Children tend to insert something at hand into their nasal cavity and it is sometimes difficult to find the foreign body in the nasal cavity unless someone sees the child insert it.

The authors experienced a case where a foreign body was found in a child patient's nasal cavity when the patient undertook panoramic radiography for their carious treatment.

It seemed from the patient's X-ray CT that the foreign body was a metal screw.

Key words : panorama X-ray photograph, intranasal foreign body, computer tomography (CT), metal screw
