#### Abstract

5-oxo-1-phenylpyrrolidine-3-carboxylic acid has been synthesized and characterized by using single-crystal X-ray diffraction, FT-IR, ${ }^{1} \mathrm{HNMR},{ }^{13} \mathrm{CNMR}$, UV-Visible spectroscopy and computational methods. The structure has been discussed and studied using density functional theory (DFT) at the theory level Becke3-Lee-Yang-Parr (B3LYP) functional and $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ as basis set. The structural and thermodynamic parameters, electrostatic potential, electrophilicity ( $\omega$ ), chemical potential ( $\mu$ ), chemical hardness $(\eta)$ and maximum amount of electronic charge transfer ( $\Delta N_{\text {max }}$ ) have been examined for this compound. Hyperconjugative interactions have been studied with the help of natural bond orbital analysis. Electric dipole moment, polarizability and first static hyperpolarizability values have been calculated. The correlation between experimental and theoretical proton and carbon NMR spectroscopic values has also been discussed. The experimental results are in good correlation with theoretical values.

Keywords: DFT, Single crystal, Spectroscopic data, Natural bond orbital (NBO), Non linear optical (NLO)

## 1 Introduction

The pyrrolidine ring system is found in a vast variety of compounds displaying an impressive range of biological activities. The incorporation of different substitution patterns and motives into the pyrrolidine heterocyclic has potential in the discovery of new substances with useful pharmacological properties ${ }^{1}$. Pyrrolidine are well known for their versatile pharmacological activities such as antimicrobial ${ }^{2-4}$, antitumor ${ }^{5}$, anticonvulsant, sphingosine-1-phosphate (S1P) receptor agonists, malicenzyme inhibitors, ketoamide-based cathepsin K inhibitors, human
characterization of 5-oxo-1-phenylpyrrolidine-3carboxylic acid with the aim to provide a complete description on the molecular geometry, vibrations and electronic features. The natural bond orbital (NBO), molecular electrostatic potential (MESP), electronic absorption spectra, Mulliken atomic charges, global reactivity descriptors and thermodynamic properties were also investigated using density functional theory (DFT) method with the basis set 6-31G (d, p). Due to

[^0]growing interest of organic materials for non linear optical devices, the non linear optical (NLO) properties of the compound have also been studied revealing that the molecule is important in pharmaceutical chemistry as well as an attractive object for future studies for nonlinear optical properties.

## 2 Materials, Synthesis and Crystal Growth

Melting point (m.p.) was determined in a melting point apparatus and was uncorrected. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{CNMR}$ spectra were recorded on a Bruker 400 MHz inctrumant Chaminon chiftc ware measured in DMSOponamit on ph TCOBE ace. Abbreviations for data quoted are: s, singlet; d, doublet; t , triplet; m , multiplet. IR spectra of compounds were recorded as potassium bromide pellets on a Perkin-Elmer Fourier transform infra-red spectrophotometer. Ultraviolet spectrum was recorded $200-500 \mathrm{~nm}$ on UV-visible Double-Beam Spectrophotometer (systronic-2203) instrument using DMSO as a solvent. Reagents and solvents used for synthesis were purchased from Sigma-Aldrich, Merck and reagents were used without further purification, unless otherwise specified. Thin-layer chromatographies (TLCs) were visualized in an iodine chamber.

### 2.1 Procedure for the synthesis of 5-0x0-1-phenylpyrrolidine-3-carboxylic acid (3)

Compound 3 was prepared according to the method reported by Paytash et al. ${ }^{6}$ A solution of aniline 1 ( $0.455 \mathrm{~mL}, 0.005 \mathrm{~mol}$ ), itaconic acid $2(0.65 \mathrm{gm}, 0.005$ mol ) and 1.5 mL water was refluxed for $\sim 1 \mathrm{~h}$ and a light yellow colour precipitate started separating. The progress of the reaction was monitored by TLC. The solution was cooled; precipitate was filtered and washed with water. The obtained solid was dissolved in ethanol, filtered to remove any impurities present, the beaker was loosely plugged with cotton to ensure slow evaporation and kept overnight undisturbed. Yellow crystals of the titled compound were obtained (Scheme 1). M.p.: $190-192^{\circ} \mathrm{C} \quad\left[189-190^{\circ} \mathrm{C}\right]$; Yield: $82.59 \% ; R_{\mathrm{f}}$ value: 0.406 [Chloroform: Methanol] (8.0:2.0 v/v) as mobile phase; IR (KBr) $v_{\text {max }} 3436.4$ (-OH stretching); 3272 ( $=\mathrm{CH}$ stretching); 2898 and 2726 ( -CH aliphatic); $1876(\mathrm{C}=\mathrm{O}$ stretching of carboxylic acid); 1724 (C=O stretching); 1040(-C-O stretching) ${ }^{1} \mathrm{H}$ NMR (DMSO): $\delta(\mathrm{ppm})=7.12-7.15(\mathrm{t}$, $1 \mathrm{H}), 7.34-7.38(\mathrm{t}, 2 \mathrm{H}), 7.62-7.64(\mathrm{~d}, 2 \mathrm{H}), 3.94-3.98(\mathrm{~m}$, $1 \mathrm{H}), 4.02-4.04(\mathrm{~m}, 1 \mathrm{H}), 2.66-2.82(\mathrm{~m}, 2 \mathrm{H}) 3.3-3.45(\mathrm{~m}$, $1 \mathrm{H})^{13} \mathrm{C}$ NMR (DMSO): $\delta=35.21,35.28,56.13,119.53$, 124.40, $128.45,128.73,129.01,139.19,171.83$, 174.26.; m/z: 205.07.

### 2.2 Single-crystal X-ray studies

Single crystal X-ray diffraction data were collected on a Bruker APEX-II Quasar CCD area-detector diffractometer equipped with an Oxford Cryosystems Cryostream 700Plus cryostat. A multilayer monochromator with Mo $K \alpha$ radiation $(\lambda=0.71073$ $\AA$ ) from an IncoatecI $\mu$ Smicro source was used. Data reduction was carried out by means of standard procedures using the Bruker software package ${ }^{7}$ SAINT and absorption corrections and the correction of other systematic errors was performed using SADABS ${ }^{8}$. The structure was solved by direct methods using SHELXS- $97^{9}$ and refined using SHELXL-97 ${ }^{10}$. X-Seed5 was used as the graphical

Scheme 1 - Synthetic pathway for synthesis of 5-oxo-1-phenylpyrrolidine-3 carboxylic acid (3).
interface for the SHELX program suite. Hydrogen atoms were placed in calculated positions using riding models. A summary of crystal data and relevant refinement parameters for title compound is presented in Table 1(a). CCDC contains the supplementary crystallographic data for title compound.

## 3 Computational Details

For a proper understanding of theoretical and experimental consistency, quantum chemical calculations were performed by density functional theory with B3LYP/6-31G (d,p) method. All the calculations were carried out using Gaussian 09W program package ${ }^{11}$ with the default convergence criteria without any constraint on the geometry ${ }^{12}$. The vibrational assignments were made on the basis of the calculated PED using GAR2PED program ${ }^{13}$. To get the graphical presentation of IR and UV spectra and for the pictorial visualization and checking of calculated data, GaussView05 program was used. The NBO

calculations ${ }^{14}$ with complete geometry optimizations were carried out at DFT/B3LYP level in order to understand various second order interactions. The time dependent density functional theory (TD-DFT) at B3LYP/6-31G (d, p) level in solvent (DMSO) by implementing IEFPCM model available in Gaussian software was used for Frontier orbitals analysis and electronic absorption spectra of the optimized molecule. Molecular electrostatic potential surface (MEP) of the molecule depicts the charge density, size, shape and the site of chemical reactivity of the molecule. Intramolecular interactions were analyzed by AIM approach ${ }^{15}$. The reason for the basis set-6$31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ used in the calculations is that it leads to results that represent a compromise between accuracy and computational cost ${ }^{16}$.

## 4 Results and Discussion

### 4.1 Crystal structure of compound

Needle shaped crystals of compound 3 were obtained by slow evaporation of ethanol at room temperature. The molecule crystallized in monoclinic system with $P 2_{1} / \mathrm{n}$ space group having two molecules per unit cell and unit cell parameters $a=6.3276(5) \AA$, $b=12.1805(9) \AA, c=12.2601(9) \AA$. The molecular structure comprises one aromatic ring and pyrrolidine ring. ORTEP diagram and intermolecular hydrogen bonding is presented in Figs 1 and 2.

The five member ring A is envelop on C11, with the Cremer and Pople puckering parameters being Q $=0.251(3) \AA, \varphi(2)=291.8$ (6) (asymmetric parameters are $\Delta \mathrm{Cs}^{11}=2.5$ (3)) for the atom sequence $\mathrm{N} 1-\mathrm{C} 7$ [17].The phenyl ring B is Centroid $\mathrm{Cg}(2)$ with symmetry $x \quad, y \quad, \quad-0.13978(17), \quad 0.77393(8)$ $0.50353(10)$.

The crystal structure is stabilized by intermolecular hydrogen bonding between hydroxyl hydrogen of carboxylic acid and oxygen atom of carbonyl group with distance of $2.615 \AA ; \angle \mathrm{O} 2-\mathrm{H} 2 \cdots \mathrm{O} 1164^{\circ}$ and is shown in Fig. 2. The other intermolecular bond are present in between C7 of pyrrolidine ring and O 3 of carboxylic acid. The results of hydrogen bonding interactions and related D-H...A angles for the title compound are recorded in Table 1(b).

### 4.1.1 Molecular geometry

Optimized and experimental structural parameters (bond lengths and bond angles) for 5-oxo-1-phenylpyrrolidine-3-carboxylic acid are presented in Table 2. It is observed, from the structural data that the experimental and the calculated values are comparable with each other, and exactly replicate the experimental structure. The atoms numbering of molecule is reported in Fig. 3. The longest distance, similar to the experimental value and attributing the pure single bond character is found to be between $\mathrm{C} 2-\mathrm{Cl} 1\left(1.52^{\circ} \mathrm{A}\right)$. The decreased bond length between

$\mathrm{O} 2-\mathrm{H} 2$ is due to the delocalization of nonbonding electrons from O 2 to the electron withdrawing carbonyl group (C2-O3) and is found to be the shortest $\left(0.82^{\circ} \mathrm{A}\right)$. The C-C and C-H bond distances of rings are in the range of 1.37-1.52 $\AA$ and 0.93-0.98 $\AA$ respectively. The factors affecting the bond angles are electro negativity of central atom, presence of electron lone pairs, and the conjugation of the double bonds in the molecule. The bond angle decreases with the decrease in electronegativity of the central atom. The repulsion between O 2 and N 1 atoms is responsible for increase in the bond angles between

O3-C2-C11 (124.3 ${ }^{\circ}$ ), O1-C5-N1 (125.2 ${ }^{\circ}$ ), C7-N1-C5 $\left(127.4^{\circ}\right)$ and $\mathrm{O} 2-\mathrm{C} 2-\mathrm{O} 3\left(124.3^{\circ}\right)$ from the usual $120^{\circ}$. In pyrolidine ring all the bond angles are reduced from the normal value of $120^{\circ}$.

## $4.2{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectroscopy

${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{CNMR}$ chemical shifts were calculated with Gauge independent atomic orbital (GIAO) approach using DFT with B3LYP and 6-31G ( $\mathrm{d}, \mathrm{p}$ ) as basis sets ${ }^{18}$. The experimental and theoretical values of ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR chemical shifts of the studied compound are given in Table 3. Presence of a broad singlet at 13 ppm for H 26 in experimental protonNMR spectrum is due to the hydroxyl proton of carboxylic acid. H21 and H22 protons are observed at chemical shift values $3.94-3.98 \mathrm{ppm}$ and $4.02-4.05 \mathrm{ppm}$ exhibiting quartet and triplet respectively, due to de-shielding by nitrogen heteroatom of pyrrolidine ring and nearby oxygen of carboxylic acid. Two protons H 24 and H 25 are also
de-shielded due to the presence of carbonyl group exhibiting a multiplet at $2.66-2.82 \mathrm{ppm}$. H 23 proton splitted into multiplet by adjacent protons (H21, H22, H 24 and H 25 ) and exhibited at $3.94-4.07 \mathrm{ppm}$.The greater de-shielding in H17 and H18 (7.627-7.646 ppm ) is due to electron withdrawing nature of N 7 of pyrrolidine ring. H16 showed triplet (7.349-7.389 ppm ) due to coupling with ortho proton (H17, J=1.2 Hz ) and para proton ( $\mathrm{H} 20, \mathrm{~J}=0.8 \mathrm{~Hz}$ ). H19 showed triplet (7.349-7.389 ppm) due to coupling with ortho proton ( $\mathrm{H} 18, \mathrm{~J}=1.2 \mathrm{~Hz}$ ) and para proton ( $\mathrm{H} 20, \mathrm{~J}=0.8$ Hz ) which is also well established by calculating coupling constant values for these protons from experimental ${ }^{1} \mathrm{HNMR}$ spectrum. The lowest chemical shift of aromatic proton in the spectrum at 7.12-7.15 corresponded to H20.The correlation graph between the experimental and calculated chemical shifts for ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR are shown in Fig. 4 (a) and Fig. 4(b), respectively. The correlation graph follows the linear

Fig. 4 - Correlation graph between experimental and calculated ${ }^{1}$ HNMR chemical shifts (a) and between experimental and calculated ${ }^{13}$ CNMR chemical shifts of 5-oxo-1-phenylpyrrolidine-3 carboxylic acid (3).
equation, $y=1.166 x+0.0691$ using B3LYP for ${ }^{1} \mathrm{H}$ NMR and $y=1.053 x+4.686$ for ${ }^{13} \mathrm{C}$ NMR where $' y$ ' is the ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR experimental chemical shift and ' $x$ ' is the calculated ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR chemical shift (in ppm). The correlation values ( $R^{2}=0.980$ using B3LYP) for ${ }^{1} \mathrm{H}$ NMR and ( $R^{2}=0.517$ using B3LYP) for ${ }^{13} \mathrm{C}$ NMR shows that the correlations between experimental and the calculated chemical shifts are very good. According to these results, the calculated chemical shifts comply with the experimental findings except for the proton of the -COOH group.

### 4.3 UV-Visible absorption spectroscopy

The UV-Visible spectrum of compound (Fig. 5) has been studied by TD-DFT method using B3LYP and functional as 6-31 G (d, p) basis sets and solvent effect has been taken into consideration by implementing Integral Equation Formalism Polarisable Continuum Model (IEFPCM). The vertical excitation energies, oscillator strengths ( $f$ ), percentage contribution of probable transitions and corresponding absorption wavelengths along with simulated UV data have been tabulated in Table 4 and
compared with experimental results. One intense electronic transitions at 300 nm with an oscillator strength $f=0.1689$ in DMSO is anticipated, showing an agreement with the measured experimental data ( $\lambda$ $=326 \mathrm{~nm}$ in DMSO) as shown in Fig. 5 and corresponds to the transition from HOMO to LUMO with $50.08 \%$ contribution. Electronic transitions from HOMO-1 to LUMO, HOMO-1 to LUMO+1 and HOMO to LUMO+3 with $1.46 \%, 2.71 \%$ and $42.61 \%$ contributions respectively are exhibited by a feeble band around 262 nm in the experimental UV spectrum of 5-oxo-1-phenylpyrrolidine-3-carboxylic acid (3). The corresponding theoretical peak in the TD-DFT UV spectrum is at 226 nm . These transitions come into view due to $n \rightarrow \pi^{*}$ and $\pi \rightarrow \pi^{*}$ transition. Molecular orbitals HOMO-LUMO, (HOMO-1) LUMO, (HOMO-1)-(LUMO+1) and (HOMO-1)(LUMO+3) of the compound are shown in Fig. 6.

### 4.4 Vibrational assignment

Representative experimental FT-IR bands together with calculated wavenumbers (scaled) and their assignments are given in supplementary Table 5. The calculated vibrational wavenumbers are higher than the experimental wavenumbers due to discard of deviation
Table 4 - Experimental and theoretical absorption wavelength $\lambda(\mathrm{nm})$, excitation energies $E(\mathrm{eV})$ of 5-oxo-1-phenylpyrrolidine-3 carboxylic acid (3).

present in real system. Therefore calculated wavenumbers are scaled down by a single factor 0.9679 for B3LYP and compared with experimental wavenumbers ${ }^{19}$. The value of correlation coefficient ( $\mathrm{R}^{2}=0.994$ using B3LYP)
showed an excellent correlation between experimental and calculated wavenumbers. Figure 7 represents the correlation graph and FT - IR spectra (experimental and calculated) are shown in Fig. 8.

### 4.4.1 OH vibrations

The O-H group vibrations are likely to be the most sensitive to the environment, so they show pronounced shifts in the spectra of the hydrogen bonded species. The hydroxyl stretching vibrations are generally ${ }^{20}$ observed at around $3500 \mathrm{~cm}^{-1}$. In the experimental FTIR spectrum, the band observed at $3436.4 \mathrm{~cm}^{-1}$ in B3LYP method with 6-31G ( $\mathrm{d}, \mathrm{p}$ ) has been assigned for $\mathrm{O}-\mathrm{H}$ stretching vibration and is in good agreement with the calculated value at $3676 \mathrm{~cm}^{-1}$. This is pure vibration with $100 \%$ contribution.

### 4.4.2 $C=O$ vibration and $C-O$ vibrations

The appearance of strong bands in the FT-IR between 1690-1800 $\mathrm{cm}^{-1}$ in aromatic compounds show the presence of carbonyl group and is due to the
$\mathrm{C}=\mathrm{O}$ stretching motion. The wavenumber due to $\mathrm{C}=\mathrm{O}$ stretch mainly depends on the bond strength which in

Fig. 7 - Correlation graph between experimental and calculated wave numbers.

Fig. 8 - Experimental and theoretical IR spectrum of 5-oxo-1-phenylpyrrolidine-3 carboxylic acid (3).
turn depends upon inductive, conjugative, field and steric effects. In the present study, a strong band at 1724 and $1876 \mathrm{~cm}^{-1}$ in FT-IR spectrum is assigned to $\mathrm{C}=\mathrm{O}$ stretching mode ${ }^{21}$. The calculated $\mathrm{C}=\mathrm{O}$ stretching modes are at $1751 \mathrm{~cm}^{-1}$ and $1817 \mathrm{~cm}^{-1}$ with PED contribution of $84 \%$ and $74 \% \mathrm{~cm}^{-1}$ for B3LYP level shows good agreement with the experimental value. The C-O stretching vibration is found at 1040 $\mathrm{cm}^{-1}[22,23]$. Band at $1054 \mathrm{~cm}^{-1}$ is due to C-O stretching vibration. Delocalization of non-bonding electrons of oxygen atom to carbonyl group results in the decrease in the force constant of carbonyl group which correspond to the lowering of wavenumber.

### 4.4.3 Phenyl ring vibrations

Phenyl ring predominantly involves $\mathrm{C}-\mathrm{H}, \mathrm{C}-\mathrm{C}$, $\mathrm{C}=\mathrm{C}$, stretching, $\mathrm{C}-\mathrm{C}-\mathrm{C}, \mathrm{H}-\mathrm{C}-\mathrm{C}$ in plane and out of plane bending along with $\mathrm{C}-\mathrm{C}-\mathrm{C}-\mathrm{C}$ torsional vibrations. The aromatic $\mathrm{C}-\mathrm{H}$ stretching vibrations ${ }^{24}$ are normally found between 3100 and $3000 \mathrm{~cm}^{-1}$. In FT-IR spectrum bands observed at $3272 \mathrm{~cm}^{-1}$ are assigned to $=\mathrm{C}-\mathrm{H}$ stretching motions. The calculated scaled wavenumbers for $\mathrm{C}-\mathrm{H}$ stretching modes of phenyl ring were found at $3165(98 \%)$, $3115(79 \%)$, $3104(60 \%), 3090(52 \%), 3082(36 \%) \mathrm{cm}^{-1}$. In aromatic hydrocarbons, skeletal vibrations involving carbon-carbon stretching within ring are absorbed in the region ${ }^{25}$ between 1600 and $1585 \mathrm{~cm}^{-1}$. The wavenumber calculated at $1304,1454,1585,1606$ $\mathrm{cm}^{-1}$ assigneto the $\mathrm{C}=\mathrm{C}$ stretching vibration in the benzene ring which show good agreement with experimental value at $1332,1353,1412,1490,1593$, $1649 \mathrm{~cm}^{-1}$.

### 4.4.4 Aliphatic $\mathbf{C}$ - H vibration

The spectral region $2960-2870 \mathrm{~cm}^{-1}$ in the FT-IR contains strong $\mathrm{CH}_{2}$ asymmetric, symmetric and C-H stretching vibrational modes. The calculated stretching wavenumbers 3041 ( $87 \%$ ), 3021 ( $84 \%$ ), 3001 ( $88 \%$ ), 2948 ( $94 \%$ ), 2907 ( $96 \%$ ), 2938 ( $56 \%$ ), 2936 ( $59 \%$ ), 2925 ( $81 \%$ ), 2819 ( $86 \%$ ) and 2811 $(86 \%) \mathrm{cm}^{-1}$ agree quite well with the observed frequencies at 2898 and $2726 \mathrm{~cm}^{-1}$ and literature values ${ }^{26,27}$. The $\mathrm{CH}_{2}$ in-plane bending vibration (scissoring) for pyrrolidine ring is calculated at 1498 ( $71 \%$ ), 1491 ( $22 \%$ ), 1440 ( $94 \%$ ) $\mathrm{cm}^{-1}$ and matches well with the FT-IR at $1461 \mathrm{~cm}^{-1}$. Below $1450 \mathrm{~cm}^{-1}$ region $\mathrm{CH}_{2}$ modes of rotator origin out of plane bending vibrations ("wagging', "twisting'", 'rocking'") are observed ${ }^{28,29}$.

### 4.5 Molecular electrostatic potential

The molecular electrostatic potential (MEP) is a common map, used extensively for characterization of molecules and in studies of biological recognition and hydrogen bonding interactions. Furthermore, it is used to visualize the reactive sites for electrophilic and nucleophilic attack ${ }^{30}$. Molecular electrostatic potential (MEP), for the title compound, was calculated at B3LYP/6-31G (d, $p$ ) to predict the reactive sites for electrophilic and nucleophilic attack. The total electron density on to which the MEP has been mapped is shown in Fig. 9. This figure provides a visual representation of the chemically active sites and comparative reactivity of atoms ${ }^{31}$. It can be seen from this figure that electrophilic reactivity is presented by the negative (red) regions, nucleophilic

Fig. $9-3 \mathrm{D}$ plots of the molecular electrostatic potential of 5-oxo-1-phenylpyrrolidine-3 carboxylic acid (3).
reactivity is shown by the positive (blue) regions and green represents region of zero potential of MEP. Potential decreases in the order red $<$ orange $<$ yellow $<$ green < blue. Major blue region is localized on the vicinity of hydrogen atom of hydroxyl group indicates the site for nucleophilic attack while rest of the region is almost neutral characterized by green colour.

### 4.6 Natural bond orbital analysis

Natural bond orbital (NBO) of the molecule explains the molecular wave function in terms of Lewis structures, charge, bond order, bond type, hybridization, resonance, donor-acceptor interactions, etc. NBO analysis has been performed to elucidate the intramolecular, rehybridization and also the interaction which will weaken the bond associated with the anti-bonding orbital. Conversely, an interaction with a bonding pair will strengthen the bond. The natural bond analysis ${ }^{32}$ (NBO) has been performed using Gaussian09 package at the B3LYP/6-31G(d, p) method. It explains charge transfer or conjugative interactions in molecular systems, intra and intermolecular bonding and interaction among bonds. It also offers a method to measure delocalization or hyperconjugation and interaction between both filled and virtual orbital spaces. To evaluate interaction between donor level bonds and acceptor level bonds, i.e., donor (i)acceptor ( $j$ ), in the NBO analysis the second order

Fock matrix was carried out ${ }^{33}$. The result of interaction is a loss of occupancy from the concentration of electron NBO of the idealized Lewis structure into an empty non-Lewis orbital. For each donor ( $i$ ) and acceptor ( $j$ ) the stabilization energy $E(2)$ associated with the delocalization $i, j$ is as follows:

$$
\begin{equation*}
E(2)=\Delta E_{i j}=q i \frac{\left(F_{i j}\right)^{2}}{\left(E_{j}-E_{i}\right)} \tag{1}
\end{equation*}
$$

Where $q_{\mathrm{i}}$ is the donor orbital occupancy, $E_{\mathrm{i}}$ and $E_{\mathrm{j}}$ are the diagonal elements and $F_{\mathrm{ij}}$ is the off diagonal NBO Fock matrix element. In NBO analysis large $E(2)$ value shows the intensive interaction between electron-donors and electron-acceptors and greater the extent of conjugation of the whole system. The corresponding results are presented in Table 6.

The NBO analysis showed strong intramolecular hyperconjugative interactions causing increased electron density (ED) and intramolecular charge transfer (ICT) giving stabilization to the system. It revealed the intramolecular charge transfer in the title molecule from $\sigma$ bonding $\mathrm{C}_{1}-\mathrm{C}_{2}$ to antibonding $\sigma^{*}$ $\left(\mathrm{C}_{3}-\mathrm{C}_{4}\right)$ and $\left(\mathrm{C}_{5}-\mathrm{C}_{6}\right)$ with stabilization energy of 21.71 $\mathrm{kcal} / \mathrm{mol}$ and $19.36 \mathrm{kcal} / \mathrm{mol}$, respectively, and from bonding $\sigma \mathrm{C}_{3}-\mathrm{C}_{4}$ to antibonding $\sigma^{*}\left(\mathrm{C}_{1}-\mathrm{C}_{2}\right)$ and $\left(\mathrm{C}_{5}-\mathrm{C}_{6}\right)$ orbitals with stabilization energy of $17.43 \mathrm{kcal} / \mathrm{mol}$ and $20.64 \mathrm{kcal} / \mathrm{mol}$, respectively. From $\sigma$ bonding

$\mathrm{C}_{5}-\mathrm{C}_{6}$ to $\sigma^{*}\left(\mathrm{C}_{1}-\mathrm{C}_{2}\right)$ and $\left(\mathrm{C}_{3}-\mathrm{C}_{4}\right)$ leading to stabilization of $20.80 \mathrm{kcal} / \mathrm{mol}$ and $19.64 \mathrm{kcal} / \mathrm{mol}$, respectively. The intramolecular charge transfer between $\sigma \rightarrow \sigma^{*}$ from $\left(\mathrm{C}_{9}-\mathrm{H}_{23}\right)$ to $\left(\mathrm{C}_{13}-\mathrm{O}_{15}\right)$ with stabilization of $5.07 \mathrm{kcal} / \mathrm{mol}$. From $\sigma\left(\mathrm{C}_{10}-\mathrm{H}_{25}\right)$ to $\pi *\left(\mathrm{C}_{11}-\mathrm{O}_{12}\right)$ orbital with increased ED ( 0.54 e ) leading to stabilization of $5.18 \mathrm{kcal} / \mathrm{mol}$. Between $\mathrm{O}_{10}-\mathrm{H}_{26}$ from $\sigma \rightarrow \pi^{*}\left(\mathrm{C}_{13}-\mathrm{O}_{14}\right)$ which increases ED (1.38 e) leading to stabilization of $5.37 \mathrm{kcal} / \mathrm{mol}$. The intramolecular charge transfer from nonbonding of $\mathrm{N}_{7}$ to $\sigma^{*}\left(\mathrm{C}_{3}-\mathrm{C}_{4}\right),\left(\mathrm{C}_{8}-\mathrm{H}_{22}\right)$ and $\pi^{*}\left(\mathrm{C}_{11}-\mathrm{H}_{12}\right)$ orbital leading to stabilization of $31.71 \mathrm{kcal} / \mathrm{mol}, 6.18 \mathrm{kcal} / \mathrm{mol}$ and $58.82 \mathrm{kcal} / \mathrm{mol}$, respectively. From nonbonding of $\mathrm{O}_{12}$ to $\sigma^{*}$ orbitals of $\left(\mathrm{N}_{7}-\mathrm{C}_{11}\right)$ and $\left(\mathrm{C}_{10}-\mathrm{C}_{11}\right)$ with stabilization energy of $28.41 \mathrm{Kcal} / \mathrm{mol}$ and 21.64 $\mathrm{kcal} / \mathrm{mol}$, respectively. From nonbonding of $\mathrm{O}_{14}$ to $\sigma^{*}$ of $\mathrm{C}_{9}-\mathrm{C}_{13}$ and $\mathrm{C}_{13}-\mathrm{O}_{15}$ with stabilization energy of 19.63 and $35.96 \mathrm{kcal} / \mathrm{mol}$, respectively. From nonbonding of $\mathrm{O}_{15}$ to $\pi^{*}$ orbital of $\mathrm{C}_{13}-\mathrm{O}_{14}$ leading to stabilization of $44.47 \mathrm{kcal} / \mathrm{mol}$. The electron density is transferred from $n(O), n(N)$ to antibonding $\pi^{*}$, $\sigma^{*}$ orbital of $\mathrm{C}-\mathrm{N}, \mathrm{C}-\mathrm{C}, \mathrm{C}-\mathrm{O}$ explaining both the elongation and red shift.

### 4.7 Non linear optical analysis

The field of nonlinear optics is the cutting edge of current research because of its importance in providing the key functions of frequency shifting, optical modulation, optical switching, optical logic and optic memory for the emerging technologies in areas such as telecommunications, signal processing and optical interconnections ${ }^{34-37}$. In the recent years, organic nonlinear optical materials have attracted great interest because of their high nonlinearity, variety of synthetical methods and better laser damage resistance compared to their inorganic counterparts. In general, derivatives of an organic aromatic system substituted with donor and acceptor substituents are most commonly designed for nonlinear applications. In this system, polarization of the molecule is increased due to the conjugated $\pi$-bonds and the donor and acceptor groups contribute their own 'mesomeric moments' to give rise to a high nonlinear optical coefficient ${ }^{38}$.

Organic molecules able to manipulate the photonic signals efficiently are of importance in technologies such as optical communication, optical computing, and dynamic image processing ${ }^{39,40}$. The first hyperpolarizability of the title compound was calculated using the B3LYP/6-31G (d, p) basis set based on the finite field approach. In the presence of
an applied electric field, the energy of a system is a function of electric field. The first hyperpolarizability is a third rank tensor that can be described by a $3 \times 3$ $\times 3$ matrix. The 27 components of the matrix can be reduced to 10 components due to Kleinman symmetry ${ }^{41}$.

Since the values of the polarizabilities $\alpha$ and the hyperpolarizability of Gaussion output are reported in a atomic mass units (a.u.), the calculated values have been converted into electrostatic units (esu) ( $\alpha: 1$ a.u = $0.1482 \times 10^{-24}$ esu; $\beta: 1$ a.u. $\left.=.0086393 \times 10^{-30} \mathrm{esu}\right)$. The results of electronic dipole moment $\mu \mathrm{i}(i=x, y, z)$, polarizability $\alpha_{\mathrm{ij}}$ and first order hyperpolarizability $\beta_{\mathrm{ijk}}$ are presented in Table 7. The calculated dipole moment, polarizability $\alpha_{\text {tot }}$ and first hyper polarizability for the title compound are equal to $2.6733 \mathrm{D}, 18.54 \times 10^{-24}$ esu and $0.27 \times 10^{-30}$ esu, respectively, for B3LYP level.

### 4.8 Reactivity descriptors

### 4.8.1 Global Reactivity Descriptors

Global reactivity descriptors such as chemical potential, molecular hardness, electrophilicity, frontier molecular orbital energies and shapes, the condensed Fukui functions have been extensively used for rationalization and interpretation of diverse aspects of chemical bonding, reaction mechanism and reactive centres in molecules. These quantum chemical descriptors are related to electronic structure of compounds and to the mechanism that is involved in the covalent bond formation between the nucleophile and the electrophile. DFT makes it possible to define and well justify different concepts of chemical reactivity.

| Table 7 - Dipole moment $\mu$, polarizability $\alpha_{\text {tot }}\left({ }^{(x 1} 10^{-24}\right.$ esu) and first order static hyperpolarizability $\beta_{\text {tot }}\left(10^{-30}\right)$ data of 5-oxo-1-phenylpyrrolidine-3 carboxylic acid (3). |  |  |  |
| :---: | :---: | :---: | :---: |

| < $\alpha>$ | 18.54496 | $\beta$ total(esu) | 0.2747 |

Molecular orbital calculations provide a detailed description of orbitals including spatial characteristics, nodal patterns and individual atom contributions ${ }^{42}$. The highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) are the most important orbital in a molecule. HOMO, which can be thought the outer orbital containing electrons, tends to give these electrons as an electron donor and hence the ionization potential is directly related to the energy of the HOMO. On the other hand LUMO can accept electrons and the LUMO energy is directly related to electron affinity ${ }^{43,44}$.

Ionization potential (IP), electron affinity (EA), electronegativity $(\chi)$, global hardness $(\eta)$, chemical potential ( $\mu$ ), global electrophilicity index ( $\omega$ ), global softness $(S)$ and additional electronic charge $\left(\Delta N_{\max }\right)$ were calculated ${ }^{45-50}$ using the following Eqs (2-9):

$$
\begin{align*}
& \mathrm{IP}=-\varepsilon_{\text {HOMO }}  \tag{2}\\
& \mathrm{EA}=-\varepsilon_{\text {LUMO }}  \tag{3}\\
& \chi=-\frac{1}{2}\left(\varepsilon_{\text {LUMO }}+\varepsilon_{\text {HOMO }}\right)  \tag{4}\\
& \eta=\frac{1}{2}\left(\varepsilon_{\text {LUMO }}-\varepsilon_{\text {HOMO }}\right)  \tag{5}\\
& \mu=-\chi=\frac{1}{2}\left(\varepsilon_{\text {LUMO }}+\varepsilon_{\text {HОМО }}\right)  \tag{6}\\
& \omega=\frac{\mu^{2}}{2 \eta}  \tag{7}\\
& S=\frac{1}{2 \eta}  \tag{8}\\
& \Delta N_{\max }=-\frac{\mu}{\eta} \tag{9}
\end{align*}
$$

All the parameters such as the energies of frontier molecular orbital ( $\varepsilon_{\text {LUMO }}, \varepsilon_{\text {номо }}$ ), band gap ( $\varepsilon_{\text {LUMO }}{ }^{-}$ $\varepsilon_{\text {номо) , ionization }}$ potential (IP), electron affinity (EA), electronegativity ( $\chi$ ), global hardness ( $\eta$ ), chemical potential ( $\mu$ ), global electrophilicity index $(\omega)$ and global softness $(S)$ for the title compound, are listed in Table 8. The title compound is stable, is expressed by its negative chemical potential and do not decompose spontaneously into the elements it is
made up of. The hardness signifies the resistance towards the deformation of electron cloud of chemical systems under small perturbation encountered during chemical process. Soft systems are large and highly polarizable, while hard systems are relatively small and much less polarizable.

### 4.8.2 Local reactivity descriptors

In the given molecule local properties such as softness (Sk), Fukui Function (FF) and electrophilicity index ( $\omega \mathrm{k}$ ) are highly desirable in establishing reactivity-oriented description of molecular systems. Global reactivity indices were estimated according to the equations recommended by Hirshfeld population analysis of neutral, cation and anion state of molecule.

Fukui Functions are calculated using following equations:
$f_{K}^{+}=[q(N+1)-q(N)]$ for nucleophilic attack
$f_{K}^{-}=[q(N)-q(N-1)]$ for electrophilic attack
$f_{K}^{0}=\frac{1}{2}[q(N+1)-q(N-1)]$ for radical attack

Where, $\mathrm{N}, \mathrm{N}-1, \mathrm{~N}+1$ are total electrons present in neutral, anion and cation state of molecule, respectively.

In addition local softnesses $s_{\mathrm{k}}{ }^{+}, s_{\mathrm{k}}{ }^{-}, s_{\mathrm{k}}{ }^{0}$ and electrophilicity indices ( $\omega_{\mathrm{k}}{ }^{+}, \omega_{\mathrm{k}}{ }^{-}, \omega_{\mathrm{k}}{ }^{0}$ ) are also associated with a site k in a molecule are defined with the help of the corresponding condensed to atom variants of Fukui function, using the following equations.
$s_{K}^{+}=S f_{K}^{+}, s_{k}^{-}=S f_{K}^{-}, s_{K}^{0}=S f_{K}^{0}$
$\omega_{K}^{+}=\omega f_{K}^{+}, \omega_{K}^{-}=\omega f_{K}^{-}, \omega_{K}^{0}=\omega f_{K}^{0}$
Where,,+- 0 signs show nucleophilic, electrophilic and radical attack respectively. The maximum values of all the three local reactivity descriptors $\left(f_{\mathrm{k}}^{ \pm}, s_{\mathrm{k}}^{ \pm}\right.$, $\omega_{\mathrm{k}}{ }^{\perp}$ ) indicate that the site is more prone site for

| Table 8 - Calculated $\varepsilon_{\text {LUмо }}, \varepsilon_{\text {номо }}$, energy band gap $\varepsilon_{\text {LUMO }}-\varepsilon_{\text {Номо, }}$ ionization potential (IP), electron affinity (EA), electronegativity $(\chi)$, global hardness $(\eta)$, chemical potential ( $\mu$ ), global electrophilicity index $(\omega)$, global softness $(S)$ and additional electronic charge ( $\Delta N_{\text {max }}$ ) in eV of 5-oxo-1-phenylpyrrolidine-3 carboxylic acid (3). |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\varepsilon_{\text {H }}$ | $\varepsilon_{\text {L }}$ | $\varepsilon_{H}{ }^{-\varepsilon_{L}}$ | IP | EA | $\chi$ | $\eta$ | $\mu$ | $\omega$ | $S$ | $\Delta_{\text {max }}$ |
| -5.385 | -1.4163 | -3.968 | 5.708 | 0.914 | 5.250 | 1.9396 | -3.768 | 3.660 | 0.257 | 1.9428 |

nucleophilic or electrophilic attack than all other atomic sites in reactants.

Fukui functions $\left(f_{\mathrm{k}}^{+}, f_{\mathrm{k}}^{-}\right)$, local softnesses $\left(s_{\mathrm{k}}^{+}, S_{\mathrm{K}}^{-}\right)$ and local electrophilicity indices ( $\omega_{\mathrm{k}}^{+}, \omega_{\mathrm{k}}^{-}$) for selected atomic sites of molecule ${ }^{51,52}$ are listed in Table 9.

The relatively high values of local reactivity descriptors $\left(f_{\mathrm{k}}^{+}, s_{\mathrm{k}}^{+}, \omega_{\mathrm{k}}^{+}\right)$observed at C8, C10 and C13 indicated that these sites are prone to nucleophilic, whereas the relatively high values of local reactivity descriptors $\left(f_{\mathrm{k}}^{-}, s_{\mathrm{k}}{ }^{-}, \omega_{\mathrm{k}}{ }^{-}\right)$at O 12 suggested that this site
is prone to electrophilic attack. These investigations can provide helpful information about the molecule to carry out further studies.

### 4.9 AIM approach

Molecular graph of the compound using AIM program at B3LYP/6-31G ( $\mathrm{d}, \mathrm{p}$ ) level is presented in Fig. 10. According to Rozas et al. ${ }^{53}$, strong H-bonds are characterized by $\nabla^{2} \rho(\mathrm{BCP})<0$ and $H \mathrm{BCP}<0$ and have covalent character whereas medium H -bonds are characterized by $\nabla^{2} \rho(\mathrm{BCP})>0$ and $H \mathrm{BCP}<0$ and

Table 9 - Using Hirshfeld population analysis: Fukui functions $\left(f_{\mathrm{k}}^{+}, f_{\mathrm{k}}^{-}\right)$, local softnesses ( $\mathrm{sk}^{+}, \mathrm{sk}^{-}$) in eV , local electrophilicity indices $(\omega \mathrm{k}+, \omega \mathrm{k}$ ) in eV for selected atomic sites of 5-oxo-1-phenylpyrrolidine-3 carboxylic acid (3).

| Laplacian of electron density $\nabla^{2} \rho(\mathrm{BCP})$ ), electron kinetic energy density ( $G B C P$ ), electron potential energy density ( $V \mathrm{BCP}$ ), total electron energy density ( $H \mathrm{BCP}$ ) at bond critical point ( BCP ) and estimated interaction energy ( $E_{\text {int }}$ ) of 5-oxo-1-phenylpyrrolidine-3 carboxylic acid (3). |  |  |  |  |  |  |  |  |  |
| Interaction | Bond length | $\rho$ (BCP) | $\nabla^{2} \rho$ (BCP) | G(BCP) | V(BCP) | H(BCP) | Elipticity | $E_{\text {int }}$ | $E_{\text {int }}(\mathrm{kcal} / \mathrm{mol})$ |
| O12-H17 | 2.1815 | +0.019539 | +0.066503 | +0.015779 | -0.01493 | 0.000849 | +0.135074 | -0.007465 | -4.6842 |

are partially covalent and weak H -bonds are characterized by $\nabla^{2} \rho(\mathrm{BCP})>0$ and $H \mathrm{BCP}>0$ and they are mainly electrostatic ( where, $\rho(\mathrm{BCP}$ ) and $H B C P$ are Laplacian of electron density and total electron energy density at bond critical point, respectively).The weak interactions are characterized by $\nabla^{2} \rho(\mathrm{BCP})>0$ and $H B C P>0$ and the distance between interacting atoms is greater than the sum of Van der Waal's radii of these atoms.

Geometrical as well as topological parameters for bonds of interacting atoms are given in Table 10 and on the basis of above criteria, as $\nabla^{2}(\mathrm{BCP})$ and $H \mathrm{BCP}$ parameter is greater than zero hence $012 \ldots \mathrm{H} 17$ is weak interaction. According to AIM calculation the total energy of intramolecular interactions was calculated as $-4.6842 \mathrm{kcal} / \mathrm{mol}$. The ellipticity ( $\varepsilon$ ) at BCP is a sensitive index to monitor the $\pi$-character of bond ${ }^{54}$. The $\varepsilon$ is related to $\lambda 1$ and $\lambda 2$, which corresponds to the eigen values of Hessian and defined by a relationship: $\varepsilon=(\lambda 1 / \lambda 2)-1$. The ellipticity values for bonds are tabulated in Table 9. The lower values of ellipticity confirmed that there is delocalization of electron in aromatic ring ${ }^{55}$.

## 5 Conclusions

The present study describes the synthesis and characterization of 5-oxo-1-phenylpyrrolidine-3carboxylic acid (3). ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}-\mathrm{NMR}$, IR, UV and single crystal X-ray diffraction studies confirmed the structure of the molecule. From the computational results presented in this work, it can be seen that all the vibrational bands observed in the FT-IR spectrum are assigned to the various modes of vibration and most of the modes have wavenumbers in the expected range. The electrostatic potential surfaces (ESP) together with complete analysis of the vibrational spectra were used to obtain structural and symmetry properties of the title molecule. The stabilization energy and the calculated HOMO and LUMO energies showed charge transfer in the molecule, which shows its bioactive properties. GIAO NMR calculations provided chemical shift values that were in excellent agreement with experimental data. In the title molecule C8, C10 and C13 sites were identified
as nucleophilic and O 12 as electrophilic centers respectively using the local reactivity descriptors. From the values of partial dipole moment, polarizability and hyperpolarizability it can be concluded that the molecule is a candidate NLO material. The thermodynamical parameters were found increasing with the increase of the temperature. $\pi \rightarrow \pi^{*}, \sigma \rightarrow \sigma^{*}$ and $n \rightarrow \pi^{*}$ hyper conjugative interactions and electron delocalization were shown by natural bond orbital (NBO) analysis, pointing to the stabilization of the molecule. Intramolecular hydrogen interaction and ellipticity studied by AIM approach showed weak hydrogen interactions and $\pi$ character of bond in aromatic ring.

## Acknowledgement

The authors express their sincere thanks to the Head, Department of Chemistry, Lucknow University, Lucknow, for providing laboratory facilities. They are also thankful to the Director, CDRI, Lucknow for spectral analysis and IIT Kanpur for providing X-ray data.
