Native Hampshire Type Ewes vs Western Corriedale Type Ewes for

(a) Lamb and Wool Production (b) Longevity

E. A. Livesay and C. J. Cunningham*

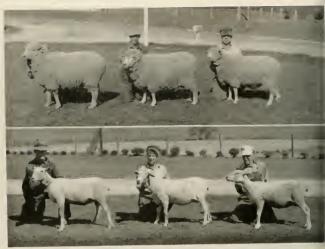

Introduction

HIS work was started at a time when it seemed almost impossible to develop native young ewes within the State without some damage from internal parasites. Copper sulphate, nicotine sulphate, and a combination of the two were being used as drenches at reguar four-week intervals; however, the control of stomach worms was far rom satisfactory. (Phenothiazine was in its infancy as a control at this ime.) It was thought that young ewes produced in the western range tates might be healthier, show less parasitic damage, be more valuable or lamb and wool production, and possibly live longer than our native wes. This flock comparison was designed to test a certain type of Naive ewes with a certain type of Western ewes. The work was actively tarted with the breeding season of 1942 and closed with the marketing of he 1952 lamb and wool crop.

wes

This study covers the productive history of 65 native grade Hamphire type and 65 western grade Corriedale type ewes. All ewes were pursased as yearlings. The native Hampshire type ewes were selected from 25 yearling ewes in Pocahontas County and were considered a good crage of ewes of similar breedings being used in commercial flocks in the County. The 65 western Corriedale type ewes were a gate cut of a rload of yearling ewes from Montana. These ewes were a good unimm flock and exhibited Corriedale characteristics in both conformation and fleece. For simplicity the flocks were designated as Native and Western. (Photos on cover and elsewhere in this bulletin give a good idea of e characteristics of the two flocks.)

^{*}E. A. Livesay was formerly Animal Husbandman and Head of Animal Husbandry; J. Cunningham is Associate Animal Husbandman in charge of Reymann Memorial permental Farms, Wardensville, W. Va.

Two-year-old Western Ewes in fleece and immediately after shearing.

Iwo-year-old Native Ewes in tleece and immediately after shearing.

Management

The 130 ewes were fed and managed as a single flock, except during the breeding season—September 15 to November 15. During this period hey were divided into four individual flocks (two westerns and two naives) and mated to four different rams. For the first four years they vere mated to four Southdown rams. The rams were rotated each year n order to level the influence of the site. In other words, every ewe in he *total* flock was mated to each of the four Southdown rams during the first four years of the test.

During the second four-year period a similar plan of breeding was tarted with four yearling Hampshire rams. One Hampshire ram died nd was replaced with another Hampshire for the seventh and eighth ears. The other three Hampshire rams were mated to all ewes during the second four years.

For the ninth and tenth years the total remaining ewes were mated a different Hampshire ram.

Following the breeding season, the entire flock ran together on pastre and was wintered as a unit. The winter roughage was either first-titing clover-timothy or first-cutting alfalfa-timothy hay which varied om fair to excellent quality from year to year. The hays were fed twice rily in quantities which were consumed with a small amount of waste, addition to the roughage, the ewes were fed 1/2 pound of grain mixtre composed of 1-part corn and 1-part oats for a period of thirty days ior to lambing, and 1 pound of the same grain mixture for sixty days lowing lambing each year.

Ewes were lost from the flock due to death, failure to lamb, and an casional bad udder. Every ewe remained in the flock as long as she is considered useful for the production of lambs and wool.

The treatment for internal parasites during the test was as follows:

- 1. The native ewes were drenched with phenothiazine at time of section or two days before they were delivered to the sub-station farm at urdensville.
- 2. Both the Native and Western ewes were placed on a salt phen hiazine mixture (9:1) as soon as they arrived on the farm. They remined on this mixture for thirty days, then they received only salt for try days. This method of alternating the feeding of phenothiazine h thirty days was continued throughout the entire ten-year period, is method of feeding phenothiazine was started because of the lack osnowledge as to its effect, if fed continuously over a long period.)

Methods of Collecting Data

The ewes were weighed each year at the start of the breeding season All lambs were recorded at birth and a complete record was kept as usingle, twins, triplets, weight, living or dead. All lambs were graded of the farm and sold the following day on the basis of the farm grades. On market grader and two station workers served as the grading committee without change, for the duration of the experiment.

Fleece weights were recorded at time of clipping and the wool was sold on the basis of the system of grading or classification in practice by the West Virginia Cooperative Wool Marketing Association. The woo was merely sorted into clear-medium and rejects. The clear-medium was practically 100 per cent 3/8 and 1/4 blood, and this accounted for 99 pecent of each annual clip. Only a few fleeces were classified as rejects-cotted, black fiber and burry.

Discussion of Results

Tables 1 to 6 (appendix) contain all essential data covering the results of the flock comparisons for the entire ten-year period.

The data of Table 1 reveal:

- (a). The Western ewes were heavier by an average of 13 pounds a the start of the breeding seasons.
- (b). The longevity of the Western ewes was superior to that of th Native ewes. There was a much heavier loss of Native ewes as the reached seven to eight years of age.
- (c). The lambs from the Native ewes graded slightly higher that the lambs from the Western ewes. (See average grade.)
- (d). The value of the lambs sold, per ewe started, was greater nir of the ten years for the Western ewes.
- (e). The weight of fleece, per ewe clipped, was approximately 10 per cent heavier in the case of the Western ewes.
- (f). The annual gross return, per ewe bred and per ewe clippe was greater for the Western ewes for each of the ten years. The diffeence varied from \$2.00 to \$12.00 per head. This average was \$6.82 p ewe.

The data in Tables 2 and 3 show that the prolificacy of the Weste ewe was superior to that of the Native ewe.

The data in Tables 4 and 5 show the marketing record of lambs from Native and Western ewes, respectively. Single, twin, and triplet lambs produced by the Western ewes were heavier at marketing time than the lambs produced by the Native ewes.

Table 6 gives a general summation of the pounds of lambs and wool marketed, and the gross returns for the ten-year period. The data in this table show that the western grade Corriedale type ewes were superior to the native grade Hampshire type ewes in number of lambs born, lambs marketed, percentage of lambs born-marketed, pounds of lambs marketed, cash return from lambs, total pounds of wool, and cash return from wool. When the cash returns from lambs and wool are summarized we find that the gross return from the native grade Hampshire type ewes was \$7,000.30 and from the western grade Corriedale type ewes it was \$11,291.66.

Table 7 gives a complete record of the salt, and salt-phenothiazine (9:1) consumption for the entire flock for the ten years. When this work was started, the cumulative effect of continuous salt-phenothiazine feeding was not known. Therefore, salt and salt-phenothiazine were alternated each thirty days for the entire ten years. It has since been proven that there are no deleterious effects from continuous feeding of salt-phenothiazine mixture. The salt-phenothiazine consumption was on an average less than the consumption of salt alone; however, the consumption was not uniform from year to year. This method of feeding phenothiazine gave good stomach worm control for the ewe flock; however, no lambs were retained for breeding purposes.

Conclusions

The grade Montana Corriedale ewes used in this test proved more profitable for lamb and wool production than West Virginia grade Hampshire type ewes. The Corriedale ewes were also slightly superior in respect to longevity.

In the summary, Table 6, the gross returns from lambs and wool may not accurately reflect the net returns. It was mentioned in connection with Table 1 that the Corriedale type ewes were heavier than the Hampshire type by approximately thirteen pounds. Therefore, we would expect feed costs to be somewhat more for the heavier ewes. The longevity of the Western ewes was slightly superior, which gave the Corriedale flock some advantages. These advantages are mentioned in order not to over emphasize the advantage of the Corriedale flock as against the Hampshire flock. Even though these advantages are mentioned, it should be kept in mind that the annual return, per ewe bred and clipped, was an average of \$6.82 per ewe greater for the Western ewe.
