February, 1984

PREFACE

In 1981, a publication entitled <u>Casco Bay Coastal Resource Inventory</u> (Hutchinson and Ferrero, 1981) reported on the marine wildlife populations in Casco Bay, Maine, and assessed potential impacts on them resulting from oil spills. The study was funded jointly by the Maine Departments of Inland Fisheries and Wildlife (IF&W), Marine Resources (DMR), and Environmental Protection (DEP). The purpose was to develop a basic resource inventory for use in mitigating the effects of oil spills. Upon completion of that study, Casco Bay became the only section of the Maine Coast, and probably the only substantial section of the entire Atlantic Coast, for which exists a complete, seasonal inventory and cataloging of its wildlife populations and habitats.

Casco Bay had been chosen for that initial study due to Portland Harbor being Maine's largest petroleum handling port. Sebsequently, 2 additional regions have been studied: Sheepscot Bay (Hutchinson and Lovett, 1983) and Muscongus Bay which is discussed in this report. All 3 studies were funded cooperatively by the 3 state agencies and all had the objective of obtaining comprehensive information on the region's marine wildlife and habitats. With the completion of the Muscongus Bay study, such information now exists for the section of Maine coast between Scarborough and Rockland.

This report details the inventory and evaluation of the marine wildlife resources in Muscongus Bay and describes a method of assessing losses to the resource from oil pollution. This detailed information on the distribution and abundance of the area's wildlife will aid in its proper management. In the event of an oil spill, this information will also aid in providing an efficient and effective response to the situation.

i

ACKNOWLEDGMENT

The authors wish to thank the many individuals who contributed their time, knowledge and energies towards the completion of this study. Special acknowledgment is due Andy Stinson of Lincoln Air, Lincoln, Maine, who served as pilot for the aerial surveys. His skill and knowledge provided for the safe and efficient completion of a hazardous task. Our gratitude is extended to Paul Adamus for his interest and contributions to many aspects of the project. Stephen Kress is thanked for providing his field data from the Muscongus Bay Islands. Susan Woodward of IF&W is deeply thanked, particularly for her assistance in the aerial surveys. Patrick Corr, Howard E. Spencer, Lee Perry, and Frederick Hurley, all with IF&W, are thanked for their support and encouragement throughout the study. Additional thanks are due Betty Jackson and Geneva Gordon, of the same department, for their patient secretarial and editorial skills.

Information regarding the shorebirds of Muscongus Bay was collected and compiled by Paul Adamus, Augusta, ME. His comprehensive report, covering much more than could be included in this report, is on file with IF&W. Technical advice pertaining to some of the illustrative material was provided by RPI Inc. of Columbia, SC. The study was funded through the Maine Department of IF&W, Federal Aid to Wildlife Restoration, Project W-62-R and through DEP's Bureau of Oil and Hazardous Material Control.

INTRODUCTION

Purpose and Objectives

Muscongus Bay, in common with all coastal Maine, is a highly productive biological environment, providing valuable habitat for and supporting a great variety of marine birds and mammals. More than 150 species of marine-related birds (Palmer 1949, Packard 1960, TRIGOM-PARC 1974) and 26 species of marine mammals (USF&WS 1980) have been reported to occur in or near its waters. The marine-related birds are a diverse group that include seabirds, shorebirds, wading birds, waterfowl, and raptors. The common thread binding them all is their traditional association with the marine environment at some time during their annual cycle. The wading birds and osprey (see Appendix A for scientific names) occur as nesters during the summer months. Seabirds nest on the islands during summer - and some are also found during migration and winter. Waterfowl primarily migrate and winter on Maine's coast but the eider also nests there. Shorebirds, although present year round, use the marine environment mainly during migration.

The marine birds of coastal Maine show a great diversity in abundance and distribution, both geographically and seasonally. Inventory information documenting this on a statewide basis is limited. It's only available for the island nesting seabirds (Korschgen 1979), mid-winter populations of waterfowl (Spencer, et al 1982), nesting heron colonies (Tyler 1977, Gibbs and Woodward 1984) and eagle nesting sites (unpubl. files, Me. Dept. IF&W). Additional information exists through people with local knowledge of specific areas. Unfortunately, the value of that data is often severely limited by its being only partial in scope. The inaccessibility of most offshore islands, ledges and headlands contributes to that limitation. Therefore, comprehensive data specific to Muscongus Bay's marine bird resource was not available prior to this study.

The harbor seal (<u>Phoca vitulina</u>) is the only common, year-round resident and breeding species of marine mammal in Muscongus Bay. The other species are infrequent visitors. Information is available regarding the distribution and abundance of marine mammals in Maine (Richardson 1973, 1976, Katona 1977, Gilbert and Stein 1981), however, it's even less extensive than that available for marine birds.

Muscongus Bay appears pristine and natural, owing largely to its many uninhabited islands, its miles of undeveloped shoreline, and its relative lack of industrial areas. In many regards, it truely is as pristine a part of coastline as can be found in Maine. Nevertheless, it's not entirely free from the pressures and threats of development and pollution. It lies between 2 major oil handling ports, Portland Harbor and Penobscot Bay, and lies just inshore of a busy, coastal tanker route. The area has, on occasion, seen oil spills. The most drastic occurred in 1963 when the tanker NORTHERN GULF went aground off Portland and spilled one million gallons of crude oil. Carried for 80 miles by wind and wave, the oil came ashore along 400 miles of coast in the Friendship-Bristol area of Muscongus Bay. Another major spill occurred in 1980 when the tanker CHRISTIAN REINAUER lost 100,000 gallons of petroleum products just east of Port Clyde.

The overall picture that emerges of Muscongus Bay is of a complex, viable marine ecosystem adjacent to major petroleum handling ports. The common assumption in today's world is that the two systems are incompatable: that the presence of the latter will necessarily lead to the degradation of the former. This may be true, particularly if both the industry and the biological resources are managed carelessly. However, a basic assumption

must be made that with responsible operation of the petroleum industry and with adequate knowledge and responsible management of the wildlife resource, the 2 systems can coexist and adverse effects can be minimized or even prevented.

DEP has the primary State responsibility regarding oil spills in Maine. DEP is most concerned with oil spill prevention, cleanup and mitigation of damages. IF&W has the responsibility of supplying DEP with the data and advice pertaining to the protection of wildlife. With the need for information on which to base sound decisions, IF&W undertook this study. The purpose was to provide basic data on the seasonal abundance and distribution of marine wildlife in Muscongus Bay and to incorporate the information in a plan to responsibly manage the wildlife resources, particularly in the event of oil spills. The objectives of the study were as follows:

- To provide a seasonal inventory of the marine birds and seal populations in Muscongus Bay.
- To determine important habitats of marine birds and seals in Muscongus Bay.
- To develop an evaluation system and establish protection priorities for the marine wildlife resources in Muscongus Bay.
- 4) To establish a workable mechanism for readily assessing and documenting damages to marine birds and seals in Muscongus Bay resulting from an oil spill.

Study Area

The area of the study (Fig. 1) included all the tidal waters, adjacent shorelines, and islands of Muscongus Bay. The physical boundaries

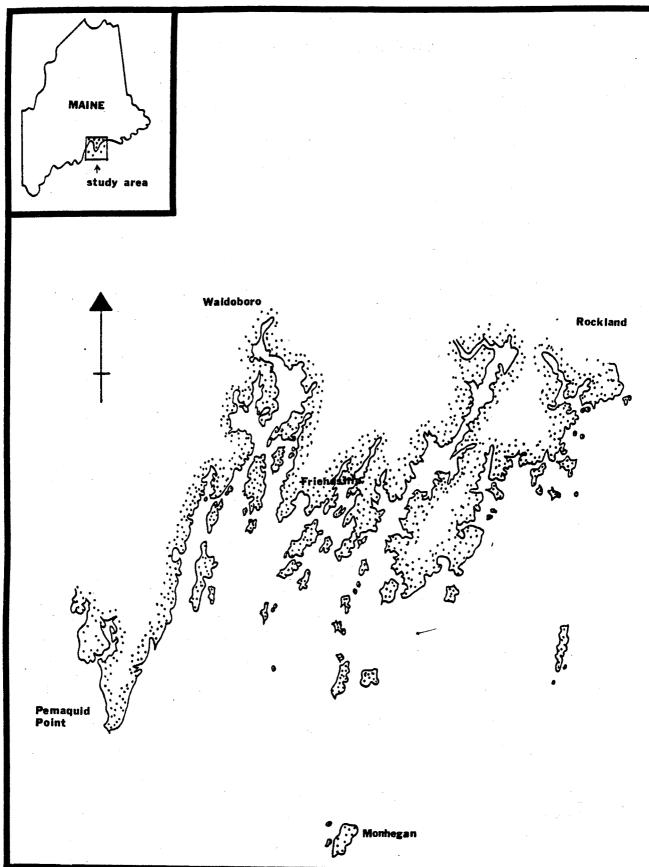

Fig. 1. Muscongus Bay Marine Wildlife Survey study area.

are defined as the coastal area between Pemaquid Point and Owls Head as shown on U.S.C. & G.S. Chart 13301. The straight line distance between those 2 points is about 20 miles. However, if the actual shoreline of all the bays, headlands and major islands are measured, the distance is greater than 300 miles. The study area encompasses more than 300 square miles and contains about 250 islands, including Monhegan and Metinic. Four major tidal rivers, the Medomak, Meduncook, St. George and Weskeag, are also included. The intertidal area includes about 500 acres of salt marsh and 5,500 acres of mud flats.

Methodology

Eleven complete aerial surveys were made of the Muscongus Bay study area between October 6, 1982 and September 28, 1983. The survey flights included most tidal stages (Table 1). The surveys were flown in a Cessna 337 at an altitude of approximately 500 ft. and a speed of about 100 mi/hr. A preplanned flight route, designed to afford complete coverage of the study area, was repeated on each survey. The route started on the Medomak River at Waldoboro, ended at Owls Head and encompassed all tidal waters, including the off-shore islands. The average time required to complete the flight was 5.3 hours.

A tape recording was made during each flight. All sightings of marine birds and seals were recorded as to species or a specific group, their estimated numbers, and their exact location. Upon return to the office, each observation was coded, tabulated, mapped on a USCG marine chart, series 13301, and entered into computer files.

Flight #	Date	Mid-survey Tidal Stage
1	October 6	High
2	November 9	Low
3	December 13	Mid-tide
4	January 14	High
5	February 15	High
6	March 18	High
7	April 6	Low
8	May 16	High
9	June 20	Low
10	August 25	High
11	September 28	Low

Table 1. Date and Tidal Stage of Aerial Surveys.

Additional observations, made from the ground, included periodic counts of birds as ground-truthing for the aerial surveys and, between May 18 and June 20, 1983, the searching of more than 200 islands for nesting marine birds. During the island searches, the survey crew consisted of 3 biologists working from a 17 ft. Boston Whaler. Each island was circled by boat and visually evaluated. If any indication was given, either through the sighting of birds or by the nature of the habitat, that the island might be used for nesting by any of the marine birds, the crew members landed and searched the island. All islands, found with nesting birds, were inventoried using a combination of direct nest counts and visual estimates. Complete nest counts were made in most cormorant colonies for all species on most small islands. On islands too large or too densely vegetated for complete counts of individual nests, total numbers of each species were visually estimated and partial nest counts were made on the island. Estimates of the number of nesting pairs were then derived. Proportions of great black-backed gulls to herring gulls were visually estimated from gulls circling the island to provide relative

numbers of nesting pairs of each species.

A separate, ground survey was conducted for shorebirds, due to their being difficult to observe from the air. More than 80 locations, comprising about 25 percent of the total area of tidal flats in the study area, were regularly visited between spring and fall migration. A thorough search of the literatures, regarding shorebirds in Muscongus Bay, was also conducted.

All sightings of seals, made from the boat or ground, were also recorded as to location and estimated numbers. The information from all the ground surveys was compiled and mapped similarly to the aerial survey data.

Tha aerial and ground data, when completed for the 12 month cycle, were evaluated on a seasonal basis. For the purpose of this study, 5 seasons were considered. The seasons and their approximate dates are as follows:

1.	Fall Migration	September 1 to November 30
2.	Winter	December 1 to February 15
3.	Spring Migration	February 16 to April 30
4.	Nesting	May 1 to June 30
5.	Post-nesting	July 1 to August 31

The seasons roughly correspond to the seasonal rhythms exhibited by Maine's marine birds and seals. The seasonal dates were determined from the literature (Palmer 1949, TRIGOM-PARC 1974, Korschgen 1979, USF&WS 1980) and from patterns of population stability and change seen during this and previous studies (Hutchinson and Ferrero 1981, Hutchinson and Lovett 1983). The dates are not absolute, but are only guides. Overlap naturally occurs from one season to the next. By compiling and analyzing the data on a seasonal basis, a conceptual framework is provided which allows for a better understanding of the resource and the development of a more refined management strategy.

The survey data, when coded and mapped, delineated marine bird and seal concentration areas. The numbers of each species were summed by area, seasonally. A relative seasonal rating, based on the species summations, was calculated for each area. This rating was then used to rank the concentration areas by relative importance. This information was incorporated into an oil spill response plan and into a method of assessing losses.

RESOURCE INVENTORY

Marine Birds

Population Assessment. The diverse species composition, seasonal distribution, and abundance of marine birds in Muscongus Bay presents a complex and dynamic situation. The Maine coast sits on the boundary of 2 distinct biological regions: the boreal or Canadian zone to the north and the northern temperate or Austral zone to the south (Shelford 1963). Muscongus Bay, therefore, in common with other sections of the Maine coast, lies near the southern limit for many northern species and near the northern limit for many southern species. This results in a wide variety and an unusual aggregation of marine birds. More than 150 species of marine-related birds have been reported from Maine's coastal waters and could occur in or near Muscongus Bay (Packard 1960, TRIGOM-PARC 1974, Pierson and Pierson 1981). All are potentially susceptible to oil spills. Slightly more than 100 of these have been reported from the Muscongus Bay study area (Adamus, pers.comm.). These are listed in Appendix A. Their seasonal occurrence and relative abundance have been discussed in a number of reports (TRIGOM-PARC 1974, USF&WS 1980, Pierson and Pierson 1981) and will not be repeated here.

The ground and aerial surveys of this study indicate that about 50 species account for over 99 percent of the total marine bird population in Muscongus Bay (Table 2). These species fall within 7 groups: the loons and grebes, the cormorants, the wading birds, the waterfowl, the raptors, the shorebirds, and the true seabirds. The other species occur so infrequently, unpredictably, and in such low numbers that they were not directly included in the analysis and discussion of this study. However, they are indirectly included since the locations used by them appear to coincide with areas identified in this report for the more common species. It should then suffice for the users of this report to know that the less-common species

do occur and could be involved in an oil spill.

The seasonal abundance of marine birds in Muscongus Bay, based on 11 aerial surveys, is illustrated in Figure 2. Population estimates varied seasonally from a low of 6,700 birds in winter to a high of 24,000 in late summer. Two peaks occurred, one during the August-September population maximum and a smaller one during spring migration, peaking in April. The large, late summer peak is caused by 3 things, a molt migration of eiders, a late summer migration of shorebirds, and the regular fall migration of other marine birds.

The seasonal composition of the marine bird population is illustrated in Figure 3. Waterfowl predominate during all seasons.

The search of the islands resulted in 66 being identified as nesting sites for marine birds. A total nesting population of 12,689 pairs was estimated. Fourteen species nested on the islands (Table 3) with eiders, estimated at 6,131 pairs on 37 islands, being the most abundant.

Table 3. Nesting Marine Birds of Muscongus Bay.

The information throughout this report must be interpreted with the knowledge that the population estimates, although made by trained biologists, are only estimates and that the absolute values could be significantly different. Trained observers commonly underestimate during aerial surveys by as much as 50 percent. This fact was clearly demonstrated during the nesting season when the aerial inventory estimate was 8,200 <u>birds</u>, while ground inventory of the nesting islands during the same period estimated over 12,000 nesting <u>pairs</u>, meaning a minimum population of 24,000 birds in the study area. Therefore, if the same error holds, a population of 40-50,000 marine birds could be present in Muscongus Bay in August when 24,000 were estimated. It is interesting to note that similar relation-ships were found during the Casco Bay and Sheepscot Surveys.

Additional caution is required in interpretation since the information in this report is from one year only and therefore gives no measure of the variation to be expected annually. However, recent studies done to verify the information from Casco Bay (Me. Dept. Inland Fisheries & Wildlife unpubl.), indicated that although some variation occurs, a strong pattern of consistency exists regarding species composition, numbers and areas of use. By understanding the strengths as well as the limitations of this data and by interpreting the information accordingly, the user of this report will find the population estimates to be adequate for the stated objectives.

<u>Areas of Importance</u>. The geographic distribution of marine birds in Muscongus Bay is not random. It is directly related to the distribution of habitat suited to the specific needs of the various species. A major objective of this study was to locate the sites in Muscongus Bay which are used intensively by marine birds. Based on the 11 aerial inventories, 134 such unique locations were identified. The areas were determined by mapping, seasonally, the aerial observations. Results of the island searches were also used. Unique areas were separated and their boundaries defined using 3 criteria: 1) the location of the birds; 2) seasonal use patterns; and 3) physical-geographic features. The 134 concentration areas are mapped and listed in Appendix B and the marine birds found within each area are given by season in Appendix C.

The concentration areas are identified as separate units so that they can be individually addressed in the event of an oil spill or for other, specific management reasons. In total, the 134 areas contain more than 95 percent of the marine birds observed throughout the study, yet represents less than 35 percent of the total study area. The important point is that a large percentage of the resource is found on a small percentage of the study area. Knowledge of this pattern of distribution allows for the efficient allocation of time, manpower and equipment in the event of an oil spill. This approach is further refined and developed in the section entitled <u>Resource</u> Evaluation.

The islands used by the colonial nesting, marine birds hold special interest for 3 reasons; first, because they are such distinct areas of con-

centration; second, because they are used traditionally year to year; and third, because they are the production sites for Maine's breeding marine bird population. Due to this, they warrant full and special consideration in the event of an oil spill. Of the 250 islands and ledges, within the study area, 66 were found to be used by nesting marine birds. Fourteen species were found, with a total, estimated, nesting population of 12,689 pairs (Table 3). Eiders were the most numerous. The puffins, petrels, laughing gulls,3 species of terns and black-crowned night herons are noteworthy. Table 4 lists the nesting colony sites and gives the estimated nesting population for each.

All of the nesting islands fall within 1 of the 134 identified concentration areas. Each colony site is indicated on the appropriate map in Appendix B. The nesting population data, from the island searches, was included with the aerial survey data for analysis in the section entitled <u>Protection Priorities</u>.

<u>Seals</u>

Two species of seals regularly occur on the Maine coast: the harbor seal and the grey seal (<u>Halichoerus grypus</u>). The harbor seal is the most common and the only seal of recent record in Muscongus Bay. It was the only seal found during this study. Little information exists on the behavior, biology or migratory patterns of the harbor seal in the Northeast. The information provided from this study is useful for estimating a minimum population size for the study area and, most importantly, for identifying areas utilized by "hauled-out" seals. Much further work is necessary before a full understanding of the harbor seal in Muscongus Bay is available.

Seals were seen hauled-out on 48 different ledges (Table 5 and maps in Appendix B). For the 82 seal observations recorded in this study, herd size ranged from 1 to 200 and averaged 36. Three of the aerial surveys were

21 Table 5. Seal Haul-out Sites¹

1. Based on 11 aerial surveys and 1 ground survey.

made during low tides when maximum numbers of seals are visible, hauled-out on the intertidal ledges. For the 3 surveys, an average of 890 seals were estimated and an average herd size of 49.4 was calculated (Table 6). The 3, low-tide surveys, accounted for 65% of all sightings (53 of 83) and for 87% of the total number of seals observed in this study.

Six locations were identified as very important haul-out sites for seals in the study area. They are Webber Dry Ledge near New Harbor, Cow Island Ledges in Bremen, Little Franklin Ledge and Shark Island Ledge in the outer bay, and Seal Ledge and Eastern Duck Rock in Monhegan. Together, these 6 sites accounted for nearly half of all the seals observed in this study. Such a high level of use of a relatively small percentage of the available habitat is evidence of strong site preferences and is the basis for the priority rating and impact appraisal scheme developed in the subsequent sections of this report.

RESOURCE EVALUATION

A major objective of this study was to develop an evaluation system for the wildlife resources of Muscongus Bay that would allow the assignment of relative priorities for use in responding to oil spills. Many options are open as to the approach and the criteria for use in setting such priorities. Studies by Bourne (1967) Aldrich (1970) and Joensen and Hansen (1977) stress the significant effects that oil spills can have when they occur coincidental to concentrations of marine wildlife. Therefore, the evaluation system developed in this study is based on the identification of locations used by marine birds and seals and the rating of each area according to the relative number of animals occurring therein. Priorities for action can then be established based on the relative rank of individual areas. The specific judgements and decisions as to exact type of action, and the specific sequence of events to follow in the event of an oil spill, must be made, on-the-spot, by trained biologists, utilizing the information from this report and an on-the-scene appraisal.

<u>Marine Birds</u>. A rating for each season was calculated for each of the 134 areas identified through the aerial inventories. An area's rating was derived by calculating for each species the percentage of its total population (in Muscongus Bay) that was found within that area. The sum of the percentages for all species found in the area for that season is the area's rating. The calculation of the winter rating for Area 73, The Medomack River, is given in Table 7 as an example.

Species	Estimated Num Medomack R.	Percent in the Medomack River	
		Muscongus Bay	
01d squaw	46	2,035	2.26
Herring gull	41	2,795	1.47
Goldeneye/bufflehead	580	4,840	11.98
Scaup	6	20	30.00
Black duck	141	1,081	13.04
Merganser	5	65	7.69
Unid. waterfowl	25	89	23.59
Bald eagle	1	2	50.00

Table 7. Winter Rating for Area 73, The Medomack River.

1. The estimated numbers of birds are totals from 3 aerial surveys during the winter season.

The totals for both the area and Muscongus Bay are combined sums for the 3 aerial surveys flown in the winter season. The calculated rating of the area's seasonal importance reflects both the number of birds and the species diversity within the area. The rating can be used to compare the importance of the areas, on a relative basis, within each season.

The 134 concentration areas were ordered by their ranking (for each season) and each area was assigned to 1 of 5 priority categories: High; Medium-high; Medium; Medium-low and Low. The areas with the highest ratings were assigned to the "High Priority" category and assignments progressed through the ordered list with the lowest ranking areas in the "Low Priority" group. The division points between-categories were selected so that each included approximately 20 percent of the total marine bird population. The higher ranking areas hold their positions due to having relatively large numbers of the various species. This results in the "High Priority" category accounting for a large percentage of the birds in a small percentage of the areas. Conversly, for the lower priorities, a progressively increasing number of areas is necessary to account for an equal number of birds. This is illustrated in Table 8 which gives, seasonally, the percentage of Muscongus Bay's total marine bird population included in the "High" and "Medium-high" priority areas. The information shows that, on average, onequarter of all the marine birds in Muscongus Bay can be accounted for on less than 5 percent of the concentration areas. The rule of "diminishing returns" comes into play as each lower priority is considered. Table 9 lists the High Priority Areas by season.

Table 8. Percentages of Muscongus Bay's Marine Bird Population and Concentration Areas Included in the Two Highest Priority Categories, by Season.

· · · · · · · · · · · · · · · · · · ·	High Priority		Medium-high Priority	
Season	% of Population	% of Areas	% of Population	% of Areas
Winter	19	7	24	10
Spring	23	6	17	6
Nesting	32	4	12	4
Post-nesting	22	2	16	4
Fall	29	4	25	10

The theoretical approach, in the event of an oil spill, would be to initiate action at the highest ranking area, then at the next highest and so-on, progressively, until the lowest ranking area is reached. It is doubtful that an actual spill would affect the entire bay, so not all concentration areas would be involved. In the event of a spill, the first step should be to identify the extent of the potentially effected region. Then, by referring to the maps and keys in Appendixes B and C, concentration areas within that region and their relative ranking and species composition can be determined. Based on those factors, a step-by-step course of action can be planned and implemented.

Table 9. High Priority Marine Bird Areas in Muscongus Bay, Listed by Season.

<u>Seals</u>. The general approach to evaluating and ranking the areas used as haul-out sites by seals was similar to that previously described for marine birds. However, due to no definite seasonal patterns of use, the rankings do not change seasonally. Also, the divisions between the 5 priority categories were derived slightly differently. The priorities for haul-out sites were based on both the number of aerial surveys recording seals on an area as well as the percentage of Muscongus Bay's total seal population recorded there. This modification was done to account for areas used infrequently but by large numbers of seals or for areas used frequently by a few seals.

The haul-out areas are listed by their priority ranking in Table 10 and are mapped in Appendix B. The 3 areas listed as "High" priority accounted for nearly one-third of all the seals observed during this study, clearly proving their ranking. The use of this information, in the event of an oil spill, would be the same as described in the marine bird section.

RESOURCE IMPACT ASSESSMENT

The third major objective of this study was to establish a workable mechanism for readily assessing and documenting all damages to marine wildlife in Muscongus Bay resulting from an oil spill and to recommend a method of determining the monetary value of the wildlife losses. The state-of-the-art of damage assessment is currently quite rudimentary. There is no complete agreement as to any particular method of choice. The most common and simplest is to keep records of the number of oiled birds found and to assign a dollar value to each. The disadvantage to that approach is that only an unknown portion of the total number of oiled birds is found and that actual damages far surpass that which is exhibited through the acute problem of severely oiled birds.

Using the information on concentration areas that is provided in this study, it is now possible to assess the losses of wildlife habitat as well as to account for the oiled birds. We recommend a 5-step process to assess and document damages. The methodology is as follows:

- Immediately upon notification of a spill, the estimated number and location of the marine birds and seals is determined via an aerial survey of the potentially effected region. The aerial survey data, plus the mapped and tabulated information from this report serves as a baseline information for immediate mitigation procedures and for eventual damage assessments.
- Overflights should be conducted periodically throughout the spill period to monitor spill size, location, and movement to document its involvement with the wildlife concentration areas.

- 3) The monitoring flights should continue through completion of the clean-up operation or through the end of the spill's obvious effects. This is to document the time and spatial extent of the spill's effects. The involvement of the spill with marine bird and seal concentration areas should be documented as fully as possible.
- 4) As part of the spill monitoring program, the nature of the impacts of the spill on the concentration areas should be determined. This may best be done from the ground or a boat. For each area, information should be recorded as to any contact of the oil with wildlife, any contact of the oil with the substrate of vegetation and the degree of the coating. Records should be maintained as to the species in the area, their total numbers, and the number of birds or seals effected and the extent of their involvement.
- 5) Based on the information compiled in the previous 4 steps, plus records compiled from wildlife cleaning operations and other sources of data pertaining to the spill, 2 summaries should be compiled: First, a compilation of the wildlife directly effected by the spill; and second, a summary for each wildlife area affected by the spill documenting the nature and extent of the effect. Included for each area should be an estimate of the percent of the area's value to wildlife that was lost due to the spill or clean-up. This should reflect both the acreage affected and the qualitative severity of the loss. An estimate should also be made as to the length of time required for each area to return to its pre-spill value

for wildlife. These estimates are used for determining the monetary value of the losses. All observations should be documented and explicit notes and maps should be kept for each area.

This completes the descriptive assessment of the effects on the marine wildlife resources. The next step is to place a monetary value on the losses. This is usually accomplished by placing a dollar value on each bird or seal. This is difficult, since wild animals carry no true market value. Approximations have been made based on the money spent by hunters to harvest animals. Perhaps a closer value could be determined by the prices paid by zoos, game farms and commercial breeders for their stocks. The U.S.F.& W.S. is developing its Habitat Evaluation Procedures for assigning a dollar value to wildlife resources. This value is determined by calculating the cost of intensive wildlife management on a piece of land needed to compensate for losses occurring on another piece. The Procedures hold promise for assessing damages from oil spills, but until they are refined for use in marine environments, the "Dollar value/bird" method remains. This approach is not perfect, but at present, the best.

A 4-step procedure is recommended for determining the monetary value of losses to the wildlife resources.

- Using the best and most current information available, assign a dollar value per seal and bird.
- 2) Based on the assigned dollar value and the number of oiled birds and seals summarized in step 5 of the "assessment procedure", calculate a total value for the known <u>direct</u> losses.

3) Calculate the <u>indirect losses</u> from habitat degradation separately for seals and birds. The calculation is based on the number of concentration areas effected, the percent of the wildlife value lost in each, the length of time of the impact and the percent of Muscongus Bay's marine bird or seal population supported by each area. An example of this procedure follows.

A hypothetical oil spill occurs off New Harbor during the fall season. Figure 2 indicates that approximately 10,000 marine birds are located in Muscongus Bay in the fall. With a hypothetical value of \$100.00 assigned per bird, the total marine bird resource is estimated at \$1,000,000.00. Step 2 of the "assessment procedure" determines that marine bird areas #2, 3, 5, 6, and 9 were effected to varying degrees (Maps 1 and 2, Appendix B). The percentage of the bay's total population of marine birds supported, in the fall, by each of these 5 areas is given in Table 11 (Table 12 for seals) and is used to determine each area's relative, monetary value based on a total of \$1,000,000.00 for the whole bay. This value is then adjusted, if necessary, to reflect the percent of each area's value to wildlife that was lost as determined in step 5 of the assessment procedures. The adjusted values are then summed to arrive at the monetary value of the indirect losses. If 2 or more seasons are involved, a monetary value is calculated for each and totaled. Also, if seal areas are effected, a similar monetary determination is made and combined with the marine bird value to give a

total for indirect losses. This example is illustrated by the following calculations.

Monetary Loss from Habitat Degradation from a

D

	нуротпе	etical Uli Spil	i in muscongus e	say.
Area	% of	\$ Value	% of Area	Adjusted
	Total	of Area's	Value Lost	\$ Value
	Resource	Resource	To Wildlife	Lost
2	1.7	17,000	100	17,000
3	0.5	5,000	100	5,000
5	0.7	7,000	100	7,000
6	2.1	21,000	50	10,500
9	0.1	1,000	25	250
Total, indirect monetary loss = \$39,750				

4) The <u>direct costs</u>, calculated in step 2, are combined with the <u>indirect costs</u>, determined in step 3, to arrive at an overall monetary value of wildlife losses. This money should be paid to the Maine Department of Inland Fisheries and Wildlife for the purpose of managing the State's marine wildlife resource.

Table 12. Percent of Muscongus Bay's Seal Population Supported by 48 Haul-out Sites.

CONCLUSIONS AND RECOMMENDATIONS

The Muscongus Bay region provides a diverse array of marine habitats which support a large and varied community of marine birds and seals. The species composition and abundance varies both seasonally and geographically. This results in a unique aggregation of species.

A total of 134 individual locations were found to be used consistently by the marine birds and seals within the bay. These concentration areas accounted for more than 95% of the wildlife occurring in the area yet comprised only a third of Muscongus Bay's total area. Comprehensive knowledge of their location, or even existence, did not exist prior to this study and exists now for only two other sections of the Maine coast: Casco Bay and Sheepscot Bay. These concentration areas warrant special consideration and management to ensure the perpetuation of the State's wildlife resource. Knowledge of them forms the basis for understanding the resource and responding to it in the event of oil pollution or other threats to the habitats.

These populations are a unique and valuable resource to the people of Maine and management efforts to ensure their presence is justified. The information provided through this study is an initial and important step towards the responsible management of the resource. Similar information is needed for the remainder of the coast. Our specific recommendation is that similar studies be done for other sections of the coast with the goal of completing the entire coast by 1986. Information now exists for the area from Cape Elizabeth to Owls Head and spans the years from 1980 to 1983. Verification surveys have shown that the information from 1980 is still accurate so could be used in concert with data from other regions from later years. The shorter the time span for complete, coastwide coverage, the better, naturally. Areas requiring particular attention are Penobscot Bay, Piscataqua River and Cobscook Bay.

Appendix A

Common and scientific names of the marine birds of Muscongus Bay¹

¹List from P. Adamus. (See page of text)

Appendix A. Marine Birds of Muscongus Bay.

Common Name	Scientific Name
Common loon	Gavia immer
Red-throated loon	Gavia stellata
Pied-billed grebe	Podilymbus podiceps
Red-necked grebe	Podiceps grisegena
Horned grebe	Podiceps auritus
Northern fulmar	Fulmarus glacialis
Greater shearwater	Puffinus gravis
Sooty shearwater	Puffinus griseus
Cary's shearwater	Puffinus diomedea
Manx shearwater	Puffinus Puffinus
_each's storm petrel	Oceanodroma leucorhoa
Ailson's storm petrel	Oceanites oceanicus
Gannet	Morus bassanus
Great cormorant	Phalacrocorax carbo
Double-crested cormorant	Phalacrocorax auritus
Great blue heron	Ardea herodias
Green heron	Butorides striatus
Little blue heron	Florida caerulea
Great egret	Casmerodius albus
Snowy egret	Egretta thula
Cattle egret	Bubulcus ibis
_ouisiana heron	Hydranassa tricolor
Yellow-crowned night heron	Nyctanassa violacea
Black-crowned night heron	Nycticorax nycticorax
Glossy ibis	Plegadis falcinellus
Canada goose	Branta canadensis
Brant	Branta bernicla brota
Snow goose	Chen caerulescens
Black duck	Anas rubripes
Mallard	Anas p. platyrhynchos
Blue-winged teal	Anas discors
Green-winged teal	Anas crecca carolinensis
Gadwall	Anas strepera
Pintail	Anas acuta
American wigeon	Anas americana
Ring-necked duck	Aythya collaris
Lesser scaup	Aythya affinis
Greater scaup	Aythya marila
Common goldeneye	Bucephala clangula
Barrow's goldeneye	Bucephala islandica
Bufflehead	Bucephala albeola
Old squaw	Clangula hyemalis
Harlequin	Histrionicus histrionicus
Common eider	Somateria mallissima
	Somateria spectabilis
King eider	Melanitta deglandi
White-winged scoter	Melanitta perspecillata
Surf scoter	nerunteta perspectitata

•

Appendix A. Marine Birds of Muscongus Bay (continued).

Common Name	Scientific Name
Black scoter	Melanitta nigra
Red-breasted merganser	Mergus serrator
Hooded merganser	Lophodytes cucullatus
Common merganser	Mergus merganser
Bald eagle	Haliaeetus leucocephalus
Osprey	Panolion haliaetus
Semipalmated plover	<u>Charadrius semipalmatus</u>
American oystercatoler	Haematopus palliatus
Piping plover	Charadrius melodus
Lesser golden plover	Pluvialis dominica
Black-bellied plover	Pluvialis squatarola
Ruddy turnstone	Arenaria interpres
Long-billed curlew	Numeninus americanus
Whimbrel	Numenius phaeopus
Spotted sandpiper	Actitis macularia
Solitary sandpiper	Tringa solitaria
Willet	Catoptrophorus semipalmatus
Greater yellowlegs	Tringa melanoleucus
Lesser yellowlegs	Tringa flavipes
Red knot	Calidris canutus
Purple sandpiper	Calidris maritima
Bairdis sandpiper	Calidris bairdii
Pectoral sandpiper	Calidris melanotos
White-rumped sandpiper	Calidris fuscicollis
Western sandpiper	Calidris mauri
Least sandpiper	<u>Calidris</u> minutilla
Dunlin	Calidris alpina
Common snipe	Capella gallinago
Short-billed dowitcher	Limnodromus griseus
Long-billed dowitcher	Limnodromus scolopaceus
Stilt sandpiper	Micropalama himantopus
Semipalmated sandpiper	Calidris pusillus
Marbled godwit	Limosa fedoa
Hudsonian godwit	Limosa haemastica
Sanderling	Calidris alba
Red phalarope	Phalaropus fulicarius
Northern phalarope	Lobipes lobatus
Wilson's phalarope	Steganopus tricolor
Pomarine jaeger	Stercorarius pomarinus
Parasitic jaeger	Stercorarius parasiticus
Slua	Catharacta skus
Glaucous gull	Larus hyperboreus
Iceland gull	Larus glaucoides
Great black-backed gull	Larus marinus
Herring gull	Larus argentatus
Ring-billed gull	Larus delawarensis
King-Dirieu guri	Latus actumuterists

Appendix A. Marine Birds of Muscongus Bay (continued).

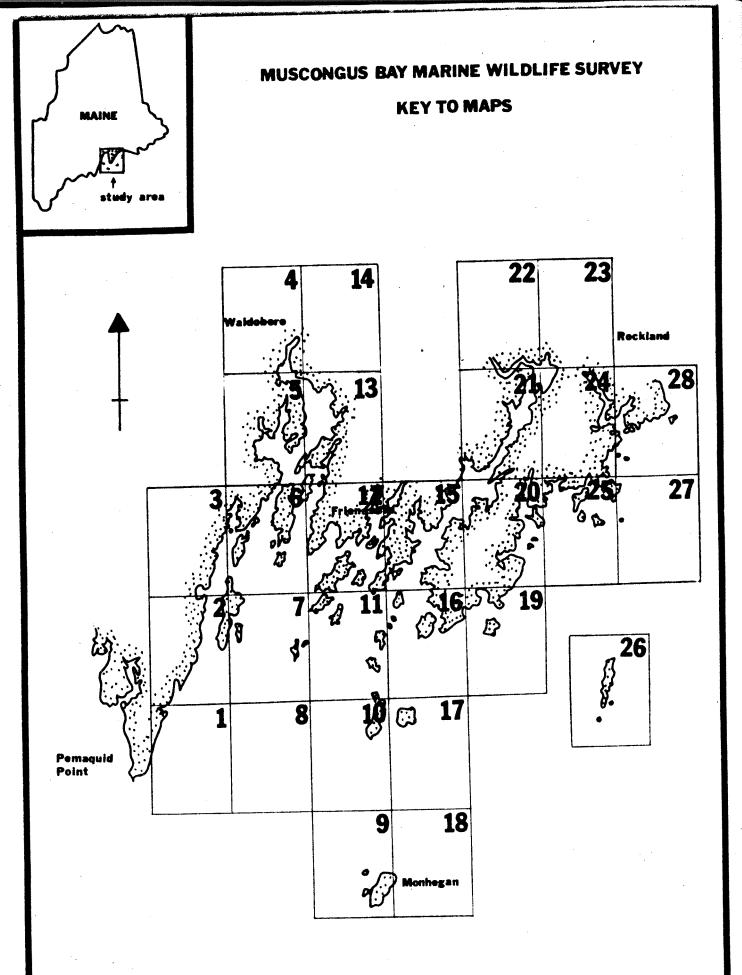

Э

Common Name	Scientific Name
Black-headed gull	Larus ridibundus
Laughling gull	Larus atricilla
Bonaparte's gull	Larus philadelphia
Little gull	Larus minutus
Black-legged kittiwake	Rissa tridactyla
Common tern	Sterna hirunda
Arctic tern	Sterna paradisaea
Roseate tern	Sterna dougallii
Caspian tern	Sterna caspia
Razorbill	Alca torda
Common murre	Uria aalge
Thick-billed murre	Uria Iomvia
Dovekie	Palutus alle
Black guillemot	Cepphus grylle
Common puffin	Fratercula artica
Kingfisher	Megaceryle alcyon
Raven	Corvus corax
Crow	Corvus branchyrynchos
Sharp-tailed sparrow	Ammospiza maritima
