Estimation of China Sectoral Emission Intensity: Based on Input-Output Model

Abstract

With strong economic growth, China's energy consumption and CO₂ emissions grow quickly. The energy shortage and environmental problem have become the bottleneck of further economic growth. The most popular method to estimate the environmental impact is the Environmental input-output analysis, and the most important data support is the sectoral emission intensities. This Resource Document describes the process to estimate the China sectoral CO₂ emission intensities based on the Disaggregated Input-Output table (suggest to read the Technical Document: Disaggregating Input-Output Models). This document includes the data sources, calculation process and the procedural notes. The calculation includes both the national China and Shanxi province.

1 Data Sources

The data in this document are from several sources, including Statistical Yearbooks, Input-Output tables, IPCC Guideline, and the journal paper.

1.1 Input-Output Tables

- 2007 China Input-Output Table (42 sectors)
- 2007 Shanxi Input-Output Table (42 sectors)

These Input-Output tables are disaggregated into the 50 by 50 sectors tables (suggest to read the Technical Document: Disaggregating Input-Output Models).

1.2 Statistical Yearbooks

- China Energy Statistical Yearbook 2008
 - Energy consumption and its composition by sector

* The energy consumption data includes eight fuel types: coal, coke, gasoline, diesel, crude oil, kerosene, fuel oil and natural gas.

- Conversion factors (KJ/Kg,m³)

* The conversion factors are the calorific value of each fuel type in China.

• Shanxi Statistical Yearbook 2008

- Energy consumption and its composition by sector

* The energy consumption data includes four fuel types: coal, coke, gasoline, and diesel.

1.3 IPCC Guideline

• CO₂ emission factor by fuel type (default value, kgCO₂/TJ)

2006 IPCC Guidelines for National Greenhouse Gas Inventories, Volume 2, Energy, Chapter 1, Introduction, Page 23, Table 1.4, provides the effective CO₂ emission factor of each different fuel type.

The CO₂ emission factors and the conversion factors that used in this document are summarized as below.

Fuel Type	IPCC CO ₂ Emission Factor	Conversion Factor (Calorific Value)
	(kgCO ₂ /TJ)	(KJ/Kg,m ³)
Coal	94600	20908
Coke	107000	28435
Gasoline	70000	43070
Diesel	74100	42652
Crude Oil	73300	41816
Kerosene	71900	43070
Fuel Oil	71500	41816
Natural Gas	56100	38931

Figure 1: CO₂ emission factors and the conversion factors

1.4 Journal Paper

The Input-Output tables that used in this document are the disaggregated 50 by 50 sectors tables. The CO₂ emissions of the new sectors are calculated according to the data in the Lindner's paper (2013).

Technology	CO ₂ intensity of power plant (gCO ₂ /kwh)	Power Generation in percentile fractions	
		National Average	North China (Shanxi)
Hydroelectricity	18	0.22	0.03
Coal sub-c	1000	0.64	0.83
Coal super-c	900	0.06	0.08
Coal USC	750	0.03	0.01
Natural gas	400	0.01	0
Nuclear	45	0.01	0.01
Wind	10	0.02	0.04
Solar - PV	30	0.01	0

Figure 2: CO₂ intensity and power generation of different power plants

2 Calculation Process and Procedural Notes

This section introduces the calculation equations and the calculation process of the CO₂ emissions and the emission intensities.

2.1 Equation of CO₂ Emissions Calculation

$$CE_i = \sum_j EC_{ij} * CEF_j * CF_j \quad (1)$$

- CE_i is the CO₂ emissions of sector i
- EC_{ij} is the energy consumption of fuel type j in sector i
- CEF_j is the CO₂ emission factor of fuel type j
- CF_j is the conversion factor of fuel type j

2.2 Calculate the CO_2 emissions of each sector

The detail sectors comparison between Input-output table and the Statistical Yearbook is in the Appendix A.

- Sector 1, 2, 3, 7, 11, 13, 15, 17, 20-22, and 24-26: these sectors are the same in the I-O tables and Statistical Yearbook
- Sector 4, 5, 6, 8, 9, 10, 12, 14, 16, 18: aggregate the sectors in the Statistical Yearbook to get the CO_2 emissions of the corresponding sectors in the I-O tables
- Sector 27-29, 30-31, and 32-42: these sectors are aggregated into three sectors in the Statistical Yearbook. These sectors are assumed to have the same emission intensities as the three corresponding sectors
- Sector 23 (Production and Distribution of Electric Power and Heat Power): this sector is the one to be disaggregated into nine new energy sectors

* Since the production of this sector are used by all the other sectors, the total CO_2 emissions of sector 23 are proportionally disaggregated according to the proportion of intermediate input from sector 23 to all the other sectors

* Disaggregated/New energy sectors: calculate the proportion of CO_2 emissions of the new sectors according to the data from Lindner (2013), to get the final CO_2 emissions of each new sectors. Assume the CO_2 emissions are from the power generation sectors, the CO_2 emissions of the sector of Transmission and Distribution is assumed to be zero.

2.3 Calculate of the CO_2 emission intensity

- Direct CO_2 Emission Intensity

$$e_i = CE_i/X_i \quad (2)$$

X_i is the total output of sector i

- Total CO₂ Emission Intensity

$$t = e(I - A)^{-1} \quad (3)$$

- CO₂ Emission Intensity Matrix

$$T = \hat{e}(I - A)^{-1} \quad (4)$$

\hat{e} is the diagonalization matrix of e

The estimation results of the CO₂ emissions, direct emission intensities and the total emission intensities of each sector for both national China and Shanxi are showing in the Appendix B.
