In 2,4-dihydroxybenzaldehyde 2,4-dinitrophenylhydrazone *N,N*-dimethylformamide solvate {or 4-[(2,4-dinitrophenyl)hydrazonomethyl]benzene-1,3-diol *N,N*-dimethylformamide solvate},  $C_{13}H_{10}N_4O_6 \cdot C_3H_7NO$ , (X), 2,4-dihydroxyacetophenone 2,4-dinitrophenylhydrazone *N,N*-dimethylformamide solvate (or 4-[1-[(2,4-dinitrophenyl)hydrazono]ethyl]benzene-1,3-diol *N,N*-dimethylformamide solvate),  $C_{14}H_{12}N_4O_6 \cdot C_3H_7NO$ , (XI), and 2,4-dihydroxybenzophenone 2,4-dinitrophenylhydrazone *N,N*-dimethylacetamide solvate (or 4-[(2,4-dinitrophenyl)hydrazono]phenylmethyl]benzene-1,3-diol *N,N*-dimethylacetamide solvate),  $C_{19}H_{14}N_4O_6 \cdot C_4H_9NO$ , (XII), the molecules all lack a center of symmetry, crystallize in centrosymmetric space groups and have been observed to exhibit non-linear optical activity. In each case, the hydrazone skeleton is fairly planar, facilitated by the presence of two intramolecular hydrogen bonds and some partial N–N double-bond character. Each molecule is hydrogen bonded to one solvent molecule.

### Comment

Hydrazone derivatives are an attractive class of non-linear optical (NLO) crystalline materials because of their large molecular non-linearities and their remarkable propensity to form non-centrosymmetric crystal systems (Serbutoviez *et al.*, 1995). The current approach to the development of practical NLO materials has focused on the use of a dihydroxy-functionalized hydrazone chromophore that can be easily synthesized and subsequently incorporated into a commercial epoxy polymer system. The preliminary goal was to provide

<sup>†</sup> Current address: Department of Chemistry, Berry College, Mt Berry, GA 30149, USA.

<sup>‡</sup> Current address: General Electric Co., Lexan Technology, One Lexan Lane, Mt Vernon, IN 47620, USA.

for a systematic variation of the chromophore structure to study the resulting structure–property relationships. To this end, three hydrazones were synthesized by coupling 2,4-dinitrophenylhydrazine (2,4-DNPH) with three carbonyl compounds, namely, 2,4-dihydroxybenzaldehyde, 2,4-dihydroxyacetophenone and 2,4-dihydroxybenzophenone, to yield hydrazones (X), (XI) and (XII), respectively.

To confirm the structures of these three hydrazones, which are part of a series of related compounds currently under investigation [including compounds (I)–(IX), which are still in progress], the single-crystal data for these compounds are reported here. While each of the three compounds demonstrates NLO properties, it should be noted that each crystallizes in a centrosymmetric space group and that each molecule lacks a center of symmetry.

As seen in Figs. 1–3, all three compounds crystallize in a 1:1 ratio with solvent molecules [*N,N*-dimethylformamide (DMF) for (X) and (XI), and *N,N*-dimethylacetamide (DMAc) for (XII)], which accept a hydrogen bond at atom O7 from atom H1A of the *para*-hydroxy group of the hydrazone. In each case, across the C7=N1 bond, N2 is *E* to C4; simultaneously, each *R* substituent at C7 is *Z* to N2. In each molecule, two intramolecular hydrogen bonds, H2A···N1 and H2B···O3, help to facilitate the planarity of each hydrazone.

The 23-atom hydrazone skeleton [atoms O1–O6, N1–N4 and C1–C13, plus atom C14 for (XI) and (XII)] of (X) is the most planar of the three compounds, as it has an r.m.s. deviation of 0.061 Å, with atoms O2 and C5 having the largest deviations [0.137 (3) and 0.117 (3) Å, respectively] from the plane. On the other hand, (XI) and (XII) display some buckling. They have larger r.m.s. deviations (0.190 and 0.122 Å, respectively), in part due to atoms with larger deviations from the plane of the skeleton. For example, in (XI), atoms O2 and O6 have deviations of 0.488 (2) and 0.491 (2) Å, respectively, while in (XII), atoms O5 and C5 have deviations of 0.330 (3) and 0.180 (3) Å, respectively, from the 23-atom plane of the skeleton.

In the case of compound (X), even the solvent molecule is coplanar with the plane of the hydrazone molecule; the r.m.s. deviation for all non-H atoms is 0.081 Å. However, neither solvent molecule in compounds (XI) and (XII) is coplanar with the hydrazone molecule (Figs. 2 and 3; Tables 3 and 5). The phenyl substituent (C14–C19) in compound (XII) is nearly perpendicular (Table 5) to the plane of the hydrazone skeleton, likely due in large part to steric problems around C7.

While the intramolecular hydrogen bonding minimizes the rotational freedom about the C4–C7 and N2–C8 bonds, rotation about N1–N2 is also reduced. The average of the C7=N1 bond lengths (Table 6) is  $\sim 3\sigma$  longer than the average of 13 C=N bond lengths (in PhC=NH coordination compounds) gleaned from the Cambridge Structural Database (CSD, Version 5.23; Allen, 2002). Similarly, the average of the N1–N2 bond lengths (Table 6) is  $\sim 20\sigma$  shorter than the average of five N–N bond lengths in hydrazine-solvated compounds in the CSD. This likely implies some N1–N2 double-bond character, thus reducing rotational mobility. The extent of this character changes as substituents vary on C7. The variation of C7=N1 bond lengths is 0.020 Å ( $\sim 7\sigma$ ), while that for N1–N2 is 0.015 Å ( $\sim 5\sigma$ ).

As seen in Table 6, some bond lengths near C7 are affected significantly ( $\geq 3\sigma$ ) by changes in the *R* substituent on C7. Specifically, increases in bond lengths are noted for C7=N1,

**Figure 1**

A view of the asymmetric unit of (X), showing the atom-labeling scheme. Displacement ellipsoids are drawn at the 50% probability level, and significant H atoms are labeled and drawn as small spheres of arbitrary radii.

**Figure 2**

**Figure 3**

A view of the asymmetric unit of (XII), showing the atom-labeling scheme. Displacement ellipsoids are drawn at the 50% probability level, and significant H atoms are labeled and drawn as small spheres of arbitrary radii.

C4–C7 and C4 $\cdots$ C5, concomitant with decreases in the N1–N2 and O2–C3 bond lengths as the *R* substituent changes from –H to –CH<sub>3</sub> to –Ph. The effect of going from H to alkyl to aromatic groups is felt as much as three bonds away from the C7–*R* bond.

## Experimental

The three title hydrazones were synthesized according to a known procedure (Vogel, 1989) by mixing a solution of 2,4-DNPH in an ethanol-tetrahydrofuran solvent mixture [1:1 for (X), 3:1 for (XI), and 2:1 for (XII)] with the three dihydroxy-carbonyl compounds in a 1:1.05 molar ratio, with concentrated HCl as catalyst. The decomposition points ( $>523$  K for each of the three hydrazones) were determined on a Thermal Analysis differential scanning calorimeter at a heating rate of 10 K min<sup>-1</sup>. Crystals suitable for diffraction analysis were grown by slow evaporation of a saturated solution in DMF for hydrazones (X) and (XI), and in DMAc for hydrazone (XII). Each crystal was placed into a capillary and sealed with mother liquor.

<sup>†</sup> Δ for (XII)–(X)    <sup>¶</sup> Δ for (XII)–(XI)    <sup>††</sup> Δ/s.u.<sub>(XII)</sub>    <sup>‡</sup> s.u.<sub>(X)</sub> is the s.u. in the bond length for (X)    <sup>§</sup> Range = maximum value – minimum value.

In all three cases, the approximate positions of the two hydroxy H atoms were first obtained from a difference map. These atoms were then placed in 'ideal' positions and refined as a rotating group. Bond lengths were constrained (AFIX 43) at 0.93 Å for aromatic C–H, 0.96 Å (AFIX 137) for methyl C–H, 0.86 Å (AFIX 43) for N–H and 0.82 Å (AFIX 147) for O–H.  $U_{iso}(H)$  values were fixed at  $1.5U_{eq}$  for OH and methyl H atoms, and  $1.2U_{eq}$  for all other H atoms. In the final stages of refinement for all three compounds, a few very small or negative  $F_o$  values were deemed to be in strong disagreement with their  $F_c$  values. The corresponding nine, 12, and 22 reflections for (X), (XI), and (XII), respectively, were eliminated from the final refine-

ment. The percentage decay of the three standards was calculated as the average of their  $\sigma(I)$  values.

For all three compounds, data collection: *P3/P4-PC Diffractometer Program* (Siemens, 1991); cell refinement: *P3/P4-PC Diffractometer Program*; data reduction: *XDISK* (Siemens, 1991); program(s) used to solve structure: *SHELXS86* (Sheldrick, 1990a); program(s) used to refine structure: *SHELXL97* (Sheldrick, 1997); molecular graphics: *SHELXTL/PC* (Sheldrick, 1990b); software used to prepare material for publication: *SHELXTL/PC* and *SHELXL97*.

David B. Hall, Northwestern University, Evanston, IL, USA, is thanked for NLO analyses.

Supplementary data for this paper are available from the IUCr electronic archives (Reference: LN1175). Services for accessing these data are described at the back of the journal.
