Alzheimer's Disease (AD) begins with loss of recent memory and is associated to pathological and histological hallmarks such as  $\beta$  amyloid plaques, neural tangles (NFT), cholinergic deficit, extensive neuronal loss and synaptic changes in the cerebral cortex and hippocampus. The amyloid cascade hypothesis implies the activity of  $\beta$ ,  $\gamma$  secretases which mediate the cleavage of Amyloid Precursor Protein (APP), the formation of amyloidogenic A $\beta$  fragment (1-42), which compacts into amyloid plaques, while the cleavage by ? secretase of APP, within the A $\beta$  segment forms sAPP and prevents the formation of AB (Zetterberg et al. 2010 Exp Gerontol 45, 23-29). Among the proteases which have  $A\beta$ -degrading activity, Metalloproteinase (MMP) 2, disclosing  $\beta$  secretase-like activity, is included, while MMP9 seems to contribute to neuronal death (Yan et al. 2006 J Biol Chem 281, 24566-74). In addition, intracellular signalling protein Protein Kinase C (PKC) can control ? secretase, preventing the formation of  $\beta$  amyloid, and prolonging the life span of AD (de Barry et al. 2010 Exp Gerontol 45, 64-69). A lipophilic molecular combination (codrug 1), obtained by joining an antioxidant molecule, lipoic acid, with an anti-inflammatory compound, ibuprofen (IBU) has been synthetized in our lab and administered in a chronic treatment during intracerebroventricular infusion of A $\beta$  (1-40) peptide in rat brains as a model of AD (Sozio et al. 2010 Arch Pharm 343,133-42).

Here we show the effects exerted by codrug 1 on PKC  $\varepsilon$ -mediated MMP2 and MMP9 levels regulation in A $\beta$  (1-40) infused rat cerebral cortex. Interestingly codrug 1, lowering Metalloproteinases expression via PKC  $\varepsilon$  down-modulation, seems to control Alzheimer's disease induced cerebral amyloid deposits, neuronal death and, lastly, behavioural deterioration. Moreover the cognitive test evidences that codrug 1 treatment decreases the number of reference memory errors and the time spent to perform the test suggesting this compound as an useful therapeutical tool against AD.

Keywords: Alzheimer's disease, metalloproteinases, PKCs, ibuprofen, lipoic acid, codrug 1
