Tuberculosis (TB) remains a global health threat, and South Africa (SA) has one of the world's worst TB epidemics driven by HIV. Among the 22 countries with the highest burden of TB, SA has the highest estimated incidence and prevalence of TB, the second highest number of diagnosed multidrug-resistant TB cases, and the largest number of HIV-associated TB cases. Although SA has made notable progress in reducing TB prevalence and deaths and improving treatment outcomes for new smear-positive TB cases, the burden of TB remains enormous. SA has the means to overcome this situation. In addition to better implementing the basics of TB diagnosis and treatment, scaling up the use of Xpert MTB/RIF as a replacement for sputum smear microscopy, strengthening case finding in and beyond healthcare facilities and a greater focus on TB prevention for people living with HIV, particularly earlier initiation of and scaling up antiretroviral therapy and scaling up continuous isoniazid preventive therapy, will have a substantial impact on TB control. New TB drugs, diagnostics and vaccines are required to further accelerate progress towards improved TB control in SA and beyond.

S Afr Med J 2014;104(3 Suppl 1):244-248. DOI:10.7196/SAMJ.7689

Tuberculosis (TB) remains a global health threat. Despite a slow decline in global TB rates, the World Health Organization (WHO) reported 8.6 million new cases of TB in 2012 (13% in people living with HIV), resulting in 1.3 million deaths (23% among HIV-positive persons).^[1] South Africa (SA) has one of the world's worst TB epidemics driven by HIV. The WHO has identified 22 high-burden countries (HBCs), which account for 81% of all estimated incident TB cases globally.

Among the HBCs, SA has the third highest absolute number of reported incident cases and the fifth highest number of estimated prevalent (undiagnosed active TB) cases.^[1] After adjusting for population size, SA has the highest incidence and prevalence of TB among the HBCs. It also has the largest number of HIV-associated TB cases and the second-largest number of diagnosed multidrug-resistant (MDR)-TB cases (after India).^[1]

The National Tuberculosis Programme (NTP), established after SA became a democracy in 1994, faced the challenge of integrating TB services into weak primary healthcare systems and the emergence of the HIV epidemic, which led to TB case rates quadrupling between 1994 and 2012 (Fig. 1).^[2] The growing burden of MDR-TB and the emergence of extensively drug-resistant (XDR) TB in 2006 added a further burden to overstretched health services. In order to respond to the dual epidemics of HIV and TB rationally, SA developed an integrated National Strategic Plan (NSP) for HIV, STIs and TB (2012 - 2016).^[3] The targets set in the NSP for TB are to halve TB incidence and mortality by 2016 and to

have no new TB infections, deaths or stigma by 2032. In this review we highlight successes and challenges in TB prevention, treatment and care and discuss strategies to achieve the NSP targets.

Fig. 1. Trends in tuberculosis case notification rates and HIV prevalence in South Africa.

TB control

The central pillars of TB control include finding, treating and preventing TB in order to avoid TB deaths and reduce transmission. The NTP has substantially strengthened the TB control programme since 1994, and the major milestones are summarised in Table 1. Encouragingly, the efforts of the NTP have contributed to a slow decline in TB case notification rates since 2009 (Fig. 1).

Find TB

SA has an extensive network of microscopy centres and diagnostic laboratories with the capacity for culture and drug susceptibility testing using the Mycobacterial Growth Indicator Tube liquid culture system. In 2011, SA introduced Xpert MTB/RIF as a replacement for sputum smear microscopy for the diagnosis of pulmonary TB. Between March 2011 and April 2013 >1.3 million Xpert MTB/RIF tests were done in SA, which accounted for more than half of the global usage of Xpert MTB/RIF. SA also pioneered the use of dried culture spots for verification and external quality assurance of Xpert MTB/RIF^[4] and implemented a central data monitoring system to remotely monitor the performance of Xpert MTB/RIF, the proportion of positive tests and the proportion with rifampicin resistance.

Although nationwide implementation of Xpert MTB/RIF is almost complete, numerous challenges to its implementation remain. Xpert is not universally utilised and there has been poor adherence to the Xpert algorithm, requiring simplification of the algorithm for monitoring treatment response and investigation of HIV-positive, Xpert-negative persons with suspected TB. Ensuring an uninterrupted supply of cartridges will remain a challenge as the global demand for Xpert cartridges increases. The recording and reporting of Xpert results remain suboptimal.

Treat TB

SA's treatment success rate among new smear-positive and smear-negative/extrapulmonary TB patients has improved to 79% and 76%, respectively, achieved largely as a result of an increase in cure rates and a decline in the treatment default rate following the introduction of community-based tracing teams.^[1] The treatment success rate among retreatment cases remains poor at 66.3%. Of concern, up to 25% of sputum smear-positive TB cases are lost to follow-up before treatment initiation, which may contribute to ongoing transmission and an increased risk of death.^[5] Strategies to reduce initial loss to follow-up are required. The mortality rate remains high even after completion of TB treatment, probably due to HIV disease.^[6] Scaling up antiretroviral therapy (ART) to all HIV-infected TB patients is required to reduce HIV-related mortality among TB patients.

The national rollout of Xpert MTB/RIF has enabled rapid diagnosis of rifampicin resistance. As a result SA is in the process of withdrawing the use of streptomycin for retreatment TB: rifampicin-susceptible retreatment TB cases are treated with a first-line regimen, and rifampicin-resistant retreatment cases are managed according to MDR-TB guidelines.

Prevent TB

Prevention of TB has been a neglected aspect of TB control. TB prevention strategies include: treatment of latent TB infection among high-risk persons; case finding to detect and treat infectious TB earlier, reducing the duration of infectiousness and transmission; early ART for people living with HIV; and TB vaccination strategies. In this regard, SA adopted the '3Is' policy of isoniazid preventive therapy (IPT), intensified case finding and infection control in 2002.

Table 1. National Tuberculosis Programme milestones

1997	Phased implementation of DOTS, establishment of DTDs
1999	Introduction of fixed-dose combination drugs Establishment of TB and HIV pilot districts
2000	MDR-TB guidelines endorsed, establishment of MDR-TB treatment facilities Four-drug fixed-dose combination tablets introduced
2001	National Drug Resistance Survey
2002	Launch of the MTDP, 2002 - 2005 Guidelines for IPT for TST-positive, HIV-infected persons
2003	TB declared an emergency and TB crisis plan launched Electronic TB register introduced
2005	Minister of Health signs 'Declaration of TB as an emergency in AFRO region'
2006	Development of MDR-TB and XDR-TB action plan
2007	Launch of the National TB Strategic Plan 2007 - 2011 Development of infection control guidelines for TB
2008	Introduction of Hain MTBDRplus as a rapid test for MDR-TB First SA TB conference
2009	'Health in South Africa' series published in <i>The Lancet</i> , including recommendations for TB/HIV WHO review of the NTP
2010	6-month IPT for all HIV-infected persons, regardless of TST status ART for TB patients living with HIV with CD4 ⁺ counts <350 cells/ μ l
2011	Introduction of Xpert MTB/Rif as a replacement for sputum smear microscopy National HIV/TB campaign Management of DR TB policy guidelines approved Decentralised management of MDR-TB introduced
2012	SA President signs SADC declaration on 'TB in the mines' ART for all HIV-infected TB patients Streptomycin removed from retreatment regimen
2013	NDoH guidelines for managing TB/HIV in prisons issued IPT for at least 36 months for TST-positive, HIV-infected persons National drug resistance survey Independent WHO Review of NTP

DOTS = directly observed therapy, short-course; DTDs = demonstration and training districts; TB = tuberculosis; MDR = multidrug-resistant; MTDP = Medium Term Development Plan; IPT = isoniazid preventive therapy; TST = tuberculin skin test; AFRO = World Health Organization Regional Office for Africa; XDR = extensively drug-resistant; SA = South African; WHO = World Health Organization; NTP = National Tuberculosis Programme; ART = antiretroviral therapy; DR = drug-resistant; SADC = Southern African Development Community; NDoH = National Department of Health.

TB screening

TB screening of high-risk persons or groups may contribute to reduced deaths and TB transmission. The WHO recommends that people living with HIV are systematically screened for TB at each contact with the health service, using a symptom screen. In 2012, 949 800 HIV-positive South Africans were screened for TB, which although impressive is still substantially below the total number of people living with HIV in care.^[1] Among persons on long-term ART,

the prevalence of undiagnosed TB remains high, and underscores the need for ongoing TB screening.^[7,8] TB screening should be scaled up to achieve high coverage to ensure that HIV-infected persons with TB are diagnosed and treated appropriately.

SA introduced a multifaceted TB screening programme in 2011, focused on high-burden districts, which included household contact tracing, HIV counselling and testing campaigns, community mobilisation, door-to-door enquiry in areas with a high burden of smear-positive TB, and screening of high-risk populations. During 2011 >150 000 household contacts were screened for TB and >3 000 new cases, which would not have been detected through routine means, were identified (Lo T, 'Rapid assessment of intensified tuberculosis case finding efforts, Republic of South Africa' – unpublished report by the US Centers for Disease Control to the National Department of Health (NDoH), 20 March 2012, available on request from Mr Lerole Mametja, Chief Director of the National TB Control and Management Cluster). This report also states that challenges to the sustained implementation of household-based case finding include funding, human resource constraints and lack of customised recording and reporting tools.

IPT

The IPT guidelines for tuberculin skin test (TST)-positive people living with HIV were initially incorporated into the ART guidelines. Uptake of IPT was poor following introduction of these guidelines, largely due to the TST creating a barrier to implementation and concerns of generating isoniazid resistance. In 2010, the IPT guidelines were revised to remove the TST to facilitate programmatic implementation of IPT. The uptake of IPT increased dramatically and in 2011 and 2012, >375 000 South Africans living with HIV initiated IPT, making SA's IPT programme one of the largest in the world. Despite this, the uptake of IPT among people living with HIV in care, including children and pregnant women, remains poor.^[9-11] The IPT guidelines were re-issued in 2013 as part of the revised ART guidelines to recommend at least 36 months of IPT to TST-positive persons or 6 months of IPT for those whose TST status is unknown.^[12-15] Stand-alone IPT guidelines are being developed for adults and children living with HIV and persons with silicosis. The reintroduction of TST into the IPT guidelines may pose a barrier to implementation of continuous IPT.

Infection control

People living with HIV and young children are at a high risk of exposure to drug-susceptible and -resistant TB when attending health facilities for care. Furthermore, healthcare workers are also at high risk of acquiring TB nosocomially, which highlights the importance of stringent implementation of infection control policies in order to reduce TB transmission of drug-susceptible and -resistant TB in healthcare facilities and other congregate settings.^[16] SA introduced a TB infection control programme in 2007, which included a structural review of healthcare facilities and process re-engineering if required. Minimum standards for health facilities have been developed by the Council for Scientific and Industrial Research. However, the implementation of infection control guidelines remains sub-optimal. Healthcare facilities should be monitored regularly to ensure consistent implementation of infection control guidelines. Infection control in other congregate settings, such as correctional service facilities, community halls, schools and public transportation (taxis and buses), is also required.

ART

ART reduces the TB risk by 65% overall, and across all CD4⁺ strata, suggesting that earlier ART initiation may contribute to national TB control activities.^[17] SA has the largest ART programme in the world. Although ART substantially reduces the risk of TB among people living with HIV, the rate of TB remains four-fold higher than among HIV-negative persons from the same community.^[18] IPT given with ART is safe and further reduces the risk of TB by 37%, regardless of TST status.^[19] SA should therefore scale up the provision of IPT to patients on ART. In order for the ART programme to contribute maximally to TB control, SA should strive to achieve high coverage of ART and consider initiating ART even earlier, including in pregnant women.^[15,20]

MDR-TB

The number of MDR-TB and XDR-TB cases in SA has increased substantially, with 15 419 and 1 596 cases, respectively, diagnosed in 2012.^[11] The treatment success rate for adult MDR- and XDR-TB remains low at 42% and 18%, respectively, for the 2010 cohort. The MDR-TB sub-programme has faced many challenges, including confirmation of MDR-TB by mycobacterial growth inhibition tube (MGIT) liquid culture drug susceptibility testing in only a third of patients; high initial loss to follow-up of MDR-TB patients, with approximately 40% of patients not initiating appropriate treatment; inadequate bed capacity; poor infection control; limited availability of appropriate second-line drugs and paediatric formulations; and poor adherence to treatment (N Ndjeka, NDoH – personal communication). In response to the large burden of MDR-TB, the NTP committed >\$200 million to the MDR-TB programme; issued a series of guidelines for the management of MDR-TB; established 45, mainly decentralised, MDR- and XDR-TB treatment units, with approximately 2 500-bed capacity; and introduced a policy framework for the decentralisation and de-institutionalisation of drug-resistant TB care and treatment.^[21,22] The current standardised adult MDR-TB treatment regimen is associated with poor cure rates. In order to improve cure rates of MDR-TB, clofazimine has been made available, the role of linezolid is being considered, and a bedaquiline access programme has been introduced.

Maternal and childhood TB

Childhood TB accounted for 13% of all new TB cases in 2012.^[23] Treatment outcomes for childhood TB are relatively good, with 82% of cases successfully treated in 2010. SA enjoys a strong political commitment for addressing the challenges of childhood TB; a blueprint for action on paediatric and adolescent HIV and TB prevention, treatment, care and support has been developed and implemented. South Africans have played a leading role in revising the 2010 WHO childhood TB treatment guidelines,^[24] which were adopted in SA. Notable advances in childhood TB include changing the age and disease categories for reporting, simplifying contact management of TB-exposed children and children living with HIV; revision of the Integrated Management of Childhood Illness guidelines to include TB screening and management; and scaling up prevention of mother-to-child transmission of HIV programmes. Many challenges persist for management of childhood TB, including the lack of fixed-dose combinations for first-line drugs; limited child-friendly second-line drug formulations; poor implementation of IPT in HIV-infected child contacts; gaps in recording and reporting of childhood TB; weak health systems to manage paediatric TB; and poor linkage to care, particularly from the hospital to the community.

TB/HIV integration

TB/HIV integration requires activities to reduce the burden of TB in people living with HIV (discussed above) and to reduce the burden of HIV in TB patients. Initiating ART while on TB treatment saves lives, regardless of CD4⁺ count, and among persons with CD4⁺ counts <50 cells/μl, initiating ART soon after initiating TB treatment is essential to reduce mortality.^[6,25] Decentralisation of ART services to primary healthcare clinics and integration with TB services have resulted in increasing numbers of TB patients initiating ART. In 2012, only 54% of HIV-positive TB patients were initiated on ART,^[1] highlighting the need to scale up ART for TB patients further by scaling up nurse-initiated and managed ART training for all professional nurses.

SA has played a leading role in evaluating strategies to integrate TB and HIV services.^[26] The PALS PLUS intervention, which promotes integration by providing on-site, case-based, iterative education led by a trainer, increased the yield of TB diagnoses.^[27] Guidelines for integrating TB and HIV services at primary healthcare facilities were developed and disseminated in 2010, but TB/HIV integration remains poorly implemented and strategies to strengthen integration of services, including ART, are required.^[28,29]

Healthcare systems

The SA government is strengthening the healthcare system through a process of primary healthcare re-engineering to balance community-based preventive services with hospital-based curative services, and phased implementation of a National Health Insurance to ensure affordability, effectiveness and universal access to quality healthcare services, including TB diagnostic and treatment services.^[30] These initiatives aim to support the implementation of TB control activities and promote integration with other primary healthcare services, including child and maternal healthcare programmes. Addressing the challenge of poor health service management will, however, be critical for effective implementation of these government initiatives.

Surveillance and information

The NTP has developed an electronic recording and reporting system for drug-susceptible TB (ETR.net) and drug-resistant TB (EDR.net). There are, however, numerous challenges with the electronic recording and reporting systems, including inadequate numbers and high turnover of data capturers and poor-quality data entry; linking between these two systems; ensuring that hospital-diagnosed cases are captured adequately; multiple programme registers and repeated data entry at facility level; and lack of a unique health identifier to track patients who move between districts and across programmes. Novel and sustainable solutions, such as the use of mobile phones and tablets to collect data in the field and in facilities, are required to strengthen the quality and use of data as well as patient management.

The performance of the NTP is routinely monitored by drug resistance and TB prevalence surveys and independent programme reviews. The NTP is currently conducting a national drug resistance survey, the first national TB prevalence survey is planned, and an independent review of the NTP has recently been completed. The NTP is also currently implementing the WHO TB Surveillance Checklist to assess the effectiveness of the various TB surveillance systems in estimating the burden of TB.

Key populations

TB has been a major health threat in the SA mining industry since its inception in the late 1800s. SA goldminers have one of the highest TB incidence rates in the world, currently estimated at 3 000/100 000 population.^[14] To address the TB epidemic in the mines, the SA

Minister of Health, Dr Aaron Motsoaledi, along with the ministers of health of Lesotho and Swaziland, spearheaded the development of a Southern African Development Community declaration signed by the heads of state that provides a framework for addressing TB in the mines at a regional level. This constitutes the first ever comprehensive multidisciplinary regional response to TB in the mines.

TB is a major health problem in SA prisons due to overcrowding. The prevalence of undiagnosed active TB is high (2.4%),^[31] and requires effective case-finding strategies linked to early treatment initiation to ensure cure. The NDoH and the Department of Correctional Services have issued TB and HIV guidelines to ensure effective control of TB in prisons. Implementation and monitoring and evaluation of these guidelines will be critically important.

Strategies to achieve the NSP targets

Additional strategies are required to meet the NSP and Stop TB partnership targets. Mathematical modelling suggests that in addition to doing the basics better, scaling up ART and initiating ART earlier, scaling up use of Xpert MTB/RIF as a replacement for sputum smear microscopy, strengthening targeted case finding in healthcare facilities and communities, and introducing and scaling up continuous IPT will have a substantial impact on TB control. However, to achieve the NSP targets, new effective TB regimens, diagnostics and vaccines need to be developed, with consideration of adults and children living with HIV.^[32]

Conclusion

SA has made notable progress in improving TB control, but the burden of TB remains enormous. This situation can be reversed. Ensuring high, sustained coverage of effective interventions for TB and HIV, including in children and special populations, will substantially reduce the burden of TB and result in the NSP targets being met. New drugs, diagnostics and vaccines are required to accelerate progress towards TB elimination.
