A-2	Sampling Errors of Differences	100

1. Introduction

In January of 1972, the staff and resident representatives of the Worcester Model Cities neighborhood contracted the Survey Research Program to work with them to conduct a survey of neighborhood residents. The purpose of the project was to collect data that would assist those in the Model Cities area to systematically measure residents' perceptions and feelings, to identify problems and needs, to plan programs, and, perhaps, at a later date to have a basis against which to measure change.

The project, as it was designed and as it was carried out, was a joint effort. A committee of residents and staff outlined the study objectives. Program staff prepared several drafts of the interview schedule for review, incorporating the committee's suggestions at each stage. The committee interviewed and helped to screen applicants for interviewers, who were then trained by Survey Research Program staff. When field work was in progress, Model Cities staff monitored the interviewers' day-by-day progress, while Program staff met with interviewers for more intensive review sessions on a weekly basis.

And so it is appropriate that the analysis of the data, too, is a cooperative effort rather than simply a document prepared by a consultant. Once the basic distributions of answers had been tabulated, Model Cities staff met with Survey Research Program staff to jointly decide on what further tabulations should be prepared. Copies of all tabulations were provided to Model Cities, so that residents and staff could begin to review and use the findings.

This document is not intended to be the product of the project, or to be the report. If we have done our job properly, there should be many products and many reports which in part make use of the study data over the next year or two. The data should be a resource that can be drawn on continuously. Consistent with this orientation, we have tried primarily to put together some of the most basic and interesting tables in a form that is accessible. For the most part, the data have only been summarized, without any attempt to derive implications or conclusions from them. Our goal was to prepare a working document, which could be used by Model Cities residents and staff as one important resource in the planning and assessing of Model Cities programs in Worcester.

2. Specific Objectives and Questionnaire Development

Together with the Model Cities staff and representatives from the neighborhood, the Survey Research Program refined study objectives and developed the research design. Working with Model Cities staff and neighborhood residents throughout the research design phase ensured that both professional and residential points of view would be fairly represented in the study. Also, the three interest groups agreed to institute regular meetings to discuss issues that might arise from time to time during data collection.

The Residents Committee developed a list of topics and specific questions to be asked in the survey. The Model Cities staff clarified the objectives of the study. The role of the Survey Research Program staff during these first sessions was primarily advisory in nature. With the proposed questions and objectives as a guideline the first task for the Survey Research Program staff was to prepare a preliminary questionnaire. This questionnaire in draft form was thoroughly discussed and made ready for pre-testing. Three experienced interviewers of the Survey Research Program staff carried out the pre-test with 11 households. Only slight changes had to be made and the final interview schedule was ready for use in March, 1972.

The complete questionnaire is attached to this report. In the main, it was designed to provide data in six major areas:

1. Background information
2. Housing and neighborhood conditions
3. Use and knowledge of Model Cities services
4. Health
5. Education, employment and occupational training
6. Formal and informal relationships outside the home

II. DATA COLLECTION PROCEDURES

1. Sampling

The sample was designed to yield 300 interviews of which 75 respondents were to be black and 75 Spanish speaking. The initial estimate of the Model Cities staff was that eight percent of the total population of 16,465 living in the Model Cities area were black and 12 percent were of Spanish descent. In order to obtain adequate representation of black and Spanish speaking respondents, such households were sampled at a higher rate than the rest of the population. At a later point a lower estimate for the Spanish population was given. The overestimate of the Spanish population and the fact that the Spanish households were more dispersed than anticipated resulted in a smaller number of Spanish in the final sample than was initially projected.

Three strata of housing units were created: a) Spanish-speaking
b) Black, and c) General.

a) The basis for the Spanish stratum was all the structures found in the City Directory in which at least one household had or appeared to have a Spanish surname. A second source of information was a list of names and addresses of Spanish households compiled by the Model Cities staff. These two sources combined yielded a list of 225 housing structures in which Spanish speaking households might be located. It was estimated that 1150 housing units might be found in those structures. Interviewers then listed all housing units at 83 of the addresses selected at random. Five hundred three housing units were found; and it was estimated from that number that

approximately 200 (or two-fifths) would be occupied by Spanish speaking households. Based on these estimates, a screening interview of every third housing unit listed was conducted. Any of those units occupied by a Spanish speaking household was eligible for a complete interview. This strategy was expected to yield 67 Spanish speaking households. Additional households necessary to reach the goal of a subsample of 75 Spanish households were expected to come from the general stratum.

However, the original estimate of 12 percent Spanish speaking population turned out excessive. A lower estimate received at a later date from Clark University appeared much more in line with the final sampling results. The Spanish stratum yielded 28 completed interviews. An additional 5 interviews were taken from the general stratum.

b) The black population seemed less dispersed over the Model Cities area than the Spanish. Any block or blockface in the area which the 1970 census data indicated to have 20 percent or more black residents was selected. An interviewer was then sent out to one half of the addresses to obtain an accurate count of the housing units per address. One hundred sixty three housing units were counted; and it was estimated that approximately 30 percent (or 50 housing units) would be occupied by black households. Interviewers screened all 163 addresses. In each housing unit occupied by black households, an interview was taken. In the black stratum 47 interviews were completed. An additional 18 interviews were taken from the general stratum.

c) Housing units for the general stratum were selected from addresses listed in the City Directory. The general population sample required at least 150 households in order to represent the total Model Cities area population. Excluded from the City Directory were all addresses which had been earlier selected for the black or Spanish stratum. Taking into account vacancies, commercial addresses, and blank lines in the Directory, an overall sampling fraction of every 22nd line in the City Directory was used, resulting in 214 housing units for interviewing. Assuming a non-interview rate of 20 percent in addition to a 10 percent loss due to vacancies, demolition, etc., this procedure was expected to yield at least 150 completed interviews.

The completeness of the sample was not dependent on the completeness of the City Directory. Interviewers went out to list all housing units at the selected addresses. The final selection rate per address was based on their findings and not on the City Directory information.

Due to a better than expected response rate (88%) 179 interviews were completed in the general sample of which 17 were conducted with black households, 5 with Spanish, 156 with white households; 1 respondent was from another ethnic background. An interview schedule translated into Spanish was used in the event that the respondent was unable to communicate in English. The following is the sampling breakdown:

	Stratum			
	General	Black	Spanish	Total
No. of housing units selected	214 } 26* } 240	163	155	558
Non-sample: Vacant H.U.'s Ineligible respondents Other reasons	18 } 0 } 36 18 }	10 } 90 } 106 6 }	15 } 99 } 123 9 }	265
No. of occupied eligible housing units	204	57	32	293
Non-interviews due to refusals, not at home or other reasons	25	10	4	39
No. of interviews completed by Ethnicity:				
White	156			156
Black	17	47		64
Spanish	5		28	33
Other	1			1
	179			254
Response rate	88%	83%	87%	87%

*The additional 26 housing units came from the Black (7) and Spanish (19) stratum: from the housing units listed in those strata, using the overall sampling fraction, every 22nd housing unit was selected and included in the sample, regardless of the ethnicity of the residents.

2. Recruitment and Training of Interviewers

The Model Cities staff screened applications for the job of interviewing. Out of a list of 35 approved applicants, the Survey Research staff made a final selection of a team of 16 interviewers. The interview team varied greatly in background, age and experience. All were residents of the Model Cities area. Only one Spanish speaking resident applied; she was subsequently hired. Later on two additional Spanish speaking interviewers were hired.

The team of interviewers underwent a week of training sessions conducted by the Survey Research staff. The interviewers were made familiar with the general purpose of the survey and the objective of each question. It was felt that the interviewers not only should know how to ask a question but also why they were asked. Knowledge of the question objectives and skillful interviewing procedures enhance the adequacy of the response. There are many techniques an interviewer must learn such as: introductory procedures, ways of creating a good interviewing relationship, 'non-directive' probing. Role playing was one of the methods used to prepare the interviewers for experiences in the field. During the training period interviewers went out in the field to list all housing units at selected addresses. Each interviewer conducted one practice interview with a household living outside the Model Cities area.

3. Field Work Procedures

Each interviewer received an assignment of cover sheets on which was indicated the address and specific housing unit to be interviewed. Before

any household was contacted, the respondent was notified in advance by letter which included information on the survey. During the first call the interviewer would check if the number of housing units as given on the cover sheet for the address was correct. At addresses in the general sample the interviewer would conduct an interview with one of the adults in the household selected at random. An adult was defined as anyone of 18 years or older or married regardless of age. In case they interviewed a household in either the black or Spanish sample, they would only proceed with the interview if in fact at the selected address a black or Spanish household was living. The interviewers were required to make at least six calls possibly, some at night and on a weekend, before a household could be considered a "never home" or a "non-interview".

Completed interviews were returned to the Model Cities office. Model Cities staff supervised the field work on a day-to-day basis while a Survey Research Program coordinator met with each interviewer once a week. During these sessions interviews were reviewed, misunderstandings were corrected, and problems in the field were discussed at length.

4. Coding and Data Processing

The 254 completed interviews were coded, punched, and put onto tapes for analysis by Survey Research Program. Since the contract required cross tabulations, one of the computer programs frequently used by the Survey Research Program ("Cross Tabs II") provided the marginals and required tables. The analysis of the results is given in the following chapters.

1. Description of the Sample

This chapter reports on the socio-economic characteristics of the 254 households in the sample which provide some reliable estimates regarding the Model Cities population as a whole. Data on the Spanish speaking population should be interpreted cautiously since only 33 Spanish speaking households were interviewed.

SUMMARY OF HOUSEHOLD CHARACTERISTICS

Table 1 provides a summary of characteristics of the Model Cities population. More detailed and complete distributions per variable are presented in Tables 2-25. In short, the majority of the heads of households are white and Roman Catholic. Twenty-nine percent are 65 years old or older. In comparison with 1969 data for the City of Boston* this percentage of elderly residents appears to be rather high. In 1969, 19 percent of the heads of households living in the City of Boston were 65 or older.

Over one-third of the households (36%) are single individuals. Again this is a rather high percentage in comparison with the City of Boston where 24 percent of the heads of households were living alone. The 1970 Census data present a percentage of 29 for the Model Cities area.

Approximately two-thirds of all employed heads are blue-collar workers and a same proportion have incomes of \$8,000 or less per year. Twelve percent are unemployed or recently laid off. One-fifth of the household heads are on some form of welfare.

*How the People See Their City: Boston 1969, Survey Research Program, Joint Center for Urban Studies of Harvard and M.I.T., 1970.

Forty-two percent live in three-family housing units. The 1970 Census found 14 percent of the housing units owner-occupied in the Model Cities area. The sample produced a very comparable estimate of 17 percent. This figure is low, however, in comparison to Boston where the rate of homeownership was 28 percent in 1969.

Of the renters 39 percent spent 30 percent or more of their incomes on rent, a rather high proportion taking into consideration the generally accepted rule that people should not spend more than 25 percent of their incomes on housing.

RESIDENTIAL AREA

The Model Cities area can be divided into three neighborhood areas: 1) Piedmont, 2) Main-South near downtown, 3) Main-South near Webster Square (see map). Main-South near Webster Square differs from the other two areas. Since only 23 households were interviewed in this area, the differences found between the Webster Square area and other parts of Model Cities indicate trends and are to be used with caution. The households near Webster Square tend to be better off financially (Table 12), are better educated (Table 9), and are living more often in three-family unit structures (Table 13).

The following section presents in subsequent tables the differences in outcome per ethnic subgroup: the white, Spanish speaking and black population in the Model Cities area.

HOUSEHOLD COMPOSITION BY ETHNICITY

Table 16 shows that the white population has the largest percentage household heads living alone (41%) compared with 20 percent for the Spanish speaking and 23 percent for the black. The black population has the largest percentage of married heads of households (52%) in comparison with 45 percent of the Spanish and 38 percent of the white heads of households.

Almost one-third of the Spanish speaking households are one-parent households with dependent children; 24 percent of the black and 11 percent white households consist of this type of households.

LIFE CYCLE STAGE BY ETHNICITY

This kind of variable combines three characteristics of the household: age of the household head, marital status, and number of children (Table 17).

White households differ significantly from the Spanish speaking and black households. Thirty-six percent of white heads of households are 65 years old or older of which more than two-thirds are living alone. Almost none of the Spanish and only 7 percent of the black household heads are 65 or older and hardly any of the elderly black heads of households are living alone (Table 18).

SOURCE OF INCOME AND EMPLOYMENT STATUS BY ETHNICITY

Over one-half (58%) of the Spanish speaking households reported income from welfare; a significantly lesser proportion of black households (32%) and of white (14%) households reported welfare assistance. (Table 19).

The unemployment rate is high among the Model Cities residents. Excluding the retired, students and housewives, it was estimated that 16 percent of the white, 32 percent of the black and 37 percent of the Spanish speaking heads of households were unemployed or recently laid off (Table 20).

RESIDENTIAL MOBILITY BY ETHNICITY AND INCOME

White households show much more stability than the other ethnic groups: half of them lived six years or longer in their present dwelling. The black households were slightly less mobile than the Spanish with 18 percent of them living in their current house for six years or more in comparison with 3 percent of the Spanish households (Table 21).

If we compare the number of moves households made during the past five years for ethnic subgroups, we find that the Spanish speaking households moved more frequently: 37 percent of them moved three times or more during the past five years (Table 23). A majority of white households did not move at all during the past five years (56%). It should be noted here that the Spanish speaking population are mainly immigrants and many of them came to Worcester only recently. Twenty-six of the 32 Spanish respondents were born in Puerto Rico.

With respect to income, the low income households (households with incomes under \$8,000 per year) are more likely to move than high income households (Table 22).

HOUSING EXPENDITURE BY INCOME AND LIFE CYCLE STAGE

As one would expect, the households with the lowest incomes carry the heaviest housing burden. Of the households with incomes under \$4,000 per

year, 75 percent spent 31 percent or more of their income on rent. Only 31 percent of the households with incomes between \$4,000 and \$8,000 spent this high a percentage of income on rent. None of the higher income households (with incomes of \$8,000 or more) spent this much (Table 24).

When we compare households at different life cycle stages the data indicates that the single people over 65 and the families with children carry the heaviest financial burden: 59 percent of the single elderly people and 45 percent of the families with children pay 30 percent or more of their income on rent (Table 25).

2. Housing in the Model Cities Area

HOUSING CONDITION

In order to have some information about housing conditions in the Model Cities area, we asked our interviewers to make an assessment of the quality of the houses they visited. They judged that 4 percent of the buildings were dilapidated, 24 percent were deteriorating and 71 percent were considered generally sound structures. It should be kept in mind that these are subjective judgments of the interviewers, unskilled in housing inspection.

Housing in the Webster Square area was rated of better quality than in the other neighborhoods. Housing conditions are worse in Main-South near downtown: 39 percent of the buildings there are dilapidated or in later stages of deterioration (Table 26).

Another measurement for housing quality is the degree of overcrowdedness. We found that 5 percent of all households are living in overcrowded conditions: that is, they have more than one person per room. The Spanish households are worse than the rest in this respect: 30 percent of the Spanish households are living in overcrowded conditions (Table 27).

SATISFACTION WITH HOUSING

Questions concerning housing satisfaction have been asked in a variety of ways in this study. One of those questions was: "Are there any serious ways this house is not a good place for you (and your family) to live?" and "What is that?" Twenty percent of the respondents answered yes (Table 28). Most frequently mentioned were dwelling-unit insufficiencies: utilities, structural, in general, a feeling of substandard conditions.

In another quite similar question the respondents were asked to list any problems they had with their housing (Table 29). Seventy-five percent of the respondents did not have any housing problems. For the people who did have problems, here too utilities were of primary concern (53 percent of all first mentions), 20 percent mentioned structural deficiencies.

Spanish speaking households tend to report serious housing problems more often than the rest of the population (Table 29).

Finally we asked the respondents to rate their housing as "Very good," "Fairly good," "Not very good," or "Not good at all." Twenty percent of the respondents were negative and rated their housing either not very good or not good at all. As one would expect, twice as many respondents living in deteriorated housing were dissatisfied over-against the number of respondents living in sound structures. However we should point out that of the number listed^{*} as living in deteriorated conditions, 64 percent of them rated their housing as very or fairly good (Table 30).

Two other variables, "Income" and "Number of years lived in Worcester," did not explain any of the variance in housing ratings.

The more frequently mentioned reasons respondents gave for continuing to live in the present circumstances rather than moving somewhere else were either locational convenience (23 percent) or reasonable housing costs (22 percent).

* The outcomes are based on the subjective housing quality assessments of the interviewers.

3. Education and Occupational Training

This chapter deals with schooling, attitudes, and need for occupational training programs.

Chapter 1 (Table 9) revealed that 54 percent of the household heads did not finish high school. Forty-three percent of the heads of households or other household members had some form of additional special job training (Table 31). Of the Spanish speaking residents a relatively small percentage (13%) received special training for their work. There is a relationship between income and training as Table 32 illustrates: people with higher incomes were more likely to have had special training, besides their formal schooling, than the people with lower incomes.

Six percent of the heads of households or other household members are presently enrolled in job training programs (Table 33). This raises the questions how many of the people might be interested in job training and do they have any knowledge where to go in Worcester for such training.

Fifty-two percent answered yes to the question: "Do you know where a person can go here in Worcester to get training for a skilled job?" Table 34 and Table 35 indicate that the better educated and the people with higher incomes were most knowledgeable about training centers. The Spanish speaking population had very little knowledge about job training opportunities in comparison with the white and black population (Table 36).

With respect to employment status, it was found that the unemployed tended to be less knowledgeable than the people who were working (Table 37).

Most often mentioned as places where one would go for job-training were the Worcester Trade School (57%) and the State Division of Employment Security, MDTA (25%).

Over half (52%) of the people said that they would consider job-training if it was available in Worcester. Tables 38-43 present the major characteristics of the people interested in training programs. In short, the largest percentage of people interested in training were found among the unemployed or recently laid off (67%); the black population (51%); people between the ages 30 and 39 (55%); heads of households under 40, married, with children (50%); people with 1-3 years of high school or 1-3 years of college (40%); and people with incomes between \$4,000 and \$8,000 (35%).

Least interested were the retired (5%); the white population (23%); people who are 65 or older (4%); the least educated (15%); and the lowest income group (24%)(which includes many aged).

4. Health Status and Health Care

The data reported in this chapter on health are a selection of the tables available. The analysis will focus on the relationships among health status, health care, health insurance, total household income, and ethnicity.

HEALTH STATUS

The health status of the respondent and the other members of the household the respondent was living with, was measured by ratings of the respondent as "excellent," "good," "fair," or "poor". All figures in this chapter present the results for the total household and not for the respondent only.

The proportion of the people with "excellent" health ratings was highest among the white population (28%) even though there are relatively more aged among whites. The health of the Spanish speaking population was reported more often as "fair" or "poor" (35%) in comparison with the rest of the population (Table 44).

Health ratings were related to income. The poorer the people, the more often their health was rated as "fair" or "poor". Thirty-seven percent of the lowest income group (people with incomes of \$4,000 or less) were reported in "fair" or "poor" health (Table 45). Fourteen percent of the people with incomes of \$8,000 or more received similar low health ratings. The fact that aged are found at a high rate among the lowest income group may partially account for this association.

HEALTH CARE

The medical care people received was measured by asking: "Within the last 12 months....about how many times did you (person) see or talk to a medical doctor about your health?" There was no strong relationship between the number of times a doctor was seen in the past year and ethnicity or income, Tables 46 and 47. People from different ethnic backgrounds visited doctors at approximately the same rate. In contrast with the national picture, our data indicated that low income people are as likely to have seen a doctor in the past year (if not more likely) as the people who are financially better off.

In a next question the respondents were asked about the recency of their last doctor's visit. Nearly two-thirds of the population saw a doctor within the last twelve months. Again the low-income people were not worse off in comparison with the more advantaged (Table 48). Also there was no significant relationship between recency of the last doctor's visit and ethnicity (Table 49).

For those who visited a doctor during the past three months, 58 percent went to a private doctor's office. The remainder went to a clinic, an office of a group of doctors, or a neighborhood health center. The Spanish speaking population were much less likely to receive medical care from private doctors (19%) (Table 50). People with incomes of \$8,000 or more were more likely (78%) to have a private doctor than the people with lesser incomes (Table 51). One of the most striking aspects of the data is the extent to which Spanish, blacks, and those with income less than \$8,000 are using sources other than private doctors.

Seventy-nine percent of private doctor's offices mentioned were located outside the Model Cities area (Table 52). Of the people who did not visit

a private doctor but went elsewhere for medical care, 38 percent mentioned the Worcester City Hospital (Table 53).

When looking at the specialty of the private doctors used by Model City residents, over half (57%) consulted a General Practitioner or a doctor specializing in Internal Medicine. Twelve percent went to an Obstetrician or a Gynecologist (Table 54). Most people (59%) went because of a specific problem and 38 percent went for a regular check-up. The black population mentioned more often than the rest that they went for a check-up (64%) (Table 55). There is no strong relationship between reasons for seeing a physician and income (Table 56).

Of the people who received medical care for a specific problem, 58 percent previously had seen a doctor about the same problem (Table 57).

Another measurement of medical care is whether or not people have a regular doctor or place they go to in case of illness. Most people (81%) did have a particular doctor, clinic, or hospital. There were no significant differences per income group.

Similar to data reported earlier in this chapter, the people who were better off financially favored a private doctor's office more than a hospital or clinic for regular health care. The Spanish depended more often on clinics and hospitals (55%) than any of the other ethnic groups (Tables 58 and 59).

TRANSPORTATION TO A DOCTOR'S OFFICE

Half the people said they used their car to visit a doctor. The lowest income group was more dependent on public transportation or taxis. The Spanish speaking population tended to use a taxi more often for transportation to and from a doctor's office (Tables 60 and 61). Most people were satisfied with their mode of transportation to doctors or clinics regardless of income or ethnicity (Table 62).

HEALTH INSURANCE

Several questions were asked about health insurance or coverage for medical expenses by medicaid, public assistance, or welfare. As one might expect, with an increase in income, the percentage of the households covered by some kind of medical insurance increases (Table 66). Of the lowest income group (people with incomes of less than \$4,000) 43 percent received public assistance for medical costs (Table 64). The Spanish population received it very significantly more often than the rest of the population (63%) (Table 63).

Of all households¹ 68 percent said they were covered by some kind of hospital insurance, and 18 percent were insured for doctor's visits² (Table 65). The Spanish population reported a much lower rate of private insurance protection. Thirty-three percent of the Spanish-speaking households had hospital insurance and only 3 percent were insured for doctor's visits.

MEDICAL COSTS AND MEDICAL CARE

When asked if "doctor's cost" had kept people from seeing a doctor in the past year, 20 percent answered, "Yes" (Table 67). However, of the Spanish population a lesser percentage (10%) felt that medical costs prevented them from going to a doctor when they should. The blacks most often cited this problem. Because private insurance does not usually cover visits to doctors--except with deductible or in emergencies--while public assistance programs do, it is common to find that costs are most often a problem for those whose incomes are just above the level required for public assistance.

¹In some cases not all household members are covered by health insurance.

²Reporting of exactly what kind of costs are covered by health insurance is known to be a difficult task for respondents, and this figure should be treated with special caution.

5. Model Cities: Knowledge and Use of Model Cities Agencies and Other Community Agencies

In order to gather some information about knowledge of Model Cities programs, the respondents were asked two general questions. First: "Do you happen to know if there is an organization in this neighborhood to which people who want to help with planning for this neighborhood can belong?" And secondly: "Which organization is that?" Thirty-two percent or 82 respondents answered Yes to the first question (Table 69). Twenty-six of the 82 respondents mentioned Model Cities, and 29 mentioned the Piedmont Opportunity Center as the neighborhood planning organization. Only a very few (18) had been active in the organizations they mentioned.

Knowledge of neighborhood organizations was unrelated to life cycle stage and ethnicity. People with higher incomes (\$8,000 or more) tended to be more knowledgeable than the rest of the population (Table 70).

To a more direct question: "Did you know.....that you were living in a Model Cities area?", 70 percent of the respondents answered Yes (Table 71). Fifty-six percent knew where a Model Cities office was located.

A lesser proportion of the population (25%) had an idea what Model Cities tried to do in their neighborhood or could mention the names of certain Model Cities agencies (Table 72). Of the 25 percent or 62 respondents who thought they knew one or more agencies, 42 of the first-mentioned agencies were in fact Model Cities agencies. Sixteen respondents did use the services of the agency they mentioned, while 13 respondents said that other members of their families were using it (Table 73).

Knowledge of Model Cities agencies was unrelated to income but did relate to education (Table 74). Of the people with an eighth grade or lower educational level, 12 percent thought they knew a Model Cities agency by name while 35 percent of the High School graduates thought they knew one or more agencies. The black population answered more often (46%) that they knew one of the agencies than the rest of the population (Table 75).

In addition to information about use and knowledge of Model Cities agencies some data was gathered on other community agencies in Worcester (Table 76). Twenty-five percent or 66 respondents said that they used community agencies over the past five years. Twenty-five of the 66 respondents contacted an agency for employment problems; 17 went to an agency for housing and neighborhood problems; 14 went because of financial problems and 9 because of health.

However, when the respondents were asked what they considered as their most serious problem and where they would go for help, the results were different (Table 77). Twenty percent of the people answered that they had no serious problems; 22 percent considered health their main concern; 22 percent mentioned financial problems; 13 percent had problems with housing or the neighborhood; 6 percent were concerned about work; and the remaining 15 percent were problems with children, crime, transportation or general problems.

No particular agency was mentioned more frequently than others as a place they would go for help. Half the population mentioned public agencies as places to go to, one-sixth would go to private agencies, and only three respondents said they would talk to a friend or relative. One-third mentioned that they would contact nobody but solve their own problems.

6. Neighborhood Services and Evaluation

The respondents were asked to compare the public services in their neighborhood with similar services in other parts of the city. Seventy-six percent of the population felt that the services in their neighborhood were better or about the same. Eighteen percent considered them worse (Table 78). This comparison did not vary among population groups with different incomes or with different ethnic backgrounds. However, nearly half the respondents (46%) wanted to see public services improved. Those who considered themselves "Middle class" answered slightly more often that public services needed improvement (54%) than those who felt that they belonged to the "Working class" (42%) or to the "Poor" (46%). There were no significant differences by area but Main-South near downtown tended to be lower in the ratings.

Answers to the question concerning the kinds of improvements they would like to see varied a great deal. Most often mentioned (20%) was police protection or law-enforcement. Street cleaning counted for 18 percent. And 16 percent called for improvements in garbage and trash collection. Again, there were no significant differences between areas.

Neighborhood Schools

Most children in the Model Cities neighborhood attend public schools (80%); 5 percent attend parochial schools. Most people were satisfied with the education the children were receiving. Eighty percent rated the education as "Very good" or "Fairly good" (Table 79). But people in Model Cities were less satisfied with the condition and maintenance of the school buildings. Over one-half (56%) considered the buildings as "Not so good" or "Not good at all" (Table 80).

In response to the question: "Compared with schools in the rest of Worcester do you think the schools in this neighborhood are better, the same or not as good as those in other parts of the city?" --41 percent felt that schools in their neighborhood were not as good as those in other parts of the city (Table 81).

Day-Care Centers

Day-care centers were not a widely familiar service among Model Cities residents; only 37 percent knew a day-care center in Worcester (Table 83).

Of the people living in households with minor children, 35 percent answered that they would use day-care centers if they were available, while 59 percent said that they would not use day-care for their children (Table 82). Six percent are presently utilizing this service.

Neighborhood Characteristics and Evaluation

Similar to the question asked about housing conditions, we asked the respondents: "Do you feel there are serious ways that this neighborhood is not a good place for you (and your family) to live?" Almost two-thirds of the residents felt that the Model Cities neighborhood was a good place for them to live (Table 84). Most of the other residents were primarily concerned with physical characteristics such as dirty streets, noise, and the like. Only very few had negative feelings about the people living in their neighborhood. When asked: "Considering everything about the neighborhood, the good and the bad things--overall how would you rate it--very good, fairly good, not so good, or not good at all?" --84 percent of the residents rated their neighborhood as either "very" or "fairly" good (Table 85).

With the exception of "Attractiveness," and "The neighborhood as a safe place for children," the ratings of specific neighborhood characteristics were also more positive than negative (Table 85). Sixty-eight percent of the people thought their neighborhood was in general a safe place to live. Older people were more likely to rate their neighborhoods as very or fairly safe (Table 86). With respect to ethnicity, the Spanish speaking population considered their neighborhood the least safe (Table 87).

Police Protection and Police Treatment

A majority of the people were very satisfied or fairly satisfied with the way policemen treat residents in their neighborhoods. In comparison, a lesser proportion were satisfied with police protection in their neighborhoods (Table 88). Older people tend to be more positive in their attitudes toward the police than younger people.

In accordance with their feelings whether or not the neighborhood was a safe place to live, here too the Spanish speaking population was the least satisfied with police protection and police treatment (Table 89).

Recreation

Three-fourths of the people did not know of any recreational services in their neighborhood. Of those who did not know of such services, 38 percent would like to have some recreational facilities (Tables 90 and 91). Most often mentioned was "a place to dance" or "being able to go to concerts."

Moving Plans

Twenty-three percent of the households had moving plans (Table 92). The primary reasons given were either a dissatisfaction with the dwelling unit or an unattractive physical appearance of the neighborhood. On the assumption that households had a free choice where to live, 44 percent would prefer to stay in their present neighborhood (Table 93). With respect to different income levels it was found that the lower income households more often prefer to stay in their area (53% of all households with incomes of less than \$4,000). Also families with children and the single elderly people more often expressed a preference to remain in the area.

7. Priorities

The preceding chapters have presented some basic tables relating to the number of possible problem areas in the model neighborhood. The basic issue, however, for policy and planning has to do with which areas are most important for increased effort and investment. There is, of course, no easy way to set priorities. How does one choose, for example, between working on a problem which affects most of the people to a moderate extent and working on a problem that affects a few people to a great extent? However, one way to at least approach the problem of priorities is to ask people in which area they would like more money or effort expended and to ask them to make choices among the various areas in which increased effort is possible.

To attempt to collect data of this kind, respondents were given a list of 16 problems or services, and asked first whether they thought more money, less money, or about the present amount of money should be spent on each of these problems and services. The list was as follows:

1. Public schools
2. Police patrol
3. Day care centers
4. Street lighting
5. Cleaning or repairing streets
6. Free medical care
7. Cleaning parks, playgrounds
8. Places for teenagers
9. Trash and garbage collection
10. Housing inspection
11. Drug programs
12. Air pollution control
13. Public transportation
14. AFDC
15. Health needs and clinics
16. Better housing

Essentially the same question was asked in cross-section sample surveys in ten cities throughout the United States.* Consequently, for most of the items, it is possible to compare the responses in the Worcester Model Cities neighborhood with the responses in ten other cities, as a basis for adding perspective to the data and enabling us to identify special areas of concern in the Worcester Model Neighborhood.

As happened in the ten city study, people were much more willing to have more money spent than to reduce expenditures (Table 94). There was no item on which even 20 percent wanted to cut back expenditures, while there were 9 items for which a majority of the population expressed a preference for greater expenditure. The nine items on which a majority wanted increased expenditures can actually be found to cover six problem areas. The highest percentage of responses was for increased expenditure on better housing (75 percent). Sixty-one percent also wanted increased expenditures for housing inspection. The level of concern about improved housing, both in terms of quality and more low cost housing, is comparable to the concern about these issues expressed in the ten-city study.

The concern about the drug problem in the Worcester Model City Neighborhood, and the desire for increased expenditure in that area (72 percent), also parallels the level of concern about drugs in other cities. The interest in increased expenditure of police patrolling the streets at night, 64 percent, is also similar to the responses in the ten-city study.

There were two areas, however, in which there was perhaps more concern or interest expressed in the Worcester Model City area than was the case in the

*"City Taxes and Services: Citizens Speak Out," Nations Cities, August, 1971.

ten-city study. First, 61 percent wanted more expenditure for cleaning and repairing streets. While the concern with dirt in the cities is a fairly wide phenomenon, this rate is substantially higher than the average in the ten-city study. A second area in which there was special concern in the Worcester Model City area had to do with cleaning up parks and playgrounds, and providing programs for teenagers. Whether the cleaning up of parks and playgrounds properly should be combined with the concern about clean streets or with a concern about recreation, the fact is that both concerns (recreation and improved maintenance of public places) seem distinctively important in the Worcester Model Neighborhood.

The other area which seems very important to the people for increased effort is low cost medical care and providing health care facilities. While this is a concern in all cities, it seems if anything a special concern in the Worcester Model Neighborhood.

Two other services should be noted. Only 42 percent of the population as a whole wanted to spend more on public schools, and only 33 percent wanted more spent on welfare or aid for dependent children. However, as we shall see there were some significant groups in the population of which majorities wanted to spend more on these areas. In contrast, the problems of day care centers, street lighting, air pollution, and public transportation were not singled out either by the whole of the population or by a majority of any identifiable subgroup. The closest that any of these came to having a majority interested in increased expenditure was that 48 percent of blacks expressed their interest in more expenditure on day care centers (Table 97).

Because of the large number of areas for which people expressed a desire for increased expenditure, the respondents were also asked to make a choice of which three items they thought were most important for increased expenditure.

Perhaps it is not surprising that there was no item which a majority of the population selected as being one of the three most important. Thirty-nine percent chose free medical care as one of the three most important problems for more effort; 33 percent selected the drug problem as one of the three most important, and 30 percent selected increased police patrols at night (Table 95).

At the other end of the continuum, less than 10 percent chose day care, trash collection, air pollution, or public transportation as one of the three most important areas for increased expenditure; less than 20 percent selected public schools, street lights, clean parks, increased payments for welfare or health clinics as one of the three most important areas for increased expenditure.

Now looking at the specific priority areas in slightly more detail, we have seen that the aged population and the whites are generally better housed than the rest of the population in the Model area. Therefore, it is not surprising that these two groups were slightly less concerned with increased expenditure for better housing and housing inspection than others in the population (Tables 96 and 97). Nonetheless, the area of housing had broad based consensus among all groups, with majorities of whites and aged along with other groups in the population favoring increased expenditures in these areas. It is fairly clear that housing is generally considered a problem of priority throughout the area.

Interest in the drug problem is fairly evenly distributed throughout the population, with majorities of all groups favoring increased effort. There is slightly more heterogeneity of interest in increased police patrols, however. The aged, those over 65, who also expressed more of a sense of safety than others in the area, were, if anything, perhaps the least interested in

increased expenditure on police (Table 96). This is different, by the way, from most cities in which the aged tend to be the most frightened and the strongest supporters of police activities. To a certain extent, there seems to be increased concern and interest in police patrols as income increases (Table 98).

In a somewhat similar way, the higher income people, those with incomes over \$8,000, are particularly interested in cleaning up the streets and cleaning the parks and playgrounds. The Spanish are the only identifiable group in which a majority did not express interest in spending more money on cleaning streets (Table 97). All groups except the aged had a majority in expressing interest for increased expenditure on cleaning up parks and playgrounds. It is interesting, then, that the aged were strong supporters for places for teenagers to play. In the Model Neighborhood area working on the problem of recreation for teenagers had majority support among all ethnic groups, among all income groups, and among all age groups.

We saw in the section on medical care that the Spanish were distinctively dependent on clinics, and were receiving public assistance for medical care at much higher rates than other segments of the population. It is not surprising then that medical care was clearly and overwhelmingly the most important issue to the Spanish in this area. Even though the number of cases of Spanish is smaller than is desirable, this pattern is so clear that there can be little argument about it. Ninety-eight of the Spanish wanted more expenditure on low cost medical care; 80 percent wanted more money spent on health needs and clinics (Table 97). Although the issue of medical care is one for which all segments of the population seem to have an interest in increased programs, it is the Spanish more than any others for whom this is clearly an essential issue. Seventy percent of the Spanish selected free medical care as one of the three most important areas for increased effort (Table 95). While the priorities of

other groups are spread around a number of issues, the medical area stands out very distinctively for the Spanish population.

We noted that there seem to be a moderate degree of satisfaction with schools in the area, though less satisfaction with the school buildings. It is perhaps for that reason, in part, that a majority of the population did not see increased expenditure on public schools as a priority issue. However, another component of this finding is the composition of the neighborhood, not surprisingly, aged and single people were not at all interested in increased expenditure on public schools, while a majority of those with children were in favor of increased expenditure on public schools (Table 96). It is also the case that the blacks, in part because of their high rate of children and perhaps in part for other reasons, as a group were more interested in the quality of public schools than others. Fifty-eight percent of the blacks wanted increased expenditure on public schools (Table 97).

Finally, because only a minority of the population, of course, receives welfare payments, it is not surprising that a majority of the people were not interested in increased expenditure in this area. It is also significant, of course, that very few people wanted to decrease payments to people on welfare. However, over 60 percent of both the Spanish and the blacks favored increased expenditure for welfare and AFDC payments. There was no income relationship overall, but this is primarily due to the fact that the aged who constitute a significant portion of those with the lowest incomes, were not at all interested in increased welfare of AFDC payments, since they are not beneficiaries thereof.

It is worth noting overall that the aged population, which we have seen to be more likely to have been long term residents and homeowners, in general, was less interested in increased expenditure for services than other segments of the population. The one area in which they were more interested than others

was increased public transportation; and even for that only 41 percent of those over 65 wanted more expenditure. For other services aged tended to be distinctively low in interest in increased expenditures (Table 96).

In conclusion then, there is not an easy answer to what the priorities in the Model Neighborhood area. What we can provide, rather, is a list of several areas that are of broad-based interest and concern. We also have certain kinds of problems that are of particular interest to certain subgroups within the population that may require special service.

The housing problem seems to be very widespread and of major concern. Medical care is also a major concern, with particular and almost unanimous concern among the Spanish. The police and safety problem, while it is of concern to a majority, if anything seems to be less of a priority issue in the Worcester Model Neighborhood area than in some other places in the country. Perhaps this is not surprising in Worcester.

In any case, as was promised in the beginning, survey data do not solve the planning problems. Respondents do not necessarily take into account all the important considerations or the costs of alternate programs available to deal with a problem. Nonetheless, they do provide one of the most representative ways of putting the preferences of people into the planning and decision-making system. Because people are different and their situations are different, it is perhaps not surprising that there is not unanimity on very many issues or on what the most important issues are. Nonetheless, as various alternatives are considered, the input from data like these should be helpful in the allocation of resources knowing what people most want should be one important consideration in resource allocation. In this perspective, survey data such as these can, in fact, make a valuable contribution to making the planning and decision-making process effective - i.e. in making it more responsive and relevant to the needs of the people to be served.

APPENDIX

RELIABILITY OF THE SURVEY DATA

Properly executed surveys of carefully selected samples of a population produce figures on the whole population that are quite reliable. However, it is very important for users of survey data to be aware of the limitations of the reliability of survey data and to exercise appropriate caution in reaching conclusions from such information.

Types of Error

There are three potential sources of error in survey data: sampling error, response error and non-response bias.

Sampling error, or sampling variability, is not biasing; that is, it does not consistently produce estimates that are different from true population values. However, because any sample of a population may be slightly different from other samples that might be drawn from that population, we have to treat sample figures as estimates that in fact may be a little higher or lower than the actual figures. Thus, if our sample indicated that 50 per cent of the households in a city were homeowners, the actual figure might be 48 per cent or 52 per cent. Fifty per cent would be the best estimate; there is no reason to think that a properly drawn sample systematically would underestimate or over estimate homeowners. However, in using the figure, one should be aware that the true figure could vary by chance from 50 per cent by a few percentage points either way.

One can calculate how far the true population value could by chance differ from the sample estimate. For reasons which are mysterious but widely accepted, it is most usual to report a range around the sample figure within which one can be 95 per cent certain that the true population value will fall. Thus it is usual to say that 50 per cent of the households in the city are homeowners, plus or minus 5 per cent. This statement would mean that there are 95 chances in 100 that the true population figure is between 45 per cent and 55 per cent. It also means that 50 per cent is the most likely figure, and that as estimates get further from 50 per cent

they are increasingly less likely to be the true population figure.

There are two things that effect the variability of a sample estimate; the size of the sample and the percentage of the sample purported to have a characteristic. Ceteris paribus, the larger the sample the smaller the range of sampling variability around a figure based on the sample. Furthermore, there is a wider range of uncertainty around an estimate that 50 per cent of the population are homeowners than there is around an estimate that 10 or 90 per cent are homeowners. Note that for this purpose, 10 and 90 per cent are equivalent; for saying that 10 per cent of the population are homeowners is equivalent to saying that 90 per cent are not homeowners. The reliability of the two statements based on the same sample is the same.

The following table presents average sampling variabilities for different percentage figures and sample sizes. The table should be used as a gauge to the reliability of sample figures. The chances are 95 in 100 that the true population figure lies in the range of the sample percentage plus or minus the number of percentage points shown in the table.*

Example: There are 254 households in the sample; 25 per cent have housing problems.

The table presents a figure of 7 percentage points for samples of 200 and percentages around 30 per cent.

Thus the chances are 95 in 100 that between 18 and 32 per cent of all households have problems with the house they live in.

In addition to knowing the reliability of population estimates, people are also interested in the reliability of obtained differences between groups. The question goes like this. In this sample, the black population is more likely to have housing problems than the white population. Is there really a difference in the population, or could this difference be due to chance variability of the sample? In other words, if we drew another sample, would we get the same answer?

Again, how big a difference is needed depends on the size of the samples and the percentage figures involved. The following table presents the differences required to be 95 per cent confident that the two groups in fact differ in the way the sample indicates.

Example: There are 156 white respondents in the sample; 19 per cent have housing problems. There are 64 black respondents in the sample; 37 per cent have housing problems. There is thus an 18 percentage point difference between the two groups.

The table shows that when comparing groups sized about 200 and about 75 for percentages near 30 per cent, a 13 percentage point difference is needed to be 95 per cent confident

*When dealing with weighted figures, the sampling errors will be slightly larger than the following tables indicate. On the average, if one uses the tables as if the N were 3/4 of the number of cases on which a given percentage is based, that is probably a reasonable to conservative basis on which to estimate sampling errors.

TABLE A-1

APPROXIMATE SAMPLING ERRORS FOR THE MODEL CITIES RESIDENT
ATTITUDE SURVEY

Chances are 95 in 100 that the central value lies within the reported value, plus or minus the number of percentage points shown in this table.

Sample Size	Sampling Errors for Reported Percentage Around				
	5 or 95%	10 or 90%	20 or 80%	30 or 70%	50%
50	-	-	12	14	15
100	-	7	9	10	11
200	3	5	6	7	8
300	3	4	5	6	6
400	2	3	4	5	6
500	2	3	4	5	5

The actual sampling errors have not been computed yet for this study. The figures in the tables are about 10 per cent higher than a simple random sample would yield, which experience indicates is a conservative basis for estimating significance for samples like these.

TABLE A-2

SAMPLING ERRORS OF DIFFERENCES

When a percentage difference between two different subgroups exceeds the figures in the table, the chances are 95 in 100 that the two sub-groups are in fact different.

Size of Sample or Group	75	100	200	350	500
For Proportions from About 30% to 70%					
75	15	14	13	12	12
100		13	12	11	10
200			10	9	8
350				7	7
500					6
For Proportions Around 20% or 80%					
75	13	13	11	10	10
100		11	10	9	9
200			8	7	7
350				6	6
500					5
For Proportions Around 10% or 90%					
75	10	10	8	8	8
100		9	8	7	7
200			6	6	6
350				5	5
500					4
For Proportions Around 5% or 95%					
200			5	4	4
350				4	3
500					3

that there is a real difference between the two groups in the population.

The difference found in the example is that large, and one can conclude that the two groups are in fact probably different.

On Statistical Tests

"Statistical significance", which is the way scientists refer to a relationship or difference that probably is real and not chance, is not the same as social or political significance. Differences as small as four or five percentage points may be statistically significant; i.e. they indicate real differences between groups. However, that does not mean that they are important differences.

On the other hand, tests of significance are useful as a guard against taking too seriously differences or relationships that may not be real. The preceding tables show that groups differing by 10 or even 15 percentage points may not be significantly different if our samples of these groups are small. Such a difference, while possibly politically significant, should be taken as suggestive -- a difference that needs to be further documented.

When one is dealing with samples of 100 or larger, it is relatively unusual for a really important difference not also to be statistically significant. However, when samples drop below 100, sampling variability rises sharply and much more caution is required. Tests of statistical significance can be very useful to determine how seriously to take figures on samples under 100.

One final note: when samples drop much below 50, the sampling variability is usually sufficiently great that even presenting the figures may be more misleading than illuminating.

Response Error

Response error refers to errors in the data resulting from either the interviewer or the respondent failing to do the job he is supposed to do. The most readily identifiable result is information that is "not ascertained" that is, the respondent did not give a codable answer to a question. Such events occur when the respondent does not know or is unwilling to give the answer; or when the interviewer fails to probe an inadequate initial answer by the respondent.

The number of such answers is usually small; but in a few cases, it may be larger. It often is reasonable to assume that "not ascertained" answers are random events. However, there are at least two types of

of situations when this may not be reasonable. First, people who do not know very much about a topic are most likely to give inadequate answers to attitude questions. In this respect, the people who give "not ascertained" responses may be systematically different from those who answer the question. Second, certain types of presumably sensitive questions, such as income, show patterns about who is likely not to answer. In the case of income, those with incomes at the extremes -- either high or low -- are more likely not to answer. Excluding the "not ascertained" answers from a distribution is, in effect, assuming that they are random, not systematic, occurrences.

Other kinds of response error are harder to identify. When an interviewer does not record an answer completely; when a respondent slants his answer in the direction he thinks will please the interviewer; when an interviewer probes directively; these are errors difficult to identify later. In general, we rely on careful, thorough training of interviewers to keep such errors to a minimum. We think for most purposes they are not prevalent enough to affect conclusions based on the data. However, it is not possible to estimate where, or how often, such errors occur.

Non-Response Bias

Non-response bias occurs because all people selected in the sample are not interviewed. Even when every effort is made, there is always a certain percentage of a sample that either cannot be reached or will not agree to participate. In so far as the non-respondents (those selected but not interviewed) differ from those interviewed, the sample of interviews is a biased sample of the population; that is, it is systematically different from the population. Note how this differs from sampling error which is not systematic, or biased, but simply a random, chance deviation from the true population.

When response rates (the percentage of the selected sample actually interviewed) is 85 per cent or above, the effect of non-response is relatively slight on most percentage distributions. As response rates get lower, the researcher has to be increasingly concerned with who in the population is not represented in his data. The effect of non-response is very slight in this study with a response rate of 87 per cent (see page 7).
