if the sun is visible; -KA is odd if the sun is eclipsed. [01/30/2016]

<sup>10</sup>Surprisingly, *sun*-KA is reportedly odd in (28), but would be felicitous in a context where the sun was rising. This is a puzzle which we leave for further research.

The data points out that the distribution of NP-KII, given in (29), is broad. It may refer to visible entities of which the NP property is true at topic time (TT), as in (3), it may refer to visible entities of which the NP property is *not true at TT*, but true at some salient time before TT, as in (5), where Bush is a former president, and, finally, as in (6), to *invisible* entities of which the NP property holds true at TT, but the entities are not visible in the topic context.

(29) DISTRIBUTION OF NP-KII

- i. entites  $x$  that are in the topic context and  $NP(x)=1$  at topic time,
- ii. entities  $x$  that are in the topic context and  $NP(x)=1$  at some time preceding topic time,  $NP(x)=0$  at topic time,
- iii. entities  $x$  that are not visible in the topic context and  $NP(x)=1$  at topic time.

With respect to NP-KA, its distribution, given in (30), is more restricted. In all of the contexts examined in this paper, -KA marked nominals referred to *visible* entities which satisfied the NP property at topic time.

(30) DISTRIBUTION OF NP-KA

entities  $x$  that are in the topic context and  $NP(x)=1$  at topic time

Comparing the generalizations in (29) and (30), we observe that the range of meanings NP-KA is associated with is a proper subset of the range of meanings NP-KII is associated with. Consequently, we propose that a competition based account between the two definite determiners can capture the -KA and -KII contrasts discussed in this paper.

## 5.2. Proposal

The contrasts observed in the Somali nominal TAM data can be explained by a competition based account, where the change of state and invisibility readings associated with -KII are derived from scalar implicatures.<sup>11</sup> The first component of our proposal is Altshuler and Schwarzschild's (2013) analysis of past stative sentences like the ones below.

- (31) a. We love this puzzle.  
b. We loved this puzzle.

The core observation regarding (31) is that (31b) gives rise to the (cancellable) cessation implicature that the group denoted by 'we' no longer loves the puzzle. Example (31a), on the other hand, does not give rise to a comparable inference. Altshuler and Schwarzschild (2013) argue that the cessation implicature in a stative English past tense sentence like (31b) can be derived by setting up a competition between the *past* tense and the *present* tense. This competition is

<sup>11</sup> A similar account is found in Thomas (2014) for Mbyá Guaraní, where the morpheme *-kue* does not semantically encode *change of state* or *existence*, as described by Tonhauser for Paraguayan Guaraní. Thomas argues that the *cessation* inference triggered by *-kue* is a scalar implicature. The existence inference is derived from the interaction between this implicature and general interpretive properties of noun phrases. His account relies on the use of the exhaustivity operator (Fox, 2007), which, depending on the meaning of the alternatives of the proposition, following Magri (2009), negates the *contextually relevant* alternatives of the given proposition.

based on the assumption that a stative sentence in the present asymmetrically entails its past tense counterpart. Gricean pragmatic reasoning then derives the result that uttering the latter, e.g., (31b), gives rise to the inference that the former, e.g., (31a), is false.

The rationale behind this entailment pattern is this. If (31a) is true *now*, that is, if the puzzle is loved now, the puzzle was also loved a moment ago. The hypothesis that a stative in the present tense asymmetrically entails a stative in the past tense, labeled by Cable (2017) as the *Open Interval Hypothesis*, is formalized in (32).

- (32) OPEN INTERVAL HYPOTHESIS: The run-time of a state is an open interval.  
 If  $s$  is a state and  $t$  is a temporal instant contained within the runtime  $\tau(s)$  of  $s$  ( $t \subseteq \tau(s)$ ), then  $\exists t'$  such that  $t' < t$  and  $t'$  is also contained within  $\tau(s)$  ( $t' \subseteq \tau(s)$ ).

In other words, if a tenseless stative clause is true at a moment  $m$ , it is also true at a moment that precedes  $m$ . Consequently, a present stative sentence entails both that the proposition is true at the time of utterance (by the contribution of present tense), and that it was true at some moment before utterance time (by the contribution of (32)). A past stative sentence, however, does not entail its present tense counterpart. This asymmetric entailment relation ensures that the use of a stative sentence in the past tense will give rise to the scalar implicature that its present tense counterpart is false. This, of course, unless independent factors block the implicature.<sup>12</sup> This account can be extended to explain the contrasts between the use of Somali -KII and -KA, if we make the assumption that a sentence with a -KA marked nominal asymmetrically entails its counterpart with a -KII marked nominal. (That is, if we assume that the former determiner patterns like the present tense, and the latter, like the past tense.) Hence, we propose that the difference between -KII and -KA resides in a temporal presupposition encoded by -KII.

Our analysis assumes that NPs are of type  $\langle e, it \rangle$ . They denote functions from entities, to functions from times to truth values. We also extend the Open Interval Hypothesis in (32) to NP properties. The temporal interval  $t_{NP}$ , the time at which the NP is evaluated (Tonhauser, 2007; Thomas, 2014) and represented in (33a), picks out topic time. Examples (33a) and (33b) recapitulate the structural assumptions for Somali DPs and the denotation of NPs. The lexical entries in (33c) and (33d) give our proposed denotations for the determiners -KA and -KII, both functions from NP denotations ( $\langle e, it \rangle$ ) to functions from times to generalized quantifiers.

- (33) a.  $[[ [NP D^0] ] t_{NP}]_{DP}$  where  $D^0$  is -KII or -KA  
 b.  $[[NP]] = \lambda x_e \lambda t_i. P(t)(x)$   
 c.  $[[KA]]^{w,t,g} = \lambda P_{\langle e, it \rangle} \lambda t_i \lambda Q_{\langle e, t \rangle} : \exists! x [x \in C \& P(t)(x)] \cdot Q(\iota x [P(t)(x)])$   
 d.  $[[KII]]^{w,t,g} = \lambda P_{\langle e, it \rangle} \lambda t_i \lambda Q_{\langle e, t \rangle} : \exists t' \exists! x [t' < t \& x \in C \& P(t')(x)] \cdot \exists t' [t' < t \& Q(\iota x [P(t')(x)])]$

<sup>12</sup>In Altshuler and Schwarzschild (2013) and Cable (2017) the cessation implicature arises only in the absence of a *salient past topic time*.

- (i) a. We love this puzzle.  
 b. We loved this puzzle (yesterday).  
 c. We loved this puzzle as soon as we started working on it.

A cessation implicature is generated in (ib), but not in (ic). We predict the same to be true in Somali.

According to the semantics in (33c) and (33d), both -KA and -KII introduce the familiar definiteness presupposition, that there is a unique  $x$  in the context such that the property denoted by the NP holds of  $x$ . For -KA, the property must hold at topic time. The determiner -KII, on the other hand, encodes the ‘precedence property,’ that there is a time  $t'$  (strictly) prior to topic time such that the property denoted by the NP holds of  $x$  at  $t'$ . Applying the *Open Interval Hypothesis*, if a proposition containing a -KA marked nominal is true at topic time, then it must also have been true at some interval preceding topic time. The fact that a proposition with a -KII marked nominal holds at topic time does not entail that its -KA marked counterpart holds at topic time. Consequently, a sentence with a -KA marked nominal asymmetrically entails its counterpart with a -KII marked one.

We propose that the cessation implicature which arises in (24b), repeated below, is derived as in (34). We predict that this reasoning can be applied to any non-permanent property (event nominals, nouns denoting temporally bounded social functions like *president* or *student*).

- (24) a. Bandhig-**ga** ma=ad daawatay?  
exhibition-KA Q=2S see.2S.PAST  
‘Have you seen the exhibition?’ → **open at UT**
- b. Bandhig-**gii** ma=ad daawatay?  
exhibition-KII Q=2S see.2S.PAST  
‘Have you seen the exhibition?’ ⇝ **closed at UT** [09/27/2015]

The pragmatic reasoning is based on computing the minimally different alternatives of a given sentence. In this case, the -KA sentence is a minimally different alternative of the -KII sentence. Given that, according to the hypothesis in (32), (24a) asymmetrically entails (24b), asserting the weaker alternative (24b) triggers the implicature that the stronger (24a) is false.

(34) PRAGMATIC REASONING FOR (24B): CESSATION IMPLICATURE

- a. The speaker asserts (24b).
- b. The utterances in (24a) and (24b) are identical with the exception of the  $D^0$  node.
- c. exhibition-KA corresponds to the unique  $x$  which is an exhibition in context C at UT.
- d. exhibition-KII corresponds to the unique  $x$  which *was* an exhibition in context C at a time  $t'$ , prior to UT.
- e. The utterance in (24a) is stronger than (24b); (24a) entails (24b) according to the *Open Interval Hypothesis*. If  $x$  is an exhibition at UT, it must have also been an exhibition at some point in time **before** UT.
- f. If the speaker uttered (24b), then the stronger alternative with -KA, that  $x$  is an exhibition at UT, is false.
- g. Therefore,  $x$  is *not* an exhibition at UT.
- h. *World knowledge*: for  $x$  to stop being an exhibition, the exhibition must have closed.

We argue that the (*in*)visibility contrast is also a derivable scalar implicature. The example in (35) is repeated from (27), where the use of -KII implies that the sun is eclipsed. We predict that the same reasoning can be applied to any noun which expresses a permanent property.<sup>13</sup>

<sup>13</sup>Our attempts to obtain data regarding invisible non-permanent properties have been unsuccessful.

- (35) a. Shalay waxa=an firinayay cadcee-**da**  
 yesterday FOC=1S look.PAST sun-KA  
 ‘Yesterday I looked at the sun’ → **visible**
- b. Shalay waxa=an firinayay cadcee-**dii**  
 yesterday FOC=1S look.PAST sun-KII  
 ‘Yesterday I looked at the sun’ ~→ **eclipsed** [01/30/2016]

Once again, minimally different alternatives are computed. Based on the hypothesis in (32), (35a) asymmetrically entails (35b), and the use of the weaker alternative implicates that the stronger alternative is false.

(36) PRAGMATIC REASONING FOR (35B): INVISIBILITY IMPLICATURE

- a. The speaker asserts (35b).
- b. The utterances in (35a) and (35b) are identical with the exception of the  $D^0$  node.
- c. sun-KA corresponds to the unique  $x$  which is a sun in context  $C$  at topic time.
- d. sun-KII corresponds to the unique  $x$  which *was* a sun in context  $C$  at a time  $t'$ , prior to topic time.
- e. The utterance in (35a) is stronger than the utterance in (35b); (35a) entails (35b) according to the *Open Interval Hypothesis*. If  $x$  is a sun at topic time, it must have also been a sun at some point in time **before** topic time.
- f. If the speaker uttered (35b), then the stronger alternative with -KA, that  $x$  is a sun at topic time, is false.
- g. Therefore,  $x$  is *not* a sun at topic time.
- h. *World knowledge*: the sun is permanent and unique, hence,  $x$  cannot stop being a sun.
- i.  $x$  is not a sun at *topic time* in  $C$ , but  $x$  is always a sun.
- j. The sun is invisible at topic time.

## 6. Concluding remarks

This paper advances the understanding of the semantics of Somali definite determiners -KA and -KII, and compares them to nominal temporal markers crosslinguistically. The comparison between Somali and Guaraní led to the conclusion that the Somali remote definite determiner -KII does not encode the *change of state* or the *existence* properties attested in Guaraní NTMs (Tonhauser, 2007). Our data point in the direction of a *temporal contrast* between the two definite determiners in Somali, and support the conclusion that the *change of state* and *invisibility* readings are, in fact, cancellable implicatures. We proposed that this contrast is semantically encoded by means of an extra temporal presupposition in the case of -KII. Assuming our proposed semantics and the *Open Interval Hypothesis* (Altshuler and Schwarzschild, 2013; Cable, 2017), -KA asymmetrically entails -KII. Under this analysis, the competition between minimally different alternatives is responsible for generating the desired implicatures.

# On the lexical semantics of property concept nouns in Basaá<sup>1</sup>

Peter JENKS — *University of California, Berkeley*

Andrew KOONTZ-GARBODEN — *The University of Manchester*

Emmanuel-Moselly MAKASSO — *ZAS, Berlin*

**Abstract.** This paper considers the link between lexical category and lexical semantics, examining variation in the category of property concept (PC) words (Dixon, 1982; Thompson, 1989)—words introducing the descriptive content in translational equivalents of sentences whose main predicate is an adjective in languages with large open classes of them. Francez and Koontz-Garboden (2015) conjecture that nominal PC words might only have mass-type denotation (conceived in the spirit of Link 1983), as diagnosed by possession in predication (e.g., *Kim has beauty/#Kim is beauty*). In Basaá, a class of PC nominals we call *substance nouns* trigger possession in predication, while a class we call *adjectival nouns* do not, thereby falsifying Francez and Koontz-Garboden’s conjecture. We offer several diagnostics that confirm the substance denotation for the substance nouns, and an individual-characterizing denotation for the adjectival nouns, speculating on whether such nouns have a degree semantics, and whether they represent a crosslinguistically rare category or not.

**Keywords:** lexical categories; semantic variation; adjectives; property concepts; mass nouns

## 1. Introduction: The meaning of lexical categories

The nature of the major lexical categories is among the most foundational yet poorly understood areas of grammar (Baker and Croft, 2017). Among the outstanding questions is whether there might be a link between lexical categories, which play a clear role in syntax and morphology, and the kind of meaning a word has. Although this is a question of longstanding interest, it is rarely discussed in the model-theoretic literature, save for the occasional suggestion that there might be something to say (see e.g., Bach et al. 1995; von Stechow and Matthewson 2008: 152–153; Kaufman 2009: 32; Koch and Matthewson 2009: 129). This paper is a modest contribution toward development of a program of study in this area. We focus our attention on what Francez and Koontz-Garboden (2015, 2017) call property concept sentences—sentences like (1) whose main predicate is an adjective or, as with (2), whose main predicate is not an adjective but is translated by a sentence whose main predicate *is* an adjective in languages like English.

(1) Your hair is long.

(2) ‘Oku loloa ho    ‘ulu.  
IMP long your hair  
‘Your hair is long.’

(Tongan; Koontz-Garboden 2007: 117)

We call the word in property concept sentences responsible for introducing the descriptive content (*long* in (1), *loloa* in (2)) the property concept (PC) word. Thanks to Dixon’s (1982;

---

<sup>1</sup>This work has been supported financially by Arts and Humanities Research Council Grant AH/H033645/1.

2004) work, it is now widely known that property concept words vary in lexical category (both internal to and across languages). In (1), for example, *long* is an adjective, while *loloa* in (2) is a verb (see Koontz-Garboden 2007).

Property concept words also vary in their lexical semantics. Our focus is on a two-way distinction based on behavior in predication pointed to by Francez and Koontz-Garboden (2015). They observe that there are PC words that require possessive morphosyntax in predication (possessive-predicating PC words) and those that do not (non-possessive predicating PC words), as illustrated for Spanish in (3) and (4) respectively.

- |     |                                                                |     |                                                         |
|-----|----------------------------------------------------------------|-----|---------------------------------------------------------|
| (3) | <i>Juan tiene miedo.</i><br>Juan has fear<br>'Juan is scared.' | (4) | <i>Juan es alto.</i><br>Juan is tall<br>'Juan is tall.' |
|-----|----------------------------------------------------------------|-----|---------------------------------------------------------|

Following Francez and Koontz-Garboden (2015), we take this contrast as diagnostic of a difference in the kind of meaning the PC words in the two classes of construction have: (i) those like *miedo* 'fear', which characterize substances (*substance*-type meanings, following Link 1983), and (ii) those like *alto* 'tall', which characterize individuals—specifically, those individuals that *have* the substance (e.g., a contextually salient portion of height) in question.

Concomitant with the difference in meaning of the PC words in (3) and (4), reflected in the morphosyntax of predication, is a difference in lexical category. While the substance-characterizing PC word in (3) is a noun, the individual-characterizing PC word in (4) is an adjective. Cross-classifying the adjective and noun categories with this two-way semantic typology leads to the picture in (5), with two gaps.

- |                  |                                                     |                                      |  |
|------------------|-----------------------------------------------------|--------------------------------------|--|
| (5)              | Nominal and adjectival property concept denotations |                                      |  |
|                  | <i>Individual-characterizing</i>                    | <i>Substance-characterizing</i>      |  |
| <i>Adjective</i> | English, Spanish adjectives                         | ???                                  |  |
| <i>Noun</i>      | ???                                                 | PC nominals like <i>miedo</i> 'fear' |  |

Francez and Koontz-Garboden (2017: Chapter 5) argue that the gap in substance-characterizing adjectives depicted in the top right corner of (5) is genuine and principled. Substance denotations are not meanings well suited to the main function of adjectives—to act as attributive modifiers. Assuming that adnominal modification selects a subset of the denotation of the modified noun, Francez and Koontz-Garboden argue that there are no nouns with meanings that substance-characterizing adjectives could non-trivially modify.

In the sample of languages that Francez and Koontz-Garboden (2015) examined, there were no languages with non-possessive predicating PC nominals, giving rise to the conjecture that the gap on the bottom left of (5) was genuine. The implication of this gap would be that nominal property concept words were *always* substance-characterizing, and never individual-characterizing. Were this conjecture true, it would have implications for the semantics of nounhood. Yet in this paper we show that in Basaá (Bantu; Cameroon), PC nouns can have both substance-characterizing and individual-characterizing denotations. The conclusion is that nominal property concept words do not uniformly have substance-characterizing denotations.

We begin with background on the semantic typology of property concept words, discussing the two kinds of meanings that these words can have. We then turn to the Basaá case study, in order to determine (i) the category of Basaá PC words, and (ii) their lexical semantics. We start by giving three arguments for the nominal categoriality of the relevant class of PC words. Drawing on a range of novel diagnostics and by contrasting these PC words with genuine substance-characterizing ones, we then show that rather than characterizing portions of substance, they instead characterize sets of individuals. We conclude with remarks on what exactly the individual-characterizing nature of the relevant class of Basaá PC nominals is, and also suggest that a comparable class of nouns exists in English. We close with discussion of the consequences of our observations for the understanding of the link between lexical category and lexical semantics.

## 2. Possessive-predicating PC nominals and their substance denotations

Francez and Koontz-Garboden (2015) observe that nominal property concept words entail possessive morphosyntax for their sample of languages. Although we will argue below that there is a class of PC words in Basaá that falsify this generalization, there is also a class of PC words in the language that conforms with it. We call this class of words *substance nouns* (SNs), and they include *mbom* ‘luck’; *nguy* ‘strength’; *másódá* ‘luck’; *ɲém* ‘courage’; *hêmlɛ* ‘hope/faith’. That such words are nominal in Basaá is uncontroversial, particularly given the fact that they are lexically associated with a noun class rather than agreeing with other nouns, fail to attributively modify nominals, can be used as the arguments of verbs, and have mass noun properties.

SNs do not behave like common nouns in predication contexts, as expected given Francez and Koontz-Garboden’s (2015) observations. Predication of a normal Basaá count noun (details of which are discussed further in §3) is copular, as shown in (6).

- (6) *a ye m-alêt.*  
 1.AGR COP 1-teacher  
 ‘He is a teacher.’ (Hyman et al. 2012:8)

Unlike with normal count nouns, attribution of a SN to an individual invokes the morphosyntax of possession. That is, the same morphosyntax—the verb *gweé* ‘have’—which is required to attribute the possession of some entity to another, whether inalienably (7a) or alienably (7b), is used to attribute the substance described by a SN to an individual, as shown in (8).<sup>2</sup>

<sup>2</sup>In Basaá, ‘have’ is morphologically complex, literally ‘be-with’, and has the paradigm in (i).

- (i) Tense paradigm for *bá-nâ* ‘have’

| Infin       | Past3       | Past2        | Past1        | Pres        | Fut1          | Fut2           | Fut3          |
|-------------|-------------|--------------|--------------|-------------|---------------|----------------|---------------|
| <i>bánâ</i> | <i>báná</i> | <i>béena</i> | <i>bákná</i> | <i>gweé</i> | <i>m!báná</i> | <i>gá!báná</i> | <i>a!báná</i> |

- (7) a. *í tēble íní í gwé<sup>1</sup>é ma-koo mánâ* (8) *a gweé ma-sóda*  
 AUG 7.table DEM AGR have 4-feet four 1.AGR have 6-luck  
 ‘This table has four feet.’ ‘(S)he is lucky.’  
 b. *Kim a gweé <sup>1</sup>n-dáp*  
 Kim AGR has 9-house  
 ‘Kim has a house.’

Drawing on the mereological approach to mass terms in Link (1983), Francez and Koontz-Garboden (2015, 2017) treat the denotations of possessive-predicating PC words as related to the denotations of familiar substance mass terms such as *gold* and *sand*.<sup>3</sup> For example, *ɲguy* ‘strength’ has such a denotation, as shown in (9), where *p* is a variable over portions of abstract matter, and *strength'* describes the property which characterizes all portions of strength.

- (9)  $\llbracket \text{ɲguy} \rrbracket = \lambda p[\text{strength}'(p)]$

Evidence that SNs have a mass-type semantics is offered in §4.1.

A substance-characterizing denotation accounts for the possessive morphosyntax used with these PC nominals. Substances, as Francez and Koontz-Garboden discuss, cannot be predicated of individuals using a copula because substances are sets of abstract portions, not sets of individuals. To the extent that any meaning is generated in ordinary copular predication with substance-characterizing words, it is an odd or metaphorical one, a fact illustrated by (10).<sup>4</sup>

- (10) a. Kim is strength.  $\neq$  Kim is strong.  
 b. Kim has strength. = Kim is strong.

Our hypothesis, following the treatment of similar examples in other languages in Francez and Koontz-Garboden (2015), is that the use of possessive morphosyntax with such PC nominals in predication is a direct reflection of their semantics. The idea is that because a substance-characterizing PC word does not characterize a set of individuals, a relation has to be introduced to relate substances to individuals in order to attribute the substance to an individual. Francez and Koontz-Garboden call the general idea that a substance can be related to an individual with the semantics of possession *substance possession*, defining it as in (11).

- (11) **Substance possession:** For any individual *a* and substance *P*, *a* has *P* iff  
 $\exists p[P(p) \ \& \ \pi(a, p)]$

In summary, the morphosyntax of possession with nominal PC terms arises due to the underlying semantics of substance possession.

<sup>3</sup>See Koontz-Garboden and Francez (2010) for an inferior analysis in terms of Chierchia and Turner’s (1988) property theory.

<sup>4</sup>In fact, in Basaá there is a group of ‘have’-predicating PC nominals which allows ‘be’-predication, but only in emphatic contexts. We take these cases to be direct ‘be’-predication of a SN, equivalent to English expressions like *Kim IS beauty* (*incarnate*), where the substance is predicated directly of the subject, meaning that Kim is literally a portion of beauty.

No such possessive semantics is at play with property concept sentences showing normal predicative morphosyntax, e.g., those with adjectives. The precise semantics for the adjectival predicates in such sentences remains an open question (see e.g., Cresswell 1977; Klein 1980; von Stechow 1984; Heim 1985; Kennedy 1997; Barker 2002; Rett 2014; Menon and Pancheva 2014; Wellwood 2015; Burnett 2016, among others). For our purposes, it does not matter what the correct theory is. What matters is simply that adjectives do not denote substances. This is the case on all theories of adjectives (and is a point explicitly argued by Francez and Koontz-Garboden 2017: Chapter 5). In one way or another, the adjectival word comes to characterize a set of individuals in some context, which can enter into ordinary processes of non-verbal predication. The headline finding of this paper is that contrary to Francez and Koontz-Garboden's conjecture, nominal PC words can have a meaning of this type, whatever its precise formal details might be.<sup>5</sup> In order to show this, we now make the case for the nominal status of ANs, and then show that they unequivocally have individual-characterizing meanings.

### 3. The lexical category of Basaá ANs

The class of PC words in Basaá of primary interest, is what Hyman et al. (2013) call *nominal adjectives* and which we call here *adjectival nouns* (ANs), in view of the fact that they are nouns, following Hyman (2003).<sup>6</sup> ANs constitute a large and open class of PC words in Basaá, with at least 100 members. Below we demonstrate that while ANs form a class of PC words that are demonstrably nominal in lexical category, they are not substance-characterizing, but rather characterize sets of individuals, falsifying the conjecture discussed in §1. In this section we argue for their nominal status, turning to their meaning in the section that follows.

Like most Niger-Congo languages, Basaá nominals are distributed into a rich set of noun classes. Which noun class a particular noun belongs to can be determined based on the initial prefix of the noun as well as subject agreement and DP-internal concord. Members of each of these classes are provided in Table 1, drawn from Hyman (2003: 263) with some simplifications in the representation of prefixal morphology. The numerals in the left column refer to the numbering system for Bantu noun classes standard since Meinhof (1906). These numerals label each combination of number and gender a separate class. Hyman (2003) discusses the phonological and morphological traits of the prefixal morphology in detail, and also provides detailed paradigms for DP-internal concord and subject agreement. The example below illustrates both DP-internal concord and subject agreement—the verb and DP internal modifiers agree with the head noun *nuní* 'bird' in noun class.

- (12) *dí-nuní dí-tân díí dí n' tóp hémbí*  
 13-bird 13.five 13.those 13.SBJ sing 19.song  
 'Those five birds are singing a song.'

<sup>5</sup>It is possible, as suggested by Beck et al. (2010); Bochnak (2013, 2015) that there might be variation in the kinds of individual-characterizing meanings that there are. Quite how Basaá ANs fit into this picture is an interesting question for future research.

<sup>6</sup>Our ANs are not to be confused with Hyman et al.'s adjectival nouns, which correspond to our substance nouns (SNs). Terminologically speaking, our adjectival nouns are their nominal adjectives, and our substance nouns are their adjectival nouns.

Table 1: Noun classes in Basaá

| Class | Singular      | Plural         |               | Singular       | Plural           |         |
|-------|---------------|----------------|---------------|----------------|------------------|---------|
| 1/2   | <i>mudaá</i>  | <i>bodaá</i>   | ‘woman’       | <i>mut</i>     | <i>bot</i>       | ‘man’   |
| 3/4   | <i>m-pék</i>  | <i>mim-pék</i> | ‘bag’         | <i>n-tómbá</i> | <i>min-tómbá</i> | ‘sheep’ |
| 3a/6  | <i>nyɔ</i>    | <i>ma-nyɔ</i>  | ‘mouth’       | <i>wɔɔ</i>     | <i>mɔɔ</i>       | ‘hand’  |
| 5/6   | <i>li-pan</i> | <i>ma-pan</i>  | ‘forest’      | <i>j-alá</i>   | <i>m-alá</i>     | ‘crab’  |
| 7/8   | <i>tɔŋ</i>    | <i>bi-tɔŋ</i>  | ‘horn’        | <i>y-oó</i>    | <i>gw-oó</i>     | ‘yam’   |
| 9/10  | <i>pén</i>    | <i>pén</i>     | ‘arrow’       | <i>ŋ-gwó</i>   | <i>ŋ-gwó</i>     | ‘dog’   |
| 9/6   | <i>kíŋ</i>    | <i>ma-kíŋ</i>  | ‘neck, voice’ | <i>n-dáp</i>   | <i>man-dáp</i>   | ‘house’ |
| 19/13 | <i>hi-tám</i> | <i>di-tám</i>  | ‘kidney’      | <i>hi-nuní</i> | <i>di-nuní</i>   | ‘bird’  |

Table 2: NAs are found in all noun classes (Hyman et al., 2013: 2)

| Class | Num.  | NA             | Gloss             |  | Class | Num. | NA               | Gloss             |
|-------|-------|----------------|-------------------|--|-------|------|------------------|-------------------|
| 1     | sing. | <i>n-lám</i>   | ‘beautiful (sg.)’ |  | 2     | pl.  | <i>ba-lám</i>    | ‘beautiful (pl.)’ |
| 3     | sing. | <i>n-langá</i> | ‘black (sg.)’     |  | 4     | pl.  | <i>min-langá</i> | ‘black (pl.)’     |
| 5     | sing. | <i>li-múgê</i> | ‘taciturn (sg.)’  |  | 6     | pl.  | <i>ma-múgê</i>   | ‘taciturn (pl.)’  |
| 7     | sing. | <i>lɔŋgê</i>   | ‘good (sg.)’      |  | 8     | pl.  | <i>bi-lɔŋgê</i>  | ‘good (pl.)’      |
| 9     | sing. | <i>mbóm</i>    | ‘big (sg.)’       |  | 10    | pl.  | <i>mbóm</i>      | ‘big (pl.)’       |
| 19    | sing. | <i>hi-peda</i> | ‘small (sg.)’     |  | 13    | pl.  | <i>di-peda</i>   | ‘small (pl.)’     |

In example (12), the noun *dí-nuní* ‘birds’ controls agreement on the numeral, demonstrative, and the verbal prefix. We take lexically determined membership in one of the noun classes in Table 1 and the ability to control agreement to be definitional criteria for nounhood in Basaá.

All earlier descriptions, including Dimmendaal (1988); Hyman (2003); Hyman et al. (2013), agree that the PCs we are calling ANs are nouns. Evidence for their nominal categorization comes from the fact that they have lexically determined inherent noun class (from Hyman et al. 2013), as described above. This is evidenced by the fact that ANs are found in all noun classes, as illustrated by Table 2. Further evidence for their nominal status comes from the fact that when they occur DP-internally, ANs subordinate the noun they modify via a connective particle, reminiscent of English *of*, and control agreement on higher adnominal modifiers (13).

- (13) a. *lí-múgê<sup>1</sup> lí hí-nuní líí lí n<sup>1</sup>tóp hémbí*  
 5-quiet 5.CON 19-bird 5-that 5.SBJ sing 19.song  
 ‘That quiet bird is singing.’  
 b. *má-múgê<sup>1</sup> má dí-nuní máá má n<sup>1</sup>tóp hémbí*  
 6-quiet 6.CON 13-birds 6-that 6.SBJ sing 19.song  
 ‘Those quiet birds are singing.’

The connective particle itself also agrees with the AN, as shown by Table 3; note that the connective which appears in this construction can be purely tonal, a low tone in class 1 and 9, and a high tone in class 3 and 7 (Hyman et al., 2013: ex. (10)). This is true generally of other

Table 3: Agreement of the connective with ANs

| Cl | AN             | of                     | N              |                  | Cl | AN               | of                     | N              |                   |
|----|----------------|------------------------|----------------|------------------|----|------------------|------------------------|----------------|-------------------|
| 1  | <i>n-lám</i>   |                        | <i>hi-nuní</i> | ‘beautiful bird’ | 2  | <i>ba-lám</i>    | <i>ba</i>              | <i>dí-nuní</i> | ‘beautiful birds’ |
| 3  | <i>n-laggá</i> |                        | <i>hí-nuní</i> | ‘black bird’     | 4  | <i>min-laggá</i> | <i>mí</i>              | <i>dí-nuní</i> | ‘black birds’     |
| 5  | <i>li-múgê</i> | <sup>1</sup> <i>lí</i> | <i>hí-nuní</i> | ‘quiet bird’     | 6  | <i>ma-múgê</i>   | <i>má</i>              | <i>dí-nuní</i> | ‘quiet birds’     |
| 7  | <i>lóggê</i>   |                        | <i>hí-nuní</i> | ‘good bird’      | 8  | <i>bi-lóggê</i>  | <sup>1</sup> <i>bí</i> | <i>dí-nuní</i> | ‘good birds’      |
| 9  | <i>mbóm</i>    |                        | <i>hi-nuní</i> | ‘big bird’       | 10 | <i>mbóm</i>      | <i>í</i>               | <i>dí-nuní</i> | ‘big birds’       |
| 19 | <i>hi-peda</i> | <i>hí</i>              | <i>hí-nuní</i> | ‘small bird’     | 13 | <i>di-peda</i>   | <i>dí</i>              | <i>dí-nuní</i> | ‘small birds’     |

DP internal modification where the modifier is nominal, as with possessive DPs and noun-noun compounds (Hyman et al., 2013). One important point to note about the construction illustrated in Table 3 is that the AN and N always agree in number, even if they occur in different genders or noun classes.

Further evidence for the nominality of ANs comes from the existence of a separate class of true adjectival PCs (adjectives) in Basaá. Such genuine adjective is illustrated in (14), where the adjective *kéŋí* ‘big’ does not control agreement on the noun or subject auxiliary, but transparently reflects the noun class of the noun it modifies. Further, it modifies the head noun without a connective, unlike nominal modifiers (with AN or not), described previously.

- (14) *hí-nuní hi-kéŋí hí hí n<sup>1</sup>tóp hémbí*  
 19-bird 19-big 19-that 19.SBJ sing 19.song  
 ‘That big bird is singing.’

The number of adjectives in Basaá is relatively small, so Basaá is therefore like many languages of the world in having a closed adjective class (Hyman et al., 2013). Crucially for our purposes, we will see below that true adjectives and ANs cannot be distinguished semantically, so they are only distinguished by their syntactic category, revealed in their morphosyntactic behavior.

#### 4. The lexical semantics of Basaá ANs

Having demonstrated the nominality of ANs, we now examine their semantics. Given the discussion above, an obvious starting point is asking how they behave in predication. Here, as already mentioned, we find behavior different from that observed with nominal PCs elsewhere, both from SNs in Basaá, discussed above, and the nominal PCs from other languages discussed in Francez and Koontz-Garboden (2015).

Basaá has a copula *ba* which occurs as the main verb in sentences with a variety of non-verbal predicates.<sup>7</sup> This copula occurs with predicate nominals (15a), locatives (15b), and genuine

<sup>7</sup>The verb *ba* ‘be’ is characterized by extensive suppletion, as shown in (i).

(i) Tense paradigm for *ba* ‘be’

| Infin     | Past3     | Past2      | Past1      | Pres      | Fut1                   | Fut2                    | Fut3      |
|-----------|-----------|------------|------------|-----------|------------------------|-------------------------|-----------|
| <i>ba</i> | <i>ba</i> | <i>bée</i> | <i>bák</i> | <i>ye</i> | <i>m<sup>1</sup>ba</i> | <i>gá<sup>1</sup>ba</i> | <i>aá</i> |

adjectives (15c), along with, crucial for our purposes, ANs (15d):

- (15) a. *Victor a ye m-alêt*  
 Victor 1.SUB be 1-teacher  
 ‘Victor is a teacher.’ (predicate nominal)
- b. *hí-nuní híí hí yé í kedé 'é*  
 19-bird 19.that 19.SUB be LOC inside tree  
 ‘That bird is inside the tree.’ (e.g. in a hole) (locative)
- c. *hí-nuní híí hí yé hi-kéŋí*  
 19-bird 19.that 19.SUB be 19-big  
 ‘That bird is big.’ (adjective)
- d. *hí-nuní híí hí yé li-mugê*  
 19-bird 19.that 19.SUB be 5-quiet  
 ‘That bird is quiet.’ (adjectival noun)

We assume that copular predication in contexts like those above is a transparent indication that the following predicate characterizes a set of ordinary individuals (cf. Partee 2002). Thus, the fact that adjectives and ANs are predicated with a copula is a transparent indication that adjectives and AN denote sets of ordinary individuals, like nominal and locative predicates. Below we present three additional arguments for this claim.

#### 4.1. Atomicity

In this section we illustrate that ANs and SNs are distinct in terms of atomicity: while ANs have atomic denotations, and are hence count nouns, SNs have non-atomic denotations and behave like mass nouns. Mass-like denotations are expected for SN given their substance-based semantics described in §2.

The simplest evidence that ANs are count nouns while SNs are mass nouns comes from the number invariance of SNs. In §3, it was shown that ANs reflect the number of the noun they modify in the AN-of-N construction (Table 3). Thus, a distinction exists between *nláám* ‘beautiful’ and *baláám* ‘beautiful’ depending on whether the noun is singular or plural in (13). By contrast, SNs do not inflect for number at all. This can be seen in both adnominal modifying and predicative environments. Beginning with attributive environments, the data in (16) demonstrate that like ANs, nominal modification with SNs requires a connective. But while ANs precede the connective, controlling agreement on higher modifiers (13), SNs follow the connective, and the modified noun controls agreement. What is crucial for our current purposes is that unlike ANs, SNs do not reflect the number of the noun which they modify. This is illustrated by (16), where the SN *ŋgûy* ‘strength’ is invariant regardless of whether it is modifying a singular or plural noun:

- (16) a. *hi-nuní hí ŋgûy hí n'tóp hémbí*  
 19-bird 19.CON 9.strength 19.SBJ sing 19.song  
 ‘The strong bird is singing’

Table 4: Substance nouns (SNs) in Basaá

| Class | N              | of        | SN              |                                     |
|-------|----------------|-----------|-----------------|-------------------------------------|
| 1     | <i>hi-nuní</i> | <i>hí</i> | <i>máaŋgé</i>   | ‘baby bird’ (bird of child)         |
| 3     | <i>hi-nuní</i> | <i>hí</i> | <i>ń-saŋ</i>    | ‘peaceful bird’ (bird of peace)     |
| 4     | <i>hi-nuní</i> | <i>hí</i> | <i>mí-yaó</i>   | ‘likable bird’ (bird of charm)      |
| 5     | <i>hi-nuní</i> | <i>hí</i> | <i>lí-han</i>   | ‘mean bird’ (bird of meanness)      |
| 6     | <i>hi-nuní</i> | <i>hí</i> | <i>má-sódá</i>  | ‘lucky bird’ (bird of chance)       |
| 7     | <i>hi-nuní</i> | <i>hí</i> | <i>ságlá</i>    | ‘annoying bird’ (bird of annoyance) |
| 8     | <i>hi-nuní</i> | <i>hí</i> | <i>bí-sagda</i> | ‘unsteady bird’ (bird of confusion) |
| 9     | <i>hi-nuní</i> | <i>hí</i> | <i>ŋgûy</i>     | ‘strong bird’ (bird of strength)    |

- b. *di-nuní dí ŋgûy dí ń'tóp hémbí*  
 13-birds 13.CON 9.strength 13.SBJ sing 19.song  
 ‘The strong birds are singing’

Furthermore, while each lexical SN can be morphologically singular or plural, each individual SN is number-invariant, occurring in either a singular or plural noun class, as shown by the data in Table 4. Thus, the singular class 3 *ń-saŋ* ‘peace’ has no class 4 plural counterpart *\*mísaŋ*. Likewise, the plural class 4 *míyaó* ‘charm’ has no singular class 3 counterpart *\*nyaó*. The difference between ANs and SNs in the ability to mark number is thus directly manifested in DP-internal environments: only ANs reflect the number of the noun they modify.

The number invariance of SNs also contrasts with ANs in predication environments. Like adjectives and predicate nominals, ANs typically reflect the number of the subject:

- (17) *dí-nuní díí dí yé ma-múgê*  
 13-bird 13.that 13.SUB be 6-quiet  
 ‘Those birds are quiet.’

The subject in (17) is plural, thereby triggering class 6 on the AN in this position.<sup>8</sup> In contrast, SNs do not exhibit number agreement with the subject of ‘have’ in predication environments, as shown by (18).

- (18) a. *a gweé \*n/mi-yáo*  
 1.AGR have 3(SG)/4(PL)-charm  
 ‘(S)he is likable.’  
 b. *bá gwé'é \*n/mi-yáo*  
 2.AGR have 3(SG)/4(PL)-charm  
 ‘They are likable.’

<sup>8</sup>Number agreement in the copular construction is not obligatory when the subject is plural. As discussed in Hyman et al. (2013), with predicates that allow collective readings, singular predicates overtly indicate a collective reading while plural predicates occur with distributive readings.

Thus, a corollary of the general number-invariance of SNs is their inability to agree with nouns in number in both attributive and predication environments. These diagnostics we believe are tied to atomicity—the question whether there are atomic parts in the denotation of the noun, as is the case with count nouns, or not, as is the case with mass nouns (Link, 1983). Consistent with our claim that SNs are substance-characterizing, then, these facts point to a non-atomic denotation for SNs. ANs, consistent with our claim that they characterize sets of (atomic) individuals, behave in the opposite manner.

A more direct diagnostic for this distinction comes from numerals: while numerals can combine with ANs, they cannot with SNs, as shown by (19a,b) respectively.<sup>9</sup>

- (19) a. *ma-múgέ 'má dí-nuní mátân*  
           6-quiet 6.6.CON 13-bird 6.five  
           'five quiet birds'  
       b. *\*míyáo (míntân) mí hí-nuní (míntân)*  
           4-charm (4.five) 4.CON 13-bird (4.five)  
           (intended: \*'five charms of the bird')

In (19a), *mátân* 'five' agrees with the AN *ma-múgέ* 'quiet', and as such the AN must preserve or share the count-status of the head noun it modifies. In contrast, (19b) illustrates that SNs cannot combine with numerals when they serve as the head of the noun phrase. As countability is a standard diagnostic for atomicity (and thereby count versus mass status, e.g. Rothstein 2010), we take the distribution of numerals to confirm that ANs have atomic denotations (and are count nouns) while SNs have non-atomic ones (and are mass), consistent with the claim that the former have individual-characterizing denotations, while the latter denote substances.

## 4.2. Weak quantifiers

Additional circumstantial evidence for the individual-characterizing denotation for ANs comes from the syntactic behavior of various quantifiers in Basaá. Landman (2003) argues that while strong determiners are generalized quantifiers, i.e. interpreted as relations between sets (Montague 1973; Barwise and Cooper 1981) indefinite determiners have adjectival meanings, and are functions from nominal denotations to a subset of the nominal denotation with restricted cardinality. For example, while *birds* denotes the set of any plurality of birds, whether two or ten thousand, *several birds* denotes a much more restricted set of bird pluralities—namely those comprised of say, 3-10 atomic bird individuals. It turns out that in Basaá weak quantifiers, by contrast with strong quantifiers, pattern like ANs in several ways. This behavior, we argue, makes sense if weak quantifiers and ANs both characterize sets of individuals. The former is consistent with Landman's claims, the latter with our claim about the semantic nature of ANs.

<sup>9</sup>That the numeral is modifying the AN in (19a) and the SN in (19b) is shown by agreement—the numeral agrees in noun class with the AN in (19a) and the SN in (19b), as is typical for adnominal numeral modifiers in the language generally.

NP-internally, weak quantifiers in Basaá pattern just like ANs. This is demonstrated by the data in (20), which shown that such quantifiers head the NPs they determine, triggering use of a linker particle the noun class agreement of which they control.

- (20) a. *ɲgandak í dínuní í yé mɪnlaŋgá*  
 3.many 3 19.birds 3.AGR be 4.black  
 ‘Many birds are black.’  
 b. *ndek dínuní í yé mɪnlaŋgá*  
 3.few (3)-19.birds 3.AGR be 4.black  
 ‘Few birds are black.’  
 c. *joga lí dínuní lí yé mɪnlaŋgá*  
 5.several 5 19.birds 5.AGR be 4.black  
 ‘Several birds are black.’  
 d. *pɛs í dínuní í yé mɪnlaŋgá*  
 3.half 3 19.birds 3.AGR be 4.black  
 ‘Half the birds are black.’

Unlike weak quantifiers, strong quantifiers do not pattern as ANs. The actual behavior of strong quantifiers is heterogeneous, as evidenced by the data in (21), where *hígíí* ‘every’ appears prenominally and *códísó* ‘all’ appears postnominally.

- (21) a. *hígíí hinuní hí yé nlaŋgá*  
 19.every 19.bird 19.AGR be 3.black  
 ‘Every bird is black.’  
 b. *dínuní códísó <sup>1</sup>dí yé mɪnlaŋgá*  
 AUG-13.birds all 13.AGR be 4.black  
 ‘All birds are black.’

In both cases, however, the quantifiers behave differently from the weak quantifiers in (20), in that neither of them heads the NP they determine or controls agreement. This is shown in (21a) by the lack of a linker particle and by the fact that *hígíí* ‘every’ agrees with the head noun ‘bird’. The quantifier *códísó* ‘all’ in (21b) simply does not agree, nor is there any question of it being in head position, as it is postnominal. This contrast in the behavior of weak and strong quantifiers makes sense if weak quantifiers and ANs are in the same semantic class (at some level), and if this class is individual-characterizing (as Landman independently argues for most weak quantifiers), the idea being that the head noun (whether AN or weak quantifier) composes with the post-linker noun through some form of predicate modification (as argued for weak quantifiers by Landman 2003: 2).

We have already seen that ANs are copular-predicating, as expected for words that characterize sets of individuals. The same is expected of weak quantifiers on Landman’s theory. This prediction is borne out, as shown by (22).<sup>10</sup>

<sup>10</sup>There are two exceptions to this, *ɲgim* ‘some’ and *tɔ* ‘no’. In the case of quantifiers like the latter, Landman (2003: 12) argues for a special treatment on independent grounds. An explanation for the behavior of Basaá *ɲgim* ‘some’ requires further investigation.

- (22) a. *dínuní tíní dí yé ɲgandak*  
 birds these AGR be a.lot  
 ‘These birds are many.’  
 b. *dínuní tíní dí yé ndek*  
 birds these AGR be few  
 ‘These birds are few.’  
 c. *dínuní tíní dí yé joga*  
 birds these AGR be several  
 ‘These birds are several.’  
 d. *dínuní tíní dí yé pɛs*  
 birds these AGR be half  
 ‘These birds are half.’

Further, as expected if strong quantifiers are not individual characterizing, but rather have some other kind of non-predicative denotation (for example relations between sets, as Landman argues), then we expect strong quantifiers to be unacceptable in predicative environments, unlike weak quantifiers. This contrast is borne out, as evidenced by the data in (23).

- (23) a. \**dínuní tíní dí yé hígií*  
 birds these AGR be every  
 \*‘These birds are every.’  
 b. \**dínuní tíní dí yé códíso*  
 birds these AGR be all  
 \*‘These birds are all.’

To reiterate, the basic observation is that weak quantifiers and ANs pattern together in some key ways. This behavior makes sense if they have the same kind of denotation, and if that denotation is an individual-characterizing one, as Landman argues for weak quantifiers on independent grounds, and as other diagnostics in this paper independently point to for ANs.

#### 4.3. Pronominal anaphora

A final argument for our claim that ANs characterize individuals comes from pronominal anaphora. The observation is simply that there is a predicate anaphor in Basaá that is restricted in the types of predicates it can be anaphoric to. Specifically, the particle in question is *wɛ́é*, and it can be anaphoric to SNs (24), but not to ANs (25), adjectives (26), or common nouns (27).

- (24) *líhat, wɛ́é Paul*  
 rich WEE Paul  
 ‘Rich, that’s Paul.’

- (25) \**nlám, wɛ́é Paul*  
 pretty WEE Paul  
 ‘Pretty, that’s Paul.’

- (26) \**ɲkɛ́ɲí, wɛ́é Paul*  
 important WEE Paul  
 ‘Important, that’s Paul.’

- (27) \**malết, wɛ́é Paul*  
 teacher WEE Paul  
 ‘Teacher, that’s Paul.’

This behavior makes sense if *wɛ́ɛ* is a sortally-sensitive anaphor, which can refer back to substance-characterizing denotations but not individual-characterizing ones.<sup>11</sup> The key fact for the purposes of the discussion here is that ANs cannot be the antecedent of *wɛ́ɛ*, by contrast with SNs, consistent with the former's lacking a substance-characterizing denotation and the latter's having such a denotation.

## 5. Some questions

The facts discussed above demonstrate that ANs do not have a substance-characterizing denotation, and have generally concluded that they are individual-characterizing. What they don't answer are (i) what precise denotation ANs have, and (ii) whether Basaá is genuinely special in having property concept nominals with this kind of denotation.

Beginning with the first question, the meaning of Basaá ANs is a difficult one because there is a fair amount of controversy about what exactly the denotation of adjectives is, with some researchers additionally claiming that adjectival meanings differ across languages (Beck et al., 2010; Bochnak, 2013; Bowler, 2016)). Three types of theory of adjective denotation are laid out in (28):

- (28) Three theories of adjectives
- a. Adjectives denote contextually sensitive sets of individuals (e.g., Kamp 1975; Klein 1980; van Rooij 2011).
  - b. Adjectives denote relations between individuals and a degree argument, with the degree to which the adjective holds specified either morphosyntactically or in context (e.g., Cresswell 1977; von Stechow 1984; Kennedy 1999).
  - c. Adjectives denote what *have* + substance nouns denote (see Menon and Pancheva 2014).

If Bochnak's (2013; 2015) analysis and diagnostics are taken at face-value, we can exclude (28a) from consideration for Basaá ANs, on the grounds that ANs behave like they have a degree (or alternatively, portion) argument—they can be used with measure phrases (29a) and in explicit comparatives (29b), for example.

- (29) a. *ŋ-koo ú yé n-tendée méda mí-tân*  
 3-rope AGR be 4-long 4.meter 4-five  
 'The rope is five meters long.'
- b. *hí.ní hí-nuní hí yé hí-láám léél hí-í.*  
 19-this 19-bird 19.AGR is 19-nice surpass 19-that.one  
 'This bird is nicer than that one.'

<sup>11</sup>The proposed contrast is similar in spirit (if different in details) to the ability of *it* and *that* in English to have predicative (but not individual-denoting) antecedents, as discussed e.g., by Mikkelsen (2005), and shown by the data in (i).

- (i) a. The tallest girl in the class, that/it's Molly.  
 b. The tallest girl in the class, she/\*it/\*that's Swedish. (Mikkelsen, 2005: 64)

The same points could be made for true adjectives in Basaá, illustrating more clearly that ANs and adjectives are semantically similar.

In addition, Bassaá has a gradable modifier that can be used with ANs, *ngandak*:<sup>12</sup>

- (30) *di-nuní dí yé min-langá ngandak.*  
 13-birds 13.AGR COP 4-black very  
 ‘The birds are very black.’

While the same modifier can be used with adjectives (31), it can also be used SNs (32), a fact which might suggest that ANs and the *have*+SN constituent should have the same type of denotation in order to give a uniform denotation to *ngandak*.

- (31) *hí-nuní hí hí yé hi-kéŋí ngandak.*  
 19-bird 19.that 19.SUB be 19-big very  
 ‘That bird is big.’ (adjective)
- (32) *kim a gweé nguy ngandak*  
 kim AGR has strength very  
 ‘Kim is very strong.’ (SN)

Nevertheless, it is still an open question whether this denotation is one that invokes degrees (and scales) or portions (and substances). To a large degree, this is a conceptual issue, though Francez and Koontz-Garboden (2015: 552–556) point to some empirical considerations which could possibly distinguish between the two kinds of theories. The issue hinges largely on the nature of the ordering relation on the degrees/portions, and whether it is antisymmetric (as it is on degree-based theories) or not (as in Francez and Koontz-Garboden’s portion-based theory). Further work is needed to examine this issue in Basaá and more generally.

The discussion thus far has been aimed simply at establishing the existence of individual-characterizing property concept nominals, and has used Basaá for the purposes of an unambiguous existence proof. We have not explored whether Basaá is unique in having property concept nominals of this type, however. As it happens, there is a case that English in fact has property concept nominals similar to Basaá ANs, even if these might be less numerous. The issue hinges on whether nouns like those in (33) are property concept nominals or not. While some of these are restricted to human nouns (*savant*, *genius*) or to inanimate nouns (*antique*), others are less restricted (e.g., *giant*), much like adjectives that could be used to paraphrase them (e.g., *huge*), suggesting that these should be classed as property concept words.<sup>13</sup>

- (33) idiot, savant, genius, giant, antique, disaster

<sup>12</sup>We have not investigated closely whether this gradable modifier shows all the requisite properties of a genuine degree/portion modifier; see Beltrama and Bochnak 2015 for discussion.

<sup>13</sup>These considerations point to the inductive nature of the notion of *property concept word*, and to the need for a property theory of what actually characterizes this class. This issue is one in need of work, and would answer the main question of Dixon (1982): why do adjectives have the meanings they have, particularly in languages with small closed classes of them, where such meanings are predictable?

This class of nouns use copular morphosyntax in predication, rather than possession.

- (34) a. This election is a disaster.  
b. #This election has disaster.

Nouns like *idiot* and *disaster* have, in fact, been investigated in some detail by Morzycki (2012), who points out that there are gradable modifiers in English that can be used with just nouns like these (but not, for example, nouns like *resident*, *teacher*, etc.), a fact which coupled with their behavior in predication, again makes them look like the Basaá ANs:

- (35) a. an utter/huge/big disaster/idiot/genius  
b. #an utter/huge/big teacher/table

In addition, these nouns can modify other nouns in a construction which closely resembles the Basaá AN-of-N construction (see Alexiadou et al., 2007: ch. 2 for an overview):

- (36) a. that idiot of a doctor  
b. the disaster of an election

We can make sense of such facts if these nouns have a denotation like adjectives (a relation between degrees and individuals, or alternatively portions of substance and individuals), with the degree argument saturated by a degree modifier, as in (35), or by *Pos*, creating a predicate of individuals. This suggests that Basaá might be special not so much in having individual-characterizing nominal property concept words, but rather having such a large, open, and productive inventory of them alongside the absence of a large open class of adjectives (cf. English).

## 6. Concluding remarks: Nominally encoded PCs have an argument in domain of substance

It is widely known by now, thanks to Dixon's (1982, 2004) observations, that property concept words can be nominal, adjectival, and verbal. More recently, Francez and Koontz-Garboden have shown that they also vary in their denotation—while property concept words in the familiar, best explored cases involving adjectives are individual-characterizing, there are many, particularly involving nouns, which are substance-characterizing. The program that the work in this paper fits into is that of determining whether all possible cross-classifications of category and meaning are attested, with the goal of using such a cross-classification to better understand the ways in which lexical categoryhood constrains word meaning. Limiting ourselves to adjectives and nouns, cross-classifying category with the two kinds of denotation identified by Francez and Koontz-Garboden leads to a picture like that in (37).

| (37) Nominal and adjectival property concept denotations |                                  |                                 |
|----------------------------------------------------------|----------------------------------|---------------------------------|
|                                                          | <i>Individual-characterizing</i> | <i>Substance-characterizing</i> |
| <i>Adjective</i>                                         | English, Basaá adjectives        | ∅                               |
| <i>Noun</i>                                              | <b>Basaá ANs</b>                 | Basaá SNs                       |

The aim of the program is to determine whether the empty cells are genuinely empty, and if so why. In the case of substance-characterizing adjectives, for example, Francez and Koontz-Garboden (2017: Chapter 6) argue that they are genuinely unattested, and that their absence (impossibility, they argue) follows from the very nature of the adjectival category itself. In this way, the program leads to a better understanding of the nature of lexical categoryhood, adjectives in particular.

The question we have explored in this paper is whether the lower-left hand corner of the table in (37) is attested or not, i.e., whether there exist individual-characterizing property concept nouns. Previously, all known nominal property concepts have had substance-characterizing denotations, leading to the conjecture that they always had this denotation. We have shown that so-called Basaá adjectival nouns are at once nominal and individual-characterizing. Outstanding is still the question of precisely how Basaá adjectival nouns characterize individuals. As discussed briefly in §2, there is much debate in the formal literature about what precisely the denotation of adjectives are. The questions raised in that literature are relevant for the consideration of the precise denotation for Basaá adjectival nouns, and more work is needed. Further, it may well be that what is right for adjectives is actually not right for Basaá adjectival nouns, raising again the question of variation in denotation, and whether that might be tied to lexical category, albeit in a different form, with different kinds of denotations under consideration. In this paper, we have limited ourselves to the question of substance-characterizing denotations versus individual-characterizing denotations, without considering in a precise fashion what the latter are. Future work on Basaá should consider in a more precise fashion than we have done here what the denotations of Basaá adjectival nouns are, and what the observations made about these denotations tells us about the interface between lexical semantics and lexical category. For now, it is at least clear that property concept nominals need not be substance-characterizing.

# Stativity and progressive: The case of Japanese ‘tokoro-da’<sup>1</sup>

Magdalena KAUFMANN — *University of Connecticut*

Stefan KAUFMANN — *University of Connecticut*

**Abstract.** The Japanese noun ‘tokoro’ (lit. ‘place’) has a grammaticalized variant with a temporal interpretation (Takubo 2011). Syntactically, this variant behaves like a noun and is typically modified by a sentence (or a suitable proform). The resulting NP ‘S-tokoro’ roughly means ‘time at which S’. With the copula ‘da/datta’ (Nonpast/Past) it can form a matrix sentence; but on its own it can also be used as a temporal adverbial. In these respects it is similar to other temporal expressions like ‘S-mae’ (‘time before S’), ‘S-ato’ (‘time after S’), and ‘S-toki’ (‘time at which S’). But the acceptability and interpretation of ‘S-tokoro’ interacts with the temporal and aspectual properties of ‘S’ in puzzling ways. Focusing on matrix uses in this paper (embedded ones being similar), we develop an analysis that accounts for those interactions.

**Keywords:** tense, aspect, temporal adverbs, modality, counterfactuality, progressive, Japanese

## 1. Introduction

The Japanese noun ‘tokoro’ (lit. ‘place’) has a grammaticalized variant as a “formal noun” (形式名詞), a dependent category taking a sentential complement to form a compound which behaves outwardly like a noun phrase. In this paper we focus on sentences formed of such an ‘S-tokoro’ phrase and a tensed form of the copula ‘da’, shown schematically in (1).<sup>2</sup>

(1) [ [ SENTENCE ] tokoro ] { da / datta }

Here SENTENCE stands for a tensed clause and ‘da, datta’ are the Nonpast and Past forms of the copula. On the temporal interpretation of ‘tokoro’ (other readings are possible, see below), (1) locates the matrix reference time relative to a time at which SENTENCE is or was true. The temporal and aspectual properties of SENTENCE play a crucial role in determining both whether the construction as a whole is well-formed, and if it is, how it is interpreted. Our goal in this paper is to give a semantic analysis which accounts for these interactions. The observation we are most interested in is that only non-stative and progressive SENTENCES are allowed under temporal ‘tokoro’, whereas lexical statives and perfects are not.

<sup>1</sup>This paper is part of an extensive ongoing project with Yukinori Takubo, to whom we are grateful for much inspiration and discussion. However, the analysis presented here is our own and differs from his in important respects. We are also grateful to Setsuko Arita, Ikumi Imani, Yuya Okawa, Yukiko Atarashiya, the audiences the workshop on *Modality as a window on cognition* (19th International Congress of Linguistics, Geneva, 2013), the Meikai University Linguistics Colloquium (2015), Sinn und Bedeutung 21 (Edinburgh, 2016), and the Meaning Group at the University of Connecticut (2016), for comments and discussion. Part of this work was carried out during a semester at Kyoto University in Fall, 2015. We are grateful to Yukinori Takubo, the Japan Society for the Promotion of Science (Grant L-15504), and Kyoto University for their hospitality and support.

<sup>2</sup>‘S-tokoro’ can also occur in other environments, but its interpretation in such contexts does not differ significantly from that in (1), so we focus on the latter for the purposes of this paper.

### 1.1. Temporal ‘*tokoro*’ with non-statives

Our analysis of the tenses follows Kaufmann and Miyachi (2011; henceforth KM11). Sentences denote binary relations between temporal intervals, i.e., sets of pairs  $\langle i, j \rangle$ . In a non-stative like (2a), the relation holds if and only if (i)  $j$  is the temporal trace of an event of Jon putting on a red jacket; and (ii) either  $i < j$  (for Nonpast) or  $j < i$  (for Past). In Reichenbachian terms, in matrix contexts  $i$  and  $j$  correspond to speech and reference time, respectively.

- (2) a. Zyōn-ga akai zyaketto-wo { ki-ru / ki-ta }  
 Jon-NOM red jacket-ACC put on-NONPAST put on-PAST  
 ‘Jon { will put on / put on } a red jacket’  
 b. [Zyōn-ga akai zyaketto-wo ki-ru] tokoro { da / datta }  
 ‘Jon { is / was } just about to put on a red jacket’  
 c. [Zyōn-ga akai zyaketto-wo ki-ta] tokoro { da / datta }  
 ‘Jon { has / had } just put on a red jacket’

In (2b), the Nonpast version of (2a) is embedded under ‘*tokoro*’ and the tensed copula. We aim to give (2a) a uniform analysis for matrix and embedded contexts, thus we assume that, as in (2a), the embedded clause ‘*Zyōn-ga akai zyaketto-wo ki-ru*’ denotes a binary relation between intervals  $\langle i, j \rangle$ . Now, however,  $i$  and  $j$  correspond to the reference times of the matrix clause and the embedded clause, respectively. Thus for (2b) and (2c) to be true, the matrix reference time must **precede** and **follow** that of the embedded clause, respectively. In both of (2b,c), the relation between the speech time and the matrix reference time is constrained by the tense on the copula. The presence of ‘*tokoro da/datta*’ means that (2b,c) are stative (in contrast to the non-stative (2a)). In this case, a co-temporal reading is available for Nonpast ‘*datta*’ under which speech and reference time coincide.

Thus (2b,c) basically assert that the reference time is/was **before** or **after** the dressing event, respectively. One may wonder how they differ from their counterparts with ‘*mae*’ and ‘*ato*’, the more canonical Japanese counterparts of ‘*before*’ and ‘*after*’. We discuss this relationship in some detail below. For now, suffice it to say that (2b,c) are indeed close in meaning to their counterparts in (3a,b), with the important difference that (2b,c) carry a connotation of **immediacy**, expressed in (2) in our gloss using English ‘*just*’, which (3a,b) lack.

- (3) a. [Zyōn-ga akai zyaketto-wo ki-ru] { mae / \*ato } { da / datta }  
 ‘Jon { is / was } just about to put on a red jacket’  
 b. [Zyōn-ga akai zyaketto-wo ki-ta] { \*mae / ato } { da / datta }  
 ‘Jon { has / had } just put on a red jacket’

### 1.2. Temporal ‘*tokoro*’ with lexical statives

Stative clauses also denote binary relations between intervals but there are differences in detail which lead to markedly different patterns in well-formedness and interpretation under ‘*tokoro*’.

In matrix-level statives, the interpretation is similar to that of non-statives, except that Nonpast allows for speech and reference time to coincide. Thus in terms of the relationship between  $i, j$ , we have  $j < i$  for Past (as with non-statives) and  $i \leq j$  for Nonpast (cf.  $i < j$  for non-statives). In embedded contexts, however,  $i$  must be contained in  $j$ ; as a consequence, Past tense is disallowed (hence the ill-formedness of (4c)) and Nonpast lacks the futurate interpretation on which  $i < j$ . These facts are shared across a range of embedding contexts (see KM11 for data and discussion), but ‘*tokoro*’ adds even more constraints: the embedded Nonpast in (4b) is also peculiar. Most informants judge it to be marginal and, if acceptable at all, restricted to the **counterfactual** reading indicated in the gloss.

- (4) a. Ie-ni { i-ru / i-ta }  
           home-LOC be-NONPAST be-PAST  
           ‘I { am/will be } / was } at home.’  
       b. ?[Ie-ni i-ru] tokoro { da / datta }  
           ‘I would { be / have been } at home.’  
       c. \*Ie-ni i-ta tokoro { da / datta }

In this paper we aim to explain the absence of a temporal reading for (4b). We leave the analysis of the counterfactual reading for another occasion.

### 1.3. Temporal ‘*tokoro*’ with derived statives

In addition to lexical statives, Japanese has aspectual operators which form **derived statives** from eventive complements. A well-studied expression of this kind is the suffix ‘-*tei*’, which combines with the stems of non-stative verbs<sup>3,4</sup> and can have either **progressive** or **perfect** readings, depending on the aspectual properties of the complement and contextual factors. This is illustrated by (5b), which has the two readings indicated in the translation.

- (5) a. Zyon-ga akai zyaketto-wo { ki-tei-ru / ki-tei-ta }  
           Jon-NOM red jacket-ACC wear-TEI-NONPAST wear-TEI-PAST  
           *Progressive*: ‘Jon { is / was } putting on a red jacket’  
           *Perfect*: ‘Jon { is / was } wearing a red jacket’  
       b. [Zyon-ga akai zyaketto-wo ki-tei-ru] tokoro { da / datta }  
           *Progressive*: ‘Jon { is / was } putting on a red jacket’  
           *Perfect*: ‘Jon would { be / have been } wearing a red jacket’  
       c. \*[Zyon-ga akai zyaketto-wo ki-tei-ta] tokoro { da / datta }

That one morpheme should have these two seemingly incompatible uses is puzzling and has made ‘-*tei*’ one of the most written-about expressions in the Japanese linguistic literature. We postpone further discussion to the analysis below. For now, we only point out that the sentences derived with ‘-*tei*’ exhibit an intriguing behavior when combined with ‘*tokoro*’, as

<sup>3</sup>Certain other derivational morphemes can intervene between the verb stem and ‘-*tei*’, for instance Passive, Causative and Potentialis, but not Negation. The details are not relevant here.

<sup>4</sup>The claim that ‘-*tei*’ combines only with non-statives is widely accepted in the literature. Incompatibility with ‘-*tei*’ is Kindaichi’s (1950; 1976) main diagnostic for the class of stative verbs in his taxonomy (*jōtaidōsi*).

shown in (5b): On the Progressive reading of ‘-*tei*-’, ‘*tokoro*’ adds a purely temporal interpretation meaning ‘while/when’, even though no such interpretation is available either with lexical statives, which force a counterfactual reading in this case (cf. (4b)), or with eventives, on which the temporal interpretation would be ‘before’ (cf. (2b)). On the Perfect reading of ‘-*tei*-’, the sentence patterns with lexical statives in that only a counterfactual reading is available. Notice also that (5c) patterns with stative (4c) and not with eventive (2c) in that the string is ill-formed.

This is the main puzzle to be addressed in this paper: On the one hand, Progressive and Perfect are generally considered derived statives, and the Japanese examples exhibit some properties that are expected under this analysis (e.g., the ill-formedness of (5c) and the relationship between the matrix and embedded reference times in (5b)). On the other hand, under ‘*tokoro*’ the Perfect is restricted to a counterfactual reading like other statives, while the Progressive has a temporal reading – which, however, is unlike that obtained with non-statives.

## 2. Theoretical background

We develop our analysis in a slightly simplified version of the framework introduced by KM11.<sup>5</sup> The major ingredients are shown in (6) along with their hierarchical structure in the sentence.

(6) [ [ [ [ SENTENCE RADICAL ] ASPECT ] TENSE ] ENVIRONMENT ]

Sentence radicals come in two major classes, stative and non-stative. We are not concerned here with the kind of sub-sentential aspectual composition that arises with quantification and distributivity, for instance, but we do need a formal representation of the stative/non-stative distinction. Aspectual operators impose temporal constraints on reference times and relate events to times. We assume that ‘-*tei*-’ is such an operator. But even sentences without ‘-*tei*-’ or other overt aspectual markers include a covert aspectual operator. In this we follow KM11. There are two tenses, Nonpast and Past, whose interpretation depends on the aspectual class of their complement as well as on the difference between matrix and embedded contexts. What we label as “Environment” in (6) is either the matrix context or one of a class of subordinating expressions which includes ‘*tokoro*’.

### 2.1. The model

Let  $\langle T, < \rangle$  be a non-empty set of temporal instants ordered by the transitive, irreflexive and connected relation  $<$ . The **temporal period structure** induced by  $\langle T, < \rangle$  is a triple  $\langle I, \subseteq, < \rangle$ , where  $I$  is the set of non-empty convex subsets of  $T$ ,<sup>6</sup>  $\subseteq$  is set-theoretic inclusion, and  $<$  is the relation of strict precedence on  $I \times I$ . An **event structure** is a join-semilattice  $\langle E, \sqsubseteq \rangle$ , where  $E$  is a non-empty set of events and  $\sqsubseteq$  is a partial order interpreted as the mereological “sub-event” relation. A **temporal model** is an octuple  $\langle I, \subseteq, <, E, \sqsubseteq, \tau, s, V \rangle$ , where  $\langle I, \subseteq, < \rangle$  is a temporal period structure;  $\langle E, \sqsubseteq \rangle$  is an event structure;  $\tau : E \mapsto I$  maps events to their temporal traces, subject to the condition that for all  $e, e' \in E$ , if  $e \sqsubseteq e'$  then  $\tau(e) \subseteq \tau(e')$ ;  $s \in I$  is a (short)

<sup>5</sup>The simplification concerns KM11’s account of absolute tense under ‘*toki*’, which is orthogonal to this paper.

<sup>6</sup>A set  $T' \subseteq T$  is **convex** iff for all  $t, t', t''$ , if  $t < t' < t''$  and  $t, t'' \in T'$ , then  $t' \in T'$ .

interval representing the speech time; and  $V$  is an interpretation function mapping non-stative and stative sentence radicals to (characteristic functions of) subsets of  $E$  and  $I$ , respectively.

We present our analysis as a compositional mapping from Japanese sentences to expressions in an extensional type-theoretical language which are then to be interpreted in temporal models. The basic types are  $i$  with  $D_i = I$  (intervals),  $e$  with  $D_e = E$  (events) and  $t$  with  $D_t = \{0, 1\}$  (truth values). We do not define the language or its interpretation explicitly because both will be obvious. We do assume that it has variables  $i, j, k, \dots$  ranging over intervals and  $e$  ranging over events; and symbols for unary predicates of intervals and events (corresponding to sentence radicals). We overload the symbols  $s, \tau, <, \subseteq$  (mapped to the speech time  $s$ , the temporal trace function, the precedence relation  $<$ , and the subinterval relation). We will define further symbols below.

## 2.2. Sentence radicals

Stative and non-stative sentence radicals denote properties of intervals and events, respectively.

- |                                                                                                                                                                                         |                                                                                                                                                                                           |

## 2.3. Aspectual operators

Next up in the structure in (6) is a slot for aspectual operators. The suffix ‘-*tei*’ mentioned above is one of these operators; we also assume, following KM11, that sentences which do not have an overt operator in this location have a covert one.<sup>7</sup> Semantically, aspectual operators map properties of intervals or events to binary relations between intervals. We use the symbols in (9) for relations between intervals, in addition to the “strict precedence” relation already defined in the model (see also Allen, 1983).

- (9)    **Relations between intervals**
- |    |                                                                                       |                                      |
|----|---------------------------------------------------------------------------------------|--------------------------------------|
| a. | $i \not\cap j := i < j \vee j < i$                                                    | [non-overlap]                        |
| b. | $i \subseteq j := \exists k, l [k \subseteq j \wedge l \subseteq j \wedge k < i < l]$ | [non-initial, non-final subinterval] |

These relations are used in the translations of the aspectual operators. We adopt from KM11 the convention of using the names  $\varphi$  and  $\rho$  for variables over properties of intervals and properties of events, respectively.<sup>8</sup>

<sup>7</sup>This simplifies the lexical entries of morphemes (such as tenses) that can combine with sentence radicals both directly and via the mediation of aspectual operators.

<sup>8</sup>We deviate slightly from KM11’s definition of  $\emptyset$  for non-statives: their  $\tau(e) \subseteq j$ , corresponds to our  $j = \tau(e)$ .

(10) **Aspectual operators**

- a.  $\emptyset \rightsquigarrow \lambda\varphi_{\langle i,t \rangle} \lambda i \lambda j [\varphi(j) \wedge [i \neq s \rightarrow i \in j]] \cup$   
 $\lambda\rho_{\langle \epsilon, t \rangle} \lambda i \lambda j [\exists e [\rho(e) \wedge j = \tau(e)] \wedge i \not\subseteq j]$
- b. ‘-tei-’  $\rightsquigarrow \lambda\rho_{\langle \epsilon, t \rangle} \lambda i \lambda j [\exists e [\rho(e) \wedge \boxed{\text{TEI}(e, j)}] \wedge [i \neq s \rightarrow i \in j]]$

At this point the expression “TEI( $e, j$ )” is just a placeholder. We return to this issue in Section 3, where we fill in the details that explain why ‘*tokoro*’ can have a temporal interpretation with the Progressive reading but not with the Perfect reading of ‘-tei-’. For now, we are more interested in the last conjunct of the formula in (10b), which establishes the relationship between the two intervals  $i, j$ . If  $i$  is not the speech time (i.e., in embedded contexts), it must be contained in  $j$ , otherwise (i.e., in matrix contexts) it is not so constrained. This condition mirrors the one imposed by the covert aspectual operator for lexical statives (the upper line in (10a)). This is the sense in which we think it correct to say that clauses modified by ‘-tei-’ are (derived) **statives**, regardless of whether the reading is Progressive or Perfect. The result of applying these aspectual operators to sentence radicals in (7) and (8) is given in (11).

- (11) Zyōn-ga nihon-ni { a. i- $\emptyset$  / b. ik- $\emptyset$  / c. it-tei }
- Jon-NOM Japan-LOC be go go-TEI
- Jon { be in / go to / go-TEI to } Japan
- a.  $\rightsquigarrow \lambda i \lambda j [\text{JONINJAPAN}(j) \wedge [i \neq s \rightarrow i \in j]]$
- b.  $\rightsquigarrow \lambda i \lambda j [\exists e [\text{JONTOTJAPAN}(e) \wedge j = \tau(e) \wedge i \not\subseteq j]]$
- c.  $\rightsquigarrow \lambda i \lambda j [\exists e [\text{JONTOTJAPAN}(e) \wedge \boxed{\text{TEI}(e, j)}] \wedge [i \neq s \rightarrow i \in j]]$

## 2.4. Tense

Next up in our structure (6) are the tenses. As mentioned above, there are two tenses in Japanese, Nonpast and Past, typically expressed on verbs with some allomorph of ‘-ru’ and ‘-ta’, respectively, except for the copula, whose forms are ‘-da’ and ‘-datta’.<sup>9</sup>

(12) **Tenses**

- a. NONPAST  $\rightsquigarrow \lambda i \lambda j [i \leq j]$       b. PAST  $\rightsquigarrow \lambda i \lambda j [j < i]$

- (13) Zyōn-ga nihon-ni { a. i-ru / b. i-ta / c. ik-u / d. it-ta / e. it-tei-ru / f. it-tei-ta }
- Jon-NOM Japan-LOC be-NP be-P go-NP go-P go-TEI-NP go-TEI-P
- ‘Jon {is in / was in / is going to / went to / ... } Japan’
- a.  $\rightsquigarrow \lambda i \lambda j [\text{JONINJAPAN}(j) \wedge i \leq j \wedge [i \neq s \rightarrow i \in j]]$
- b.  $\rightsquigarrow \lambda i \lambda j [\text{JONINJAPAN}(j) \wedge j < i \wedge [i \neq s \rightarrow i \in j]]$ <sup>10</sup>
- c.  $\rightsquigarrow \lambda i \lambda j [\exists e [\text{JONTOTJAPAN}(e) \wedge j = \tau(e)] \wedge i < j]$
- d.  $\rightsquigarrow \lambda i \lambda j [\exists e [\text{JONTOTJAPAN}(e) \wedge j = \tau(e)] \wedge j < i]$
- e.  $\rightsquigarrow \lambda i \lambda j [\exists e [\text{JONTOTJAPAN}(e) \wedge \boxed{\text{TEI}(e, j)}] \wedge i \leq j \wedge [i \neq s \rightarrow i \in j]]$
- f.  $\rightsquigarrow \lambda i \lambda j [\exists e [\text{JONTOTJAPAN}(e) \wedge \boxed{\text{TEI}(e, j)}] \wedge j < i \wedge [i \neq s \rightarrow i \in j]]$ <sup>10</sup>

<sup>9</sup>One class of adjectives also carries tense, expressed with ‘-i’ and ‘-katta’ for Nonpast and Past, respectively. The negative suffix ‘-na{-i/-katta}’ belongs to this paradigm.

<sup>10</sup>Notice that (13b,f) imply that  $i = s$ , in line with the observation that Past statives only occur in matrix contexts.

## 2.5. Embedding environments

Next up we now reach the position filled by ‘*tokoro*’ or other embedding temporal expressions, such as ‘*toki*’ ‘when’, ‘*mae*’ ‘before’, etc. It is instructive to compare several such items to ‘*tokoro*’. In (14) we give four examples along with their interpretations from KM11.

- (14) a. *mae* ‘before’  $\leadsto \lambda\varphi_{\langle i, \langle i, t \rangle \rangle} \lambda h \lambda i \exists j [\varphi(i)(j) \wedge i < j]$   
 b. *ato* ‘after’  $\leadsto \lambda\varphi_{\langle i, \langle i, t \rangle \rangle} \lambda h \lambda i \exists j [\varphi(i)(j) \wedge j < i]$   
 c. *uti* ‘while’  $\leadsto \lambda\varphi_{\langle i, \langle i, t \rangle \rangle} \lambda h \lambda i \exists j [\varphi(i)(j) \wedge i \subseteq j]$   
 d. *toki* ‘when’  $\leadsto \lambda\varphi_{\langle i, \langle i, t \rangle \rangle} \lambda h \lambda i \exists j [\varphi(i)(j)]$

All of these items are of the same type, viz.  $\langle \langle i, \langle i, t \rangle \rangle, \langle i, \langle i, t \rangle \rangle \rangle$  (i.e., modifiers of binary relations between intervals). Their arguments are the denotations of tensed sentences – relations between intervals  $i, j$  which, in matrix sentences, are interpreted as the speech time and the reference time, respectively. In (14) we see that a new time is introduced when tensed sentences are embedded under temporal connectives. The idea is that now  $h, i$  are interpreted as the speech and reference time of the matrix sentence, and  $i$  anchors the temporal interpretation of the embedded clause. The relation that the embedded sentence imposes on  $i, j$  is now, in Reichenbachian terms, imposed on the reference time and event time of the embedded clause.

The semantic contribution of most of the items in (14) is an added condition on the temporal relation between  $i, j$  (an exception is ‘*toki*’, which does not add any new constraint). This condition is conjoined with whatever the complement clause already requires of the two intervals. The result may be a contradiction, resulting in ill-formedness (e.g., in the case of ‘*mae*’ ‘before’ with Past tense or ‘*ato*’ ‘after’ with Nonpast). Some of the results are shown in (15) and (16).

- (15) Zyōn-ga nihon-ni { a. *ik-u* / b. *\*it-ta* } *mae*  
 Jon-NOM Japan-LOC go-NPST go-PST before  
 ‘before Jon {goes / went} to Japan’  
 a.  $\leadsto \lambda h \lambda i \exists j [\exists e [\text{JONToJAPAN}(e) \wedge j = \tau(e)] \wedge i < j \wedge i < j]$  ✓  
 b.  $\leadsto \lambda h \lambda i \exists j [\exists e [\text{JONToJAPAN}(e) \wedge j = \tau(e)] \wedge i < j \wedge j < i]$  ✗
- (16) Zyōn-ga nihon-ni *i-ru* { a. *\*mae* / b. *\*ato* / c. *uti* / d. *toki* }  
 Jon-NOM Japan-LOC be-NPST before after while when  
 ‘{before / after / while / when} Jon {is / was} in Japan’  
 a.  $\leadsto \lambda h \lambda i \exists j [\text{JONInJAPAN}(j) \wedge i < j \wedge i \subseteq j]$  ✗  
 b.  $\leadsto \lambda h \lambda i \exists j [\text{JONInJAPAN}(j) \wedge j < i \wedge i \subseteq j]$  ✗  
 c.  $\leadsto \lambda h \lambda i \exists j [\text{JONInJAPAN}(j) \wedge i \subseteq j \wedge i \subseteq j]$  ✓  
 d.  $\leadsto \lambda h \lambda i \exists j [\text{JONInJAPAN}(j) \wedge i \subseteq j]$  ✓

Table 1 shows the overall pattern resulting from the interaction between the various temporal constraints. *iku* ‘go’ and *iru* ‘be’ are non-stative and stative, respectively. The rightmost column shows the data with ‘*tokoro*’ that we outlined earlier. Our goal is to add a semantic entry for ‘*tokoro*’, replacing the question marks in the top row.

Table 1: Temporal constraints contributed by temporal connectives (top row) and their clausal complements (left column), and the resulting well-/ill-formedness of the combinations.

There are three major challenges to this project. First, as seen in the table, ‘tokoro’ is sensitive to a distinction that the other particles do not track, distinguishing between the upper three rows (Nonstative *ik-u/it-ta* ‘go’; Progressive reading of ‘-teiru’) and the lower rows (Stative *i-ru/i-ta* ‘to be’, and Perfect reading of ‘-teiru’). None of the other connectives is sensitive to this distinction, nor is it expressed in the relation between the intervals  $i, j$ , which was sufficient to account for the patterns discussed so far. Secondly, ‘tokoro’ adds a connotation of “immediacy” to the temporal relations in the top rows, which our rendering in English as ‘right before’ and ‘right after’ is intended to convey. Finally, ‘tokoro’ alone has a counterfactual reading in cases in which a temporal reading is unavailable.

### 3. Analysis

We address the challenges just discussed in terms of an interaction between ‘tokoro’'s aspectual properties and a certain notion of “immediacy.” For instance, recall that with non-stative complements, ‘tokoro’ comes to mean ‘right before’ or ‘right after’, depending on the embedded tense. We want to formalize this notion in such a way that the more peculiar properties of ‘tokoro’ – its well-formedness with Progressive but not with Perfect ‘-teiru’ and the availability of a counterfactual reading with Perfect ‘-teiru’ and statives – also fall out.

One way to describe the peculiar behavior of ‘tokoro’ in combination with ‘-teiru’ is that on the Progressive reading of ‘-teiru’ these sentences behave like non-statives, whereas on the Perfect reading they behave like statives. We need to explain, not only why one and the same morpheme, ‘-tei-’, can have such disparate uses, but also why on the Progressive use it has a certain eventive “flavor” which is absent from the Perfect use.

What is this eventive “flavor,” and how should it be represented? It is a widely held view that events involve **change** or **development** of some kind, and that their progress can be **measured**

<sup>11</sup>Past statives can in principle occur in embedding contexts, but only with an **absolute** reading of the Past tense (i.e., one anchored to the speech time rather than the matrix reference time). Whether such a reading is available depends on the embedding connective. It is not available under ‘tokoro’, therefore we ignore it in this paper. It is available under ‘toki’, hence the asterisk in the corresponding cell in our table is a simplification. See Kaufmann and Miyachi (2011) for details.

in various ways, whereas states have none of those properties. The stative/non-stative distinction is often taken to be an ontological fact about different kinds of eventualities (Smith, 1991; Bach, 1986<sup>12</sup>); the notion that events can be measured is discussed and formalized in various ways depending on whether the measurement draws on incremental themes, expressions of creation, changes of state or degree, paths, or yet some other notion (Dowty, 1991; Krifka, 1989, 1992; Tenny, 1994; Hay et al., 1999; Kennedy and Levin, 2008, *i.a.*).

In this paper we stop short of committing ourselves to a particular view on the origins of event measurement. We are more interested in the question of how, once such measurement is introduced, it can have repercussions throughout the compositional process. For recall that ‘*tokoro*’ does not combine directly with event-denoting sentence radicals, and not even with ‘*radical+tei*’ compounds. Instead, it combines with tensed clauses, and we have been assuming throughout that tensed clauses denote binary relations between temporal intervals. Since there is no direct link to the underlying eventualities, the “eventive flavor” of the Progressive cannot be implemented straightforwardly in terms of the denotatum of ‘*tokoro*’’s complement. Instead, we need a way to let the stative/non-stative distinction that is accessible lower in the derivation leave an “imprint” on the intervals higher up.

To implement this, we enrich our representation of temporal traces. We do this in two steps: in Section 3.1, give ‘*-tei-*’ access to different phases of an event (*viz.* its run-time and its result state, where available); in Section 3.2 we add a representation of event measurement.

### 3.1. The versatility of ‘*-tei-*’

While space does not permit us to do justice to the extensive literature on ‘*-tei-*’, we do need to introduce the basic facts about its semantic versatility. Most discussions of ‘*-tei-*’ distinguish at least three readings: Progressive, Resultative Perfect, and Experiential Perfect. Which of them are available for a particular sentence containing ‘*-tei-*’ depends on the preadjacent’s aspectual properties (and possibly other factors). The clearest cases exhibiting all readings are accomplishments with an activity phase and a result state. The examples in (17) are from Igarashi and Gunji (1998), adjusted to our transliteration and glosses. (17a,b) illustrate the Progressive and Resultative Perfect readings, as highlighted by the English glosses. In (17c), the combination of the past adverbial ‘*sannen mae-ni*’ ‘three years ago’ with Nonpast tense forces the Experiential Perfect reading (Fujii, 1976; Ogihara, 1998).

- (17) a. Ken-wa ima tonari-no heya-de kimono-wo ki-tei-ru [PROG]  
 Ken-TOP now next-GEN room-LOC kimono-ACC put on-TEI-NPST  
 ‘Ken is now putting on a kimono in the next room’  
 b. Ken-wa kesa kara zutto ano kimono-wo ki-tei-ru [RESULT]  
 Ken-TOP this morning from always that kimono-ACC put on-TEI-NPST  
 ‘Ken has been wearing that kimono since this morning’

<sup>12</sup>Bach distinguishes states, processes and events, with the latter two being subsumed under the class of “non-states.” We use the labels “non-stative” and “eventive” interchangeably.

- c. Ken-wa ano kimono-wo sannen mae-ni ki-tei-ru [EXP]  
 Ken-TOP that kimono-ACC three years before-LOC put on-TEI-NPST  
 (i) 'Ken has the experience of putting on that kimono three years ago' [EXP I]  
 (ii) 'Ken has the experience of wearing that kimono three years ago' [EXP II]

Igarashi and Gunji (1998) argue that the Experiential (17c) can actually have two readings, depending on which of the two phases of the accomplishment – the putting on or the wearing of the kimono – is said to have taken place in the past. The two translations in (17c) are meant to bring out that difference. Gunji (2004) puts even more emphasis on this distinction, extending the traditional tripartite taxonomy by treating the two variants of the Experiential Perfect as distinct (though related) readings. This allows him to account for the full picture in terms of the interplay between two independent dimensions of variation: Activity vs. Result State reading of the prejacant, and Ongoing vs. Anterior reading of '-tei-'.<sup>13</sup> The competing view of the traditional tripartite taxonomy is that the distinction between Activity and Resultative reading of the prejacant is only relevant under the Ongoing reading of '-tei-', but neutralized under its Anterior reading (Ogihara, 1998).

We adopt (Igarashi and) Gunji's position that there is a major distinction between the Progressive and Resultative Perfect reading on the one hand, and the Experiential reading(s) on the other.<sup>14</sup> This distinction seems related to a grammatical difference, as shown by the ability of past adverbials to co-occur with Present tense only under the Experiential reading.<sup>15</sup> We stop short of postulating two distinct readings of the Experiential, however. This is in part because space is limited and a formal implementation which draws the distinction would require further modifications to the framework. Moreover, most informants report having a hard time seeing a clear semantic difference between the two readings. For the purposes of this paper, at least, we treat (17c) as one reading in which the Activity/Result State distinction is neutralized.

For our formal analysis, this means that we need to encode two distinctions: the Activity/Result State distinction for the prejacant, and the Ongoing/Anterior distinction for '-tei-'. Furthermore, we follow those who assume that the two distinctions are not independent: Activity and Result State are only distinguished under Ongoing '-tei-'. Finally, we want to account for the fact that past adverbials can occur with Nonpast tense under Anterior but not Ongoing '-tei-'.

<sup>13</sup>Gunji uses different terminology: at both levels, he distinguishes a **basic** view (基本視野; in our terminology, Activity at the level of the precedent and Ongoing at the level of '-tei-') from a **stative** view (状態視野, our Result State (prejacant) and Anterior ('-tei-')). We prefer our terminology for its mnemonic value (for us), but nothing hinges on this choice. Notice also that Gunji considers '-tei-' complex. He attributes the Ongoing/Anterior distinction to the semantics of '-te-' alone, while taking 'i' to be semantically inert.

<sup>14</sup>A separate class of approaches, which we do not discuss in detail here, seeks to unify the Resultative Perfect and the Experiential Perfect reading, setting them apart from the Progressive. See Ogihara (1998) for discussion.

<sup>15</sup>Past adverbials **can** modify sentences with '-tei-' under the other readings, but only if the matrix tense is Past:

- (i) Ken-wa ano kimono-wo sannen mae-ni ki-tei-ta  
 Ken-TOP that kimono-ACC three years before-LOC wear-TEI-PST  
 'Ken was { putting on / wearing } that kimono three years ago.'

These cases do not pose a problem for our analysis on the assumption that the adverb here has '-tei-' in its scope, rather than *vice versa*.

We start with Ongoing ‘-tei-’ and the two readings it gives rise to. Our preliminary definition of ‘-tei-’ from (10b) is repeated below.

$$(10b) \quad (\text{preliminary}) \lambda\rho_{\langle\epsilon,t\rangle}\lambda i\lambda j[\exists e[\rho(e) \wedge \boxed{\text{TEI}(e, j)}] \wedge [i \neq s \rightarrow i \in j]]$$

We now need to spell out the expression  $\text{TEI}(e, j)$  in the box in (10b). The idea is that ‘-tei-’ makes the inner stages of an event available for linguistic reference. We could simply replace the the box with the condition that  $j = \tau(e)$ , thus locating  $i$  within the runtime of the event in embedded contexts. However, this would only make the Progressive interpretation available, not the Perfect.

To add the Perfect, we adapt from Igarashi and Gunji (1998); Gunji (2004) the main idea behind their classification. In principle, not one but two intervals can be associated with an event in the extension of a sentence radical: one is the familiar temporal trace of the event itself, the other is the interval over which its result state holds.<sup>16</sup> Whether both of these intervals are available depends on the aspectual class: activities have no lexically encoded result state, whereas achievements may have a result state but no temporal extension in the triggering change-of-state event (i.e., no interval corresponding to an Activity part). Consequently, under ‘-tei-’, activities typically only have Progressive readings and achievements only Result state readings, whereas accomplishments can have both.

Formally, we define an **extended temporal trace** function  $\tau^+$  from events to sets of (one or two) intervals. The intention is that  $\tau^+(e)$  is true of the conventional temporal trace  $\tau(e)$  but also of the maximal interval of which  $e$ ’s result state holds, in case the latter is defined. In (18) we use the auxiliary notation *result* for the partial function mapping events to their result states.<sup>17</sup>

(18) **Extended temporal trace**

For all events  $e$ ,  $\tau^+(e) := \lambda i[i = \tau(e) \vee \exists j[j = \text{result}(e) \wedge i = j]]$

Our definition for Ongoing ‘-tei-’ draws on this notion:

$$(19) \quad \text{‘-tei-’}_{\text{ONG}} \rightsquigarrow \lambda\rho_{\langle\epsilon,t\rangle}\lambda i\lambda j[\exists e[\rho(e) \wedge \tau^+(e)(j)] \wedge [i \neq s \rightarrow i \in j]]$$

We now turn to the Anterior reading of ‘-tei-’. What would seem to be the most straightforward way to include this reading – by modifying (19) to allow for the case that  $j < i$  – is not viable.

<sup>16</sup>Note that Igarashi and Gunji’s implementation differs from ours: their constraints refer to the boundaries of the intervals in question, calling them the “start time” and “finish time” of the event (the latter also serving as the start time of the result state, where applicable), and the “reset time” marking the end of the result state. Aside from this difference, and modulo further fine distinctions that we cannot go into for lack of space, the intuitions are similar to our implementation, as far as we can see.

<sup>17</sup>This way of implementing the idea has certain consequences for the underlying notion of events. Ogihara (Ogihara, 1998, p. 96) points out that two different descriptions of the same state of affairs can have different aspectual properties. For instance, different sentences referring to the same opening of a door may or may not have Progressive readings depending on the grammatical form. This means that the value of  $\tau^+(e)$  may differ depending on the sentence used. In order to avoid untoward consequences of this possibility (e.g., ensuring that  $\tau^+$  is a function), we have to assume that in such cases the model actually contains two distinct events representing the very same opening of the door which can serve as denotations of the different linguistic expressions.

This is because Anterior ‘-tei-’ allows for the coexistence of past adverbs like ‘*kyonen*’ ‘last year’ with Nonpast tense. In our framework, this would mean that the adverb places  $j$  within the year preceding that of the speech time, while the Nonpast tense rules out the possibility that  $j$  precedes  $i$ , leading to contradictory constraints in matrix contexts (where  $i$  ends up referring to the speech time). We avoid this unwelcome consequence by giving Anterior ‘-tei-’ a denotation of an altogether different type and assuming that in the syntactic derivation it behaves in some respects more like a tense than an aspectual operator. Specifically, we assume that it co-occurs with, and outscopes, the covert aspectual operator  $\emptyset$ . Consequently, its complement denotes a relation between intervals, not a property of events, and this makes it possible for temporal adverbs to scope lower than ‘-tei-’. At the same time, as seen in the denotation in (20b), ‘-tei-’ introduces an additional interval  $k$  at which the prejacent  $\varphi$  is evaluated and which can be constrained by temporal adverbs. The tense above ‘-tei-’, meanwhile, constrains the relation between  $i$  and  $j$ . Thus past adverbs and present tense may co-occur without contradiction.<sup>18</sup>

- (20) a. ‘-tei-’<sub>ONG</sub>  $\rightsquigarrow \lambda\rho_{\langle e,t \rangle} \lambda i \lambda j [\exists e [\rho(e) \wedge \tau^+(e)(j)] \wedge [i \neq s \rightarrow i \in j]]$   
 b. ‘-tei-’<sub>ANT</sub>  $\rightsquigarrow \lambda\varphi_{\langle \langle i,t \rangle, \langle \langle i,t \rangle, t \rangle \rangle} \lambda i \lambda j [\exists k [\varphi(j)(k) \wedge k < j] \wedge [i \neq s \rightarrow i \in j]]$

We illustrate with a few examples. (21) is a matrix sentence with the temporal adverb ‘*kyonen*’ ‘last year’. (21a) shows the denotation (the conditions imposed by Present or Past tense are listed in the last conjunct) which is then evaluated at the speech time  $s$  (fixed by the model) and reference time  $r$  (contributed by context). In this case the two constraints contributed by LASTYEAR and tense are imposed on the same pair of intervals  $s, r$ . The ill-formedness of the Present-tense variant arises at this point due to the inconsistency of LASTYEAR( $s$ )( $r$ ) and  $s \leq r$ .<sup>19</sup>

- (21) *Kyonen kimono-wo ki- { \*ru / ta }*  
 last year kimono-ACC wear NPST PST  
 [ [*kyonen*] [ [*kimono-wo ki*]  $\emptyset$  ] ] { \*ru / ta } ]  
 a.  $\rightsquigarrow \lambda i \lambda j [\exists e [\text{KIMONO KI}(e) \wedge j = \tau(e)] \wedge i \emptyset j \wedge \text{LASTYEAR}(s)(j) \wedge \{i \leq j / j < i\}]$   
 (21a)( $s$ )( $r$ )  $\Leftrightarrow \exists e [\text{KIMONO KI}(e) \wedge r = \tau(e)] \wedge \text{LASTYEAR}(s)(r) \wedge r < s$

We next turn to ‘-tei-’. For ease of exposition, we list examples of its Ongoing and Anterior use separately. The surface strings are indistinguishable, but we indicate the respective intended derivations in the bracketed representations. First consider Ongoing ‘-tei-’, which due to its type must combine directly with the sentence radical and scope under the temporal adverb. Only the Past-tense variant of the sentence can have this reading; the Nonpast is ruled out in the same way as the Nonpast of (21) above. Which readings (Activity and/or Result State Perfect) (22) can have depends on which intervals are made available by the extended temporal trace  $\tau^+(e)$ . Which reading it has in any particular instance further depends on how  $\tau^+(e)$  applies

<sup>18</sup>The reader may notice that according to (20b) the “high” ‘-tei-’ has the same type as the tenses – both are modifiers of binary relations between structured intervals. This means that the denotations do not by themselves enforce the observed structural relationship, i.e., that tense invariably sits higher in the syntactic tree than ‘-tei-’. We assume that this relationship is enforced independently by syntactic factors.

<sup>19</sup>Note that it is not the past reference *per se* that is incompatible with Present tense. For instance, embedded under connectives like ‘*toki*’ ‘when’ and ‘*mae*’ ‘before’, Present tense is not interpreted as restricting  $s, r$  and can thus happily coexist with past intervals like ‘*kyonen*’.

to  $j$  (ultimately,  $r$ ): it is a (non-initial and non-final) subinterval of either  $\tau(e)$ , giving rise to the Activity reading, or of  $result(e)$ , corresponding to the Result State Perfect reading.

- (22) Kyonen kimono-wo ki-tei<sub>ONG</sub>- { \*ru / ta }

 $(22a)(s)(r) \Leftrightarrow \exists e [KIMONO KI(e) \wedge \tau^+(e)(r)] \wedge LASTYEAR(s)(r) \wedge r < s$

For the Anterior reading of ‘-tei-’, we do not predict that past adverbs with Nonpast tense result in inconsistency. This is shown in (23).

- (23) Kyonen kimono-wo ki-tei<sub>ANT</sub>-ru  
 last year kimono-ACC wear-TEI-NPST  
 [ [ [ kyonen [ [ kimono-wo ki ]  $\emptyset$  ] ] tei ] ru ] [PRES EXP]

 $(23a)(s)(r) \Leftrightarrow \exists k [\exists e [KIMONO KI(e) \wedge k = \tau(e)] \wedge LASTYEAR(s)(k) \wedge k < r \wedge s \leq r]$

But we do not predict Anterior ‘-tei-’ to be inconsistent with Past tense either. In fact, we derive two readings for (24), corresponding to two positions of the adverb relative to ‘-tei-’. On the reading in (24a/b), the adverb restricts  $k$ , the event of putting on the kimono; the reference time  $r$ , which must lie strictly between  $k$  and  $s$ , is thus a time at which the experiential state holds. On this interpretation the sentence means that at some point in the recent past (say, a week ago) it was true (or it turned out) that the subject had worn a kimono last year. On the reading in (24c/d) the adverb restricts the reference time  $r$ , while the time  $k$  of wearing the kimono must be found at an even earlier time. In other words, it turned out last year that (already then) the subject had the experience of having worn a kimono. We take it that both readings exist.

### 3.2. Event measurement

Traditionally, the temporal trace of an event has been taken to be an interval (assigned to the event by the function  $\tau$ , Krifka (1989)), and we have followed this convention thus far. The left-hand side of Figure 1 is an illustration. We propose a straightforward modification of this simple picture: The temporal trace function  $\tau_S$  maps events to **structured intervals**, our term for sets

Figure 1: Left: Temporal trace  $\tau$  mapping events to intervals. Middle: Temporal trace  $\tau_S$  mapping events to structured intervals (top) and induced order  $\preceq_{\tau(e)}$  on  $T$  (bottom). Right: Stative denotation  $i$  (top) and pre-order  $\preceq_{\{i\}}$  on  $T$  (bottom).

of intervals which contain their own union.<sup>20</sup> In our type-theoretic compositional framework, structured intervals are represented by their characteristic functions, i.e., in  $D_{\langle i, t \rangle}$ , and we use variables  $\mathbf{i}, \mathbf{j}$ , etc. to range over them. For ease of exposition, we switch between talk of these characteristic functions and the sets of intervals they characterize, using variables like  $\mathbf{A}, \mathbf{B}$ , etc. for the latter. No confusion should result from this.

(25) A set  $\mathbf{A}$  of intervals is a **structured interval** iff  $\cup \mathbf{A}$  is an element of  $\mathbf{A}$ .

The relations between intervals defined above can be extended to structured intervals straightforwardly as follows:

(26)  $\mathbf{A} < \mathbf{B} := \cup \mathbf{A} < \cup \mathbf{B}$     $\mathbf{A} \emptyset \mathbf{B} := \cup \mathbf{A} \emptyset \cup \mathbf{B}$     $\mathbf{A} \in \mathbf{B} := \cup \mathbf{A} \in \cup \mathbf{B}$     $\mathbf{A} \supset \mathbf{B} := \cup \mathbf{A} \supset \cup \mathbf{B}$

The shift from simple to structured temporal traces does not affect their durations, just their internal structure. Thus we assume that each  $\tau_S(e)$  contains  $\tau(e)$  as its greatest element.

(27) A **structured temporal trace** is a function  $\tau_S$  mapping events to structured intervals, subject to the condition that for all events  $e$ ,  $\tau(e) = \cup \tau_S(e)$ .

Next, we use sets of intervals to derive a pre-order on the entire set  $T$  of times as in (28).<sup>21</sup> For our example in Figure 1, the relative ranking of the equivalence classes of the pre-order induced by  $\tau(e)$  is shown in the lower middle graph.

(28) **Induced pre-order on  $T$**

Let  $A$  be a set of intervals. The pre-order  $\preceq_A$  on  $T$  induced by  $A$  is defined as follows:  $t \preceq_A t'$  iff all intervals in  $A$  which contain  $t$  also contain  $t'$ .

<sup>20</sup>In fact, the structured intervals we consider here are **nests** of **final** subintervals; but we refrain from imposing those stronger properties by definition since nothing in our proposal depends on them.

<sup>21</sup>This notion of an induced pre-order is inspired by Kratzer's treatment of modality (Kratzer, 1981, *i.a.*); but notice that here the order is reversed, in the sense that times that are contained in more intervals are ranked higher, rather than lower.

This latter change also affects the interpretation of statives. Recall from above that they were mapped to properties of intervals. This remains unchanged, but now what gets passed up in the compositional process is the singleton sets containing those intervals. Singleton sets of intervals induce single-step pre-orders as shown on the right-hand side in Figure 1. There, all points in  $i$  are ranked equally and strictly higher than any point outside of  $i$ . This is in line with the intuition that the denotations of statives do not involve any notion of change or development.

The switch to set-valued temporal traces requires minor adjustments to the overall system. Recall that our goal is to allow for expressions higher up in the syntactic tree, such ‘*tokoro*’, which do not directly compose with event-denoting sentence radicals, to have access to the structure of the temporal traces despite the intervening tenses (and possibly other temporal/aspectual material). We achieve this by generalizing to the worst case, as it were, using structured intervals throughout the compositional process. For the most part, that change is insignificant. For instance, the denotation of the covert aspectual operator ‘ $\emptyset$ ’, first given in (10a) above, changes to (29). The upper line, for stative complements, requires that there be an interval  $k$  of which  $\varphi$  is true and such that  $\mathbf{j}$  is the singleton set containing  $k$ . The lower line, for non-statives, now implies that  $\mathbf{j}$  encodes the structure of  $e$ . However, this information about the structure of  $e$  leaves no imprint on  $\mathbf{i}$ , since  $\mathbf{i}$  and  $\mathbf{j}$  are required to be disjoint.

$$(29) \quad \emptyset \quad \rightsquigarrow \lambda\varphi_{\langle i,t \rangle} \lambda \mathbf{i} \lambda \mathbf{j} \exists j [\varphi(j) \wedge \mathbf{j} = \lambda k [k = j]] \wedge [\mathbf{i} \neq \mathbf{s} \rightarrow \mathbf{i} \in \mathbf{j}] \cup \\ \lambda\rho_{\langle \epsilon, t \rangle} \lambda \mathbf{i} \lambda \mathbf{j} [\exists e [\rho(e) \wedge \mathbf{j} = \tau_{\mathbf{S}}(e)] \wedge \mathbf{i} \cap \mathbf{j} = \emptyset]$$

In fact, to keep things simple, it is a good idea to assume that the structured intervals used in the derivation are generally singleton **unless** they are non-trivially structured by the temporal trace of an event. Formally, this can be done by defining a predicate in the translation language that is true of structured intervals just in case they are singleton (e.g.,  $\text{sg}(\mathbf{i}) := \exists i [\mathbf{i} = \lambda j [j = i]]$ ) and assert this predicate of all the intervals that are not used to record event measurement (i.e.,  $\mathbf{i}$  in (29),  $\mathbf{j}$  in (31a), and both  $\mathbf{i}, \mathbf{j}$  in (31b)). We refrain from doing so in the interest of readability, but we do make the assumption that the structured intervals are singleton unless stated otherwise, and this assumption will in fact be significant below.

For the denotation of ‘*-tei-*’, we redefine the notion of an extended temporal trace. Recall from (18) above that  $\tau^+(e)$  is the property of being either the traditional temporal trace  $\tau(e)$  or the result state  $\text{result}(e)$ . From  $\tau^+$  and the notion of a structured temporal trace  $\tau_{\mathbf{S}}$  we now define a function mapping events to properties of structured events:  $\mathbf{T}(e)$  is the property of being either the structured trace  $\tau_{\mathbf{S}}(e)$  or the singleton set  $\text{result}(e)$ .

$$(30) \quad \text{Let } \tau^+ \text{ be an extended temporal trace function and } \tau_{\mathbf{S}} \text{ a structured temporal trace function defined on the same domain. The corresponding } \mathbf{extended structural temporal trace} \text{ function } \mathbf{T} \text{ maps events to properties of structured intervals as follows:} \\ \mathbf{T}(e) = \lambda \mathbf{i} [\mathbf{i} = \tau_{\mathbf{S}}(e) \vee \exists j [j = \text{result}(e) \wedge \mathbf{i} = \lambda k [k = j]]]$$

With this notion in place, we adjust our definition of ‘*-tei-*’ to structured intervals as in (31).

$$(31) \quad \text{a. } \text{‘-tei-’}_{\text{ONG}} \rightsquigarrow \lambda\varphi_{\langle \epsilon, t \rangle} \lambda \mathbf{i} \lambda \mathbf{j} [\exists e [\varphi(e) \wedge \mathbf{T}(e)(\mathbf{j})] \wedge [\mathbf{i} \neq \mathbf{s} \rightarrow \mathbf{i} \in \mathbf{j}]] \\ \text{b. } \text{‘-tei-’}_{\text{ANT}} \rightsquigarrow \lambda\varphi_{\langle \langle i, t \rangle, \langle \langle i, t \rangle, t \rangle \rangle} \lambda \mathbf{i} \lambda \mathbf{j} \exists \mathbf{k} [\varphi(\mathbf{j})(\mathbf{k}) \wedge \mathbf{k} < \mathbf{j} \wedge [\mathbf{i} \neq \mathbf{s} \rightarrow \mathbf{i} \in \mathbf{j}]]$$

Figure 2: Permissible (left) and excluded (right) positions of  $i$  relative to the order induced by  $j$ .

### 3.3. ‘Tokoro’: the uphill condition

‘Tokoro’ takes as its complement a tensed clause, which as we saw denotes a binary relation between structured intervals, constrained by the temporal semantics of the complement. ‘Tokoro’ adds a single further condition on the pairs  $i, j$  in this relation: informally put,  $i$  must be adjacent to an interval with strictly higher “ $j$ -ness.” Somewhat more formally:  $i$  must abut an interval which ranks strictly higher than  $i$  on the order induced by  $j$ . We introduce special terms and notation for this relationship in (32) and give the denotation of ‘tokoro’ as in (33).

#### (32) Uphill and downhill

Let  $i$  and  $j$  be structured intervals.  $i$  is **downhill from**  $j$  (and  $j$  is uphill from  $i$ ), written  $i \curvearrowright j$ , iff there is an interval  $k$  such that  $\cup i \leq_j k$  and  $\cup i \supset k$

$$(33) \quad \text{‘tokoro’} \rightsquigarrow \lambda \varphi \langle \langle i, t \rangle, \langle \langle i, t \rangle, t \rangle \rangle \lambda h \lambda i \exists j [\varphi(i)(j) \wedge i \curvearrowright j]$$

Figure 2 shows various possible locations of  $i$  relative to an order  $\leq_j$ , all of which may be delivered by the compositional semantics of the prejacent of ‘tokoro’. For instance, the pictures on the left are consistent with the denotations of a non-stative clause with simple Past, Progressive ‘-tei-’ plus Present, and simple Present. These options are illustrated in (34) and (35).<sup>22</sup> In (34), where the precedence relation between  $i$  and  $j$  is fixed by the tense and aspect of the prejacent, ‘tokoro’ strengthens this requirement to **immediate** precedence. In (35), the inclusion of  $i$  within  $j$  is ensured by ‘-tei-’,<sup>23</sup> and ‘tokoro’ imposes in the additional condition that  $j$  have internal structure, i.e., that it be the temporal trace of an activity (or of the activity phase of an accomplishment). This is the case for the Progressive reading of ‘-tei-’.

$$(34) \quad \text{Taro-ga} \{ \text{aruku} \quad // \text{aruita} \} \text{tokoro} \{ \text{da} \quad / \text{datta} \}$$

Taro-NOM walk-NPST walk-PAST TOKORO COP-NPST COP-PAST

‘Taro {is/was} about to walk // {has/had} just walked’

$$\begin{aligned} \text{a. } & \lambda h \lambda i \exists j [\exists e [\text{TAROARUK}(e) \wedge j = \tau_S(e)] \wedge i \not\subseteq j \wedge \{i \leq j // j < i\} \wedge i \curvearrowright j \wedge \{h \leq i / i < h\}] \\ & (34a)(s)(r) \Leftrightarrow \\ & \exists j [\exists e [\text{TAROARUK}(e) \wedge j = \tau_S(e)] \wedge \{r < j // j < r\} \wedge r \curvearrowright j \wedge \{s \leq r / r < s\}] \end{aligned}$$

<sup>22</sup>Notice that the matrix tense in these sentences is irrelevant for the present discussion, since it constrains the relation between  $h$  and  $i$ , which does not interact with ‘tokoro’.

<sup>23</sup>Here Past tense on the prejacent is ruled out because the position under ‘tokoro’ is an embedding context.

- (35) Taro-ga arui-tei- { ru // \*ta } tokoro { da / datta }  
 Taro-NOM walk-TEI- NPST PAST TOKORO COP-NPST COP-PST  
 ‘Taro {is/was} walking.’  
 a.  $\lambda h \lambda i \exists j [\exists e [\text{TAROARUK}(e) \wedge \mathbf{T}(e)(j)] \wedge i \in j \wedge i \leq j // j < i] \wedge i \dashv j \wedge \{h \leq i/i < h\}]$   
 $(35a)(s)(r) \Leftrightarrow \exists h [\exists e [\text{TAROARUK}(e) \wedge \mathbf{T}(e)(j)] \wedge r \in j \wedge r \dashv j \wedge \{s \leq r/r < s\}]$

Statives, on the other hand, do not have the right temporal denotations to serve as the prejacent of ‘tokoro’. This is shown for lexically statives in (36). Here *i* is placed within *j*, similarly to the Progressive reading available for (35) above; this time, however, the order induced by *j* is flat around *i*, thus the contour condition imposed by ‘tokoro’ is not met, as on the right-hand side in Figure 2. The Perfect reading of (35) is ruled out in the same way.

- (36) Zyon-ga Nihon-ni { iru // \*ita } tokoro { da / datta }  
 Jon-NOM Japan-LOC be-NPST be-PAST TOKORO COP-NPST COP-PAST  
 a.  $\lambda h \lambda i \exists j [\exists j [\text{JONINJAPAN}(j) \wedge j = \lambda k [k = j]] \wedge i \in j \wedge i \dashv j \wedge \{h \leq i/i < h\}]$   
 $(36a)(s)(r) \Leftrightarrow \exists j [\exists j [\text{JONINJAPAN}(j) \wedge j = \lambda k [k = j]] \wedge r \in j \wedge r \dashv j \wedge \{s \leq r/r < s\}]$

Finally, the Anterior reading of ‘-tei-’ is also incompatible with ‘tokoro’. The corresponding structure and interpretation for (35) is shown in (35’).

- (35’) [ [ [ [ [Taro-ga aruk ]  $\emptyset$  ] tei<sub>ANT</sub> ] {ru/\*ta} ] tokoro ] {da/datta} ]  
 ‘Taro {has/had} the experience of walking.’  
 a.  $\lambda h \lambda i \exists j \exists k [\exists e [\text{TAROARUK}(e) \wedge k = \tau_S(e)] \wedge k < j \wedge i \in j \wedge i \dashv j \wedge \{h \leq i/i < h\}]$   
 $(36a)(s)(r) \Leftrightarrow$   
 $\exists j \exists k [\exists e [\text{TAROARUK}(e) \wedge k = \tau_S(e)] \wedge k < j \wedge r \in j \wedge r \dashv j \wedge \{s \leq r/r < s\}]$

It is worth noting that the formula in (35’a) as it stands does not imply contradiction and ill-formedness, since it does not require *j* to be a singleton structured interval. This is not as it should be, since ‘-tei-’ does not in fact have an experiential reading under ‘tokoro’ (except for the counterfactual reading, which we do not deal with in this paper). It is here that our assumption that all structured intervals are singleton unless stated otherwise comes into play. We predict the unavailability of this reading if (and since) we assume that *j* in (36) is singleton, even though in the interest of readability we refrain from enforcing this in the formulas.

#### 4. Conclusion

Rather than summarize what we have accomplished in this paper, we mention two things we left for future work. We already mentioned that we did not deal with counterfactual readings of lexical statives and non-Progressive ‘-tei-’ under ‘tokoro’. We also did not touch on cases in which contextually given information can rescue a temporal reading. For instance, (37) can have a temporal interpretation even under a resultative reading of ‘-tei-’, as indicated by the English gloss, if the state in question occurs as part of a set sequence of eventualities, as for instance in describing which outfit a model is wearing at this point as part of an ongoing fashion show.

- (37) Tada ima kimono-wo ki-tei-ru tokoro da.

# Parentheticality, assertion strength, and discourse<sup>1</sup>

Todor KOEV — *University of Düsseldorf*

**Abstract.** Sentences with so-called SLIFTING PARENTHETICALS (e.g. *The dean, Jill said, flirted with the secretary*; Ross 1973) grammaticalize an intriguing interaction between speech act function and conventional meaning, one that is not found in regular embedding constructions (e.g. *Jill said that the dean flirted with the secretary*). In such sentences, the main clause is independently asserted and at the same time is interpreted in the scope of the parenthetical, which typically serves an evidential function. The discourse effect of this pragmasemantic set-up is that slifting parentheticals modulate the strength with which the main part of the sentence is asserted (Urmson 1952, Asher 2000, Rooryck 2001, Davis et al. 2007, Simons 2007, Maier and Bary 2015). Building on Davis et al. (2007), this paper proposes a probabilistic discourse model that captures the role of parentheticality as a language tool for qualifying speaker's commitments. The model also derives two empirical properties that set apart slifting parentheticals from regular embedding constructions, i.e. (i) the fact that slifting parentheticals invariably express upward entailing operators and (ii) the fact that they usually do not occur in subordinate clauses.

**Keywords:** parentheticals, evidence, assertion, polarity, embedding, probability.

## 1. Introduction

The interpretational properties of sentences with SLIFTING PARENTHETICALS (Ross 1973) are perhaps best illustrated by direct comparison to regular embedding constructions. Consider the minimal pair of sentences below.

- (1) The dean, Jill said, flirted with the secretary.
- (2) Jill said that the dean flirted with the secretary.

The slifting sentence in (1) is largely synonymous with its embedding counterpart in (2). In most contexts, uttering either sentence would imply, in some weak sense, that the dean flirted with the secretary and attribute this information to Jill. The strength of such weak implications is contingent on the additional information provided, including the lexical properties of the attitude predicate (e.g. *say* leads to a weaker claim than *discover*) and the quality of the source (e.g. Jill might be a more trustworthy source than Marissa when it comes to the dean's flirtations). We see that parentheticals as well as embedding constructions can both be used to express claims with a varying degree of strength.

However, slifting sentences exhibit a range of properties that set them apart from regular embedding constructions. Here I discuss two such differences. The first difference concerns the

---

<sup>1</sup>I would like to thank Dan Lassiter, Roger Schwarzschild, Peter Sutton, and the audiences at *Backgrounded Reports* 2016 and *Sinn und Bedeutung* 21. For judgments, I am indebted to Kurt Erbach, Jeremy Perkins, and Peter Sutton. All mistakes are my own.

observation that the former constructions obey certain polarity restrictions. Jackendoff (1972), Ross (1973), Hooper (1975), and Maier and Bary (2015) already notice that slifting parentheticals usually cannot host negation. Generalizing this observation, we could say that slifting parentheticals may create upward entailing but not downward entailing environments. This is illustrated in (3), where *I think* expresses an upward entailing operator and *I doubt* expresses a downward entailing operator. In contrast to parentheticals, the matrix clause of embedding constructions is not sensitive to the direction of the polarity it creates (4).

(3) Snowden is a Russian spy,  $\left\{ \begin{array}{l} \text{I think} \\ \text{\#I doubt} \end{array} \right\}$ .

(4)  $\left\{ \begin{array}{l} \text{I think} \\ \text{I doubt} \end{array} \right\}$  Snowden is a Russian spy.

Second, slifting parentheticals have a more limited syntactic distribution than embedding clauses. The former do not easily modify subordinate clauses and thus do not appear in the scope of a propositional operator (5). This is in contrast to the latter constructions, which can easily be further embedded (6).

(5) #Selena thinks that Justin, the vocal coach said, is a talented singer.

(6) Selena thinks the vocal coach said that Justin is a talented singer.

The upshot of this preview of properties is that any good semantic theory of slifting sentences needs to explain why such sentences give rise to claims comparable in strength to the claims expressed by embedding constructions. At the same time, the theory should be able to derive the unique properties of slifting sentences that distinguish them from embedding constructions.

Section 2 states the main assumption of the paper. In Section 3, I show how graded claims can be modeled by using standard tools from probabilistic reasoning. Section 4 discusses the polarity and scopal properties of slifting parentheticals. Section 5 is the conclusion.

## 2. One sentence, two assertions

The main claim of this paper is that slifting sentences stand apart from regular embedding constructions because of a single basic fact. Following similar claims in previous literature, I assume that slifting sentences make two semantic contributions as part of their conventional meaning (cf. Urmson 1952, Hooper 1975, Bach 1999, Asher 2000, Potts 2005, Simons 2007, Maier and Bary 2015, Hunter 2016). More specifically, I assume that the slifted clause (the non-parenthetical part of the sentence) invariably encodes the main assertion while the sentence as a whole expresses secondary, typically evidential information. Hooper and Simons put this idea succinctly:

“[...] the effect of complement preposing is to make the complement proposition the main assertion of the sentence while reducing the original main clause to parenthetical or secondary status. [...] there are two assertions, or two claims to

truth. The first one, from the preposed complement, is given more importance in this construction, and the parenthetical assertion is clearly subordinated.”

(Hooper 1975: 95)

“From a discourse or usage point of view, it seems quite clear that the main point of an utterance of a slifted sentence will be the content of the slifted (i.e. non-parenthetical) clause, with the syntactically parenthetical clause serving a parenthetical function.”

(Simons 2007: 1039)

This assumption can be summarized as follows.

(7) **DOUBLE ASSERTION HYPOTHESIS**

A slifting sentence makes two assertions. The main assertion is expressed by the slifted clause and the parenthetical asserts secondary information.

This hypothesis implies that the sentence in (8), repeated from (1), asserts both (8a) and (8b).

(8) The dean, Jill said, flirted with the secretary.

a. The dean flirted with the secretary. (MAIN ASSERTION)

b. Jill said that the dean flirted with the secretary. (PARENTHETICAL ASSERTION)

I argue that the Double Assertion Hypothesis can explain the potentially weakening effect of slifting parentheticals on the main claim and derive the ways in which such sentences differ from regular embedding constructions. While the latter constructions can be used to trigger weak implications as well, these implications need not be written into the semantics and can be derived through reasoning.

It is important to emphasize that the privileged semantic role of slifted clauses correlates with their apparent syntactic status as main clauses. Grimshaw (2011) presents a battery of arguments in support of the claim that English slifted clauses are indistinguishable in form from main clauses. She shows that, unlike subordinate clauses, slifted clauses cannot be non-finite (9), cannot be headed by a complementizer (10), require subject–auxiliary inversion when the parenthetical includes an interrogative predicate (11), and generally block quantifier binding from the parenthetical (12). The following data are adapted from Grimshaw (2011: 4–6).

(9) a. \*To leave, I promised them.

b. I promised them to leave.

(10) a. \*That it was raining hard, they thought.

b. They thought that it was raining hard.

(11) a. Had she made a mistake, he wondered.

b. \*He wondered (whether) had she made a mistake.

- (12) a. ??She<sub>i</sub> liked the film, every girl<sub>i</sub> said.  
 b. Every girl<sub>i</sub> said that she<sub>i</sub> liked the film.

This argues for a main clause analysis of slifted clauses (Jackendoff 1972) over one which views them as raised or “s(entence-)lifted” complements (Ross 1973). While the precise syntactic analysis of slifting sentences is not the focus of this paper, given the weight of the empirical evidence, I will assume that slifted clauses are main clauses and treat slifting parentheticals as adjuncts.

### 3. Modulating assertion strength

We have already seen that the strength with which a clause is implied can be qualified by parenthetical modification or through semantic embedding. For example, the unqualified claim in (13) can be weakened as in (13a) or (13b).

- (13) Jack is married to a nurse.  
 a. Jack, Emmy said, is married to a nurse.  
 b. Emmy said that Jack is married to a nurse.

There are two simple yet important observations to be made about (13a)–(13b). The first observation is that the degree to which (13) is implied is modulated by the quality of the evidence stated in the parenthetical or the matrix clause. For example, changing *Emmy said* to *Emmy discovered*, *Emmy might have said*, or *Everyone claims* may result in a stronger or a weaker claim. The second observation is that if the context is held constant, the relative strength with which (13) is implied by each sentence is roughly the same. If we schematically represent slifting sentences as  $C, E$  and embedding constructions as  $E(C)$ , where  $C$  and  $E$  are mnemonics for “claim” and “evidence” (respectively), these two empirical observations can be summarized as follows.

- (14) If  $C, E$  and  $E(C)$  are uttered in the same context, then:  
 a. STRENGTH DEPENDENCE: The implication strength of  $C$  is contingent on  $E$  in both  $C, E$  and  $E(C)$ .  
 b. STRENGTH SIMILARITY:  $C$  is implied with approximately the same strength by  $C, E$  and  $E(C)$ .

I take it that Strength Dependence is quite uncontroversial. One piece of evidence for Strength Similarity is the fact that the main claim put forward by slifting or embedding sentences can be doubted or denied by the speaker with a comparable degree of ease.

- (15) Jack, Emmy said, is married to a nurse, but  $\left\{ \begin{array}{l} \text{I doubt he really is} \\ \text{I'm sure he isn't} \end{array} \right\}$ .

- (16) Emmy said that Jack is married to a nurse, but  $\left\{ \begin{array}{l} \text{I doubt he really is} \\ \text{I'm sure he isn't} \end{array} \right\}$ .

There appears to be some variation in judgment regarding the strength of slifted clauses, though.

Jackendoff (1972), Asher (2000), Murray (2014), and Hunter (2016) claim that slifted propositions cannot always be denied, even when the respective embedded proposition can.<sup>2</sup>

- (17) a. Myrtle will come tomorrow, Margaret believes, (#but she actually came yesterday).  
 b. Margaret believes that Myrtle will come tomorrow, but she actually came yesterday. (examples from Jackendoff 1972: 97)
- (18) a. #John, Mary assures us, can be trusted, but I don't trust him.  
 b. Mary assures us that John can be trusted, but I don't trust him. (examples from Asher 2000: 36)

If these data are real, one possible explanation is that the contrast in judgment may have to do with the central discourse status of slifted clauses (see Section 4.2). However, I discovered that English speakers tend to accept (17a) and (18a). Moreover, all speakers I consulted find such sentences felicitous if a weaker follow-up (e.g. *but I seriously doubt it*) is used, such that the possibility that the slifted clause is true is left open. I will then assume that slifted clauses imply commitments that more or less match the commitments implied by the respective embedded propositions.

How can we model weak assertions? Davis et al. (2007) hypothesize that there are two major language strategies for qualifying a claim. The first strategy involves semantic embedding under an appropriate modal operator, which weakens the original claim by manipulating its truth conditions. This is the strategy illustrated by embedding constructions. Under the second strategy, first suggested in Lewis (1976), the speaker specifies the source of information and may weaken the original claim by lowering the quality threshold for asserting it.<sup>3</sup> Since slifting parentheticals provide evidential support for the main claim, slifting sentences arguably lexicalize this latter strategy (see also Simons 2007, Murray 2014, Hunter 2016). To illustrate the evidential strategy, Davis et al. (2007: 81) outline the following three-step procedure (here slightly adapted).

- (19) If a parenthetical sentence  $C, E$  is uttered by an agent  $a$  and in a context  $c$ , then:  
 i.  $a$  assumes a commitment to having  $E$ -type evidence for  $C$ ,  
 ii. the quality threshold  $\theta^c$  is readjusted to the reliability of  $E$ , and then  
 iii.  $a$  asserts  $C$  against  $\theta^c$ .

One intuitive way of fleshing out Davis et al.'s idea is to assume that propositions enter the common ground as indexed by quality thresholds, which impose a lower bound on their certainty level. The threshold against which a slifted clause  $C$  is asserted will depend not only on the context but also on the reliability of the evidence  $E$  provided by the slifting parenthetical. This threshold could then be less than the default for the given context. In contrast to parentheticals,

<sup>2</sup>For reasons of uniformity and in order to do justice to the proposal, in borrowed examples I will often substitute ungrammaticality marking (\*) with pragmatic unacceptability marking (#).

<sup>3</sup>Davis et al. (2007) call these the MODAL and the EVIDENTIAL strategy, respectively. I find this terminology confusing in both directions. On one hand, slifting parentheticals contain modals as main predicates; on the other hand, modal verbs often contribute evidential meanings (von Stechow and Gillies 2010, Lassiter 2016).

an embedding sentence  $E(C)$  will always be evaluated against the unmodified threshold. If  $C$  is weakened, this is because it is interpreted in the semantic scope of  $E$ , not because it is weakly asserted.

As an illustration, consider a context with a quality threshold of 0.9 and one in which the likelihood of Emmy's words being true is 0.7. If *Jack, Emmy said, is married to a nurse* is uttered, we will add to the common ground both the proposition that Emmy said Jack is married to a nurse (indexed by 0.9) and the proposition that Jack is married to a nurse (indexed by 0.7). In turn, if *Emmy said Jack is married to a nurse* is uttered, only the former proposition will be added to the common ground, and it will be indexed by 0.9.

This way of looking at things does not yet derive Strength Dependence or Strength Similarity. We still need to explain why embedded clauses, although not asserted, are implied with a comparable degree of confidence to slifted clauses, and why in both cases this degree depends on the quality of the evidence. Both of these constraints can be accounted for if we assume that contexts are associated with PROBABILITY MEASURES.<sup>4</sup> Probability measures are functions  $\mu$  from propositions (sets of possible worlds) to real numbers between 0 and 1 such that (i)  $\mu$  maps the universal set of worlds to 1 and (ii)  $\mu$  maps the union of any two disjoint propositions  $p$  and  $q$  to the sum of  $\mu(p)$  and  $\mu(q)$ . Instead of representing common grounds as sets of indexed propositions, i.e. as objects of the form  $CG = \{\langle p_1, \theta_1 \rangle, \dots, \langle p_n, \theta_n \rangle\}$ , we can view them as effectively specifying a probability measure, i.e. a function  $\mu$  such that  $\mu(p_1) = \theta_1, \dots, \mu(p_n) = \theta_n$ .

We now want to model the intuition that discourse-new information may modify the likelihood of discourse-old information. Assume that we are given a prior probability for  $p$  and just learned that  $q$ . How should we update the probability of  $p$  in light of the new evidence  $q$ ? One could employ the mechanism of CONDITIONALIZATION, which involves redistributing probability weights after new information is obtained. In its simple form, the probability measure  $\mu$  conditionalized on the proposition  $q$  is defined as follows, for any proposition  $p$ .

(20) SIMPLE CONDITIONALIZATION

$$\mu_q(p) = \frac{\mu(p \cap q)}{\mu(q)}, \text{ where } \mu(q) \neq 0$$

However, simple conditionalization is too rigid for our threshold-based discourse model. It presumes that the newly obtained information  $q$  is certain and tells us how much of its probability weight is assigned to  $p \cap q$ . But what if  $q$  itself is uncertain, e.g. asserted against a threshold of  $\theta = 0.9$ ? Work in philosophy and cognitive science has adopted a slightly more complicated mechanism, called JEFFREY CONDITIONALIZATION (Jeffrey 1990). While not previously used in formal semantics to the best of my knowledge, it gives us what we want because it is expressed in terms of simple conditionalization but also factors in the uncertainty of the evidence.<sup>5</sup>

<sup>4</sup>Probability measures have been widely studied and have well-understood properties. Less-familiar tools for modeling uncertainty include Dempster–Shafer belief functions, possibility measures, etc. (see Halpern 2003 for an overview).

<sup>5</sup>Jeffrey himself called this generalized form of conditionalization “probability kinematics”. Notice that this

(21) JEFFREY CONDITIONALIZATION (Jeffrey 1990)

$$\mu_{\langle q, \theta \rangle}(p) = \theta \mu_q(p) + (1 - \theta) \mu_{\neg q}(p), \text{ where } 0 < \mu(q) < 1$$

Here the evidence is made sensitive to its likelihood:  $\mu_{\langle q, \theta \rangle}(p)$  stands for the probability of  $p$ , given that the likelihood of  $q$  is  $\theta$ . It is easy to see that when the evidence is certain, i.e.  $\theta = 1$ , Jeffrey conditionalization reduces to its simple relative. That is,  $\mu_{\langle q, 1 \rangle} = \mu_q$ , for any  $q$ . The following example illustrates the usefulness of Jeffrey conditionalization in accumulating new evidence.

**Example** Let  $p$  stand for the proposition *It is raining*,  $q$  stand for the proposition *Mary said it is raining*, and  $\mu(p) = 0.5$ ,  $\mu(q) = 0.5$ ,  $\mu_q(p) = 0.7$ . That is, we are completely ignorant as to whether  $p$  or  $q$  are true but we know that learning  $q$  would substantially increase the likelihood of  $p$ , e.g. because Mary is a fairly reliable source of weather information. What is the posterior probability of  $p$  if  $q$  is uttered at a 0.9 quality threshold?

- By Bayes' rule, the prior probability of  $q$  given  $p$  is:  $\mu_p(q) = \frac{\mu_q(p) \mu(q)}{\mu(p)} = \frac{0.7 \times 0.5}{0.5} = 0.7$ .
- By the complement rule, the prior probability of  $\neg q$  is:  $\mu(\neg q) = 1 - \mu(q) = 1 - 0.5 = 0.5$ .
- By Bayes' rule and the complement rule:  $\mu_{\neg q}(p) = \frac{\mu_p(\neg q) \mu(p)}{\mu(\neg q)} = \frac{(1 - \mu_p(q)) \mu(p)}{1 - \mu(q)} = \frac{(1 - 0.7) \times 0.5}{1 - 0.5} = 0.3$ .
- By the Jeffrey conditionalization rule and given that  $q$  is uttered at a threshold of 0.9, the posterior probability of  $p$  is:  $\mu_{\langle q, 0.9 \rangle}(p) = 0.9 \mu_q(p) + (1 - 0.9) \mu_{\neg q}(p) = 0.9 \times 0.7 + 0.1 \times 0.3 = 0.66$ .

The probability of rain thus increases from 50% to 66%. This is lower than the 70% produced by simple conditionalization, since the latter rule does not take into account that we are only 90% certain that Mary said it was raining. **End of example**

The effect of slifting and embedding sentences on the probability measure of the context can now be rendered as follows.

$$(22) \quad \text{Slifting sentences } C, E: \quad \mu \xrightarrow{\langle [E(C)], \theta \rangle} \mu' \xrightarrow{\langle [C], \mu'([C]) \rangle} \mu''$$

$$(23) \quad \text{Embedding sentences } E(C): \quad \mu \xrightarrow{\langle [E(C)], \theta \rangle} \mu'$$

rule falls out from a few basic facts of probability theory. Proof:

$$\begin{aligned} \mu(p) &= \mu(p \cap q) + \mu(p \cap \neg q) && \text{total probability law} \\ &= \mu(q) \mu_q(p) + \mu(\neg q) \mu_{\neg q}(p) && \text{conditional probability} \\ &= \mu(q) \mu_q(p) + (1 - \mu(q)) \mu_{\neg q}(p) && \text{complement} \\ &= \theta \mu_q(p) + (1 - \theta) \mu_{\neg q}(p) && \theta = \mu(q) \end{aligned} \quad \text{QED}$$

If a slifting sentence  $C, E$  is uttered, the probability measure is first conditionalized on  $\langle \llbracket E(C) \rrbracket, \theta \rangle$  and then conditionalized on  $\langle \llbracket C \rrbracket, \mu'(\llbracket C \rrbracket) \rangle$  (22). The strength of the evidential proposition  $\llbracket E(C) \rrbracket$  is then the threshold value  $\theta$  and the strength of the main proposition  $\llbracket C \rrbracket$  is its prior probability  $\mu$  conditionalized on the evidential proposition at  $\theta$ . In turn, if an embedding sentence  $E(C)$  is uttered, the probability measure is conditionalized on  $\langle \llbracket E(C) \rrbracket, \theta \rangle$  alone (23). Even though in this latter case the embedded clause is not asserted, speech participants may employ probabilistic reasoning to infer that the likelihood of  $C$ , given that  $E(C)$  was asserted against  $\theta$ , is  $\mu_{\langle \llbracket E(C) \rrbracket, \theta \rangle}(\llbracket C \rrbracket)$ . This story accounts for both Strength Dependence and Strength Similarity: the strength of  $C$  depends on the strength and relevance of  $E(C)$  in both cases. Slifting sentences and embedding sentences are then predicted to play a similar role when it comes to what inferences speakers may draw from them. They only differ in that the former assert (perhaps weakly) the slifted clause while the latter do not assert the embedded clause.

#### 4. The uniqueness of slifting parentheticals

The analysis of varying assertion strength proposed in the previous section does not directly predict any substantial interpretational differences between slifting and embedding sentences. However, as already mentioned in the Introduction, the two constructions differ in polarity and distribution. This section discusses these differences in depth and argues that they both are rooted in the Double Assertion Hypothesis and general principles of discourse organization.

##### 4.1. Polarity restrictions

Other things being equal, one might expect that slifting parentheticals can have the same grammatical make-up as matrix clauses. For example, the fragment *Jill said* can be used parenthetically and it can also serve as a matrix clause. However, Jackendoff (1972), Ross (1973), Hooper (1975), and Maier and Bary (2015) notice that, unlike matrix clauses, slifting parentheticals need to make a “positive” or “affirmative” import. At least initially, it appears that slifting parentheticals cannot contain negation or lexically negative predicates.

$$(24) \quad \text{John is, } \left\{ \begin{array}{c} \text{I think} \\ \text{\#I don't think} \\ \text{\#I doubt} \end{array} \right\}, \text{ a fink.} \quad (\text{Jackendoff 1972: 97})$$

$$(25) \quad \left\{ \begin{array}{c} \text{I think} \\ \text{I don't think} \\ \text{I doubt} \end{array} \right\} \text{ John is a fink.}$$

The same authors also observe that there is no syntactic ban on slifting parentheticals hosting negation or negative predicates. If a slift contains a lexically negative verb (like *doubt* or *deny*) that is negated, the sentence becomes acceptable.

$$(26) \quad \text{John is, I don't doubt, a fink.} \quad (\text{Jackendoff 1972: 97})$$

(27) Mushrooms are great on diets, I don't doubt. (Ross 1973: 155)

(28) It's a long shot, I don't deny. (Hooper 1975: 107)

The positive/affirmative import generalization must then be a semantic one and it must constrain the entire slifting parenthetical, not just its main predicate. I propose that it should be stated in terms of monotonicity.<sup>6</sup>

The monotonicity properties of operators have been widely discussed in the literature on polarity items and elsewhere. The two crucial notions of upward and downward entailingness are standardly defined as follows (e.g. Ladusaw 1980).

- (29) a. An operator  $O$  is UPWARD ENTAILING iff for any propositions  $p$  and  $q$ , if  $p \subseteq q$  then  $O(p) \subseteq O(q)$ .  
 b. An operator  $O$  is DOWNWARD ENTAILING iff for any propositions  $p$  and  $q$ , if  $p \subseteq q$  then  $O(q) \subseteq O(p)$ .

Asher (1987) develops a semantic typology of a wide range of propositional attitude predicates. He proposes that verbs like *say*, *think*, *believe* are upward entailing while verbs like *deny* or *doubt* are downward entailing.<sup>7</sup> Indeed, if Jimmy believes I own a Porsche (and he also knows that Porsches are cars), then he must believe that I own a car. In turn, if Jimmy doubts I own a car (and knows that Porsches are cars), then he must doubt that I own a Porsche as well.

The polarity generalization about slifting parentheticals can now be stated as follows.

- (30) UPWARD MONOTONICITY  
 A slifting sentence  $C, E$  can be felicitously uttered only if  $E$  expresses an upward entailing operator.

Assuming that no operator can be both upward and downward entailing, Upward Monotonicity correctly bans shifts from creating downward entailing environments. It also rules out shifts that express non-monotone operators, i.e. operators that are neither downward nor upward entailing. The verb *lie* is one example of a non-monotone propositional operator; e.g. there is no entailment relation between (31a) and (31b).<sup>8</sup> Upward Monotonicity then correctly predicts that the sentences in (32), which host non-monotone shifts, are not acceptable.

- (31) a. Jeremy lied that he resides in Vancouver.  
 b. Jeremy lied that he resides in Canada.

<sup>6</sup>There appear to be further restrictions on what can go into slifting predicates that go beyond polarity and that are not addressed in this paper. See Ross (1973), Hooper (1975), and Haddican et al. (2014) for discussion.

<sup>7</sup>I will sometimes loosely talk of lexical items themselves as being upward or downward entailing. What is meant is that the operators that those items denote have the claimed monotonicity.

<sup>8</sup>The reason *lie* is non-monotone might be that *a lied that p* implies both *a said p* and *not-p*. Since *a said* is upward entailing while *not* is downward entailing, the combined effect is that of non-monotonicity. I am indebted to Emar Maier for the suggestion that *lie* expresses a non-monotone operator.

- (32) a. #Paul had never known his mother, he lied.  
 b. #The CEO, his girlfriend lied, is a true gentleman.

There are two cases of seeming violations of Upward Monotonicity that deserve further mentioning. The first case involves situations when the speaker echoes a previous utterance and disagrees with it by using a segment that resembles a negated slifting parenthetical. This use is illustrated in (33), and can be read as *Mushrooms are great on diets? I don't think so*. The second case involves what looks like a negated slifting parenthetical attached to a negated main clause (34). The apparent function of such parentheticals is to qualify the categorical denial of a claim expressed by the first part of the sentence.

- (33) Mushrooms are great on diets, I don't think so.

- (34) Matt doesn't like phonology, I don't think.

It is fairly clear that (33) is not a slifting sentence at all. This is because the argument slot in the second segment is filled by a *so*-anaphor and without it the sentence becomes unacceptable. Genuine slifts do not allow *so*-insertion (cf. *\*The dean, Jill said so, flirted with the secretary*). While examples as in (34) do exhibit the grammatical form of slifting constructions, they turn out to have a very limited distribution and quirky interpretational properties. Ross (1973) and Hooper (1975) observe that in such examples the negation in the parenthetical is licensed by a negation in the main clause. Just any downward entailing operator in the main clause cannot support a negated slift (cf. *\*Few people like phonology, I don't think*) and just any downward entailing slift cannot be licensed by a negated main clause (cf. *\*Matt doesn't like phonology, I doubt*). In addition, the putative parenthetical may modify a non-clausal argument (cf. *Matt doesn't like phonology, I don't think he does*) and has to appear at the end of the sentence (cf. *\*Matt, I don't think, doesn't like phonology*). Ross (1973) also notices that such doubly-negated sentences are restricted to Neg-Raising predicates (cf. *Matt doesn't like phonology, I don't think / \*I don't fear*). Most importantly, as noted in Huddleston and Pullum (2002: 845), the negation in the slift is semantically vacuous, and (34) is synonymous with *Matt doesn't like phonology, I think*. I will then tentatively assume that such constructions illustrate some sort of negative concord and are actually upward entailing. If so, the data in (33)–(34) do not challenge the Upward Monotonicity restriction.

Where does Upward Monotonicity come from? Two explanations have been suggested in the literature, although none of them seems able to explain the full range of data. One idea is that this generalization falls out from the relative strength with which a main clause is asserted. Hooper (1975), Scheffler (2009), and Hunter (2016) propose that, roughly, upward entailing slifts imply the main clause with a sufficiently high level of confidence while downward entailing slifts do not. Assuming that  $\tau$  is the minimal threshold that any assertion (whether weak or strong) in the given context should meet, we could then propose the following constraint.

- (35) ASSERTION STRENGTH  
 A slifting sentence  $C, E$  can be felicitously uttered only if  $\mu_{\langle [E(C)], \theta \rangle}([C]) \geq \tau$ .

However, this constraint immediately runs into empirical difficulties. A segment like *it seems* entails its propositional argument in a fairly weak sense but can serve as a parenthetical (cf. *Noah majored in psychology, it seems*). In contrast, a segment like *he regrets* contains a factive predicate that presupposes the truth of its propositional argument, yet it is unacceptable as a parenthetical (cf. *#Noah majored in psychology, he regrets*). Assertion Strength leaves these facts unexplained.

A related idea is that Upward Monotonicity is tied to the evidential role of slifting parentheticals. Haddican et al. (2014) and Maier and Bary (2015) suggest that upward entailing operators provide a good source of evidence while downward entailing operators do not. We could then require that parentheticals raise the likelihood of the main sentence being true.

(36) EVIDENTIAL SUPPORT

A slifting sentence  $C, E$  can be felicitously uttered only if  $\mu_{\langle [E(C)], \theta \rangle}(\llbracket C \rrbracket) > \mu(\llbracket C \rrbracket)$ .

The main challenge for this constraint is negative evidence. Evidential Support predicts that in the given context (37a) is infelicitous, and it would not let us expect that there is anything wrong with (37b). Indeed, if Putin rarely tells the truth, what he says is likely to be false and what he denies is likely to be true. The attested data are the exact opposite of what is predicted.

(37) *Putin is a rogue leader who typically makes false claims in order to deceive his enemies.*

- a. There are Russian troops in Ukraine, Putin said.
- b. #There are Russian troops in Ukraine, Putin denied.

I propose that Upward Monotonicity has less to do with the semantics of slifting parentheticals and more to do with the fact that slifted clauses do double duty: they are independently asserted (albeit perhaps weakly) and they serve as arguments to slifting parentheticals, as stated by the Double Assertion Hypothesis. Slifting parentheticals are upward entailing because slifted clauses in particular and main clauses in general act like POSITIVE POLARITY ITEMS (PPIs). For example, (38) hosts a main clause interpreted under an upward entailing (UE) operator and the sentence is acceptable; (39) hosts a main clause interpreted under a downward entailing (DE) operator and the sentence is unacceptable.

(38) [Snowden is a Russian spy]<sub>PPI</sub>, [Mary thinks]<sub>UE</sub>.

(39) #[Snowden is a Russian spy]<sub>PPI</sub>, [Mary doubts]<sub>DE</sub>.

The positive polarity status of slifted clauses may be taken to follow from fact that assertions should allow speech participants to draw entailments, which are weaker inferences. In other words, asserted sentences need to be closed under their entailments, as stated by the following constraint.

## (40) ENTAILMENT CLOSURE

A sentence  $S$  can be felicitously uttered only if  $S$  and all of its entailments meet the quality threshold of the context.

This type of general constraint may appear to be of little value when it comes to single assertions, because entailments are less specific than what is said and Entailment Closure will always be met. But some constraint along those lines becomes important in slifting sentences, where the slifted clause serves an argument of the parenthetical yet it is also independently asserted, as per the Double Assertion Hypothesis. It is then plausible to require that parenthetical assertions are closed under the entailments of the slifted clause.

## (41) PARENTHETICAL ENTAILMENT CLOSURE

A slifting sentence  $C, E$  can be felicitously uttered only if, for any entailment  $C'$  of  $C$ ,  $E(C')$  meets the quality threshold whenever  $E(C)$  does.

This constraint can be further elucidated by drawing attention to the fact that the two assertions  $C$  and  $E(C)$  associated with a slifting sentence  $C, E$  are proportional with respect to their informativity. When  $E$  is upward entailing, the strength of  $E(C)$  is directly proportional to the strength of  $C$  and any weakening of  $C$  makes  $E(C)$  weaker, i.e. truth is always preserved. If, however,  $E$  is downward entailing, the strength of  $E(C)$  is inversely proportional to the strength of  $C$ . In this case, a weaker  $C$  makes  $E(C)$  stronger, and truth need not be preserved. In other words, only upward entailing slifting parentheticals will obey Parenthetical Entailment Closure.

To illustrate, notice that speakers may draw all sorts of entailments from the main clause in (39), including that Snowden is a spy. However, this would violate Parenthetical Entailment Closure, because the parenthetical assertion does not guarantee that Mary doubts Snowden is a spy; it only guarantees that Mary doubts Snowden is a *Russian* spy. No such problem arises in (38), because here the truth of the parenthetical assertion is preserved for all entailments of the main clause. In particular, if Mary thinks that Snowden is a Russian spy, it follows that she also thinks Snowden is a spy.

Before closing this section, one should point out that the positive polarity status of main clauses is visible from data that go beyond slifting sentences, thereby strengthening the case for an entailment closure constraint of the form proposed above. As Ross (1973), Szabolcsi and Zwarts (1993), and Potts (2002) notice, an upward monotonicity restriction is operational in *as*-parentheticals as well.

(42) John is our hero,  $\left\{ \begin{array}{l} \text{as you know} \\ \text{\#as no one knows} \end{array} \right\}$ . (after Szabolcsi and Zwarts 1993: 246)

Verb second embedding in German is restricted in the same way. Although main clauses are verb second and embedded clauses are verb final, German draws a grammatical distinction between regular embedding of *dass*/'that' complements with a verb final syntax and embedding of verb second clauses. Importantly, Scheffler (2009) points out that while attitude verbs of any monotonicity can occur in regular embedding constructions, verb second embedding is restricted to upward entailing attitudes.

- (43) a. Peter glaubt, Maria ist schwanger.  
Peter believes Maria is pregnant  
'Peter believes that Maria is pregnant.'  
b. #Maria bereut, sie ist nach Berlin gezogen.  
Maria regrets she is to Berlin moved (Scheffler 2009: 184)

Finally, certain speaker-oriented adverbs exhibit similar behavior. Jackendoff (1972) and Bellert (1977) mention the fact that discourse adverbs do not have negative counterparts.

- (44) a.  $\left\{ \begin{array}{l} \text{Truthfully} \\ \text{Honestly} \\ \text{Sincerely} \end{array} \right\}$ , I can't tell you the answer.
- b.  $\left\{ \begin{array}{l} \text{\#Falsely} \\ \text{\#Dishonestly} \\ \text{\#Insincerely} \end{array} \right\}$ , I can't tell you the answer. (Jackendoff 1972: 99)

Apparently, these polarity restrictions have a common source. I suggest that they are all based on a mechanism similar to the one proposed for English slifting sentences.

## 4.2. Main clause modifiers

A second difference between slifting and embedding sentences concerns their embeddability. It has been noticed that slifting sentences typically modify main clauses and cannot appear in subordinate clauses (Ross 1973, Rooryck 2001). Embedding constructions do not have this property and can readily be further embedded.

- (45)    a. #Martin now realizes that Sheila is, I had claimed, a luscious yummy.  
               b. #Selena thinks that Justin, the vocal coach said, is a talented singer.
- (Ross 1973: 152)
- (46)    a. Martin now realizes that I had claimed Sheila is a luscious yummy.  
               b. Selena thinks that the vocal coach said Justin is a talented singer.

The data in (45) also show that the scope of slifting parentheticals is clause-bounded, i.e. that slifts obligatorily modify their host clause. If that were not the case, (45a) and (45b) would be acceptable under a reading whereby the parenthetical takes scope over the entire sentence.

I propose that the main clause restriction on slifting parentheticals once again follows from the Double Assertion Hypothesis. Recall that this hypothesis states that slifted clauses play a primary discourse role while the parenthetical component serves a subsidiary function. An empirical reflex of this contrast in pragmatic status is the fact that a slifted clause but not the entire parenthetical sentence can resolve a question, as demonstrated below.

- (47) Q: Why is Fred not here?  
A: He has quit his job, the secretary told me.

- (48) Q: What happened next?  
A: #There is life on Mars, she announced.

In a similar vein, Asher (2000: 33) gives the following example.

- (49) A: The party, Mary assures us, is over.  
B: #Does she?

How can we flesh out the non-central discourse status of slifting parentheticals? Asher assumes that the parenthetical component of a slifting sentence is connected to the main clause through an Evidence discourse relation. But evidentiality alone would not explain why (48) and (49) are unacceptable, since in principle evidential information can answer questions (cf. A: *Lena is dating someone*. B: *How do you know?* A: *She always leaves work early.*). The subordinate status of slifting parentheticals must then come from somewhere else.

I propose that what is wrong with (48)–(49) is not that the parenthetical assertion cannot resolve a question but rather that the main assertion must but does not do so. I assume, quite plausibly, that main clauses are conventionally marked as AT-ISSUE, where the property of at-issueness is understood as relevance to the question under discussion, as argued in Simons et al. (2010) and much subsequent work. Arguably, this is the reason why the discourses below are degraded.

- (50) A: Who was Louise with last night?  
B: Henry  $\left\{ \begin{array}{l} (?)\text{hopes} \\ ?\text{wishes} \\ ?\text{dreamt} \end{array} \right\}$  that she was with Bill. (Simons 2007: 1036)

- (51) Q: What is Peter's favorite color?  
A: ?Peter, whose favorite color is blue, never wears white shirts.

The following constraint requires that main clauses pick out one of the alternatives introduced by the question under discussion.

- (52) AT-ISSUENESS  
A (declarative) main clause  $C$  can be felicitously uttered in a context with a question under discussion  $Q$  only if  $\llbracket C \rrbracket \in Q$ .

Given that slifted clauses are main clauses, At-Issueness entails that a slifting sentence  $C, E$  can be felicitously uttered only if  $\llbracket C \rrbracket \in Q$ , where  $Q$  is the question under discussion in the given context. One way to read this is that slifting parentheticals attach to clauses that are obligatorily at-issue, i.e. main clauses. It is then to be expected that such parentheticals do not occur in syntactically subordinate positions. Since embedded clauses need not be marked for discourse status, embedding predicates can freely be further embedded.

In the remaining part of this section, I address one type of exception to the non-embeddability of slifting parentheticals. The following sentence is acceptable and the parenthetical seems to take narrow scope with respect to the matrix verb (see also Ross 1973).

(53) Sarah said that Will, she thinks, has strong qualifications.

One possible reaction would be to say that embedded clauses too can take on at-issue status.<sup>9</sup> However, this begs the question of why slifting parentheticals do not embed on a regular basis. What I would like to suggest is that examples as these are likely based on some sort of an agreement mechanism whereby the slift restates what is already expressed by the matrix clause. In support of this view, notice that (53) deteriorates if the slift presents a fresh perspective by introducing a different attitude holder (54). Also, such examples seem to require predicates that can describe the same attitude, e.g. *say* and *think*. (53) becomes unacceptable if the matrix and the slifting predicates do not line up semantically (55).

(54) ?Sarah said that Will, the committee thinks, has strong qualifications.

(55) #Sarah imagined that Will, she thinks, has strong qualifications.

I leave the precise analysis of such examples to further research, here merely noting their special properties.

## 5. Conclusion

This paper investigated the semantic properties of sentences with slifting parentheticals. The main claim was that such constructions function as a means of modulating assertion strength. I proposed a probabilistic account whereby the assertion strength of the slifted clause is derived from the background discourse information conditionalized on the evidence described by the parenthetical component. The account was shown to capture the intuition that the implication strength of slifted clauses varies depending on the quality and certainty of the evidence. Importantly, slifting sentences were not reduced to embedding constructions and their unique properties were preserved. In particular, the proposal was able to explain why slifting parentheticals express upward entailing operators and why they typically modify main clauses. The paper argued that those properties follow from the double assertion nature of slifting sentences and general principles of discourse management.
